President's Perspective
ICASE and the 1990s - Building from Strength
by Bob Lepischak
ICASE President
Canada

During the period 1973-1990, ICASE has extended its sphere of influence to some 80 member associations worldwide. ICASE has met the challenge of its original agenda, that of extending and improving education in science for all children and youth throughout the world by assisting member associations. ICASE has served its members by:

• Developing a communication network through the ICASE Newsletter, a quarterly publication which serves to provide an update on regional and national projects.

• Providing to its members scholarly publications such as Resource Notes, Yearbooks, Commemorative Issues, Proceedings from science education meetings worldwide, and topic specific Annotated Bibliographies.

• Liaising and cooperating on projects with other international organisations including UNESCO, ICSU-CTS and the Commonwealth Secretariat.

• Facilitating, endorsing, or assisting with major world meetings such as the conference on Science Technology and Future Human Needs (Bangalore 1985), the ICASE World Conference (Canberra 1988), and the upcoming World Environment Energy and Economic Conference (Winnipeg 1990).

The challenges of the 1990s are many. ICASE has traditionally addressed the needs of science and technology education. The new world agenda currently being addressed by many nations, is a sustainable development strategy. This approach encourages technological and economic growth but with a stewardship of the environment. Education has a key role in marketing this new approach. Currently under study by the ICASE Executive Committee, is the development of an association platform statement on science education. This platform statement may well serve to make ICASE a partner with nations facing the "new world agenda".

Currently in Canada four representatives from industry, government, post-secondary education and the media act as consultants to ICASE. The aim of the Association is to extend a similar liaison network to other ICASE regions. Emphasis has, as with the September 1990 ICASE Symposium on Industry-Education Liaison (Brussels, September 1990), been on building bridges of cooperation, by educators, with the business community and industrialists. Cadres of regional advisors would serve to extend the networking process.

Mr Claude Gadbois, Past President of the Quebec Science Teachers Association (APSQ), has been appointed as an ICASE Special Project Officer - French/Spanish Liaison. ICASE will endeavour to extend member services to French and Spanish speaking associations.

ICASE will, during the 1990s, continue building on the strength of its publication capability. A Space Science Commemorative Issue is currently in preparation in the United States under the leadership of Dr Linda Crow. The Canadian Association for Science Education is collecting ideas for a "teacher user friendly" booklet of science demonstrations and motivational activities using simple demonstrations and motivational activities using inexpensive materials. The ICASE Newsletter has now been upgraded to a journal - Science Education International.

Individuals who have contributed in an outstanding manner to the promotion of international science education have been recognised by receiving an ICASE Award. Pursuant to the Fifth General Assembly Meeting, ICASE has extended its award scheme to include:

• ICASE Distinguished Service Award
• ICASE Regional Service Award
• ICASE Association Award

Member associations are encouraged to nominate potential recipients to the ICASE Executive Committee.

ICASE has on many occasions been a partner in planning, together with other organisations or associations, science and technology education meetings of interest to the international community. A vision which I have shared with a number of my colleagues from the ICASE community is that of ICASE initiating, planning and conducting a World Congress on Science Education. The experiences of nearly two decades as "best supporting actor" has matured the Association to the point where it is, I believe, ready to take on a challenge of some magnitude. Drawing on the strength of its committee and its member associations, ICASE could provide a world class science education meeting for its members.

The strength of ICASE is its member associations and the committee members who unselfishly give of their time and talents. Building on the existing strengths, ICASE will continue to make large contributions to international science education during the 1990s.

Photo: Bob Lepischak was elected as ICASE President at the Fifth ICASE General Assembly held in Ottawa, Canada in October 1989, following his four year term as Vice President.
New ICASE Award Scheme

The Fifth ICASE General Assembly has approved a new scheme of awards for individuals who make outstanding contributions to international science education. There are three types of awards:

1. The ICASE Distinguished Service Award

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

There will be no more than one such award each year. Any individual member of an ICASE Member Association may nominate a candidate for the award. The nominator must provide to the Executive Secretary by 1 May 1990, a letter of nomination and support, a recent curriculum vitae for the candidate, and four additional letters of support from individual members of ICASE Member Associations, three of which must be from outside the candidate's region.

2. The ICASE Regional Service Award

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels. Candidates should have a high regional profile resulting from their involvement with and impact upon several science teacher associations within the region.

There will be no more than one such award per ICASE region each year. Any individual member of an ICASE Member Association may nominate a candidate from their region for the award. The nominator must provide to the ICASE Regional Representative by 1 May 1990, a letter of nomination and support, a recent curriculum vitae for the candidate, and two additional letters of support from individual members of ICASE Member Associations, which must be from two different Member Associations in the candidate's region.

3. The ICASE Association Award

This award recognises individuals who, within their science teacher association, has made a significant contribution to the international activity of their association.

There will be no more than one such award per Member Association each year. An ICASE Member Association may name an individual member of their association to receive an ICASE Association Award, by notifying the Executive Secretary by 1 May 1990.

Regional Meetings in Africa

by Isaiah O Ikeobi
African Representative, ICASE

The Nigeria Federal Ministry of Education is also hosting an Africa Regional Meeting on Science Education Program for Africa (SEPA) at the Ministry of Education Headquarters in Lagos, Nigeria 2-3 May 1990.

Mr Ikeobi (photo above), ICASE African Representative and President of the Science Teachers Association of Nigeria together with Prof O C Nwana, the President of the Forum for African Science Educators (FASE), will be taking the opportunity to brief these regional meetings on ICASE activities worldwide.

Prof John Penick, ICASE Special Projects Officer, is shown here proposing the new ICASE Award Scheme at the 5th ICASE General Assembly held in Ottawa, Canada in October 1989. The Assembly welcomed the new scheme as an important strategy in encouraging and promoting international initiatives in science education within ICASE member associations and regions.

Shown behind is Prof J David Lockard, USA, and his wife Mary. Dr Lockard was the founding ICASE President.
Progress Report on the
ASETT-ICASE International Conference August 1990

by Althea Maund
ICASE Representative
Caribbean-South American Region

In January, the second circular for this International Conference was distributed, calling for abstracts. The Conference is being organised by the Association for Science Education of Trinidad and Tobago (ASETT) with the assistance of ICASE.

The Conference theme is Education in Science and Technology for Development: Perspectives for the 21st Century and focuses on topics such as the impact of developments in science and technology on life now and in the 21st century; curricular trends in science and technology education in the Caribbean and Latin American region and worldwide - primary through tertiary; social and cultural issues in science and technology education; science for all; educational technology and the teaching of science and technology.

5000 attend ASE Meeting
by Drs Jan Hendriks
European Representative
ICASE
The Netherlands

The ASE Annual Meeting held in January 1990 in Lancaster, UK attracted more than 5000 participants, including many from overseas. The extensive program included several sessions concerning international science education.

One of these sessions was a workshop entitled "Stepping into Science around the World with ICASE". In this workshop Sue Dale Tunnicliffe, the ICASE Project Officer for the primary project "Stepping into Science", introduced her plans for this new and exciting international project to approximately 40 delegates representing several countries.

One of the features of the program was a Symposium for delegates of European science teacher associations, involving participants from the UK, Ireland, Belgium, The Netherlands and Greece. The agenda for the symposium included the establishment of European links, reports from European associations, a report on ICASE activities in Europe and beyond, a proposal for the writing of a European SATIS unit, and the establishment of an international page in journals produced by European science teacher associations.

A third circular, outlining details of the program, will be available at the end of March. The venue will be Port-of-Spain, Trinidad and Tobago.

For further information, write to Conference 90, ASETT, Faculty of Education, University of the West Indies, St Augustine, Trinidad, West Indies.

Photo: Althea Maund, an Education Officer in the Curriculum Unit of the Ministry of Education in Trinidad, is a key member of the Organising Committee for the Conference.

Greece. The agenda for the symposium included the establishment of European links, reports from European associations, a report on ICASE activities in Europe and beyond, a proposal for the writing of a European SATIS unit, and the establishment of an international page in journals produced by European science teacher associations.

ICASE Symposium
Industry-Education Liaison
Brussels 5-7 September 1990

Member Associations in Europe, USA, Canada and Australia have been invited to nominate teachers to participate in this symposium. Nominations must be sent no later than 1st April 1990 to:

Jan Hendriks
Konijnenpad 3
7921 BM Zuidwolde (DR)
Nederland

This exciting program is open to 10 international delegates, representing ICASE Member Associations. The seminar and workshop program will be held at the NASA Lyndon B Johnson Space Center, Houston, Texas, USA from 9 July to 14 July.

Based on the last three years' programs involving Canadian science educators, sessions will include illustrated lectures; VIP tours of NASA facilities including Jet Propulsion Labs, Space Shuttle Orbiter Training Facility, Physiological Training Center, Vacuum Chambers, and the Weightless Training Facility; a model rocketry workshop; and social events.

Participants will receive print and visual resources ideal for classroom use. Use of cameras and videotape equipment has been cleared for participants. Full duplication facilities for 35mm slides and NASA video resources are available at the Teacher Resource Center for the cost of blank film and videotape only.

Participants will be responsible for airfare, hotel accommodation (available at very reasonable rates through the organiser), meals and registration fee (Cdn$135). The organisers suggest that science teacher associations, school districts, and local industries be approached to help provide funding support for participants.

The deadline for applications is 30 April 1990. Application forms are available from:

Stepping into Science - a new primary science project

Sue Dale Tunnicliffe has been appointed Project Officer for a new ICASE initiative in primary science known as Stepping into Science. For some time now, Sue has been developing a very successful approach to the teaching of primary science and technology in the UK and it is as a result of this work that Sue proposed to the ICASE Executive the Stepping into Science Project.

The Project aims to establish an international information network for sharing ideas on the teaching of primary/elementary science, and to establish a badge award scheme for primary children throughout the world, motivating them to participate in science activities. A Project Coordinating Committee is being established by a Steering Committee consisting of Lucille Gregorio (ICASE President Elect), Brenton Honeyman (ICASE Journal Editor) and Sue Dale Tunnicliffe (ICASE Project Officer).

One plan is to produce a Stepping into Science Newsletter, containing ideas for class activities, ideas for children to try at home, ideas for families to work together, comments by network users on common problems and issues, and lists of useful resources and contacts.

Sue has presented sessions on the Stepping into Science Scheme at conferences in several regions of the world and, judging from the interest shown so far, the potential of the project appears to be enormous. For further information, contact Sue Dale Tunnicliffe, Stepping into Science Project, 18 Octavia, Bracknell, Berkshire RG12 4YZ, UK.

Changes to the ICASE Constitution concerning Membership

The Fifth ICASE General Assembly passed a number of amendments to the ICASE Constitution during its meeting at Ottawa, Canada in October 1989. As a result, the following categories of ICASE membership are now available. 1990 membership dues are shown.

Full Members
Full members may be national associations for the promotion of science education, national associations for the promotion of education through separate science disciplines, or science education sections of national scientific associations or national educational associations. Membership dues range from US$30 for associations with a membership of less than 100, to US$1200 for associations with a membership of more than 10000.

Associate Members
Associate members may be sub-national groups concerned with the promotion of science education, multi-national associations concerned with the promotion of science education in particular geographical regions, or other international federations and associations. Associate membership dues range from US$30 for groups of less than 100, to US$792 for associations of more than 10000.

Institutional Members
Institutional members may be colleges of education, faculties of education or faculties of education in universities, science centres or science education centres, science museums, or other institutes with an interest in science education. Institutional membership dues are US$50 for small institutions and US$100 for large institutions.

Foundation Members
Foundations interested in supporting science education may become an ICASE member. Foundation membership dues are US$500 for small foundations and US$1000 for large foundations.

Company Members
Company members may be publishers of science books, scientific suppliers, companies producing educational materials of a scientific nature, or other companies with an interest in science education. Company membership dues are US$200 for small companies, US$500 for medium companies, and US$1000 for large companies.

Membership Enquiries
Please direct membership enquiries to Dr Jack Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong.

Plans well underway for 7th ICASE-Asian Symposium

Meetings were held in Hong Kong from 6 to 12 February 1990 between the ICASE Executive Secretary, and representatives of the Hong Kong Association for Science and Mathematics Education (HKASME), Shanghai Science and Technology Society (SSTS), and East China Normal University. The purpose of these meetings was to plan for the 7th ICASE-Asian Symposium to be held at East China Normal University, Shanghai from 29 March to 3 April 1991. The conference theme is Making science education in schools more relevant. The program will include presentations by internationally renowned science educators; poster displays; papers, workshops and discussions. Sessions will focus on:

- The development of more appropriate curricula - integrated science vs separate sciences, STS approaches
- Innovations in teaching - the place of project work, science communication, skills, low cost equipment, fieldwork; technology in education
- Technology in education - effective use of visual aids, industrial visits, the place of the computer
- Research in science education - children's learning in science, assessment techniques
Historical Implications of the Development of Public Education in the USSR under conditions of Reorganisation

by Prof Viktor A Kumanyov

An edited version of an address given at the International Conference on Science Education Ottawa, Canada, October 1989

For some years now, public education reforms have been carried out in the USSR. The initial outcomes vary; there has been appreciable progress in some areas while, in other areas, progress has been slow and there is an urgent need to remedy a number of problems. The process of democratisation in schools is not likely to be smooth and painless; no doubt it will experience obstacles and setbacks.

We readily agree that knowledge, including scientific knowledge, will continue to expand and exceed society's rate of development. In the foreseeable future, we can be confident that educational requirements and expectations will be far higher than they are today. In 10 to 15 years time, providing the democratisation process gains momentum, our society may have educational institutions which meet those requirements. The reform initiatives are generating optimism as they provide an opportunity for scientific, technological and social progress.

The 21st century will no doubt see improved teaching methods (by a new contingent of teachers!), superior technical equipment and more effective text materials - all of which will help students to develop the ability to think creatively and continually widen their scientific and general understanding.

During the initial stages of the reform, it has been difficult to bring about some aspects of the platform due essentially to the few changes which have taken place in school management, which has remained bureaucratic. Progress has been further hindered by a clear disregard for innovation and a lack of liaison between those interested in improving education - the school, pedagogical science, the family, and the public.

Since the 1920s the Soviet school (together with other social institutions) has suffered periods of retreat from democratic principles. The violation of democratic forms of control over the development of education by the public has resulted in the growth of bureaucratic procedures; the establishment of formalism, voluntarism and red-tape in solving various pedagogical and organisational issues; and the appearance of dogmatism and overemphasis in educational content. The Education Ministry of the Union was established in the early sixties, but when Brezhnev - a narrow-minded and dogmatic man - came to power, it was generally thought that changes in education (or the economy) were not possible. This stagnation actively promoted the growth of the bureaucracy in education and effectively cut off the education system from any international experience. In summary, as happened during the Stalin era, it seemed that any effort to develop pedagogics as a science was suppressed. There were, of course, talented educators who contributed significant developments, but those who rejected the Stalinist scholasticism and dull schematics, found it difficult to overcome the formidable isolationism of the school from the real world. Hence perestroika (the reorganisation) even now is struggling along this uneven road of the past.

If we in the USSR seriously intend to establish a different school, we are going to need a different teacher.

From this background, there arose a commitment to stop the landslide that was occurring in schooling and to put education on a path of genuine renewal. Ushinsky said "In education, everything should be based on the personality of the educator, for educational power emanates only from the living source of human personality. No rules and programs, no artificial organism of an institution, no matter how intricate, can replace the personality in education." In this age of rapid progress in science and technology and in the era of computers, the teacher is the key factor in the educational process and in any school reform. When we examine the personalities of teachers, it is as if we are looking into a social mirror, and the mirror, as a Russian proverb says, cannot be blamed for what it reflects! If we in the USSR seriously intend to establish a different school, we are going to need a different teacher.

How can a country afford to save on its teachers - the very ones who prepare the country's future?

There are five million teachers in the Soviet Union and I would suggest that at least 50% of this enormous contingent are teachers by "accident"! No amount of reform or reorganisation will be effective unless we radically change the teaching corps. Perestroika in the USSR has raised acute questions about the teacher. No doubt we need educators who know the subject thoroughly, who are in command of modern methodology, and who are well grounded in the psychology of training - but this is not enough.

Also required are an understanding of culture, a thirst for knowledge, a constant striving to be creative, and an unlimited love for students. Although over 200,000 teachers complete their training annually, the USSR experiences a constant shortage of teachers. In addition the quality of training leaves a lot to be desired. The average salary of a teacher in the USSR is 197.5 roubles - less than the national average salary! How can a country afford to save on its teachers - the very ones who prepare the country's future?
Under Brezhnev, the prestige of teaching and the social status of teachers became quite low. Accordingly many who entered pedagogical higher education institutions used the opportunity to gain a higher education without any intention of becoming teachers. Fortunately, measures are being taken today to prevent this from happening.

The Soviet Union requires a teacher who focuses on children and their inner natures and who is attuned to their individual abilities.

Since the current period of education reform began in 1984, the press has made many suggestions about the type of teacher needed for perestroika and the country's future - the Soviet Union requires a teacher who focuses on children and their inner natures and who is attuned to their individual abilities. There is a need for a new type of thinking professional, who is ready to master the changing content of education and new teaching technologies, who is ready to master a new way of pedagogical and universal thinking. Research in the USSR indicates that there are only five to six percent of such teachers. Although 72% of teachers recognize that there is a need for fundamental changes in schools, half of these have no idea of what needs to be done or how to go about it. Statistics on the feelings of teachers toward their task are important to note - 2% are merely "marking time"; 4% approach their task gladly and willingly; 14% have mixed or changing feelings; 19% regard teaching as a difficult duty; and 61% approach teaching with constant alarm and concern! Many teachers, even though they denounce the directive-bureaucratic style of management, themselves adhere to this approach in their communication with students, placing them under considerable stress. For many teachers, therefore, their most critical task is to achieve an inner perestroika.

The current reform was slow to gain momentum. For some time, there was merely a mention of specific shortcomings - the low level of general knowledge of teachers and students, the lack of quantitative indicators of performance, the poor state of physical education, and others. It was not until after the 1987 and 1988 CPSU Plenums, and the All Union Teachers Congress held last fall, that a change in public consciousness concerning school and higher education establishments became apparent. Since then, there has been an escalation of pedagogical thought, a pluralism of opinions, a lack of fear of dissidence, a focus on historical and present-day experience, including the global context, and a preparedness to consider bold, well-substantiated proposals. Accordingly, many fresh initiatives have arisen from within the teaching profession.

In 1988, the USSR Ministry of Education was abolished and replaced by Ministries of Public Education in the Union Republics. These ministries are responsible for preschool education, school education, professional secondary education, and higher education. The USSR State Committee for Public Education, a newly formed all-union centre for the administration of education, has taken a firm course towards democratising schooling and its administration. However some members of the former bureaucracy remained in control with the result that the comprehensive secondary school reverted again to an eleven-form school - as it had done under Kruschev! The system of classic schools and Luceums is being re-established. These institutions conduct special, indepth programs in areas including languages, literature, logic, mathematics, physics, and history, providing greater opportunities for students to enter establishments of higher learning.

Motivation to learn can only occur in a system of education where there is a love for children. The teacher should not view them as "someone else's" children or youngsters! A teacher should be a model of humaneness, culture and decency and a person to whom a student is able to relate (Koumanov, 1986). Socrates saw each of his students as a friend to whom he did not simply hand on truth, but with whom he sought the truth. Leo Tolstoy, who held that children were more sound morally and more talented than adults, believed that children are inexhaustible wells of intellectual forces, capable of solving the most complex issues and problems and of making breakthroughs into the unknown. These premises point the way to a genuine humanisation of education.

Liberalisation of schooling, as a critical initial step, is untenable unless procedures are put into place for the legal and psychological protection of the student. In terms of perestroika in the USSR, this means placing a categorical ban on the use of any forms of student punishment which lay outside state-approved school regulations, and which infringe upon the dignity of the student thereby causing humiliation. Some schools in Moscow now have psychological and pedagogical commissions, to whom students may apply in the event of a conflict.

Even during this period of perestroika and glasnost (publicity), the time has not yet come for students and
teachers to engage in equal intellectual discussions. Nevertheless, teachers should maintain open dialogue with their students, respond willingly to new ideas by students, and avoid putting up their own ideas as absolute. Children will believe in themselves only if they believe in their teacher.

The development of teaching techniques in the course of educational reform is a complex and many-faceted task requiring the coordinated input of scholars, teachers, sociologists, psychologists and others - a fact which has been acknowledged by the All Union Teachers Congress. The Congress supported moves to develop urgent solutions to the problems of education and endorsed the move by schools and higher education institutions to humanise the education process.

At the commencement of perestroika, the USSR Academy of Sciences was ill-equipped to take up the challenge of providing support for school and higher education reform. Its orientation toward a partial, rather than a radical modernisation of education, its considerable isolation from schools and their needs, its lack of independence due to its position within the framework of the former USSR Ministry of Education, and its poor knowledge of the world experience, meant that it required a substantial reorganisation. To date, the Academy's perestroika has only achieved cosmetic changes, and its isolation from schools and their needs persists (Pravda, 18 April 1989).

The textbook has been used as a "divine service book" with the teacher like a clergyman performing a liturgy.

Textbooks and teaching manuals have, as a rule, been written in dull, inexpressive language with poor graphic support. There has been a desperate need for experienced teachers and scholars who are familiar with the needs of students, to work together in the production of textbooks. Unfortunately, the textbook, usually the one text produced by the millions, has been used as a "divine service book" with the teacher like a clergyman performing a liturgy. Upon my return from a visit to Canada 10 years ago, I shared with colleagues in the Academy of Sciences and the USSR Ministry of Education, the concept of producing a series of short modular texts (such as I had seen in Canada) in order to supplement the curriculum and provide opportunities for students to select a wider variety of content options. Although many appeared to nod their approval at the time, the idea was typically not taken up. However, the bureaucratic wall is beginning to collapse. Today, textbooks in many areas are being updated. Perestroika is correcting a number of serious distortions which have been perpetuated through older textbooks.

There is a serious shortage of technical facilities for schools and higher education institutions. Computers have the potential to generate more time for teachers to be creative, as well as accelerating communication and the exchange of information, but the State allocates insufficient resources in the field of education to provide computer facilities on a wide scale. Even if they were to be provided, there would be insufficient computing specialists to train educators in their use. Television programs on computer education are broadcast, a magazine Computer Science and Education is published, and computing seminars are periodically held at the State University of Moscow and other universities, but these are timid, first steps in a psychological perestroika in accepting computers as modern working devices.

Perestroika and glasnost have provided a perfect opportunity to confront the problems.

The main objective of the reform is to move away from a static approach to education based on hopelessly out-dated reference knowledge, to a "scientific" approach that models the processes of science and reflects the dynamics of scientific and technological progress. As Lenin emphasised as early as 1920, in order to manage, one needs to be competent, to know totally and thoroughly all conditions of production, to know the machinery involved in production, and to have a certain "scientific education" (Lenin, 1920). It is only since the period of perestroika that the term "scientific education" has received serious attention.

Perestroika and glasnost have provided a perfect opportunity to confront the problems and revise the methods of teaching, the selection of content, and even the selection of teachers themselves. The positions of instructors at higher education institutions are now being declared vacant after five years. Salary systems are being reviewed according to certification. No doubt the USSR Union of Teachers will continue to promote change and to see that words are being put into practice.

It is critical that schools ensure that children's capabilities are recognised as early as possible, and that children are helped to develop their true potential. My father, a well known Soviet pedagogue, used to say "Children should be loved as they are with all their shortcomings, but with a faith that they have a great future, and that kindness will bring out the very best in them. While loving children as they are, it is essential to perfect their nature, and to inspire them to be optimistic about the possibility of their own perfection" (Koumanev 1986).

Integrated Science Teaching in Thailand

by Manee Chandavimol

The rapid advance of science and technology during this decade has made a significant impact on our society, and it is in the field of science education where the greatest effect of this impact can be seen.

The teaching of science in Thai schools has received increased attention since this subject forms the very foundation of technology. Our students need to be educated in a way that will enable them to contribute to and, indeed, to thrive in an ever-changing world. The development of science curricula, therefore, must be a continuous process, allowing the teaching and learning of science to become more dynamic and more relevant to the needs of society. To facilitate this process it is imperative to implement a program of frequent assessments and revision to evaluate the effectiveness of the curricula and to make appropriate modifications.

Rationale

In Thailand, the national policy has now placed emphasis on science and technology for the development of economic and social welfare. It also recognises the need to educate people so that they may be able to more wisely make use of the growing capabilities science and technology now offer. A close look at our science curricula revealed that some areas were inadequate. The tremendous growth in the range and application of technology during the years since our IPST integrated science curriculum was first implemented in 1978, had rendered the science curriculum inadequate in fulfilling the plan of the national policy.

From the follow-up program and research study on the implementation of the IPST integrated science curriculum, there was evidence suggesting that some topics were too difficult for the age level being taught, and some needed modification. Furthermore, there was a need to improve the flexibility of the integrated science curriculum to better accommodate the local situation in order to fulfil the general aims of the national education plan. Also, there was a need to emphasise the development of inquiry processes of learning, enhance student attitudes and interest towards science, and promote creativity so that students would be well prepared, educated members of society.

The modification of the curriculum

Although some minor changes and improvements to courses had been implemented, it wasn't until 1988 that Ministry of Education approved a major revision of the IPST integrated science curriculum (grade 7-9). The original philosophy of the 1978 IPST integrated science curriculum was found to be still useful. Its features reflected a student-centered approach; an emphasis on inquiry approaches to teaching; the integration of various fields of science (chemistry, physics, biology, environment); the development of science process skills; and the relevance of applications to students.

In accordance with the 1988 IPST integrated science curriculum, the curriculum objectives have placed more emphasis on the understanding of science and technology for the development of society and quality of life and, in particular, a positive attitude towards science. The nature of the course has been modified by integrating the teaching of technology at a level appropriate to students' abilities. The overall emphasis is concerned with the daily life of students and the quality of life in general.

In Grade 7, the focus is on the basic requirements for life such as water, matter, plants, animals and the environment. In Grade 8, studies are extended to include the topic of the human body - body function, mechanism and growth. In Grade 9, topics become increasingly concerned with technology as it relates to both our daily lives and the environment around us - for example, the development and conservation of our natural resources, and energy as it is used in daily life and communication. This course involves 3 periods of study per week.

Teaching approach

In addition to the curriculum content changes, teaching methods have been examined and improved. More emphasis is now being placed on encouraging students to perceive science as interesting and challenging. To achieve this, teachers are providing opportunities for students to take part in discussions and activities, to conduct investigations through experiments and science projects, to perform role plays, etc. These activities may take place both in and out of the classroom, in a school science club or independently at home.

**Objectives**

**IPST Integrated Science Curriculum**

- Develop an understanding of the basic principles and theories of science
- Develop an understanding of the nature, scope and limitations of science
- Develop skills important for scientific investigation and communication
- Develop a scientific attitude
- Develop an understanding of the application of science to everyday life and of the consequences of science on people and their physical and biological environment
- Be able to apply the knowledge and understanding of science and technology for the development of society and the quality of life
- Develop students' respect for, interest in and curiosity about science and technology
Problem solving skills are being developed and practised regularly in order to promote reasoning and creativity. Skills include observation, collecting and organizing data, forming hypotheses, predicting outcomes, recognising advantages and disadvantages, and being able to take all parts of a problem into consideration. It is hoped that such skill development will enhance student self-reliance and contribute to their ability to solve problems in their own lives.

Teaching materials

Teaching-learning materials have undergone many improvements. Textbooks are now written so that content is integrated with activities; they include more experiments and problem solving questions for students to do in and out of the classroom; they contain more examples of technological applications related to daily life in Thai society; and they include more pictures and cartoons which illustrate concepts and heighten student interest and enjoyment.

Teachers' guides have been written concurrently with texts. They clarify objectives for activities and experiments; summarise the concepts and principles of each activity; list equipment and chemicals required; include suggestions for alternative activities; and contain sample answers to student questions.

Supplementary reading materials for teachers provide additional background to help teachers answer questions, provide explanations and choose appropriate activities for their local situation. They also include an enrichment program of reading, activities and projects for students who have a special interest in science.

Trends and current issues

An important trend in science education today is the move towards a balance between scientific knowledge and scientific processes. The science course described here is a core program, designed for all junior secondary students with the aim of inspiring an interest in science, as well as providing them with the scientific knowledge and skills needed to become productive and responsible members of society. In order to accommodate the various needs, interests and abilities of students, additional elective courses will be offered, thereby helping students to prepare themselves to meet the challenges that their future plans will bring.

With the environment as a world-wide issue, the public needs to develop an understanding of the environment, its importance, how it is being threatened, and how it can be protected and conserved. There is a need for the study of the environment to be introduced earlier in a child's education, and to be a more prominent part of the curriculum - at present, it is a mere part of an integrated curriculum. There is a need, therefore, to develop a new course - environmental science - with a "hands on" emphasis through field trips and science projects.

Another trend concerns the use of educational technology in the teaching of science. With the advent of the use of computers in the classroom, the practicality and relevance of computers must be considered. There are problems concerning the appropriateness and quality of software, and the lack of trained personnel. Meanwhile, greater use could be made of existing technology such as slide-tapes, transparencies, videos, etc.

The role of the teacher remains a vital one, although it has changed from being an instructor to being a facilitator. Teachers cannot be replaced by computers or machines - the human relationship in the learning process will always be indispensable.

Concluding remarks

The rapid advancement of science and technology has had a significant impact upon education; as a result, science educators, science curriculum developers and science teachers must strive to be well acquainted with current events and the latest research not only in the field of science education, but also in the area of science and technology. Ongoing staff development is crucial, and requires special attention if we wish to keep our curriculum up to date and relevant.

In order to achieve high standards of education, further support is essential from both the government and the private sector. Cooperation with business and industries can help provide practical course materials and direct experiences for students. International and regional cooperation is also essential if we are to enhance science curriculum development. As science educators, we need to access information and ideas through international and regional workshops, seminars and publications.

Science, Technology and Mathematics for All
A report on the 6th ICASE Asian Symposium
Brunei Darussalam, 4-10 December 1989

by Dr Jack Holbrook
Executive Secretary, ICASE
University of Hong Kong, Hong Kong

Science, technology and mathematics for all was considered from three perspectives:

- Informal education: the need to assist the general public to better appreciate science; the need to popularise science thereby promoting its image.

- Nonformal education: the promotion of student out of school activities which motivate students and help to redress gender differences.

- Formal education: relevant science, technology and mathematics appropriate for all; the move to contemporary models which encourage skills such as problem solving and decision making.

Science teacher associations are in a position to provide much needed assistance to teachers, although association efforts and expertise may not have always been recognised.

In the area of informal education, associations can contribute by arranging lectures on popular science topics for the public, and by inviting the general public to attend various science competitions, displays and exhibitions which are organised by associations.

Associations can promote nonformal education through organising out of school programs such as science fairs, science weeks, student competitions and student badge award schemes.

Formal education poses the greatest challenge to science teacher associations. Here, efforts are directed to the teacher rather than the student. Associations can help teachers to interpret the curriculum by arranging seminars, and by publishing guidelines, viewpoints and ideas in their newsletters and journals. Many teachers need help in translating the curriculum for a particular class in a particular locality.

Associations can do much to provide resources and support in the form of teaching resources, newsletters and journals, low cost equipment, industry/field visits, and lectures by specialists. In addition, associations have an important role to play in providing curriculum development support in areas such as assessment methods and development of teaching materials. They can provide a source of suggestions and tips for teaching, produce helpful publications, arrange talks, and initiate projects involving collaboration between teachers.

Through networks such as ICASE, science teacher associations can help teachers to widen their horizons by making formal or informal links with teachers in science teacher associations in other countries. Possibilities include the exchange of curriculum materials (visual aids, equipment, printed materials, case studies), a program of exchange visits, and the organisation of regional and international symposia for teachers.

Needs for Education in the 1990s

by Dr Kenneth R Roy
North American Representative, ICASE
NSSA National Director, USA

In a recent Curbstone Clinic Series sponsored by the National Science Supervisors Association's LISE Center, supervisors of science, mathematics and technology education developed a joint list of needs for education in the 1990s. Four groups - two science, one mathematics and one technology education - first met by discipline to brainstorm needs. A second session was used to combine disciplines with representation in each group by supervisors of science, mathematics and technology education. The common element outcomes of each group were then focused on to develop an action plan. Included in the list of six items were:

1. **Interdisciplinary curriculum development:** Supervisors saw the need to begin building bridges to other disciplines. The real world is spectral in vision and experience. Today's school curricula deter learning in this
respect. Interdisciplinary instruction can be a successful approach and needs to be explored. However, ultimate success depends upon securing discipline credibility. A variety of highly successful pilot programs exist such as science/technology education courses.

2. Staff Development: With the advent of a myriad of national reports and recommendations, supervisors need to be effective catalysts and change agents. A major component in effecting these changes is the school district’s commitment to providing staff development programs. These go well beyond simply providing workshops. Teaching faculty must be directly involved in program development, planning, evaluation and more. A program designed to only meet organisational needs is unrealistic and can be totally ineffective. The supervisor needs to be able to help facilitate this process if staff development is to be successful.

3. Scheduling: As supervisors move to meet the needs of students and faculty into the 21st century, new models for scheduling must be adopted. This issue is especially true for science and technology education where hands-on programs are critical at the elementary and secondary levels. Innovative scheduling models, possibly even beyond the regular school day, may be necessary to entertain.

4. Coordination and articulation of the Curriculum K-12: A major concern of supervisors was the lack of knowledge and skill coordination horizontally and vertically in the curriculum. As science curricula move toward “step learning”, it is imperative that we consider models of coordination and articulation. One model is to provide additional release or planning time for faculty committees with K-12 supervisors as facilitators to focus on improved coordination and articulation.

5. Linkage to the real world: The learner must have practical applications to real world situations. If these disciplines are to be motivating and meaningful to students, there must be linkage or relevance to their real world experiences. Science, technology and society (STS) and other approaches foster practical applications in learning for students. As noted in Project 2061, there must be education provided for all students, not just for the select few who will become scientists, technologists or mathematicians. In this way, it is imperative to cross old discipline lines. Mentorship programs for faculty, supervisors and students are one of several components which serve to provide bridges to the real world.

6. Finding resources to support change: A major concern on the part of supervisors was the need for change agents to have resources. The need for and types of resources will vary from district to district and school to school. However, some common resources may be secured through business and education alliances, Federal government programs, state programs, professional association resources and, most importantly, professional networking.

The LISE Center is a leadership development and resource center of the National Science Supervisors Association. Its services include providing Curbside Clinic programs on issues relevant to science supervisors and teacher advocates.

For additional information, please contact Dr Kenneth R Roy, NSSA LISE Center, Copernicus Hall (Suite 227-228), Central Connecticut State University, New Britain, CT 06050, USA.

Primary Science Workshop Report
Sierra Leone, Africa, 7-9 August 1989

An edited version of a report by Samuel E Johnson
President, Sierra Leone Association of Science Teachers

The Sierra Leone Association of Science Teachers (SLAST) organised and conducted a workshop for primary science teachers from the 7th to 9th August 1989. 30 participants attended, representing 20 primary schools in the Freetown area. The workshop aimed to:

- Provide an opportunity for primary teachers to share and acquire experiences in teaching science using the officially prescribed text *Primary Science for Sierra Leone*.
- Familiarise teachers with the principles and objectives of the primary science course.
- Explore ways for teaching topics effectively regardless of school location.
- Identify areas of possible misinterpretation in texts in order to correct them.

Participants formed into three groups or resource teams. Resource team A focused on the teaching of process skills to pupils with a particular emphasis on observation, recording of information, and classification. Practical exercises with living organisms enabled participants to focus on skill development, and to gain elementary knowledge of the structure and life of animals and plants likely to be encountered in the children’s environment.

Resource team B discussed problems relating to the teaching of agriculture at the primary level. Ideas discussed included selecting a garden site and producing livestock. Participants also classified crop plants, and studied crop diseases. Recommendations to the Ministry of Education, Cultural Affairs and Sports included making available land for schools or groups of schools to use in the teaching of agriculture, providing fencing and security personnel for this land, and funding the establishment of small scale animal husbandry programs.

Resource team C focused on the physics and chemistry aspects of the science program. Participants carried out a number of simple experiments including the absorption of water by different materials, the making of mixtures, the effect of heating on substances, and the reflection of light using mirrors.

A more detailed report of this very successful workshop can be obtained by writing to the Editor.
To Encourage, Don't Praise

by John E Penick

Abstract
Verbal praise, often seen as a necessity in the classroom, may, in fact, be more negative than positive. Rather than encouraging a student to learn, praise may have exactly the opposite effect. Encouraging learning can be more effectively accomplished by listening to student responses, giving attention to students, and providing recognition for efforts rather than mere praise.

Motivating students to learn has always been a major problem faced by teachers. Some have faced the problem squarely and honestly, seeking to motivate through interest and good teaching. Some have resorted to gimmicks and ruse. Still others have denied the problem by asserting that the teacher's role is to provide teaching skills and content and the learner's is to provide motivation.

Likewise, educators have spoken widely and eloquently on the subject. Many educational strategies using praise or other outside rewards have been devised and implemented while reams have been written about the individual's strong need for praise. An equally vocal segment condemns praise, reinforcement, and behaviour modification as inhumane, manipulative, and not in accordance with the goals or best interests of our society. Teachers, meanwhile, are caught in the middle, wanting to encourage and motivate, not wanting to harm children, but not being absolutely sure about what is best.

Praise
Many studies (O'Leary and O'Leary, 1977; Lipe and Jung, 1971) have demonstrated well that praise can be reinforcing when it is used to reward the performance of a specific behaviour or skill. It has often been pointed out that people tend to learn along whatever lines they find rewarding (Torrance and Myers, 1970). Unfortunately, teachers may not always use praise in a deliberate reinforcement attempt. In fact, praise may be a spontaneous reaction to a student behaviour (Brophy, 1979).

Several classroom studies of praise indicate it occurs far less frequently than criticism and punishment and is often used inappropriately. Other studies found teachers giving more praise to high ability students than low ability students (Brophy and Good, 1974). Good students tend to get praise for good answers, less able students get praise for non-less related aspects such as dress or appearance. Praise for behaviour often goes to those students who are high achieving, quiet, conforming, and hardworking - clearly those least in need of reinforcement of such behaviour. And, praise has been shown to be motivating only when directly focusing on significant performance. In addition, for praise to be effective it must be given privately, for public praise of one may be viewed as rejection by another and even embarassing for the one praised.

Even if used correctly and specifically, praise may still pose a problem for teachers. The use of praise may lead to results which are not desired. It has often been noted that praise implies differential status. The giver of praise becomes the authority who is judging the person receiving praise. Further, many find praise embarassing and it may lead to dependent behaviour on the part of the individual receiving praise. Praise reduces rather than increases motivation when the person has previously been performing a behaviour for its intrinsic value (Deci, 1975). Many students, unless they are very immature or teacher dependent, feel manipulated or punished by praise. Actually, the teacher may be the one being manipulated. Several studies indicate that much teacher praise is elicited and reinforced by students themselves (Brophy, 1979).

Teachers, through praise, may also be promoting rather covert sexism in our schools. Dweck et al (1978) noted that teachers praise boys for successful performance and girls for neatness, following instructions, speaking clearly, and other matters of form rather than substance. When making negative evaluations, teachers criticise girls for unacceptable performance and boys for form. As a result, boys attribute their success to their own ability and their failures to the external attitudes of the teacher or their own efforts. Boys are encouraged by this pertinent praise and ignore criticisms. Girls, on the other hand, are not encouraged by praise since much of it is for form rather than substance. Girls are very discouraged by criticism since they attribute their failures to their own lack of abilities and their successes to the external factors. Girls see this as personal inadequacy. They try their best but still fail. Giving girls (or anyone, for that matter) praise when they have attained no object may lead to undue reliance on others for direction and evaluation.

If students do see and understand the use of praise they may be humiliated if it is directed at them (my teacher must think I'm really dumb if she praises me for that!). Or, such students may question a teacher's competence if they
see the teacher praising work which is mediocre.

A brief summary should make most teachers cautious in their use of praise for any reason:
- Praise is not synonymous with encouragement.
- Praise does not generally correlate with increased student achievement.
- Praise does not always or even usually function as a reinforcer.
- It is questionable whether praise can be successfully used as a reinforcer except in one-to-one interactions.
- Praise may not have inherent value.
- Many find praise embarrassing or punitive.
- Teacher praise is often under the control of student behaviours.
- Teachers tend to praise "teacher's pets".
- Pressure from without rarely promotes desirable behaviour.

Encouraging children

To encourage children without risk of negative overtones, teachers can help students learn to set goals and to evaluate their own performance. In doing this, students supply self-reinforcement without relying on the teacher. Then, they can attribute positive outcomes to their own efforts rather than to the teacher or other external causes.

Teachers who encourage put value on the child as he is, not just as they wish him to be. To do this teachers must have faith in the child and his own ability. Having faith is shown by focusing on strengths and assets, helping in skill development, and using the interests of the child to organise instruction. Rather than correcting the child, teachers must encourage self-evaluation by asking questions which require reflection. Encouraging also means giving the child recognition for effort, success, and individuality. Teachers can give recognition verbally by asking questions, responding to answers or other comments, and by taking time for meaningful interaction. Nonverbals such as glances, smiles, or winks also let a student know they are noticed.

By guaranteeing the student certain rights and privileges, providing opportunities for success, and accepting, teachers do much to encourage a child's learning and self-concept. It is also useful to be pleased with a good attempt, letting them know they can do it. At the same time, the students must feel that, in your class, it's alright to try; failure is no crime. They will feel this and be encouraged if you show confidence in their ability to become competent and capable.

Coal nations to cut carbon dioxide

An environmental report

Leading coal producing nations are planning to introduce new technology to reduce carbon dioxide output from the burning of coal by up to 50 per cent as the debate about the greenhouse effect warms up. The technological developments were the key topic of discussion at a meeting of the eight nation International Committee for Coal Research in Sydney, Australia recently.

The committee's chairman and president of the National Coal Association of the US, Mr Richard Lawson, said that while much of the technology was still in the laboratory stage, the nations were confident that it could be applied soon to plants using coal to produce energy.

Mr Lawson predicted the new technology would be operating in several countries by 1991, when the committee will hold its next meeting to present its findings to the world's scientists. Research indicated the new technology - which involves the use of more efficient equipment such as coal burning ovens which capture negative emissions - could improve the efficiency of plants by 25 to 45 per cent, he said.

Mr Lawson denied the coal producers' research was being spurred on by growing debate about global warming and the effect on the atmosphere of the carbon dioxide output from the burning of coal. He said he believed the improvements in the energy conversion process would develop faster than the on-going debate on the greenhouse effect.

At present, the International Committee for Coal Research was committed to putting the technology into the hands of developing nations such as China, India and Brazil. Mr Lawson said although the new technology would not be cheap, its cost would be offset by greater efficiency.

Building Questioning Power

Ronald J Bonnstetter

Science Education Societies from all over the world are placing new demands on classroom teachers. Teachers worldwide are being asked to develop students who possess critical thinking skills, problem solving ability, and powers of analysis. Not only are these goals quite different from our tradition of fact dissemination, but they call for very different teaching strategies.

The role of questioning by the classroom teacher can play an important role in addressing this international objective. The following activity has been used effectively to help both preservice and in-service teachers to recognize their own questioning behaviors and learn to ask many different kinds of questions.

Participants are first surveyed to determine their knowledge of Bloom's Taxonomy and how this can relate to different levels of questions. Then to simplify the process, knowledge and comprehension level questions are grouped and called closed-ended questions. Application, analysis, synthesis, and evaluation questions are referred to as open-ended or extended-answer questions. Participants are given a simple numeric code for different teacher verbal actions. For example, number 1 stands for closed-ended questions and 2 for open-ended questions. Once participants have shown an understanding of these differences and can code various questions, the following activity is used.

Participants are placed in groups of three and given the following assignments and information. In each small group, one participant is responsible for coding the interaction, while another role-plays the questioner (teacher) and the third the respondent (student). Only three minutes are allowed for this first exercise after which time roles are switched and another coding period occurs until all three participants have performed each task. The assignments vary with the role. The questioner is to find out all he/she can about, for example, favourite hobbies, by asking as many open-ended questions as possible. The responder is to answer these questions without getting carried away giving information that was not specifically requested. The responder is also encouraged to listen closely and answer all closed-ended or short answer questions and yes/no questions accurately. For example, "Can you tell me what your favourite hobby is?" should be answered with a simple "Yes".

The coding for this first activity is kept at a very simple level by grouping all responses into only four categories - short answer question, extended answer question, student response, and, if noticeable, wait time. The resulting three minute coding is almost always dominated by short answer questions. Debriefing usually exposes the fact that coming up with open-ended questions on the spot is very difficult.

The next day, after discussing several papers designed to build their understanding and rationale for questioning, a second questioning activity is conducted. To reinforce the idea that open-ended questions do not arise spontaneously, each participant is told in advance to come prepared with at least five open-ended questions. The topic is up to them but should be an area of science for which they feel extremely comfortable and that other members of their group would have very little knowledge.

Additional rules include allowing the questioner to build a small content base by making two or three sentence statements that lead into their questioning. Again, the questioner is to make every effort to ask extended answer questions and allow time for responses - wait time. The coders for this second round are asked to start looking for an additional code - probing. This code is used when the teacher asks the student to clarify or expand their comment.

The third day questioning activity focuses on using the student response. For every question and answer given, the teacher is requested to ask for clarification or in some way use the information obtained before going on to the next prepared extended answer question.

This simple activity has been very well received by both preservice and in-service teachers. A teacher recently shared how the activity had affected his teaching. He was known for ending class with "Do you have any questions?" and found that by simply asking "What questions do you have?" he now receives many more questions. Being aware of one's behavior is the first step to improving.

About the Author
Ronald J Bonnstetter is Director of Secondary Science Education at the Center for Curriculum and Instruction, University of Nebraska, Lincoln, Nebraska, USA.
Dr Ang Wai Hoong
Singapore

Ang Wai Hoong is a staunch believer that science is for all and she enthusiastically promotes the learning of science through the fun way. She takes the stand that academic learning at school is important and that science club activities give more relevance and added meaning to the learning of science in the classroom.

She has served the Science Teachers Association of Singapore in various capacities, and was Chairman for 6 years. She is still an active member. She was the driving force behind the establishment of the Singapore Science Fortnight which is a major annual event for about 100,000 pupils between the ages of 9 to 19 years old. It has now become a major regional event which attracts to it teachers and students from Brunei, Malaysia, Thailand, Philippines, Hong Kong, Australia and New Zealand.

She initiated the Young Scientist Scheme in 1985. Since then, thousands of pupils in primary schools wear badges as Young Ecologists, Young Chemists, etc. Primary schools in Singapore now have science clubs which hold school zonal as well as national exhibitions undertaken by them.

Having obtained considerable educational experience in Australia, England, United States and Singapore, she has sought to integrate the outstanding features of each system and apply them in the Singapore context. She has made key contributions to the way science is taught at school, first as Assistant Director of Science and then as Deputy Director of Curriculum at the Ministry of Education. She continues to influence the teaching of science in her current position as Director of the Curriculum Development Institute of Singapore where science text books are being published. Currently, she is strongly promoting the greater use of technology in the teaching of science. She has presented papers in this area at conferences in several countries. She also holds positions on the Singapore Science Centre Board, the Governing Board of RECSAM (SEAMO), the Basic Education Advisory Council, the National Computer Board, and is Chairman of the Association for Supervision and Curriculum Development (ASCD) Singapore.

Dr Ang has always been a strong supporter of ICASE and its activities, and organised the very successful ICASE-Asian Symposium held in Singapore in 1981. In recognition of her significant impact upon and contributions to international science education over many years, she has been honoured with the ICASE Award.

Netherlands bold pollution plan
An environmental report

The Netherlands has unveiled details of an ambitious long-term environmental plan which aims to cut all forms of pollution by at least 70 per cent by the year 2010.

The Dutch Environmental Minister, Mr Ed Nijpels, predicted the plan would become a model for other European nations, especially West Germany, which has joined the Netherlands at the forefront of the green camp in the European Community.

Under the scheme, the total cost of environmental clean-up efforts sustained by Government, producers and consumers would nearly double to FL15 billion by 1994. About 80 per cent of costs will be borne by the polluter - industry, farmers or consumers. Industry is expected to pass to consumers 60-70 per cent of its added costs. By 1994, each household is expected to be paying FL130 a month towards saving the environment - 50 per cent above current levels.

The plan includes several hundred measures to cut pollution in soil, air and water by 70-90 per cent over the next 20 years. The measures would reduce acid-causing sulfur emissions, greenhouse gases and conserve energy.

Mr Nijpels said the plan was based on the idea of sustainable development, the notion that economic growth must not jeopardise future generations' ability to provide for their own needs.

He said that, by some indicators, the Netherlands was the most polluted country in Europe because of its high density of population, cars and industry. The Dutch feel acutely vulnerable, because of their geographical location, to air and water pollution from West Germany and Britain. Their country is also the most intensively farmed in Europe.

From Habitat Australia, October 1989

Science from everyday materials  
by Sue Dale Tunnicliffe  
Primary Science Section Editor

One of the constant comments received from primary teachers all over the world is that science requires resources which primary schools do not have. While we do need some technical resources, most elementary science topics can be studied using items which are readily available.

One of the features of the ICASE Stepping into Science Project is that children can investigate the same topic but use different resources to assist them in their studies. The resources used vary according to where they live.

You are invited to share your resources with others in the ICASE network. What, for instance, do you use in your school:

• to function as a container for investigating solubility  
• to make electric circuits  
• to function as a pipette  
• to function as masses  
• to measure volume  
• to house small animals

The collection of Stepping into Science activities (challenges) is growing. These challenges have been organised into a number of stages or levels.

What do you think? Is it appropriate to have a series of activities structured according to various levels of difficulty? Many of the tasks collected so far can be investigated at a number of levels of difficulty according to whatever science skills a child may have.

Send your ideas to:

Sue Dale Tunnicliffe  
ICASE Project Officer  
Stepping into Science  
18 Octavia  
Bracknell  
Berkshire RG12 4YZ  
UK

Getting wet!

Here is an activity for your pupils to try. Stepping into Science involves children in the following steps:

• Planning their investigation  
• Choosing equipment to use  
• Carrying out their investigation  
• Recording their observations and measurements  
• Communicating their findings to a wider audience

Challenge  
What happens if you put a drop of water on different kinds of surfaces?

Discussing  
Ask what is a drop? How do you put a drop on a surface? Will you need special equipment? Can you let it drip off a finger? How can you make this fair? What kind of surfaces can be used? What do you predict will happen when drops of water are put on different surfaces? Will the drop stay as a drop? Will the drop soak into the surface? Will the drop run off the surface?

Planning  
Ask how they will carry out this investigation. What will they do first? If they are working in a group, what jobs will each do?

Choosing equipment  
Ask what equipment they will need. They may need a container for water, and various surfaces such as newspaper, flat stone, foil, cotton fabric, wood, bread, sand, leaf, etc. Drops can be placed onto surfaces using a pipette, a straw, or simply a finger.

Doing the activity  
Do pupils change their plan as they do the activity?

Recording  
What observations are they making? How are they recording their observations?

Evaluating  
What did they observe? What does it mean? What have they found out?

Communicating  
How will they share their findings? Children are welcome to send a report to Sue Dale Tunnicliffe, ICASE Project Officer for the Stepping into Science Project.
Ozone depletion - What can you do?
A student activity

Chlorofluorocarbons or CFCs are a family of chemicals. Although not directly hazardous, over recent years there has been increasing scientific concern that when released into the atmosphere they damage the ozone layer. There is now international agreement that CFCs should be controlled because of their potentially damaging effect. Public opinion has been heightened by the recent media attention given to the 'ozone hole' over Antarctica. The major uses of CFCs are in refrigerators and air conditioners, the making of plastic foams and some aerosol products.

ACTIVITIES

• Survey the aerosols at home (e.g. the bathroom, laundry and kitchen).
• Make a list of those products containing chlorofluorocarbons or freons (another name for CFCs). How many did you find?
• Go to the supermarket and try to find alternative products that do not use CFCs.
• Write down any alternative products next to your original list.

• Are there any products you could not find alternatives for? Discuss these items with your classmates.
• Show your parents your list and suggest that they consider buying the CFC-free products. Explain why.

CFCs are used in a multitude of products that are part of our everyday lives. With a little effort and knowledge you can help prevent ozone damage by buying wisely, refusing to use non-essential products and by explaining to others how emissions can be minimised.

DISCUSSION POINTS

• How would labelling of products containing CFCs reduce emissions?
• How is public education and awareness related to labelling?
• What options are there for recycling?

• What alternatives are available for CFC products?
• What are the effects of increased ultra-violet radiation?
• Car and other airconditioners can be a large source of CFCs if not properly maintained. What maintenance can be done to minimise emissions?
Assessing a technology
A student activity

Our society and environment have been dramatically affected by technological change - just think, for example, of the effects of the motor car! At present there are many new technologies like communication satellites, superconductors, wind, and solar power generation competing for public support and acceptance.

But which technologies should be supported? Should some be opposed? Many people think of technologies simply as tools which are neither good or bad in themselves. But it can also be argued that the solar panel and the nuclear reactor cannot be understood merely as different types of hardware. They are products of different human values and purposes and may serve very different social interests. A lot of the publicity given to new technologies is just another form of glossy advertising. But who tests the new technologies for their social and environmental costs and benefits?

Paste a picture "advertising" a new technology in the middle of a large sheet of paper. Divide the paper into four sections as shown below. Write your answers to the following questions in the appropriate sections:

Section A
What values, assumptions, purposes and social interests seem to have led to this technological innovation?

Section B
What might be the social and environmental consequences of this technology becoming widely used?

Section C
Why might people support this technology's widespread use?

Section D
Why might people oppose this technology's widespread use?

Science and Technology in Society - a new project for 7 to 14 year olds
Reprinted from Science Education Newsletter, January 1990 published by The British Council

The success of the Science and Technology in Society (SATIS) materials for 14-16 year olds led to the SATIS 16-19 Project. A new three year project, Early SATIS, has been launched by the ASE with financial support from industry. The Early SATIS Project aims to:

- Introduce 7-14 year old pupils to the SATIS approach
- Broaden the base of science and technology experiences, giving them a social context

The project will address the needs of teachers by helping to develop teachers' own understanding of science, especially the place of science in society.

Further information about the project is available from:

John Stringer

Acknowledgement

The activities on pages 18-19 are based on the teacher's notes and activity sheets in Our Changing Environment: A Choice of Futures, a publication produced by the Commonwealth Department of the Arts, Sport, The Environment, Tourism and Territories, Australia 1988. A number of ideas and activities in this package are adapted from R A Slaughter Future Tools and Techniques, Lancaster, UK: University of Lancaster, 1987; and from J Fien "The Future of the Australian Environment" in Living in the Australian Environment, Canberra CDC, 1988.
Resources

Clean water - a right for all

This resource pack for teachers contains explanatory notes for teachers with background information on the discovery of bacteriology, water-borne diseases, the effect of flood and drought, and water supply and sanitation around the world. There are also suggestions for activities, with photocopyable worksheets, to allow children, aged 8 to 13 years, to discover the properties of water and its place in their lives. The resource pack has been published by Unicef and is available at a cost of £5.95 from Unicef-UK, 55 Lincoln's Inn Fields, London WC2A 3NB, UK.

Evaluation of teaching effectiveness

A selection of principal papers presented at the ICASE Europe Research Seminar on the evaluation of teaching effectiveness held in Caserta, Italy in October 1989, has been published in a special edition of the journal of AIF, the Italian Association for the Teaching of Physics. The papers have been published in both English and Italian. Copies of the journal are available (£5.00 or US$8.00) from Dennis Chisman, Honorary Treasurer, ICASE, Knapp Hill, South Harting, Petersfield GU31 5LR, UK.

1989 ICASE Yearbook
Science education and the quality of life

This 200 page publication includes 6 theme addresses and 50 selected papers which were presented at the ICASE World Conference/CONASTA 37 in Canberra, Australia, July 1988. The yearbook includes papers on developments in science education, social and ethical issues, people and health, computing and educational technology, the environment, industry and technology, energy, chemical science and technology, and science education research. Copies are available (Price £7.00 or US$12.00) from Brenton Honeyman, ICASE Journal Editor, 10 Hawken Street, Monash ACT 2904, Australia.

PASCO scientific
An ICASE Company Member

PASCO scientific has been a designer, manufacturer, and distributor of educational physics apparatus for over 25 years. Their equipment supplies the educational laboratories of most major universities in the United States, as well as universities, colleges and secondary schools in over 35 other countries.

As a distributor, PASCO carries a diverse range of over 400 products covering all the disciplines of physics. Along with the classics of educational physics, such as the air track and the force table, they also carry the latest computer aided experimental systems and simulation software.

As a designer, PASCO's efforts have two main thrusts. The first is to update and upgrade the classic equipment of the physics lab, such as developing an "air track" for studying rotational motion, or designing a more complete optics system that incorporates magnetic mounting. This also includes implementing modern manufacturing techniques to provide equipment of a higher quality at a reduced price. The recently completed h/e Apparatus, for example, can be used to study the photoelectric effect and to measure Planck's constant with much greater accuracy and reliability than was previously possible in student labs.

The second thrust of PASCO's design effort is to develop equipment and software that enables educators to use the computer more effectively in labs and demonstrations. PASCO's Smart Pulley, for example, is an inexpensive instrument that provides a versatile link between the computer and almost any moving object (dynamics cart, pendulum, mass on spring, etc).

PASCO prides itself in being a "full service" supplier. Each piece of equipment comes with a complete manual. Where applicable, the manual will include one or more worksheet style experiments that can be photocopied for use directly by the students - some systems come with 10 or more experiments in the manual.

Beyond this, PASCO maintains a technical support staff that knows physics equipment and physics. With direct access to the equipment designers and to active educators, they can provide helpful technical assistance in selecting and in using their equipment. As the manufacturer of most of what they sell, PASCO can ensure rapid after sales service so your equipment will always be ready for use.

For more information on PASCO's line of educational physics equipment or to receive a free copy of their catalogue, contact your local representative, or:

ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1990

April 5-8
National NSTA Convention
Location: Atlanta, Georgia, USA
Contact: Michael J Padilla, University of Georgia, Science Education, 212 Aderhold Hall, Athens, Georgia 30602, USA

April 8-11
NARST Annual Meeting
Location: Atlanta, Georgia, USA
Contact: Jane Butler Kahle, Chair, NARST Program Committee, 221 WTHR Bldg, Purdue University, West Lafayette, IN 47907, USA
The National Association for Research in Science Teaching invites educators to participate in the program of contributed papers, poster sessions, panels, symposia and round table discussions.

April 22-27
International Symposium on Fieldwork in the Sciences
Location: Field Study Centre, Orvelte, Netherlands
Contact: Drs Henk Lindeman, Secretary of FISFIS, Field Study Centre, Zuiderweg 10, 9441 TZ Orvelte, Netherlands
This symposium has been endorsed by ICASE and aims to acquaint participants with different curricula and developments in fieldwork for geography, physics, biology, chemistry and science subjects. Teachers in primary, secondary and tertiary education, teacher trainers, staff members of field study centres, curriculum developers and others interested in the integration of fieldwork and education are invited to attend. The symposium will be conducted in English and includes active fieldwork sessions based on world trends in fieldwork, plenary sessions on the role and implementation of fieldwork in environmental education, poster presentations, workshop and discussion groups, and fieldwork excursions. A Proceedings of the symposium will be prepared.

April 23-27
International Conference on Physics Education through Experiments
Location: Tianjin, China
Contact: Prof Li Chun, President, Peking University Branch Campus, Beijing, China
This international conference, a joint activity of the International Commission on Physics Education (ICPE) and the Asian Physics Education Network (ASPEN), will focus on the use of demonstration experiments, student home-made experiments and modern teaching aids in the teaching of university and high school physics.

May 6-11
GASAT Conference: Science and Technology - A Future for All
Location: Jonkoping, Sweden
Contact: Ingrid Granstam, European & Third World GASAT Secretariat, Jonkoping University College, PO Box 2264, S-55002 Jonkoping, Sweden
"Science and Technology - A Future for All" is the main theme of this second European Conference. The framework for contributions will be (1) girls and women in science and technology education: from preschool to higher education and in adult education formal and informal experiences; (2) women in the workplace: in science and technology at all levels. Important themes are seen to be progress and promotion; training and retraining; recruitment and retention; coping strategies in a male environment; feminist strategies on technology; evaluation of strategies for change; historical perspectives; future perspectives.

June 6-8
ICASE Europe Research Seminar
Location: University of Dortmund, Dortmund, F R Germany
Contact: Prof Dr Hans-Jurgen Schmidt, Department of Chemistry, University of Dortmund, Otto-Hahn-Strabe, D-4600 Dortmund 50, F R Germany
The theme of this research seminar is "Empirical Research in Science and Mathematics Education". The aim of the seminar is to discuss the methodology of empirical research in this field. Approximately twelve 40 minute papers will be presented (in English) and then discussed. A Proceedings will be printed and available through ICASE.

June 7-9
Second European Conference on Health Education
Location: Warsaw, Poland
Contact: Mrs M A Modolo, Europe Office, Centro Sperimentale per l'Educazione Sanitaria, Universita di Perugia, CP 35 PG 3, Via del Giochino 4, 06100 Perugia, Italy
Organised by the European Region of the International Union for Health Education, this conference will focus on young people as the target group. Innovative educational
approaches will be introduced to improve communication and the quality of health education. During the conference, a competition organised particularly for secondary school pupils, based on their own interests (environment, school life, community) will take place.

June 25 - July 6
Second International Workshop on New Technology Course Materials
Location: MEDC, Paisley, Scotland, UK
Contact: Dr Peter Williams, Director, MEDC. 8/14 Storie Street, Paisley PA1 2BX, Scotland, UK
This cooperative workshop will develop materials for the new technologies. Groups from different institutions and countries will select topics of common interest on which to produce computer aided learning packages, videos, open learning or other appropriate materials. All resulting materials from all groups will belong to all participants.

July 4-6
ASPEN Regional Workshop II on Conceptual Structures and Change in Physics Learning
Location: Quezon City, Philippines
Contact: Dr Vivien Talisayon, ISMED, University of the Philippines, Diliman, Quezon City, Philippines

July 9-13
CONASTA 39 Annual Conference of the Australian Science Teachers Association
Location: Alice Springs, Northern Territory, Australia
Contact: Peter Deacon, Convenor, CONASTA 39, PO Box 705, Alice Springs NT 0871, Australia
The CONASTA 39 theme is “Science Education and Technology for the 90's”. The Conference will provide a forum for science educators to examine important issues confronting us in the new decade. The program includes keynote addresses, practical sessions, excursions and social events. This is an ideal opportunity for visitors to experience the world renowned attractions of central Australia.

July 9-14
NASA Space Science Seminar and Workshop
Location: NASA Lyndon B Johnson Space Center, Houston, Texas, USA
Contact: Evhan Uzhybshyn, Science Consultant, Manitoba Education, 409-1181 Portage Avenue, Winnipeg, Manitoba, Canada R3G OT3
This program is open to selected applicants from Canada and up to 10 international delegates. Application forms must be submitted by 30 April 1990. The program includes special lectures by NASA researchers, and an extensive program of visits to facilities including the site research and testing facility, NASA Jet Propulsion Labs, Space Shuttle Orbiter Training Facility, Physiological Training Center and the Weightless Training Facility. Participants will be responsible for their own airfare, hotel accommodations (at group rate), meals, and a registration fee of Cdn $135.

July 14-17
1990 ASERA Meeting
Location: Freeway Hotel and Curtin University of Technology, Perth, Western Australia
Contact: Dr David Treagust, SMEC, Curtin University of Technology, Bentley, WA 6102, Australia
Science educators interested in science education research are invited to attend the annual meeting of the Australian Science Education Research Association, an ICASE member association. For those attending CONASTA, there will be a direct flight from Alice Springs to Perth on the 14th July. A subsidy is available for those presenting their first ever paper.

August 19-24
Third International Conference on Teaching Statistics
Location: University of Otago, Dunedin, New Zealand
Contact: The Secretary, ICOTS 3 Local Organising Committee, Department of Mathematics & Statistics, University of Otago, PO Box 56, Dunedin, New Zealand
ICOTS 3 aims to improve the quality of statistics instruction on a world-wide basis, fostering international cooperation among teachers of statistics, and promoting the interchange of ideas about teaching materials, methods and content. The program includes plenary, invited and contributed paper sessions, workshops, panel and poster sessions. Teaching from beginning school to college, polytechnic and university level will be included, as well as sessions on teaching statistics in government, business and industry. Opportunities will be provided to see and experiment with the latest computer hardware and software. You are invited to submit a contributed paper, workshop, poster or exhibit.

August 26-31
SCICON 1990
Location: University of Canterbury, Christchurch, New Zealand
Contact: Conference Secretary, SCICON 1990, Department of Continuing Education, University of Canterbury, Christchurch, New Zealand
SCICON 1990 will be the seventh biennial conference of the New Zealand Science Teachers Association. Workshops, laboratory sessions, seminars, discussion groups, access sessions, and keynote addresses will address the theme Science for tomorrow’s world. The program also includes field trips and visits to research institutes, industries and places of scientific interest.

August 27-30
ASETT-ICASE Conference on Science & Technology for Developing Countries
Location: Port of Spain, Trinidad, West Indies
Contact: Conference 90, ASETT, Faculty of Education, University of the West Indies, St Augustine, Trinidad & Tobago, W1
The Association for Science Education of Trinidad and Tobago (ASETT) in collaboration with ICASE will host a conference on “Education in Science and Technology for
Development: Perspectives for the 21st Century." The conference will be open to science and technology educators of all countries, but Caribbean problems will be of particular interest. The conference aims to provide a varied program focusing on (1) scientific and technological developments as they impact upon our lives at present, and are likely to impact upon our lives in the 21st century; (2) social and ethical issues consequential on developments in science and technology; (3) the thrust of modern technology and the implications for science and technology education; (4) educational technology and the teaching of science - developments in resource materials production for the teaching of science and technology; (5) appraising present curriculum trends in science and technology education in the Caribbean and Latin American subregions and worldwide; (6) the schools and universities/industry interface; (7) bridging the gap in science education - primary through tertiary; and (8) action towards the goal of science and technology education for all with appropriate emphasis on the popularisation of science, science clubs and out of school science activities.

August 31 - September 2
CTC-IUPAC Meeting: International Symposium on the Environment and Chemistry Teaching
Location: Moscow State University, Moscow, USSR
Contact: Prof Y Treutinkov, Chemistry Department, Moscow State University, Moscow 117234, USSR

September 5-7
ICASE European Symposium on Industry and Education
Location: Brussels, Belgium
Contact: Drs Jan Hendriks, ICASE Executive, Konijnepad 3, 7921 BM Zuidwolde (Dr), Netherlands
Invitations have been sent to member associations of ICASE and to other bodies in Europe, USA, Canada and Australia to nominate education representatives to attend this seminar. Industry representatives are being invited by Conseil Européen des Fédérations de l'Industrie Chimique (CEFIC). The symposium is being organised to (1) provide opportunities for the exchange of information and experiences in schemes for industry-education liaison, (2) develop models for industry-education liaison, (3) establish a network for information exchange for future developments, and (4) publish a resource book for teachers and administrators on industry-education liaison.

September 10-20
Seminar on STS Education
Location: University of Oxford, Oxford, UK
Contact: The Director, Courses Department, The British Council, 65 Davies Street, London W1Y 2AA, UK
The British Council announces its forthcoming seminar on "Science Technology and Society Education: Developing a Relevant Science Education for the Future." This seminar has vacancies for 40 participants and is intended for experienced science teachers, senior educators with responsibility for science curriculum development, school science inspectors and advisers, and teacher trainers. The seminar will consider a wide range of educational issues which arise when science and technology are taught in the context of their social interactions. The following topics will be considered - rationale for STS, developing new curriculum materials in schools, innovations in teaching STS, research into STS in the classroom, studying the environment, ethical and gender considerations, monitoring changes in new technology, media influence on our students' ideas, and the way forward.

October 18-20
World Environment Energy and Economic Conference
Location: Winnipeg Convention Centre & Holiday Inn, Winnipeg, Canada
Contact: Mr Jack Pyra, Past President STAM, John W Gunn School, Winnipeg, MB R2C 3C9, Canada; or Mr Bob Lepischak, Vice President ICASE, Neepawa Area Collegiate, Neepawa, MB R0J 1H0, Canada
This conference, endorsed by ICASE and the Canadian Association for Science Education, and hosted by the Science Teachers Association of Manitoba, will focus on the theme "Sustainable Development Strategies - The New World Agenda". A program is being prepared to interest educators, youth and the general public. Businesses and industries are being invited to participate. The conference will enable participants to examine and discuss the links that must be fashioned so as to integrate environmental concerns with continued development on the energy, resource and economic fronts. The program will address the role that curriculum, teachers and schools can play in helping students understand the environmental realities which are the cornerstone of sustainable development.

An International Symposium on Sustainable Development will precede the conference on October 15-17. International representatives from education, government and industry will meet to examine the implication of sustainable development upon the curriculum and students of tomorrow.

November 7-11
NABT Annual Meeting
Location: Westin Galleria & Westin Oaks Hotels, Houston, Texas, USA
Contact: National Association of Biology Teachers, 11250 Roger Bacon Drive, Reston, Virginia 22090, USA
The theme of this conference is Planet Earth in Crisis. International delegates are welcome. A feature of this year's program will be contributions by international participants and an international reception.

December 12-14
ASPEN Meeting on Demonstration Experiments and Computer-Aided Learning in Physics
Location: Pune, India
Contact: Prof Arun Nigavekar, Physics Department, Poona University, Pune, India
December 27 - January 1
International Conference on Teaching of Physics
Location: Karachi, Pakistan
Contact: Mrs Aziz F Hasnain, Head, Department of Physics, APWA Government College for Women, F 'B' Area, Karachi, Pakistan
The theme of this international event is The changing face of physics education in developing countries. The conference aims to discuss techniques for conceptual teaching in physics, to create awareness among physics teachers about modern teaching methods including the use of computers and audiovisual aids, and to establish a research program in physics education.

1991

March 27-30
NSTA National Convention
Location: Houston, Texas, USA
Contact: Linda Crow, Asst Professor, Baylor College of Medicine, One Baylor Plaza, Room 633E, Houston, Texas 77030, USA

March 29 - April 3
7th ICASE-Asian Symposium
Location: East China Normal University, Shanghai, China
Contact: Dr Jack Holbrook, Executive Secretary, ICASE, Department of Curriculum Studies, University of Hong Kong, Hong Kong
The ICASE Executive Committee have accepted a proposal from the East China Normal University in conjunction with the Shanghai Association for Science and Technology and the Shanghai Board of Education to host an ICASE Conference in March-April 1991. The symposium will be conducted in English/Mandarin and will address the theme Making science education in schools more relevant. The program will focus on (1) the development of appropriate curricula, the issue of integrated science vs separate sciences, the introduction of STS in science courses; (2) innovations in teaching, the role of project work, the teaching of science communication skills, low cost equipment, fieldwork; (3) technology in education, the effective use of visual aids, visits to industry, the place of the computer; and (4) research in science education, children's learning in science, assessment techniques. The program will consist of presentations by internationally renowned science educators; papers, workshop and discussion sessions; poster displays; and an exhibition.

July
GASAT 6 International Conference
Location: University of Melbourne, Victoria, Australia
Contact: Ms Gaell Hildebrand, School of Education, University of Melbourne, Parkville, Victoria 3052, Australia
In order to be placed on the mailing list for calls for papers, etc, write to Gaell Hildebrand at the address above.

August 4-9
ChemEd 91 Conference
Location: Oshkosh, Wisconsin, USA
Contact: Bruce G Smith, Co-Director, Appleton High School-West, Appleton, Wisconsin 54914, USA or Paul Kelter, University of Wisconsin, Oshkosh, Wisconsin 54901, USA
ChemEd 91 is a major chemical education conference of interest to university, college, secondary and elementary educators from North America and beyond. Throughout the weeklong conference, activities are planned for all members of the family including excursions, field trips, sports activities and social events - a feature of ChemEd conferences.

August 25-30
11th International Conference on Chemical Education
Location: University of York, UK
Contact: Dr John F Gibson, ICCE 11, Royal Society of Chemistry, Burlington House, London W1V OBN, UK

August 26-30
Fourth Asian Chemical Congress
Location: Beijing, China
Contact: Prof Dehe Zhang, Secretary General of 4ACC, Chinese Chemical Society, PO Box 2709, Beijing 100080, China
The 4th Asian Chemical Congress will be held under the sponsorship of the Federation of Asian Chemical Societies. The Congress will focus on the important role of chemistry in raising the health conditions and living standards for all people. The program of plenary lectures, invited papers and contributed papers will be conducted in English and will concern various topics including organic chemistry of natural products, analytical chemistry and instrumentation, environmental chemistry, agrochemistry, coordination chemistry and its applications in medicine and agriculture, polymer science, photochemistry, computers in chemistry, catalysis, and chemical education.

Subscriptions
Member associations, institutions, centres, foundations and companies receive Science Education International as part of their membership entitlements. Individuals and libraries may subscribe to Science Education International by forwarding an annual subscription (cheques payable to "ICASE") to:

Dennis Chisman, ICASE Honorary Treasurer
Knapp Hill, South Harting, Petersfield GU31 5LR, UK
Individuals £9 per annum, Libraries £18 per annum

or to one of these subscription centres:
John Penick, ICASE Special Projects
Science Education Center, University of Iowa, Iowa City 52242, USA
Individuals US$15 per annum, Libraries US$30 per annum

Brenton Honeyman, Editor, The ICASE Journal
10 Hawken Street, Monash ACT 2904, Australia
Individuals A$20 per annum, Libraries A$40 per annum

Jack Holbrook, ICASE Executive Secretary
Department of Curriculum Studies, University of Hong Kong, Hong Kong
Individuals HK$120 per annum, Libraries HK$240 per annum
Editorial
ICASE - enhancing its image through publications
by Brenton Honeyman
Journal Editor

Since its inception in 1973, ICASE has been active in the area of publications, providing to its members scholarly publications such as Resource Notes, Yearbooks, Commemorative Issues, Proceedings from science education meetings worldwide, and topic specific Annotated Bibliographies.

ICASE is currently undertaking a number of new initiatives to extend its services to member associations, institutions, centres, foundations and companies.

This journal, which has taken the place of the ICASE Newsletter, is an important component of ICASE's strategy to not only strengthen communications with and services to member associations, but also provide useful resources directly to individual science educators who are interested in what is going on in science education around the world. Hence this new journal, Science Education International, is available through a low cost subscription scheme to individuals and libraries.

I encourage member associations to take every opportunity to promote this journal to individuals and libraries in their countries. As the number of subscribers grows, the Editorial Team can increase the size of the journal to include more feature articles, more news of science education around the world, more practical ideas for educators in primary, secondary and tertiary classrooms. Your support in making the journal known will help ICASE to produce a bigger and better quarterly publication for us all.

ICASE is enhancing its reputation of producing quality publications - not only in content, but also in presentation. If you haven't yet seen some of the recent publications produced in recent months, order a copy of the just released

<table>
<thead>
<tr>
<th>This section provides news for the information of member associations, institutions, centres, foundations and companies. The Executive Committee encourages members to reproduce this section in journals and newsletters to communicate this information to as many as possible.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Commemorative Issue entitled APOLO 11: A Teacher Resource Book, or the 1989 ICASE Yearbook: Science Education and the Quality of Life, or the report on the ICASE Europe Research Seminar: Evaluation of Teaching Effectiveness. See page 22 for details of how to order these and other affordable ICASE publications.</td>
</tr>
<tr>
<td>ICASE is currently developing an information pack ICASE - the people and the organisation, which includes a profile on the people within the ICASE organisation, and the activities and projects in which ICASE has been, and is currently involved. This information pack will also contain position statements on science education; relationships with member associations, other international organisations and business and industry; and priority areas for future action. This information pack, once the position statements have been adopted at the next meeting of the Executive Committee in January 1991, will be useful in ICASE's endeavour to widen its network of member associations, institutions, centres, foundations and companies; and to enter into collaborative projects with other organisations, business and industry.</td>
</tr>
<tr>
<td>Another new ICASE initiative is the Who's Who in Science Education Around the World 1991 Edition. This valuable reference book will contain profiles on prominent science educators and their work. The information will help you to contact colleagues in both developing and developed countries who may be working on projects of interest to you, who may be potential speakers at your next meeting or convention, or who may be invited to work on collaborative projects. Copies will be sent to all ICASE member associations, institutions, centres, foundations and companies. Copies will also be available to individuals and other organisations at an affordable price. See insert for further details.</td>
</tr>

Photo: Brenton Honeyman, Editor of "Science Education International", in his home office where the quarterly ICASE Journal is produced. It is here that the various sections of the journal are wordprocessed, edited and compiled into page proofs using a Macintosh SE computer. The Editor prints page masters to 300 dpi resolution using a laser printer, and sends these air express to Dr Jack Holbrook, ICASE Executive Secretary, who supervises the printing and distribution of the journal to ICASE member associations, and a growing number of individual and library subscribers worldwide.
Stepping into Science in the Middle East

by Sue Dale Tunnicliffe
ICASE Project Officer

The ICASE Primary Project Stepping into Science has been gaining momentum in several countries. One of the latest regions to become involved in the project is the Middle East.

Yunus Solar, a science teacher at the British School - Muscat, has implemented this approach to primary science education with 4 to 8 year olds. He has developed colour coded certificates for use at different levels. Other teachers in the region may order these certificates (please indicate how many of each colour and include postage).

Yunus Solar can be contacted at the British School-Muscat, PO Box 4907, Ruwi, Sultanate of Oman.

He will share how he has implemented the Stepping into Science program in his school at the ASE Annual Meeting in Birmingham, UK in January 1991.

This ISY (International Space Year) conference was sponsored by NASA and CNES (Centre National d'Etudes Spatiales, France) and hosted by CNES on behalf of the Space Agency Forum of the ISY (SAFISY). This meeting was a direct follow-up of the Frascati SAFISY meeting held in April 1989, and focused on the education and applications aspects of ISY. 175 participants from 41 countries, including developing countries in the regions of Africa, Latin America and Asia, participated in the Deauville meeting. Some representatives had been nominated by ICASE and ICSU-CTS. The conference was organised around two main themes.

Theme A focused on remote sensing training applications, and was chaired by Dr Isaac Rivah of CNES, France. Theme B focused on education and space, and was chaired by Dr Frank Owens of NASA, USA.

Theme A was further subdivided into three working groups: (1) environment resources, monitoring and management (2) geology and natural hazards (3) urban and environmental planning. Theme B was also subdivided into three working groups: (1) earth observation in education (2) space science in education (3) space communications in education. Each of the working groups produced recommendations for specific projects and activities.

The Space Science in Education group, chaired by Bill Aldridge, Executive Secretary of NSTA, USA, formulated a number of suggestions, including:

• Production of an annotated bibliography of resource materials for space science education in schools and colleges
• Teacher training courses, including 1991 summer institute programs in the USA for teachers from overseas countries
• Space Olympiad for students
• Development of teaching modules for space science
• Worldwide distribution of a special 1991 edition of Quantum devoted to space science. Quantum is a students' journal produced in the USSR, and is now published in an English version by NSTA.

Dr David Moore, General Secretary of ASE, presented these suggestions on behalf of ICASE and ICSU-CTS to the Deauville conference. A proposal was developed to produce an international set of resource materials on space science for teachers of science, complementary to the ICSU-CTS curriculum project on global change. This proposal includes:

• Production of an annotated bibliography of existing documents and publications relating to space science in schools, using the networks of ICASE, ICSU-CTS, INISTE (UNESCO), etc.
• Compilation of existing teaching and learning resources into a publication suitable for use by students. This would include visual materials, computer software, etc., and be compiled using ICASE and other networks.
• Development of exemplar modules on space science useful for enriching science lessons.

It was proposed that this project be undertaken during the period 1990-91 so that materials are published and distributed in late 1991.

The proposal for an International Space Olympiad in 1992 involves student teams drawn from existing annual Olympiads in chemistry, mathematics and physics, augmented by earth and life science team members. The final competition would take place on a global video hookup.
This Finite Earth
by Chris G Trump
Honorary Conference Chair

World Environment Energy and Economic Conference
Winnipeg, Canada, 17-20 October 1990

It was the Apollo astronauts returning from the Moon who remarked that our planet looked like a blue marble in the vastness of space - a spacecraft in its own right that alone held the promise for the sustenance of human life. Just as they were dependent on the narrow confines of their capsule to stay alive, so the astronauts’ earth has its limits in ensuring life for the billions that inhabit its surface. We discharge noxious gases into the atmosphere; pour pollution into the waters. But in the end there will be no escaping the penalties of these practices. Acid rain leads to lakes devoid of life and hillsides denuded of forests - to say nothing of the mighty works of man - the Acropolis, cathedrals and other structures that crumble in the onslaught. Rivers and coastlines are no longer fit for fishing or for swimming as offal and algae blooms give warning of worse to come.

Yet hope springs eternal. When the Cuyahoga River of Ohio caught fire and Lake Erie threatened to become a dead sea, a joint US and Canadian effort reversed the toll. In Toronto blue boxes cart away bottles, plastic and cans for re-cycling; in Europe huge incinerators preserve landfills and generate heat as a by-product. In the Soviet Union citizen action is serving notice that the world’s deepest body of water, Lake Baikal, must not go the route of Lake Erie. Conscience drives us to a new consciousness because, in truth, we are all looking...not only at what we are doing to each other, but to those who will come after us.

All of these signs are positive, yet they need continual reinforcement. Too often profit for the present subsumes preservation of the future. Out of sight, out of mind is a mindset that is difficult to overcome. The blob in the St Clair River, the dead zone in the Atlantic offshore from New York, the sump that is Halifax Harbour - all bear mute testimony to the human condition.

Ways must be found to engage another human imperative - that of profit - in halting this abuse. What needs to be driven home is that to preserve and conserve pays better than to waste and pollute. Self-interest sustained, if you will, can do more to improve our mutual lot than the common good ignored.

This was the purpose of the Brundtland Commission’s examination of Our Common Future. It sought sustainable development as something to meet the needs of the present “without compromising the ability of future generations to meet their own needs.”

It is a tall order, and much of the report seems to deliver itself of a catalog of problems, followed by a telephone book of solutions: “Solving the impending urban crisis will require the promotion of self-help housing and urban services by and for the poor, and a more positive approach to the role of the informal sector, supported by sufficient funds for water supply, sanitation and other services.”

What is urgently needed now is to make a few of these calls and begin to show by way of example what must be done. Water supplies just don’t happen - they are made. And they must be paid for. So it is with sanitation - and all the other services. A wish list is not a program.

That is why the World Environment Energy and Economic Conference is such an important event. Here in Winnipeg - a city grappling with its own water needs - will gather planners, government officials, businessmen and concerned citizens. The objective will be to learn from programs that have worked and to chart new ones that will widen the circle of sustained development. How can good water pay for itself? In what ways can the proper diversion of pollution pay dividends?

This conference seeks to light a few candles of realism. They will illuminate practical solutions that will in time make for the critical difference in our planet’s future. It is an exercise well worth the effort.

Chemistry in Dance, Drawing, Drama and Daily Life

Zafra M Lerman

Columbia College is an open-admissions, four-year college, located in downtown Chicago where 52% of students are women, 40% are minorities, and 90% come from Chicago inner city high schools, at which they received very little math of science education. Most of our students display a well-developed fear of math and science. They come to Columbia primarily to major in communications and fine arts (Dance, Art, Theatre, Television, Radio, Photography, Film, Journalism, etc).

We decided from the beginning that we would develop a unique Science Department whose goals were to educate students from every major field of study to appreciate science, to enable them to better understand the world around them, to teach them to use science in any endeavour they pursue. The popular media shape our lives and, because our students are entering media professions, by instilling a strong science background in these future media professionals, we are assuring a better understanding of science for the citizens of today and for future generations.

The objectives in all our classes are to make the subject relevant to the students' lives and personal interests, and to their different majors, and to teach the students the scientific method and problem solving. To this end, we incorporate in our classes subjects which deal with the environment, the arms race, nutrition, drugs, health issues, etc. We also try to make the course material interesting enough to foster within each student an active interest in science, which will last even after graduation from college.

We initially had difficulties in obtaining acceptance among both students and colleagues. As a personal example, facing resistance created by students' preset prejudices against chemistry, which had been fostered by a hostile, anti-science attitude in the art and communications faculty, I invited a group of twenty students to a local pub. As the drinks arrived, I initiated a discussion on the composition of the drinks, which developed into an in-depth description of alcohol (ethanol), in its chemical structure and properties. After a lengthy conversation, the students became hungry, so salads were ordered, but I insisted on an oil and vinegar dressing. Vinegar then became the main topic, which led into the structure and properties of acetic acid. The reaction between ethanol and acetic acid was described and the resultant product, nail polish remover (ethyl acetate), was explained. The students were fascinated by this explanation, despite initial fears that nail polish remover was being formed in their stomachs (a reaction which would require a catalyst). After three hours of discussion, I then pointed out to the students that they had just participated in, and enjoyed, a chemistry class. Since our semester lasts fifteen weeks, I told these students that they only had fourteen classes left, if they immediately enrolled in the chemistry course. Most of them signed up.

After the first semester, there were no problems attracting students to take this chemistry class entitled "Chemistry in Daily Life"; word-of-mouth rapidly spread among the student body of an interesting chemistry course being offered.

To help students relax in their first chemistry class, they are told that if they feel completely saturated during a lecture they should hold up a sign that says "saturation", meaning they can absorb no more information. Students are reminded of their experience of dissolving sugar in coffee or tea - after the solution is saturated, the excess sugar settles on the bottom of the cup.

To explore the chemical phenomenon of saturation, students are given a beaker of water and asked to slowly add table sugar. Everyone observes that the sugar dissolves, and the analogy is drawn to their ability to retain ("dissolve") lecture material. As they continue to add sugar, they reach the point where the sugar no longer dissolves - this is defined as the saturation point. These saturated solutions are heated on hot plates and the students observe that additional sugar will dissolve in the heated solutions. The students are asked at this point if raising the temperature in the room will help them absorb more material. (When the laughter dies, we conclude that the analogy doesn't stretch quite that far.)

At the conclusion of this experiment, the topic of crystallization is investigated, and students who suspend a string in their sugar solutions can return to class the following week, examine the crystals that have formed, and indulge in the pleasure of eating the results (rock candy).

This coursework then continues by addressing the social issue of nuclear power, which starts with a discussion of the structure of the atom, atomic orbitals, the chemical bond, and examples of ionic bonds and covalent bonds. The discussion continues with the nucleus, radioactivity, fission, fusion, the development of the atomic bomb and the hydrogen bomb, and ends with an examination of the science, technology and environmental effects of nuclear power plants. Under the title of Acid Rain, we discuss acids and bases, salts, pH indicators and titrations. Students are asked to bring in samples of their own shampoos, and soil from their houses and gardens, to analyse the pH. Rain samples are also collected, and we try to detect any differences in acidities from different areas on different dates.

When we consider nutrition, we talk about proteins, hydrocarbons and DNA, then synthetic polymers, and we continue by discussing fertilisers, foods, food additives, household chemicals, cosmetics and drugs, as well as the chemistry of muscles in sports and dance. Most of these
topics are accompanied by relevant lab experiments and demonstrations. To keep the class material up-to-date, students are asked to bring in articles from newspapers on the subjects being covered, and to present these articles in class.

Chemistry in Daily Life was the first chemistry course we offered and, after the students expressed a tremendous interest in the variety of covered topics, we began to branch out and offer courses on specific subjects as general chemistry, organic chemistry, forensic chemistry, biochemistry, analytical chemistry, etc. To generate student interest, these courses were given attractive titles such as The Science of Nutrition; Energy and the Planet Earth; Human Involvement and the Environment; Lifesavers or Killers: The Story of Drugs; Scientific Investigation: From Sherlock Holmes to the Courtroom; Chemistry of Living Things; Chemistry of the Human Body; Modern Methods in Science: Discovering Molecular Secrets; The Science of Art and Color; Science, Technology and Ethics; Science and Social Issues; and Scientific Issues Behind the News. We continue adding to our curriculum to meet student demand.

All these courses are taught from the economic, environmental, societal and ethical points of view, and as such are made very relevant to the students' lives and interests.

As part of the requirements in each of our courses, students working as individuals or in groups must complete projects on scientific (or science-related) topics, and present them to the class using the tools of their majors. Creativity and originality are strongly encouraged, and students incorporate not only their skills and talents into these projects, but their personal interests and hobbies as well.

A music student presented a paper on "The Chemical Elements Used in Making Strings of Musical Instruments". In order to demonstrate his topic, he built some primitive instruments and played them for the class. Another student studying music and poetry prepared a project on depression and anti-depressant drugs. He wrote it as a poem, set it to music, and presented it to the class, accompanying himself on the guitar.

Students majoring in art use their talents by presenting their projects as a lecture invariably accompanied by some artwork. One student presented his lecture on chemical and physical defense mechanisms employed by fish alongside a colorful poster (Fig.1). Another accompanied her lecture on AIDS with a poster titled "AIDS: The disease doesn't care who you are" (Fig.2).

Another art student made an extremely creative multi-media sculpture which demonstrates the excitation and flow of anthropomorphised electrons through metal wire (Fig. 3).

A student cartoonist created a comical "soap opera" which personified electrons and told of the intricate lives and relationships they lead during chemical bonding (Figs. 4, 5).

Students make polyurethane in a regular laboratory experiment in the Chemistry in Daily Life Class; many creative students mould the polyurethane, while still pliable, into various amusing and inventive shapes.

A videotaped project titled "Early Afternoon with David Foltman" (based on a popular American Night-time television program), was a comical talk show interview with a "famous bond expert" who discussed the human skeleton. Another student incorporated his love of sports in his project, which explores both the materials used in baseball construction, as well as the physics involved in different baseball pitches. "Acetylcholine - The Motor Neurotransmitter" was a videotape on the chemicals involved in muscular reactions. A group of television students presented a project which takes a humorous look at the different sciences involved in forensic crime-scene investigations.

A group of theatre students presented a project explaining the periodic table, the metallic and non-metallic elements, atomic orbitals, and the ionic bond. The project, presented as a Shakespearean tragedy, was entitled "Sodium and Chlorine: A Love Story". The students wrote the script, memorised it, and performed it in front of the class - a fascinating chemistry project and an amusing love story. A group of dance students choreographed Mitosis, illustrating replication and separation of the chromosomes. This dance was videotaped by television students.

Another art student presented a lecture on fusion and Einstein's theories, accompanied by a large painting. Another student presented her paper on Einstein's theories and how they were interconnected with the principles of the universe. Along with her paper, she presented a multi-media sculpture with a picture of the universe behind a portrait of Einstein.

This creative approach to science was demonstrated this year by a poetry book written by a very famous chemist and Nobel laureate, Roald Hoffman, in which he communicates science through poetry. One of his poems, Man and Molecules, very effectively illustrates how poetry can be used in science:

ICASE Endowment Fund

Associations and individuals are invited to contribute to this fund to support the activities of ICASE.

Contact the Honorary Treasurer of ICASE for further details.
Figure 1  Defense Mechanisms in Fish

Figure 2  AIDS - The disease doesn't care who you are

Figure 3  Visual Concept - Electricity in a Wire - Multimedia Sculpture
...With the molecules of magnesium and oxygen...

John is an electron that lived on the valence shell of the magnesium molecule along with his brother. Now... they were no more.

On the oxygen molecule everyone was happy except, they felt incomplete...

Don't it feel like something missing...?

The valency of the oxygen molecule is 2, and needed only 2 more to become just like the noble gas neon.

However, magnesium had a valency of 2, and following the octet rule of 8, didn't need the 2 electrons electrons in its outer shell...

But suddenly one day...

MAGNESIUM WASN'T HAPPY...

They read the book, they looked outside... a little girl was running.

And magnesium gave up the electrons to oxygen making magnesium oxide...

The theory is that the elements on the left (metals) of the table tend to give up electrons to the elements on the right (non-metals) of the table. The crystal solids are held together by the attraction of oppositely charged ions... this attraction is called...

**IONIC BOND**

...and magnesium gave up the electrons to oxygen making magnesium oxide...
Cantilevered methyl groups, battered in endless anharmonic motion. A molecule swims, dispersing its functionality, scattering its reactive centres. Not every collision, not every punctilious trajectory by which billiard-ball complexes arrive at their calculable meeting places leads to reaction. Most encounters end in a harmless sideways swipe. An exchange of momentum, a mere deflection. And so it is for us. The hard knocks must be just right, the eyes need to be opened, and glimmers of intend penetrate. The setting counts. A soft brush of mohair or touch of hand. A perfumed breeze. Men (and women) are not as different from molecules as they think. (Hoffmann, 1987)

In answer to survey questionnaires, the projects are invariably rated as the students’ favourite segment of the courses, because each student feels they can apply their talents and interests to the course material, and they always enjoy the experience.

We used these teaching methods in levels kindergarten to adult, and in settings ranging from formal to informal, and have always had the very best success. We feel that these methods closely follow the late I I Rabi’s (Nobel laureate in physics) description of how science should be taught: “Science is an adventure of the whole human race to live in and perhaps to love the universe in which they are. To be a part of it is to understand, to understand oneself, to begin to feel that there is a capacity within man far beyond what he felt he had, of an infinite extension of human possibilities .... I propose that science be taught at whatever level, from the lowest to the highest, in a humanistic way. It should be taught with a certain historical understanding, with a certain philosophical understanding, with a social understanding, and a human understanding in the sense of the biography, the nature of the people who made this construction, the triumphs, the trials, their tribulations.” (Rabi, 1972)

About the author
Prof Zafra M Lerman is Chairperson of the Department of Science, Columbia College, Chicago, USA. This article, so typical of the author’s creative approach to the teaching of chemistry, has been reprinted from the 1989 ICASE Yearbook “Science Education and the Quality of Life” on the occasion of Prof Lerman receiving the National Catalyst Award in recognition of her distinguished career in the teaching of chemistry. Prof Lerman is an active supporter of ICASE activities and Columbia College Chicago is an Institutional Member of ICASE.

1988/89 CASTME AWARDS

First Prize
No first prize was awarded

Second Prize
Murugiah Atuphanathan (Seychelles) Developing a teaching sequence for the theme biosphere for lower secondary science in the Seychelles

Joint Third Prize
Mrs Ann Glover (Zimbabwe) O-level ecology project: a teaching aid for science in the Zimbabwe O-level syllabus
Mr A Christie (India) Save your waits, save your money

Commendations
Ms Desiree Coleiro (Malta) A textbook and teachers’ guide for primary environmental education
Mrs Lee Lee Tee (Malaysia) Biological utilisation of wastes for the cultivation of mushrooms
Mr Ramanlal Hiralal Gujar (India) An examination of mathematics deficiencies of pupils in the first standard by observation of tests

You are what you eat
This has a whole new meaning if you’re a caterpillar. A biologist at the University of California, Davis, recently discovered that Nemoria arizonaria caterpillars, which hack in the spring and feed on an oak’s male flowers or catkins, soon take on catkins’ fuzzy, golden appearance - even down to rows of dots on their backs resembling catkin pollen sacks. In contrast, Nemoria arizonaria hatchling in the summer after catkins are gone look like greenish-grey oak twigs - a result of tannins in the leaves that they eat. This is the first known case in which diet alone dramatically affects an insect’s appearance.

From “Science Notes” Newsscience Vol 14 No 2, a publication of the Ontario Science Centre
250 teachers, including delegates from England, Scotland and the Netherlands, attended the 29th Annual General Meeting of the Irish Science Teachers Association at St Enda's College, Galway, 6-8 April 1990.

The broad and diverse program included the following sessions:

John Foeman, an environmental scientist and historian who is best known for the television series "Exploring the Landscape" presented a session on The science and magic of bogs which examined the fascinating spectrum of Ireland's bogland heritage, its importance, and its role in the teaching of science.

Dr Emer Colleran, lecturer in microbiology at University College in Galway, in her talk on Conserving the Irish environment, focused on the link between development and conservation, the long term benefits to be gained from informed environmental concern, and the role of classroom teachers in helping to create informed concern.

Dr David Thompson from Northern Ireland presented a session on Electronics teaching equipment - just how do you choose? in which he outlined the major criteria for choice of equipment.

Dr Jim Murdoch of Scotland addressed the topic Solving real problems - bringing industry into the chemistry classroom. This session described how materials for Standard Grade Chemistry (a new course for 14-16 year olds in Scotland supported by an Understanding British Industry Project and financed by BP) were produced.

The project focuses on real problems for pupils to solve using a variety of strategies including role plays, practical investigations, and group decision making.

Dr Brendan Keegan, lecturer in zoology at University College, Galway, introduced new hi-tech developments in the area of marine biology during his address Old problems - new solutions.

In his lecture on Corrosion, Dr Liam Carroll, lecturer in physical chemistry at University College, Galway, described simple ways to communicate information using common everyday examples.

Billy Reidy explored in Teaching science in the primary school the opportunities that science provides for developing skills and involving children in their own education.

Jackie Jones, a health educator, addressed a number of issues confronting teachers when dealing with topics related to sex. In her session Sex, science and school ethos, she presented a model to explain how and why topics on sex are treated differently.

The program also included workshops for biology, chemistry and physics teachers, tours and social events.

Many national reports in the United States have suggested that students learn best through programs that provide substantial hands-on laboratory experience. Such programs make science teaching complex and challenging.

The National Science Supervisors Association's LISE Center recently held the first in a series of leadership development clinics dealing with laboratory safety programs.

The Clinic, held in the state of Florida, provided teachers, supervisors and administrators with information and advice on laboratory safety procedures and policies, and helped them to develop pertinent communications and supervisory skills. The objectives of the Clinic were as follows:

- To inform participants of the laws, codes, regulations and accident case
MNU to celebrate 100 years as an association

1991 will be the 100th anniversary of MNU (des Mathematischen und Naturwissenschaftlichen Unterrichts) in Germany. Special celebrations will take place from 24-29 March 1991 at Gottingen, including a meeting devoted to international issues and problems confronting science education. It is hoped that this meeting will lead to similar meetings in other European countries.

The MNU is conducting a survey to determine the amount of time spent on science teaching in schools. It is their belief that this is a useful indicator of the priority given to science education, and the association plans to use this data in order to strengthen the case for a higher priority being given to science education.

The survey form asks respondents to indicate the number of hours per week allocated to integrated science, to biology, to chemistry, and to physics at each age level.

MNU is keen to obtain comparative data from science teachers in other countries. Those willing to contribute to this MNU project are invited to request a survey form by writing to:

FRG

The Harare Generator
Zimbabwe, Africa, September 1990

The University of Zimbabwe, in association with the Committee on the Teaching of Science of the International Council of Scientific Unions (ICSU-CTS) will be hosting this meeting to develop Africa-relevant adaptations of educational innovations. The Harare Generator will have the theme "Innovative techniques in science and technology education in Africa". It will be a regional followup to the ICSU-CTS Conference on Science and Technology and Future Human Needs which was held in Bangalore, India in 1985.

A number of African countries have begun to adopt the ideas raised in Bangalore to make curriculum changes in schools, colleges and universities. The Harare Generator will provide an opportunity for African countries to share the results of these developments since Bangalore. It will involve presentations, demonstrations and hands-on workshops by leaders in educational innovation. However, the Harare Generator is not a conference. Participation will be by invitation only.

The aim is to develop a tangible product that can be immediately copied and issued to participants on departure.

This product will be a pack containing:

- proceedings of key presentations
- videotapes of key demonstrations and workshops
- computer disks with samples of software demonstrated or developed during the Generator
- blueprints and prototypes of low-cost equipment demonstrated, designed or built during the Generator
- project proposals and funding awards constructed or negotiated with representatives of Development Aid Agencies

The organisers are keen to find out who are the key, creative people in Africa to contribute. Suitable people would be those using or developing innovative techniques in science and technology in Africa; those with an ability to adapt ideas for trials in African conditions; those in a position to make further progress in such work; and those in a position to disseminate the results of the Generator.

Recommendations for participants should be sent to Mike Robson, Harare Generator, Faculty of Science, University of Zimbabwe, PO MP 167, Harare, Zimbabwe, Africa

For additional information, please contact:

Dr Kenneth R Roy
NSSA LISE Center
Suite 227-228
Copernicus Hall
Central Connecticut State University
New Britain, CT 06050
USA.
UNESCO calls for articles on science education

by John Ellick

The Science Education Section of UNESCO is interested in receiving submissions from science teachers and teacher trainers who would be willing to write short articles (2-3 pages) for UNESCO based on their classroom experience of teaching or observing the teaching of the following topics:

- biotechnology
- bioethics
- marine science
- use of microcomputers in science
- chemistry and energy resources
- chemistry and the environment
- science and technology for rural areas
- educational games for teaching science
- community resources for out-of-school science teaching
- science and technology for women in rural areas
- technology in the basic science curriculum
- science curriculum for self-sustaining economies

The submissions should contain a brief outline of professional experience, and either a summary of a proposed article or an article on that topic already published by that author. Submissions should refer to accounts of exemplary teaching content or method which is an accepted improvement in present educational practice in that region of the world.

Furthermore, the Science Education Section would like to receive expressions of interest from teachers and teacher trainers who would be able to:

- edit a comprehensive guide for using laboratory apparatus and chemicals and safety instructions
- edit primary science and agriculture teachers' guides for schools in tropical areas
- improve illustrations of science and agriculture topics for primary and junior secondary material

Send submissions to Science Education Section, UNESCO 7 place de Fontenoy, 75700 Paris France

Children's Learning in Science Research

The Children's Learning in Science Research Group at the University of Leeds in the UK has been established to bring together researchers, teachers and others to investigate and disseminate ways of improving children's learning. The foundations for the work of the research group have been laid by the work of the Children's Learning in Science Project (CLISP) since 1982.

The central focus of the Children's Learning in Science Research Group is the study of the way science ideas and concepts develop in children from age 5 to 16; and ways of promoting more effective learning in classroom, laboratory and fieldwork settings.

The group is involved in the following research and development projects.

Conceptual change in science project

This project is funded by the Economic and Social Research Council and involves CLISP, the Computer-based Learning Unit at Leeds, and teams from Glasgow and the Open University. The aim of the project is to develop and evaluate computer software that contributes to the process of conceptual change in secondary school pupils in the field of mechanics. The software will be included in classroom teaching and its effectiveness will be investigated in this context.

Science and technology in action project

This project is funded by the British Nuclear Forum. The aim of the project is to develop teaching resources that relate science to a range of social, industrial and economic concerns. Materials are being developed for two topics Energy technology and Food technology for 14-16 year olds.

The materials will encourage decision making involving economic factors, environmental consequences, and social and individual concerns.

National curriculum science support project

The National Curriculum Council has sponsored a project to investigate progression in children's ideas across the 5-16 age range; and act as a resource for studies on progression in science. The project started in January 1990 and will concentrate on understandings of biological concepts.

Further information can be obtained from the Children's Learning in Science Research Group, CSSME, University of Leeds, Leeds LS2 9JT UK.

Reprinted from Science Education Newsletter March 1990

Quantum - a new magazine for students

Quantum, a student mathematics and science magazine, appeared last January, published by NSTA in collaboration with the American Association of Physics Teachers and the National Council of Teachers of Mathematics, and in cooperation with the Soviet Academy of Science. This magazine, to be published in both the USA and the USSR, enables students around the world to share the pleasures and challenges of Quantum's problems, articles and other features.

This is the first of a number of cooperative projects in science education which are to be undertaken by the USA and Soviet organisations.

It is based on material from Kvant, a popular science monthly magazine which has been circulating in the USSR for the past 20 years.

The magazine contains recreational material, lively illustrations, humour and amusing anecdotes from the history of science. Articles in physics and mathematics require hard thinking in order to be understood, and the problem corner is intended for those who like Olympiads and other problem solving competitions.

For more information, write to the Editors, Quantum Magazine, 1742 Connecticut Avenue NW, Washington DC 20009, USA.
The Effects of STS Instruction on Student Learning

by Robert E Yager

Science Technology Society (STS) is defined broadly using the definition advanced by the STS Initiatives Task Force of the National Science Teachers Association.

"STS represents an appropriate science education context for all learners. The emerging research is clear in illustrating that STS experiences result in students with deeper concept mastery and ability to use process skills. All students improve in terms of creativity skills, attitude, use of science concepts and processes in their daily living and in responsible decision making."

"There are no concepts and/or processes unique to STS; instead STS provides a setting and a reason for considering basic science and technology concepts and processes. STS means determining ways that these basic ideas and skills can be seen as useful. STS means focusing on real-world problems instead of starting with concepts and processes which teachers and curriculum developers profess to be useful to students." (NSTA, 1990)

In STS classes, students and teachers are active learners. Students often identify their own problems and strategies for solutions. Teachers work with students on projects; they are not holders of all knowledge. Typically, student problems involve their communities, including the people. Iowa students have studied the impact of local airports, water pollution, sewage treatment, and care of the elderly.

Nearly 1500 teachers from every level, K-12, have participated in the Iowa STS Chautauqua Program since 1983. This program helps teachers develop goals, strategies, materials, and assessment efforts appropriate for integrating the teaching of Science Technology and Society. Since 1983 nearly 5000 students have experienced one or more STS modules and have participated in assessment efforts designed to determine the impact of such instruction. The Chautauqua in-service model includes:

- A one-week leadership conference during which teachers who have tried and succeeded with STS are prepared to assist with instruction; leaders from industry, college scientists, area supervisors, and school administrators also participate.
- A two-week summer workshop for 30-50 new teachers who are attracted to STS and possible improvements in their teaching and in their selection of materials. The staff team consists of experienced teachers from the leadership conference.
- A two-day fall short course which follows a five to ten day trial with the STS module planned during the summer. A similar staff is involved. Half the time is spent on assessment strategies.
- Contact is via mail, telephone, and in-school visits between the fall and spring short courses for encouragement support and assistance.
- A two-day spring short course for sharing teaching experiences, reporting of assessment efforts, identification of most successful teachers for new leadership, and discussion of next step strategies.

Assessment of student growth following STS instruction is basic to the Iowa Chautauqua Program. Assessment has used the five domains of science education proposed by Yager and McCormack (1989). These domains include (1) concept mastery (2) use of science process skills (3) attitude toward science, science classes, science teachers, science careers, and usefulness of science study (4) creativity skills, including questioning, proposing causes, and predicting consequences (5) applications of concepts and connections to the lives of the students.

Several reports of student growth with STS as defined by NSTA and as taught by teachers who have experienced the Iowa Chautauqua Program have appeared (Yager, 1987; Myers, 1988; McComas, 1989a, 1989b, 1989c, 1989d, 1989e; Yager, 1989a, 1989b; Yager, Myers, Blunk, & McComas, 1990; Yager, in press).

Although first time STS teachers and classrooms show good results, the most striking student growth occurs in classrooms taught by the experienced lead teachers. In many instances these teachers have used STS approaches for five years and have transformed entire courses into STS. Most of these teachers are from classrooms from grades 4 through 9 - the grade levels first targeted in the Iowa program.

Early elementary programs encounter special problems associated with such skills as reading and utilizing resources - both material and human - from the community as a whole. In the high school there are numerous problems focusing on the college preparation of
students, test scores, electives, and concentrations of energies for the brightest students.

Some of the assessment reports have produced dramatic and significant results illustrating the advantages of STS instruction. An analysis of these results in each of the five domains permit the emergence of generalities about the power and advantages of STS for all learners.

Concepts
When concepts are identified prior to instruction as ones likely to be encountered because of the questions and themes which initiate module planning, growth between pre- and post-testing invariably occurs. When STS and non-STS class sections are compared, little difference is noted in terms of the quantity of concepts seemingly learned when using classical testing procedures. Some teachers have achieved statistically significant advantages in favor of the STS sections. Invariably this results from higher scores for average and below average students. Although it is not conclusive, early indications suggest far greater retention of concepts for STS students, presumably because the learning took place in real situations rather than in the typical mode of learning stimulated by teacher urging or the promise of the necessity of recalling the information for examination.

Processes
Most measures of improvement in student understanding in the use of science process skills produce disappointing results, probably reflecting a failure to focus upon mastery of such skills either during instruction or for testing. STS demands the use of most of the process skills in work upon questions and issues raised by students. As a result it is not unexpected that growth in this domain for the most successful STS teachers is statistically significant. In many cases the growth in specific processes doubles the growth observed in non-STS sections taught by the same teacher. STS seems to be a useful and successful way to stimulate students of all abilities to improve in the understanding and use of science process skills.

Attitudes
While traditional science teaching results in students developing a progressively more negative attitude about science, science classes, science teachers, and science careers, this decline is invariably halted with STS. In STS courses taught by the most successful and enthused, student attitude about science is enhanced by a factor of two. One of the major advantages of STS is a dramatically improved student attitude. Such positive reactions are least dramatic for the best students as teachers and schools shift to STS. Conversely, the greatest increases occur for average and below average students.

Creativity
STS focuses upon questions, explanations for given situations, and predictions of consequences of certain actions. Time is spent determining the most useful questions, the most accurate causes, and the most reasonable consequences. Hence it is not surprising that the research reports all indicate that STS is far superior to traditional approaches to science instruction in this domain. For some teachers the quantity of questions, causes, and consequences is not so much greater for STS students when compared to those in traditional classes. However, the quality and usefulness of the responses for STS students is invariably superior - again by a factor of two.

Applications/Connections
For many teachers STS means starting with applications, and for many students STS means a greater focus on applications and connections to their

ICASE AWARD SCHEME
for outstanding contributions to international science education

ICASE Distinguished Service Award
This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations

ICASE Regional Service Award
This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

ICASE Association Award
This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Department of Curriculum Studies, University of Hong Kong, Hong Kong

14
real world. It is not surprising then to find the most common and significant advantages of STS instruction to occur in the area of student ability to apply information, to use it in new settings, to connect to the real world.

Interestingly, this holds true for students in the elementary school, where common belief holds that application is a higher order skill, possible only for the most gifted and for those in the secondary school. Third grade teachers report fantastic results with their students applying concepts and process skills in all kinds of situations in the STS format. In summary, STS approaches produce a variety of advantages in student learning. These include:

- The quantity of concepts learned is as great as that found when concepts are given to students and stressed as important to remember in traditional classrooms.

- Emerging evidence suggest that concepts learned in an STS setting are retained longer and are more useful.

- Student attitudes about science, science teachers, science classes, and science careers are enhanced by STS.

- Creativity skills (quantity and quality of questions, probable causes, and possible consequences) are enhanced by STS instruction.

- STS instruction produces students who can apply science concepts and process skills; they can connect their learning to the real world around them.

Do you like loud headphone music?
If you do, you're in danger of damaging your hearing. But now there's a new product to reduce the risk. The headphones developed by a British electronics company will shut off if they are played too loudly. Inside the phones is a pair of diodes that continuously monitors the level of the incoming signal and compares it to a preset threshold of 92 decibels - that's about the level of sound that would come from a home hi-fi turned up loud.

If the incoming signal exceeds the threshold, the diodes cut it off before it reaches the speakers. As soon as the listener turns down the sound to a non-dangerous level, the headphones start working again.

Pasteur and Microbes
A Teacher Resource Book
Commemorating the 100th Year of the Pasteur Institute 1888-1988

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute. It also contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few. These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation.

Building & Assessing a Teaching Rationale

Ronald J Bonnstetter & John E Penick

Teachers who only know what to do and how to do it will always be led by those who know why they are doing it. Helping students create a research-based rationale for the why can be a valuable preservice program outcome.

The culminating methods class activity at the University of Iowa and the University of Nebraska involves writing a rationale paper and defending its content during a lengthy one-on-one exit interview. In this 10 to 12 page paper students include comments justifying why they will do what they describe and to include research support. Some aspects of their teaching addressed include:

- Why you will teach science
- What your goals are for your students
- What your materials will look like
- What your students will be doing in the classroom (be specific)
- What you will be doing in the classroom (be specific)
- How you will evaluate your program
- Several sample lesson plans
- List of references

Instead of having a final paper and pencil test, students are scheduled into 90 minute exit interviews where they defend their present views of teaching. In the process many reach new levels of understanding and commitment.

The following represent examples of questions that have been used. The final direction and actual questions are determined by a review of the student’s rationale paper and other work handed in during the semester. The interview focuses on the how, not just the what. This is a very important concept for the interviewer to keep in mind. Many times preservice teachers will have a goal but will have little or no idea as to how that goal will be met. For example, if the student says "I will allow my students to be creative", the interviewer must ask and seek the answer to the question “What will you do that will allow your students to be creative?” Other examples of rationale defense questions include the following.

How does your rationale now compare with the beginning of the semester? What is the most important goal that you have for your students? What are your major concerns as you prepare to become a teacher? If you could change one thing in education, what would it be?

How would you define curriculum? What influences what goes into a curriculum? What are the major components of a curriculum? If you could design your own curriculum, what would it look like?

What is the role of the teacher? What does the ideal teacher look like? What are the characteristics of a good teacher? What do you consider to be your greatest strengths as a teacher? What are your weaknesses at present? If I walked into your classroom, what would I see? What will you be doing? How will you evaluate your teaching?

What is science? How would you define the difference between science and technology? What role would science/technology/society issues play in your classes? Why? What percent of time? What would such a class look like? How would you teach for scientific literacy?

How would you rate the importance of developing a positive student attitude towards science? What would you do to enhance this goal? What would you do to enhance the development of critical thinking skills? How would you know if this goal had been accomplished?

Define teaching strategies. What are the main teaching strategies or teacher behaviour that you plan to use on an everyday basis? How often will you lecture? Why? What percent of the time? Describe how you would run a discussion? What, if any, are the differences between an open-ended lab and a hands-on lab? What does an open-ended lab look like? How would you use computers in your teaching? How would you use a film in your teaching? What components of your teaching strategies would you want present in every class period?

How will you evaluate your students? Would you give a pretest? Why? How would you use the results?

How will you handle classroom management? What are the rules for your class?

How will you use research related to how children learn in your teaching? What assumptions are you willing to make about the students that come into your class? What does research say about the sequence for effectively teaching a new concept?

What is the purpose of getting involved in professional organisations?

How did you feel about this session? What questions do you have of me? What grade do you deserve for this course and why?
Having a rationale means that a preservice teacher not only knows what and how to teach but why. Such a teacher is prepared to defend their curriculum and teaching and to influence others. In addition, the teacher with a rationale is less likely to forget their sometimes idealistic notions about teaching and will continue growing and learning as teachers.

More on Science Teacher Education

Postgraduate Certificate in Environmental Education
Jordanhill College, Glasgow, in association with the World Wide Fund for Nature (UK), has introduced a new modular environmental education course for teachers from overseas. It is a three month postgraduate course for experienced teachers, teacher trainers and curriculum developers either within schools or in higher education. The course consists of four modules:

- planning and process
- theory and practice in environmental education
- curriculum, school and community
- independent study

The first module is compulsory and the fourth will be integrated within the other modules. Students will have to complete a practical study project to produce a curriculum design package suitable for use in their home country. The satisfactory completion of this will be essential for the award of a certificate.

Further information is available from Director of Overseas Courses, Jordanhill College, Southbrac Drive, Jordanhill, Glasgow G13 1PP, UK. 
From Science Education Newsletter March 1990

Chemsource Project
The Chemsource Project, funded by the US National Science Foundation, is being developed by the Committee on Education of the American Chemical Society. The project aims to provide detailed support for inexperienced secondary school chemistry teachers, pre-service teachers and in-service chemistry teachers during their first three years of teaching. The two major features of the project will be Sourcebook and Sourceview.

Sourcebook is a resource being prepared by eleven regional cluster groups of high school and university teachers of chemistry. It will provide teaching tips and instructional ideas relating to over thirty topics commonly taught in the high school curriculum. It will also contain laboratory activities, demonstrations and common misconceptions.

Sourceview will use video and other technologies to introduce inexperienced teachers to successful learning strategies related to laboratory and classroom instruction and management.

Both Sourcebook and Sourceview are being developed and piloted over the next three years. Further information is available from Mary Virginia Orna, Department of Chemistry, College of New Rochelle, New Rochelle, NY 10801, USA.

From Science Education Newsletter March 1990

Video Network Project
The Finnish INISTE network has set up a videotape exchange project, which involves the development of videotapes on methods of teaching, application of various learning theories, new ideas for practical work, and comparing varying styles amongst teachers.

For further information, contact Maarit Rossi, Karhutie 9, SF-02400 Kirkkonummi, Finland.

Teachers Notes
Most children meet this challenge by making a magnifier using (1) a piece of card with a hole in it, or (2) a piece of wire with a small loop to hold the water. The loop needs to be dipped into water so that a film is formed across the loop. If the card is used, the hole can be made by a pencil point or the sharp end of a safety pin. Remind children about the safe use of the pin, that they should pierce the card while it rests on a surface or pad of paper, and that it should be closed as soon as they have made the hole.

The card/paper needs to be waterproofed by rubbing a candle or wax crayon across the surface. A hair clip makes an ideal holder for the water drop. An unbent paper clip or piece of wire will do just as well if the children can form a small enough loop.

Using thinking triggers can be helpful in the initial discussion, for example pictures of steps in making a paper clip loop, or steps in making a hole in a card and then covering the card with wax. Better still, collect the various items of equipment and let the children handle them while discussing the challenge and planning their solution.

One technique for "measuring" the amount of magnification or reduction is to draw the object without the drop, and again when viewing through the drop, and comparing the drawings.

Usually the children will see that the drop magnifies the viewed object, but sometimes they will notice that, in certain positions, the object is smaller and upside down.

Lead the discussion onto a teaching point about magnifying glasses and the properties of lenses if this is appropriate for the age group you are teaching.

Water as a magnifier
Here is an activity for your pupils to try. Stepping into Science involves children in the following steps:

- Planning their investigation
- Choosing equipment to use
- Carrying out their investigation
- Recording their observations and measurements
- Communicating their findings to a wider audience

Challenge
What happens if you look through a drop of water?

Discussing
Ask have you ever looked through water? What do you see when you look at something through a glass of water? Have you ever looked at something on the bottom of a dish or pan full of water? What happens if you reach for something you see on the bottom of the bath? Refer to the activity about water drops on page 17 of the March issue of Science Education International.

Planning
Ask where this investigation will be carried out. Inside, outside, at a sink? How will they make a drop? Will the drop be put on paper, or held in a holder? What will they look at?

Choosing equipment
Ask what equipment they will need. They may need a container for water, a paper clip with a loop in one end, a piece of paper with a hole in it.

Doing the activity
Do pupils change their plan as they do the activity? Once they have looked through the drop, do they change what they planned to do?

Recording
What observations are they making? Can anything be measured?

Evaluating
Did their plan work? What did they see? Is this what they expected? What have they found out?

Communicating
How will they share their findings? Children are welcome to send a report to Sue Dale Tunnicliffe, ICASE Project Officer for the Stepping into Science Project.
4th World Exhibition of Young People's Inventions

by Maris Silis

Introduction

Throughout the world many societies are actively encouraging and fostering the development of creativity and inventiveness in their younger members. These societies recognise that creative individuals, and communities that value originality and creativity, are essential for desirable economic and social development.

In 1991 a World Exhibition will provide opportunities for students from around the world to display the products of their inventiveness and to develop international understanding and friendship.

Japan Institute of Invention & Innovation

The Japan Institute of Invention & Innovation (JIIN) has a long history of providing encouragement, information and help to inventors (JIIN, 1989a). Since 1941 it has, among other things, hosted an annual "Concourse of Schoolchildren's Inventions" for Japanese students. In 1972, 1975 and 1985, World Exhibitions were organised. Figure 1 displays the 30 countries which contributed a total of 161 entries for the 3rd World Exhibition in 1985.

The JIIN now invites submissions of appropriate "devices of invention and innovation" for the 4th World Exhibition of Young People's Inventions to be held in Tokyo in 1991.

Figure 1 Countries participating in 3rd World Exhibition 1985

Key Details

- Entry is open to girls and boys born between 1 January 1972 and 31 December 1980 inclusive.
- Applicants must construct and submit a device. Drawings or descriptions alone, are not sufficient.
- An official entry form must be submitted by 30 June 1990.
- Upon receipt of the completed entry form, the JIIN will provide instructions about how devices should be sent to Japan.
- There are no application fees or transportation costs for devices.
- Devices will be displayed in Japan between March 1991 and March 1992.
- A Commendation Ceremony will be held in March 1991, and selected applicants will be invited from different countries. In 1985, three applicants, plus their guardians, from different countries were invited.
Examples of students’ work

In 1985 entries for the World Exhibition included an automatic slide projector; a computerised boomerang tracker; a battery based upon the action of bacteria; a device for pressing wooden sheets; a solar water heater; a talking watch for blind people; an alarm activated by vibrations or other changes in the environment; a set of straight and curved blocks which can be used in various combinations to make park benches, steps, etc; a device that retrieves metallic objects such as needles from a carpet; a punch card robot; a savings box; a hydrogen producer for fuel; and a tuner for musical instruments. Other devices are shown in the following photographs.

Rat-Repulsing Apparatus
Igor Zachar (17 years) Czechoslovakia
The concept of this device is derived from the fact that rat catchers used to use whistles to drive away rats. A part of a phone receiver is used to emit a sound of a certain frequency which is irritating to rats in order to drive them away.

Safety Socket
Xiu Chen (12 years) China
This socket is designed to prevent electrical shock when plugging or unplugging a cord. When a plug is pulled from the socket, the openings of the socket are closed because of a valve which is opened or closed by a spring inside the socket.

Telephone Extension System
Roberto Ramon Castro Garcia (19 years) Peru
In this invention, three telephones are connected to one line, each of them functioning independently. An incandescent electric lamp is attached to each of the receivers and its ON or OFF state indicates the state of usage of the other receivers.

Electricity from Wind
Rajeshore Vaidya & Atendra Lal Shrestha (both 16 years) Nepal
This invention consists of a fan, a generator and a storage battery. When the wind blows, the fan revolves and the revolution is transferred to the generator while the generated electricity is stored in the battery.

Tool for Stripping Insulation
Katarzyna Kimmel (18 years) Poland
This tool easily removes the vinyl insulation from wire. The angle of the peak of the edge is 20 degrees. The insulation is removed easily simply by making a slight cut in it and pulling it off.
Potential benefits

There are many personal benefits for student inventors. Identification of a need or problem, and the designing, construction, evaluation and modification of a device can help develop many desirable skills and attitudes such as those discussed by Gilbert (1987).

Students learn that finding and solving real problems involves much more than following directions provided by a teacher or published in a book. Blind alleys, lack of knowledge and skills, and competing demands for time are just a few of the obstacles that may need to be recognised and overcome.

Scientific knowledge must be combined with other kinds of knowledge and skills. Judgements may have to be made about aesthetic and economic aspects of a device as well as about its functional capabilities. Students can develop communication skills and also attitudes such as confidence, perseverance, self-criticism and, most importantly, willingness to "have a go".

The skills and attitudes referred to above should also help students cope with other problems and to participate more fully and productively in modern society. Society, in turn, benefits from the collective talents of its members.

The World Exhibition also promotes scientific, technological and cultural exchange, the strengthening of ties of friendship and the development of better understanding between participating countries.

Further details

Further details and entry forms are available from:

Maris Silis is Senior Lecturer at the Salisbury Campus of the South Australian College of Advanced Education. At the October 1989 ICASE General Assembly, he was elected Australasian-Pacific Representative on the ICASE Executive Committee.

---

Women inventors - how many can you name?

Inventors? There are greats like Leonardo, Galileo, Franklin, Morse, Bell, Edison, but can you name one female inventor other than Marie Curie? Not easy, is it!

Research, however, suggests that women were inventors from the beginning, introducing everything from cooking and pottery-making to weaving, tanning, hut-construction and crop-raising.

Prior to about 1800, women had trouble getting recognition as inventors because they were not allowed to own patents. Even when they could, some women would simply share their inventions with friends or freely publish their findings. Such was the case with Marie Curie, the only person ever to win two Nobel Prizes (1903 and 1911). Refusing to patent for gain, Curie "discovered" radium, invented a process for extracting radioactive material from uranium ore and created the prototype of what is now known as the geiger counter.

When women extended their workplace and education, their inventions changed accordingly. Munitions work during the Great War resulted in weaponry patented by women - an automatic pistol, a bomb launcher, an incendiary ball, a railway torpedo, a front sight for firearms, a submarine mine, and others.

More recently, Stephanie Kwolek invented Kevlar arimid fibre used in radial tyres and bulletproof vests; Dr Marguerie Shue-Wen Chang invented a trigger mechanism for underground nuclear testing; 3M employee Patsy Sherman co-invented Scotchguard; Barbara Askins won the US National Inventor of the Year Award for creating a way to obtain clearer pictures from old negatives.

Over the years, many female inventors have been overlooked. Lady Mary Montagu introduced smallpox inoculation to Europe in 1717, 80 years before British physician Edward Jenner. Madame Lefebvre of Paris patented the process of making nitrate fertiliser out of nitrogen gas as early as 1859, 50 years before the world was ready to "re-invent" her idea.

Martha Costin's signal flare helped the North win the Civil War, but it became known as the "very pistol" after Lieutenant Very patented a very small improvement to it. Nuclear fission was discovered and named by Dr Lise Meitner, providing world powers with the "ammunition" to develop the A-bomb that ended World War II. Yet it was her male colleague who received the Nobel Prize in 1944.

Adapted from Newscience Vol 14(2)
Apollo 11: Commemorative Issue

This book (184 pages) commemorates the twentieth anniversary of the Apollo 11 Moon landing (1969-1989) and is intended as a teacher resource. It provides background information and activities for both elementary and secondary science students. In addition, it offers multi-disciplinary activities that can be used in Language Arts and English.

The teacher resource book has been compiled and edited by Linda W Crow and Donna L Hare, and published by I CASE as the latest in the series of commemorative issues. This valuable resource is available at a cost of US$10.00 or £6.00 from I CASE (see I CASE Publications in this section).

The Greenhouse Effect: Exploring the Theory

This activity book, published by CSIRO Australia in 1990, is for 11-16 year olds. It is a rich and useful source of ideas for teachers working with primary and secondary students who enjoy learning from direct experience. There are activities suitable for classroom situations, and others for individuals. The examples are Australian, but the activities are appropriate for classrooms in any country. An information page, photos, graphs, maps and tables appear before each set of activities. These lead the greenhouse explorer through aspects of the greenhouse theory and put the activities in perspective. The activities develop skills needed to better understand atmospheric and climatic change. With these skills, students will be able to critically evaluate the information, opinions and arguments concerning environmental and climatic issues. Chapters include greenhouses and the greenhouse effect, how are we affecting the Earth's atmosphere, sea level changes, climate changes, engineering changes, farming changes, changes in our daily lives. This book is available (A$9.95 plus postage) from CSIRO Publications, 314 Albert Street, East Melbourne, Victoria 3002, Australia.

Bibliography in Integrated Science Teaching

This book, compiled by Judith Reay, is No 36 and the latest in the Document Series on Science and Technology Education published by UNESCO. It is an annotated bibliography which samples publications from 1978 to 1988. The book uses the term "integrated science teaching" in its broader sense, covering topics such as science technology society education, and environmental education. Levels include primary, secondary, higher, vocational and teacher education.

The bibliography contains more than 370 entries which are arranged chronologically by year of publication. Each entry contains an annotated description of the subject and a set of keywords which are used in the subject index.

The bibliography is an attempt to meet the needs of educators worldwide, and therefore aims to represent as many local publications as possible, together with a selection of internationally known items. Only English language publications have been included. This publication is available from the UNESCO Division of Science Technical & Environmental Education, 7 place de Fontenoy, 75700 Paris, France.

Science and Technology in School Curricula Series: Case Study 5 Pakistan

UNESCO has recently published this latest case study, which focuses on (1) the place of science, mathematics and technology in the curricula of primary and secondary schools (2) the content of SMT curricula (3) the content of courses in integrated science and a summary of the content of the separate sciences courses (4) the Ministry of Education policy on the place of technology education in primary and secondary schools. It is available, free of charge, from Documentation and Computer-Assisted Management Service, Education Sector, UNESCO, 7 place de Fontenoy, 75700 Paris, France.
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1990

June 6-8
ICASE Europe Research Seminar
Location: University of Dortmund, Dortmund, F R Germany
Contact: Prof Dr Hans-Jurgen Schmidt, Department of Chemistry, University of Dortmund, Otto-Hahn-Strabe, D-4600 Dortmund 50, F R Germany
The theme of this research seminar is "Empirical Research in Science and Mathematics Education". The aim of the seminar is to discuss the methodology of empirical research in this field. Approximately twelve 40 minute papers will be presented (in English) and then discussed. A proceedings will be printed and available through ICASE.

June 7-9
Second European Conference on Health Education
Location: Warsaw, Poland
Contact: Mrs M A Modolo, Europe Office, Centro Sperimentale per l'Educazione Sanitaria, Universita di Perugia, CP 35 PG 3, Via del Giochino 4, 06100 Perugia, Italy
Organised by the European Region of the International Union for Health Education, this conference will focus on young people as the target group. Innovative educational approaches will be introduced to improve communication and the quality of health education. During the conference, a competition organised particularly for secondary school pupils, based on their own interests (environment, school life, community) will take place.

June 25 - 29
International Symposium on Evaluation of Physics Education: Criteria, Methods and Implications
Location: University of Helsinki, Finland
Contact: Prof V Meisalo, Department of Teacher Education, University of Helsinki, Ratakatu 2, SF-00120 Helsinki, Finland
This symposium, organised by the Teaching Section of the Finnish Physical Society in cooperation with the Department of Physics and the Department of Teacher Education at the University of Helsinki, aims to provide a forum for presenting and discussing new ideas for the goals, content, means and evaluation of physics education.

June 25 - July 6
Second International Workshop on New Technology Course Materials
Location: MEDC, Paisley, Scotland, UK
Contact: Dr Peter Williams, Director, MEDC, 8/14 Storie Street, Paisley PA1 2BX, Scotland, UK
This cooperative workshop will develop materials for the new technologies. Groups from different institutions and countries will select topics of common interest on which to produce computer aided learning packages, videos, open learning or other appropriate materials. All resulting materials from all groups will belong to all participants.

July 4-6
ASPEI Regional Workshop II on Conceptual Structures and Change in Physics Learning
Location: Quezon City, Philippines
Contact: Dr Vivien Talisayon, ISMED, University of the Philippines, Diliman, Quezon City, Philippines

July 9-13
CONASTA 39 Annual Conference of the Australian Science Teachers Association
Location: Alice Springs, Northern Territory, Australia
Contact: Peter Deacon, Convenor, CONASTA 39, PO Box 705, Alice Springs NT 0871, Australia
The CONASTA 39 Theme is "Science Education and Technology for the 90's". The Conference will provide a forum for science educators to examine important issues confronting us in the new decade. The program includes keynote addresses, practical sessions, excursions and social events. This is an ideal opportunity for visitors to experience the world renown attractions of central Australia.

July 9-14
NASA Space Science Seminar and Workshop
Location: Houston, Texas, USA
Contact: Evhan Uzwheshyn, Science Consultant, Manitoba Education, 409-1181 Portage Avenue, Winnipeg, Manitoba, Canada R3G OT3
This program for selected Canadians and up to 10 international delegates includes lectures by NASA researchers, and an extensive program of visits to facilities such as the site research and testing facility, NASA Jet Propulsion Labs, Space Shuttle Orbiter Training Facility, Physiological Training Center and the Weightless Training Facility.
July 14-17
1990 ASERA Meeting
Location: Freeway Hotel and Curtin University of Technology, Perth, Western Australia
Contact: Dr David Treagust, SMEC, Curtin University of Technology, Bentley, WA 6102, Australia
Science educators interested in science education research are invited to attend the annual meeting of the Australian Science Education Research Association, an ICASE member association. For those attending CONASTA, there will be a direct flight from Alice Springs to Perth on the 14th July. A subsidy is available for those presenting their first ever paper.

August 19-24
Third International Conference on Teaching Statistics
Location: University of Otago, Dunedin, New Zealand
Contact: The Secretary, ICOTS 3 Local Organising Committee, Department of Mathematics & Statistics, University of Otago, PO Box 56, Dunedin, New Zealand
ICOTS 3 aims to improve the quality of statistics instruction on a world-wide basis, fostering international cooperation among teachers of statistics, and promoting the interchange of ideas about teaching materials, methods and content. The program includes plenary, invited and contributed paper sessions, workshops, panel and poster sessions. Teaching from beginning school to college, polytechnic and university level will be included, as well as sessions on teaching statistics in government, business and industry. Opportunities will be provided to see and experiment with the latest computer hardware and software.

August 20-24
British Association for the Advancement of Science Annual Meeting
Location: Swansea, UK
Contact: Dr Connie Martin, British Association for the Advancement of Science, Fortress House, 23 Savile Row, London W1X 1AB, UK
The theme of the 1990 Annual Meeting will be "The Environment" which will be addressed through a program of lectures, debates, demonstrations, exhibitions and a young people's program. There will also be an education program on the theme International Perspectives of Education, which will include sessions on the development of education in Commonwealth countries, in European countries, and in environmental education.

August 26-31
SCICON 1990
Location: University of Canterbury, Christchurch, New Zealand
Contact: Conference Secretary, SCICON 1990, Department of Continuing Education, University of Canterbury, Christchurch, New Zealand
SCICON 1990 will be the seventh biennial conference of the New Zealand Science Teachers Association. Workshops, laboratory sessions, seminars, discussion groups, access sessions, and keynote addresses will address the theme Science for tomorrow's world. The program also includes field trips and visits to research institutes, industries and places of scientific interest.

August 27-30
ASET-ICASE Conference on Science & Technology for Developing Countries
Location: Port of Spain, Trinidad, West Indies
Contact: Conference 90, ASETT, Faculty of Education, University of the West Indies, St Augustine, Trinidad & Tobago, WI
The Association for Science Education of Trinidad and Tobago (ASET) in collaboration with ICASE will host a conference on "Education in Science and Technology for Development: Perspectives for the 21st Century". The conference will be open to science and technology educators of all countries, but Caribbean problems will be of particular interest. The conference aims to provide a varied program focusing on (1) scientific and technological developments as they impact upon our lives at present, and are likely to impact upon our lives in the 21st century; (2) social and ethical issues consequential on developments in science and technology; (3) the thrust of modern technology and the implications for science and technology education; (4) educational technology and the teaching of science - developments in resource materials production for the teaching of science and technology; (5) appraising present curriculum trends in science and technology education in the Caribbean and Latin American subregions and worldwide; (6) the schools and universities/industry interface; (7) bridging the gap in science education - primary through tertiary; and (8) action towards the goal of science and technology education for all with appropriate emphases on the popularisation of science, science clubs and out of school science activities.

August 31 - September 2
CTC-IUPAC Meeting: International Symposium on the Environment and Chemistry Teaching
Location: Moscow State University, Moscow, USSR
Contact: Prof Y Tretinkov, Chemistry Department, Moscow State University, Moscow 117234, USSR

September 5-7
ICASE European Symposium on Industry and Education
Location: Brussels, Belgium
Contact: Drs Jan Hendriks, ICASE European Representative, Konijnepad 3, 7921 BM Zuidwolde (DR), Netherlands
Invitations have been sent to member associations of ICASE and to other bodies in Europe, USA, Canada and Australia to nominate education representatives to attend. Industry representatives are being invited by Conseil Europeen des Federations de l'Industrie Chimique (CEFIC). The symposium will (1) provide opportunities for the exchange of information and experiences in schemes for industry-education liaison, (2) develop models for industry-education liaison, (3) establish a network for information exchange for future developments, and (4) publish a resource book for teachers and administrators on industry-education liaison.
September 10-20  
Seminar on STS Education  
Location: University of Oxford, Oxford, UK  
Contact: The Director, Courses Department, The British Council, 65 Davies Street, London W1Y 2AA, UK  
The British Council announces its forthcoming seminar on "Science Technology and Society Education: Developing a Relevant Science Education for the Future". This seminar has vacancies for 40 participants and is intended for experienced science teachers, senior educators with responsibility for science curriculum development, school science inspectors and advisers, and teacher trainers. The seminar will consider a wide range of educational issues which arise when science and technology are taught in the context of their social interactions. The following topics will be considered - rationale for STS, developing new curriculum materials in schools, innovations in teaching STS, research into STS in the classroom, studying the environment, ethical and gender considerations, monitoring changes in new technology, media influence on our students' ideas, and the way forward.

October 18-20  
World Environment Energy and Economic Conference  
Location: Winnipeg Convention Centre & Holiday Inn, Winnipeg, Canada  
Contact: Mr Jack Pyra, Past President STAM, John W Gunn School, Winnipeg, MB R2C 3C9, Canada; or Mr Bob Lepischak, President ICASE, Neepawa Area Collegiate, Neepawa, MB, Canada R0J 1H0  
This conference, endorsed by ICASE and the Canadian Association for Science Education, and hosted by the Science Teachers Association of Manitoba, will focus on the theme "Sustainable Development Strategies - The New World Agenda". A program is being prepared to interest educators, youth and the general public. Businesses and industries are being invited to participate. The conference will enable participants to examine and discuss the links that must be fashioned so as to integrate environmental concerns with continued development on the energy, resource and economic fronts. The program will address the role that curriculum, teachers and schools can play in helping students understand the environmental realities which are the cornerstone of sustainable development.  
An International Symposium on Sustainable Development will precede the conference on October 15-17. International representatives from education, government and industry will meet to examine the implication of sustainable development upon the curriculum and students of tomorrow.

November 7-11  
NABT Annual Meeting  
Location: Westin Galleria & Westin Oaks Hotels, Houston, Texas, USA  
Contact: National Association of Biology Teachers, 11250 Roger Bacon Drive, Reston, Virginia 22090, USA  
The theme of this conference is Planet Earth in Crisis. International delegates are welcome. A feature of this year's program will be contributions by international participants and an international reception.

December 12-14  
ASPEN Meeting on Demonstration Experiments and Computer-Aided Learning in Physics  
Location: Pune, India  
Contact: Prof Arun Nigavekar, Physics Department, Poona University, Pune, India  

December 27 - January 1  
International Conference on Teaching of Physics  
Location: Karachi, Pakistan  
Contact: Mrs Aziz F Hasnain, Head, Department of Physics, APWA Government College for Women, F 'B' Area, Karachi, Pakistan  
The theme of this international event is The changing face of physics education in developing countries. The conference aims to discuss techniques for conceptual teaching in physics, to create awareness among physics teachers about modern teaching methods including the use of computers and audiovisual aids, and to establish a research program in physics education.

1991

January 4-7  
ASE Annual Meeting  
Location: University of Birmingham, Birmingham, UK  
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK  
Full details of this large international event will be circulated with the September issue of Education in Science, the journal of the Association for Science Education. A special feature of this meeting will be an ICASE Symposium. Non-members of ASE and those outside the UK who wish to receive details should write to the contact above.

March 27-30  
NSTA National Convention  
Location: Houston, Texas, USA  
Contact: Linda Crow, Asst Professor, Baylor College of Medicine, One Baylor Plaza, Room 633E, Houston, Texas 77030, USA

March 29 - April 3  
7th ICASE-Asian Symposium  
Location: East China Normal University, Shanghai, China  
Contact: Prof Mi Zihong, Department of Physics, East China Normal University, Shanghai 200062, China  
The ICASE Executive Committee have accepted a proposal from the East China Normal University in conjunction with the Shanghai Association for Science and Technology and the Shanghai Board of Education to host an ICASE Conference. The symposium will be conducted in English/Mandarin and will address the theme Making science education in schools more relevant. The program will focus on (1) the development of appropriate curricula, the issue of integrated science vs separate sciences, the introduction of STS in science courses; (2) innovations in teaching, the role of project work, the teaching of science communication.
skills, low cost equipment, fieldwork; (3) technology in education, the effective use of visual aids, visits to industry, the place of the computer; and (4) research in science education, children's learning in science, assessment techniques. The program will consist of presentations by internationally renown science educators; papers, workshop and discussion sessions; poster displays; and an exhibition. Write to the above address for the second circular. Titles and abstracts of contributed papers should be sent to Prof Mi Zihong by 31 October 1990.

July
GASAT 6 International Conference
Location: University of Melbourne, Victoria, Australia
Contact: Ms Gaell Hildebrand, School of Education,
University of Melbourne, Parkville, Victoria 3052, Australia
In order to be placed on the mailing list for calls for papers, etc, write to Gaell Hildebrand at the address above.

August 4-9
ChemEd 91 Conference
Location: Oshkosh, Wisconsin, USA
Contact: Bruce G Smith, Co-Director, Appleton High
School-West, Appleton, Wisconsin 54914, USA or Paul
Keller, University of Wisconsin, Oshkosh, Wisconsin
54901, USA
ChemEd 91 is a major chemical education conference of
interest to university, college, secondary and elementary
educators from North America and beyond. Throughout the
weeklong conference, activities are planned for all members
of the family including excursions, field trips, sports
activities and social events - a feature of ChemEd
conferences.

August 25-30
11th International Conference on Chemical
Education
Location: University of York, York, UK
Contact: Dr John F Gibson, ICCE 11, Royal Society of
Chemistry, Burlington House, Piccadilly,
London W1V OBN, UK
This biennial conference on the theme Bringing Chemistry
to Life is being organised by the IUPAC Committee on
Teaching of Chemistry in conjunction with UNESCO and
the Association for Science Education. The conference will
focus on (1) making chemistry accessible to all students (2)
new curricula at primary, secondary and post-secondary levels
(3) new teaching strategies at all levels (4) teaching and
learning at a distance (5) new frontiers of chemistry and their
impact on teaching, and (6) research in chemical education.
The program will include plenary lectures, poster papers,
symposia, workshops, exhibitions, times for participants to
discuss aspects of chemical education of special interest,
social events and local visits. A first circular detailing the
broad program and how to contribute is available now. The
second circular will be published in October 1990.

August 26-30
Fourth Asian Chemical Congress
Location: Beijing, China
Contact: Prof Dehe Zhang, Secretary General of 4ACC,
Chinese Chemical Society, PO Box 2709, Beijing 100080,
China
The 4th Asian Chemical Congress will be held under the
sponsorship of the Federation of Asian Chemical Societies.
The Congress will focus on the important role of chemistry
in raising the health conditions and living standards for all
people. The program of plenary lectures, invited papers and
contributed papers will be conducted in English and will
concern various topics including organic chemistry of natural
products, analytical chemistry and instrumentation,
environmental chemistry, agrochemistry, coordination
chemistry and its applications in medicine and agriculture,
polymer science, photochemistry, computers in chemistry,
catalysis, and chemical education.

August 27 - September 1
5th International Environmental Education
Conference
Location: Cusco, Peru
Contact: MSc Eduardo Gil Mora, National University of
Cusco, Zaguanc del Cielo L-9, Cusco, Peru
The conference will focus on the relationship between the
environment and development, and on the changes needed in
today's behaviour for tomorrow's world. The program will
enable participants to learn of developments, approaches and
strategies in environmental education in different countries,
and will cater for primary, secondary and tertiary educators;
and for teacher trainers, curriculum developers, and
policymakers.

Australia
Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

ICASE in East Europe

by Dennis Chisman
Honorary Treasurer, ICASE

ICASE is pleased to welcome the first Institutional Member from East Europe - the University College of Education, Erfurt, German Democratic Republic.

This institution is a teacher training college, with a number of institutes for the training of different subject specialist teachers for schools - including technology, craft and science subjects.

The college is planning a major pan-European symposium on technology education for schools in 1992. ICASE is supporting this meeting. Watch for further details in future issues of Science Education International.

The contact person for the University College of Education is:
Prof Dr Dietrich Blandow
Vice Rector
Pädagogische Hochschule 'Dr Theodore Neubauer'
Nordhauser Strasse 63
Erfurt 5064
DDR

New member of ICASE

The Education Division of the Royal Society of Chemistry has become a member of ICASE. The Division has 4000 members, including about 1000 school teacher members.

The Royal Society of Chemistry is one of the oldest chemical societies in the world - it celebrates its 150th anniversary in 1991. It has more than 40,000 members, of whom about one fifth are outside the United Kingdom.

The Education Division is one of several divisions of the Society serving specialist interests. The Education Division itself has subgroups concerned with curriculum, assessment, educational techniques, chemical education research, and tertiary education.

One of the major international activities with which the Division is concerned at present is the organisation of the Eleventh International Conference on Chemical Education to be held in York, UK from 20-26 August 1991. Refer to the Calendar section in this issue.

Mr Dennis Chisman, the Honorary Treasurer of ICASE, is the President of the RSC Education Division.

The contact for the Royal Society of Chemistry Education Division is:
Dr A D Ashmore
Education Officer
The Royal Society of Chemistry
Burlington House
Picadilly W1A 2BN, UK

Who's Who in Science Education Around the World

A new ICASE initiative is to publish a Who's Who in Science Education Around the World 1991 Edition. This valuable reference book will contain profiles on prominent science educators and their work.

The information will help you to contact colleagues in both developing and developed countries who may be working on projects of interest to you, who may be potential speakers at your next meeting, or who may be invited to work on collaborative projects.

Copies will be sent to all ICASE member associations, institutions, centres, foundations and companies. Copies will also be available to individuals and other organisations at an affordable price. Your help in recommending individuals worthy of inclusion in this biographical volume will be much appreciated. Please send names and full addresses of those you would like to nominate to:

Ampy, an Education Program Specialist from the Philippines, is in Australia participating in a training program for physics educators.
ICASE takes active role in NSTA Convention

by Dr Kenneth Russell Roy
North American Representative

ICASE President Bob Lepischak, Honorary Treasurer Dennis Chisman, North American Representative Kenneth Russell Roy, and Special Projects Officer John Penick took an active role at the 1990 NSTA National Convention in Atlanta, Georgia. The Convention entertained approximately 16,000 science educators and leaders from North America. A large number of international representatives also attended.

ICASE hosted an International Breakfast which was attended by representatives from several continents. Each had a chance to share information before the group.

The NSTA International Committee heard presentations by Bob Lepischak and Ken Roy on the activities and future endeavours of ICASE. ICASE representatives took part in the meeting for the purpose of discussing relevant issues and plans of action. In addition, ASE General Secretary David Moore took part in the discussions. The committee is chaired by John Penick.

ICASE also hosted a luncheon at the Convention. Representatives from around the world attended and spoke about their activities and initiatives.

A special forum was coordinated by John Penick where participants could learn more about science education from various countries via in-depth discussions with representatives. This was a highly effective activity in that it allowed for individual dialogue on important issues.

In the exhibitor area, ICASE set up a booth with samples of publications and information brochures on various projects, including ICASE-endorsed meetings. Many delegates stopped to chat about ICASE and its activities.

As can be noted, ICASE fostered international education as a people process in Atlanta. Plans are being made to increase the profile of ICASE at the next National Convention in Houston, Texas next year.

ICASE is grateful to NSTA for the assistance given in arranging these accommodation costs, particularly participants from developing countries.

At the recent world conference on Education for All held in Thailand in March 1990, the importance of developing scientific and technological literacy was affirmed. The congress will provide an excellent opportunity for the international community to follow up the outcomes of this meeting; and to focus on new developments in science technology society education, of which scientific and technological literacy is a key issue.

The ICASE Executive is keen to receive ideas for potential themes for symposia, pre-congress projects which would provide data for and input to the program.

World Congress in Scientific and Technological Literacy

ICASE is currently negotiating with other international organisations to hold a major World Congress in Scientific and Technological Literacy in 1993.

It is envisaged that a large international delegation, representing every region of the world, will meet in Paris, the proposed venue, to consider this important theme, so critical to local, national and international development.

It is hoped that substantial funding will be made available to assist delegates with travel and

ICASE associated with student scholarship program

The Max McGraw Foundation and the National Science Supervisors Association are co-sponsoring the 1990-1991 Thomas Edison/Max McGraw Scholarship Program. This scholarship program is open to junior and senior high school students with an interest in science and engineering, and awards 10 scholarships to students who best exemplify the creativity and ingenuity demonstrated by the life and work of Thomas Edison and Max McGraw. Students in grades 7-12 in the USA, Canada or other participating nations are eligible to apply by submitting a proposal on a completed experiment or a projected idea which would have practical application in the fields of science and/or engineering.

Eighth ICASE-Asian Symposium

by Prof V K Samaranayake
Chairman SLASME

The Sri Lanka Association for Science and Mathematics Education (SLASME) has accepted an invitation from ICASE to host the Eighth ICASE-Asian Symposium in Sri Lanka, 2-7 August 1992.

An Organising Committee has prepared a draft program, and preliminary planning is well underway. For further enquiries, write to:

Mr Asoka Weerasinghe
Trinity College
Kandy
Sri Lanka
Free Circulation of Scientists
An ICSU Statement

ICASE is an affiliate to ICSU, through its close association with ICSU-CTS, the Committee on Teaching of Science. As such, this ICSU Statement applies to ICASE and its activities. In a world where so much activity is determined on the basis of political alliances and boundaries, it is important to reflect on the principles outlined in this statement.

The International Council of Scientific Unions (ICSU) is the oldest existing non-governmental body committed to international scientific cooperation for the benefit of humanity.

Created in 1931, after its predecessor, the International Research Council, was dissolved because of discrimination against scientists of certain countries, ICSU has been vigorously pursuing a policy of non-discrimination ever since. ICSU maintains that discrimination hinders the free communication and exchange of ideas and information among scientists and thereby blocks the progress of science, which depends on their collective efforts.

ICSU’s Members are 20 International Scientific Unions and 76 national academies of science or research councils. Together these set up international mechanisms to carry out scientific programs of an interdisciplinary nature.

An important factor in the success of these activities, which are concerned with issues such as the protection of the environment, Antarctic regions or space research, is that they are carried out under the aegis of a respected independent and international scientific body such as ICSU. Each Member adheres to the Council’s Statutes when involved in activities carried out within ICSU’s framework. One of the basic principles in these Statutes is that of non-discrimination, which affirms the right and freedom of scientists to associate in international scientific activity without regard to such factors as citizenship, religion, creed, political stance, ethnic origin, race, colour, language, age or sex. All of these rights are embodied in a variety of articles in the International Bill of Human Rights. ICSU seeks to protect, and promote awareness of, the rights and fundamental freedoms of scientists in their scientific pursuits.

ICSU has a well established non-political tradition which is central to its character and operations and it does not permit any of its activities to be disturbed by statements or actions of a political nature.

As the intrinsic nature of science is universal, its success depends on co-operation, interaction and exchange, much of which goes beyond national boundaries. In order to achieve its objectives, scientists involved in ICSU activities must therefore be able to have free access to each other and to scientific data and information. It is only through such access that science can produce its fruits and international scientific co-operation can flourish.

ICSU recognises that scientists are not working in a world where such open access is always assured, and it uses its best endeavours privately to resolve difficulties where they arise. In most cases it has been successful. Where such consultations have failed ICSU has, however, had to publicise acts of discrimination against scientists and take steps to prevent their repetition, even to the extent of encouraging members of the ICSU family to decline invitations to hold meetings in the country concerned. On the basis of its firm and unwavering commitment to the principle of the free circulation of scientists ICSU continues to oppose any tendency to weaken or undermine this principle.

New ICASE Publication
APOLLO 11
A Teacher Resource Book

This new publication, the latest of a series of Commemorative Issues produced by ICASE, has been compiled to commemorate the 20th anniversary of the Apollo 11 Moon Landing 1969-1989. The book, compiled and edited by Linda Crow and Donna Hare, provides information and activities for both elementary and secondary science students.

The Use of Role Play with School Students in Swaziland
A Case Study

by Quinton Reissman and Marissa Rollnick

Introduction
Interest has been generated in the developed world in science teaching which starts from the pupils' experience and actively involves them in the learning process. Curricula such as the Salters Chemistry Course (University of York, 1987) have been developed for GCSE. Further courses are being developed in this line for Balanced Science, and A Level Chemistry. Although it is too early to assess the long term effects of the Salters courses, initial impressions are that it generates enthusiasm and interest in both teachers and pupils.

In the developing world, on the other hand, much of education is at the stage of formalism as defined by Beeby (1966) and teaching tends to be traditional and examination oriented. One important reason for this is the importance of paper qualifications in obtaining employment. It has been asserted that the only way to change teaching styles is to change the type of examination at the end of the course. It is also true to say that the only way to convince teachers to use a new piece of curriculum material is to show them that 'it is in the syllabus'. A further problem for teachers is lack of resources and large class sizes, frequently over 40 students.

This article describes the development and trial of a role play exercise in Swaziland, a small country in southern Africa. This role play is based on the production of ethene and was named The Ethene Role Play.

The ethene role play
The ethene role play is a revision exercise in organic chemistry, aimed at students in Swaziland preparing for O levels, examined by the Cambridge Examination Syndicate. It is a group discussion exercise with the class divided into groups of about eight students. In a class of 40 students, this would mean five groups.

The play takes the form of a discussion between top officials from government, industries and other interested parties, and is chaired by a project evaluator from Tibiyo takaNgwane, a parastatal investment agency with access to both local and international funds. It is a body well known to the public in Swaziland.

Motivation for the project
The role play is an aid to teacher educators, to show that role plays in science at high school are both feasible and useful to inspire student and practising teachers to undertake such exercises. It is for this reason that the teachers' guide includes a detailed listing of the aims and objectives which the role play helps to fulfill. They are quoted directly from the handbook of one of the commonly used syllabi - the Cambridge GCE. As mentioned, most of the science taught in Swaziland is very syllabus oriented, and concentrates on factual content. It tends to neglect the social, political and economic issues surrounding the application of science in society. One of the main objectives of the role play exercise is to show that this active method, rather than the usual teacher-centred discussion, can meet these broader objectives of the syllabus and in fact does so more effectively than other methods.

The package was designed to help practising teachers to conduct the role play with a minimum of time and effort. Since the idea of this kind of play is foreign to the great majority of teachers, a videotape of the trials was produced, including all the preparatory stages to the final performance of the role play. It was hoped that this would make the procedure clear enough for the role play to be undertaken confidently by any teacher.

Writing the role play
Organic chemistry was chosen as the topic for the role play since fermentation features strongly in the syllabus, and Swaziland is also a sugar producing country, which depends on imported petroleum products. The choice of an ethene producing plant is a little artificial, since local demand is not really enough to warrant an ethanol cracker. However it does give much more syllabus coverage than a simple ethanol fermenter and distiller, and reinforces the idea that an organic chemical industry could theoretically be built up through sugar via ethanol and ethene.

An attempt was made to keep the various characters within the realm of the possible, drawing from the biographies of many well known public figures. Similarly the intention was to present as many social, political and economic realities as possible. The following proved to be useful resources:

- The Times of Swaziland, for information about an ethanol fermenter that seems to have been 'in the pipeline' for a number of years now (Times of Swaziland, 1989)
- Facts and Figures for Investors, issued by the SASOL company (Sasol, 1988)
- A personal interview with the chairman of the Swaziland sugar producers association
- The Ethene A Level Package produced by Salters Science Projects (Utley, 1987)
- The booklet Transporting Chemicals which served as a model for the role play (University of York, 1987)

Relationship of the role play to the syllabus
This was a crucial question to address, as teachers are not generally motivated to teach material unrelated to the syllabus.
The ethene role play was designed to help teachers meet certain educational aims and objectives (see opposite) quoted from the 1991 Cambridge combined science and additional combined science syllabus (University of Cambridge Overseas Examination Syndicate, 1988).

**The structure of the role play**

Roles were devised for eight characters to take part in the discussion. The role play has been deliberately designed so that there is no 'right' answer to the discussion. The final decision depends on the character and persuasiveness of the participants.

The bulk of the background information was given to the pupils in the form of a general fact sheet. This sheet contained information about the characters in the role play, uses and production of ethene and some facts and figures related to issues such as plant size, number of jobs, cost, and pollution hazards. They were also given a schematic diagram illustrating the three processes to be discussed in the meeting.

The fact sheet told the pupils that ethene can be made by a number of different processes, each with advantages and disadvantages for Swaziland. A decision as to which type of plant should be built, was to be made by their meeting.

The characters used in the role play were as follows:

- **Mr/Ms Nsibandze**, chairperson and project evaluator from Tibiyo takaNgwane, the parastatal funding organisation
- **Mr/Ms Brown**, representative of the Swaziland Sugar Producer Association proposing an ethanol-based process at Mhluwe, the site of one of Swaziland's sugar mills
- **Mr/Ms du Toit**, representative of the South African Trade Mission, proposing a SASOL type plant near Mpaka, the site of Swaziland's coal mine
- **Mr/Ms Dlamini**, representative of oil companies hoping for a petroleum-based plant at Matsapha, Swaziland's industrial area
- **Chief Busa Hlobhe**, representative of the Swaziland government, pushing for employment and foreign exchange
- **Mr/Ms Leary**, representative from the National Trust Commission, with environmental interests
- **Mr/Ms Mavuso**, representative of the communities in the areas around Mpaka and Mhluwe
- **Mr/Ms Simelane**, representative of the Swaziland Federation of Trade Unions

Each pupil was given a briefing sheet for their role. The role briefing sheets contained thumbnail sketches of the character to be portrayed. For example, the chairman's role is outlined as follows:

*You are in your early forties. After leaving school, you started out as a bank teller and worked your way up to become the manager of a large bank at Nhlangano. This experience gave you the opportunity to get a job at Tibiyo takaNgwane where you have now been promoted to the position of senior project evaluator. You are confident, well experienced with big business and used to keeping people in line. You also know the importance of tact and courtesy when dealing with others in positions of authority, like the delegates at this meeting.*

**Aims**

1. . . . to enable students to acquire sufficient understanding and knowledge to:
   1.1 become confident citizens in a technological world, to take an informed interest in matters of scientific import
   4. stimulate interest and care for the environment
   5. promote an awareness that:
   5.1 the study and practice of science are co-operative and cumulative activities, and are subject to social, economic, technological, ethical and cultural influences and limitations
   5.2 the applications of sciences may be both beneficial and detrimental to the individual, the community and the environment

**Assessment Objectives**

A. Knowledge and understanding

Students should be able to demonstrate knowledge and understanding in relation to:

5. scientific and technological applications with their social, economic and environmental implications

B. Handling information

Students should be able to:

1. locate, select, organise and present information from a variety of sources
2. translate information from one form to another
4. use information to identify patterns, report trends and draw inferences
5. present reasoned explanations for phenomena, patterns and relationships
6. make predictions and hypotheses

**Subject Content**

12. Organic chemistry

12.2 Fuels

- describe petroleum as a mixture of hydrocarbons and its separation into useful fractions by fractional distillation
- name the uses of petroleum fractions

12.5 Alkenes

- describe the manufacture of alkenes and of hydrogen by cracking
- name some uses of poly(ethene) as a typical plastic

12.6 Alcohols

- describe the formation of ethanol by fermentation
- name the uses of ethanol as a solvent; as a fuel; as a constituent of wine and beer
The sheet also provided advice on the part they were to play in the discussion and their interests.

Trialling of the role play

The class chosen for the trial was one preparing to sit for their O level exam (Form 5 in the Swaziland system). It was a co-educational class in a day school, with a mean age of 17 or 18, in an urban setting. The school itself, although not an elite school, is known as one of the better government schools.

This group was perhaps easier to work with than a class in a rural area where the grasp of English is more of a problem. Although English is a second language to almost all students, secondary school instruction, in this case for the past 5 years, is conducted in English. Most students have had their primary school instruction in Siswati, though a handful may have come from English medium primary schools.

In trials it proved useful at the outset to let the class think that they would be having a revision test in organic chemistry. Two double periods were used on different days.

Day 1

On the first day of the exercise, Mr Reissman, the class teacher was assisted by Dr Rollnick, some of her education students and a TV cameraman. Some 40 minutes were spent going through the general fact sheets with the whole class, and dealing with any problems that arose. Then, 15 minutes were spent allocating roles to the various members of the class. Time could have been saved by the teacher doing this unilaterally beforehand, but it was felt that better co-operation would be obtained if individuals were allowed to select their roles as far as possible. The only role where no freedom of choice was allowed was that of chairperson, where it was thought that the teacher's judgment may improve the end result. Although the girls in this particular class tended not to be very assertive, one girl was deliberately made to take the role of chairperson.

For the remainder of the lesson, eight groups were formed, each focusing on one of the characters, and they prepared and discussed problems and strategies relevant to their role. The importance of this stage cannot be underestimated. Most students entered into the spirit of the exercise only after forming into these groups and receiving their role outline. At this stage, the assistant and the teacher all circulated freely among the groups of students, joined in with their discussions, and sorted out a great number of difficulties.

Day 2

The following day, the 39 students in the class were divided into five different "meetings", each located in a different part of the science laboratory. The assistants were again present, but not taking an active part in the proceedings.

The chairpersons commenced the discussions, which were allowed to proceed for 35 minutes. The only intrusions into the discussions were made by the camera crew who tried not to affect the flow of the discussions. Most of the time, the students were so engrossed in their discussions that they did not take much notice of the camera or the microphone.

After 35 minutes, some discussions were beginning to flag, and all groups were asked to wind up within 5 minutes. Each chairperson was called forward one at a time to present the group's conclusions.

Problems encountered in the exercise

As the role play started, many students were still somewhat unsure of themselves, and not quite sure how they ought to start. Such a problem is not easily overcome, but would ease if role plays were used more often in science and in other subjects. Schools with access to a video cassette recorder could show part of the video produced in the trial as part of the introduction to students. The somewhat stilted introduction shown in the video was found to be one way of breaking the ice.

Problems were encountered in obtaining accurate information for the sheet which compared costs for each of the proposed plants. The SASOL corporation volunteered some information, but more with a view to attracting shareholders than to foster a technical grasp of the operation. The Annual Statistical Bulletin issued by the government statistical office was of some help in assessing national requirements of petro-products. Curiously, Tibiyo takNgwane and the sugar companies, which are known to have been involved in feasibility studies for ethanol production, were evasive when approached for information. Hence the data table is one of the weaker items of the package, and needs revision.

During the trial, a team of assistants was available to help solve problems facing particular characters. Teachers, undertaking a role play single handedly for the first time, would no doubt experience some problems.

The video, although revealing, was necessarily of amateur quality since it was made on a domestic VHS camera and edited on two domestic video tape players. Professional
equipment was unavailable.

Other criticisms, mostly from participating students, were:

- Name tags should have been worn by the characters.
- Groups should have been given more privacy. As the discussion became more animated, neighbouring groups tended to distract each other.
- The aim of the exercise was not clear enough.
- Estimated coal reserves for the Mpaka coal mine should have been included in the data table.
- The pollution hazards of each process should have been more accurately stated in the data table.
- The ratio showing capital expenditure vs jobs created should have been included in the data table.
- Roles could have been doubled up in each group of students so that the actors could give each other moral support.
- Why spoil an entertaining exercise by setting a homework followup?

Conclusion: achievements of the role play

Almost all of the class took an active part in the exercise, including those who would not normally contribute - the girls who are often shyer than the boys, and those students who are not known achievers and often afraid to speak out in a teacher-led discussion.

The exercise had great novelty value and stimulated considerable interest from the class.

Most groups became emotionally absorbed in the discussion and came to grips with the issues at stake. In the later stages of discussion, students were generally unaware of the microphone and camera. Science issues were correctly used in arguments, and relational numbers, rather than figures, were often used.

Although English is a second language for most students, they generally succeeded in expressing themselves clearly. The absence of a supervising teacher in the groups encouraged less inhibited discussion. In rural schools where the command of English is generally not as good, teachers would need to decide whether or not to allow discussion to proceed in the vernacular or in mixed language.

The role play was presented to teachers at a workshop in Swaziland, and conducted with the teachers playing the various roles. The teachers were enthusiastic about the exercise, although expressed doubts about conducting it in rural schools where students may not be as forward, or not as aware of current events. This case study has demonstrated that pupils who were normally quiet, were active and involved in this exercise. Once pupils in rural schools appreciated the idea of the exercise, they too should become more vocal.

About the Authors

Mr Quinton Reissman is a teacher at Herman Gmeiner School, Swaziland. Dr Marissa Rollnick is a science educator at the University of Swaziland.

A Matchbox Magnifier

Betty Graham of Santa Fe, New Mexico, USA, sent this idea to the Primary Science Section Editor for a low cost magnifier, following the suggestions in Science Education International Vol 1 No 2 June 1990.

Betty presented this idea at the CESI "Make and Take" at the NSTA National Convention in Atlanta, USA in April of this year.

For more ideas in Primary Science, refer to pages 24 to 26 of this issue.
OBSERVING PENDULUMS

1. Cut a piece of thread as long as your arm.
   Tie a paper clip to one end.

2. Tape it to the bottom edge of your table like this.

3. Pull the paper clip to one side, then let it go. Describe how the paper clip moves.

4. Find a way to make your pendulum swing faster; then slower. Tell how you did this.

5. Hang another pendulum next to your first.

6. Make both pendulums “march together” for at least 10 cycles back and forth. Tell how you did this.

7. Predict how these pendulums will swing. Give reasons for each answer.
LESLIE NOTES
Gather just 7 items to teach all 5 lessons. These
quantities are based on a class size of 30 students
working in pairs:
2 spoons thread.
15 pair scissors
4 rolls tape; masking tape works best
2 boxes paper clips of uniform size and
weight (about 200)
30 coins or washers
1 wall clock with second hand sweep; or
substitute wrist watches
15 rubber bands

Activity 1: Observing Pendulums
4. To lengthen or shorten the pendulum, it's easiest to
simply pull the thread through the tape.
Allow students to discover the relationship be-
tween length and frequency in their own time.
Don't rob them of the joy of discovery by telling them
the "correct" answer before they've had a chance to do
their own experimenting.
5. Fix the second piece of tape even with the first, flush
with the bottom edge of the table. This insures that both
pendulums will hang from the same height.

ANSWERS
3. The paper clip swings back and forth through an arc.
It moves fastest through the bottom of its arc, slows to
a complete stop at the top, then accelerates back down
in the opposite direction. (The paper clip also de-
scribes an ellipse when swung in a circle.)
4. To make a pendulum swing faster, decrease its length;
to slow a pendulum, increase its length.
6. Adjust each pendulum to the same length.
7. Pendulum A swings fastest; C swings slowest; B
and D swing with the same frequency.

Activity 2: Clock Pendulums
1. Note who stood closest to the mark, but don't
declare the winner until everyone is standing.
3. An accurate pendulum clock measures 24.6 cm
from the middle of the paper clip to the pivot point.
Students who adjust their pendulum clocks near
this length, will stand in choir-like unison after 1 minute.

ANSWERS
4. Yes. I estimated much closer to the 60 second mark
when using the pendulum clock. So did the rest of
the class because we all stood up nearly together.

Activity 3: Heavier or Longer?
Write these pendulum terms on your blackboard.

<table>
<thead>
<tr>
<th>CYCLE</th>
<th>FREQUENCY</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="" alt="Diagram of pendulum swing" /></td>
<td><img src="" alt="Diagram of frequency" /></td>
</tr>
</tbody>
</table>

A cycle is two swings, once back and once forth.
The frequency of a pendulum is the number of cycles
it makes in a minute.

Illustrate these terms by making a paper clip
pendulum, counting cycles over a one minute interval
and expressing the resulting frequency in cycles/minute.

ANSWERS
Student answers may differ from these, depending on
the final length of the pendulums they measure:
3. 80 cm. 4. 80 cm. 5. 54 cm.
6. To reduce frequency, make the pendulum longer.
When 10 clips were hung in a long chain, the fre-
quency dropped from 80 cm to 54 cm. It was in-
creased length, not weight, that made this difference.
When the 10 clips were added in a bunch, the fre-
quency remained unchanged at 80 cm, despite the added
weight.

Activity 4: Little Swings / Big Swings
4. At large amplitudes, the pendulum may swing a
cycle or two slower than at medium or very small
amplitudes. This is a real difference brought on by
jerky, uneven motion in the bob. Random experimen-
tal error may also scatter the values to some extent.

ANSWERS
4. Student values may differ from these, depending on
the exact length of the pendulums they measure:
4a. Frequency for LARGE amplitude = 48 cm.
4b. Frequency for MEDIUM amplitude = 49 cm.
4c. Frequency for SMALL amplitude = 49 cm.
5. The amplitude has little effect on pendulum fre-
quency. Pendulums moving through large, medium
and small amplitudes all had frequency values that
remained relatively unchanged at 48 or 49 cycles per
minute.
6a. Shorten a pendulum to increase frequency.
Lengthen a pendulum to decrease frequency.
6b. Bob weight has no effect on frequency.
6c. Amplitude has little effect on frequency. (Large
amplitudes may reduce the frequency slightly.)

Activity 5: Energy Transfer
Think about pushing someone in a swing. You
can only push at the height of the backswing, when
the person just stops and begins moving forward. This
swing, like all pendulums, only accepts energy when
delivered in phase with its own natural frequency.
Demonstrate this principle with a long and short
pendulum. Notice how you must push the long pendu-
ulum slowly to keep it going, but the short pendulum
rapidly, each in time with its own natural frequency.
If this energy is not delivered in phase, it won't keep
going. Illustrate by pushing the long pendulum too
rapidly and the short pendulum too slowly.

ANSWERS
3. The pendulums shift their energy of motion from one
to the other. As one slows to a stop, the other reaches
maximum energy. Then the process reverses.
4. A high rubber band transfers the energy between
pendulums rather slowly. As you move it down, these
energy transfers become more rapid.
5. No. When you set one pendulum in motion, it will not
be able to transfer much energy to the other. Because
it has a different frequency (different length), it swings
cut of phase with the other.
6. The pendulum you swing first transfers only part of
its energy before gaining it back again. It slows down
and speeds up while the other, originally at rest, starts
and stops.
CLOCK PENDULUMS

1. Stand up when you think exactly one minute has passed. Your teacher will keep time to see who comes closest.

   Put all watches out of sight... ...get ready, get set, GO!

2. Now make a pendulum clock that ticks exactly 60 seconds in a minute.

   a. Tie an arm-length thread to a paper clip.
   b. Lightly fold a small piece of masking tape over the middle of the thread.
   c. Slide the thread through the tape until you find a length where your pendulum swings exactly one cycle each second.

   PULL THROUGH

   1 second, 2 seconds, 3 seconds, ... 60 seconds

3. Repeat the class experiment in step 1. This time use your pendulum clock to keep time.

   Hide your watches! Ready, set, GO!

4. Did your pendulum clock help you guess one minute more accurately? Explain.
HEAVIER OR LONGER?

1. Cut some thread as long as this paper. Tape it to the edge of your desk so it forms a loop.

2. Hang a paper clip from this loop to make a pendulum.

3. Count how many cycles your pendulum makes in one minute. Frequency?

4. Now make your pendulum heavier. Hang 10 paper clips from the loop. 10 CLIPS THROUGH THE LOOP!

5. Now make your pendulum longer. Arrange the 10 clips to form a chain. ONE LONG CHAIN!

6. To slow a pendulum (make it swing with less frequency) should you make it heavier or longer? Use numbers to support your answer.

---

LITTLE SWINGS / BIG SWINGS

1. Make a paper clip pendulum so it hangs about halfway to the floor.

2. Pull out the arm of the paper clip to make a hook.

3. Add about 10 clips to the hook to make a heavy pendulum bob.

4. Amplitude is the amount of swing. Find the frequency (in cycles per minute) for these 3 amplitudes.
   - a. Frequency for large amplitude.
   - b. Frequency for medium amplitude.
   - c. Frequency for very small amplitude.

5. When you change the amplitude, does the frequency change by much? Include frequency values in your answer.

6. Tell how each variable changes the frequency of a pendulum (if at all).
   - a. LENGTH
   - b. BOB WEIGHT
   - c. AMPLITUDE

Copyright © 1988 by TOPS Learning Systems. Reproduction limited to personal classroom use only.
ENERGY TRANSFER

1. Tape 2 coins to pieces of thread. Hang them from your table like this:

   Twice as long as this paper.

2. Loop each pendulum over a rubber band so it rests about halfway up.

   Loop each side.

3. While 1 coin hangs still, pull back the other and let it swing.

   Do the swinging coins transfer energy? Explain how you know.

4. What happens as you move the rubber band up or down?

5. Predict: Can one pendulum transfer all its energy to the other if they have different lengths? Explain your reasoning.

   REMEMBER: Each pendulum swings at a different frequency.

6. Test your prediction. How do the pendulums interact?
Consultation Meeting on Information Exchange in STME

by Lucille C Gregorio

At the Institute for Science and Mathematics Education Development, University of the Philippines, UNESCO-INISTE, the Information Network for Science and Technology Education organised a consultation meeting on *Information Exchange in Science Technology and Mathematics Education*. This was held on 18-20 April 1990.

The meeting was attended by participants who were science educators and information specialists from Bahrain, Jordan, Republic of Korea, Malaysia, Nepal, Philippines and Thailand. UNESCO Paris was represented by Ms Maria Malevri, Assistant Program Specialist in Information Exchange; while ICASE and ICSU-CTS were represented by Mr Dennis Chisman, the Honorary Treasurer of ICASE. Co-ordinating the meeting was Mrs Lucille C Gregorio, President Elect of ICASE.

The objectives of the meeting were:
- to discuss suggestions for possible future cooperation among INISTE members
- to explore further the fields of science, technology and mathematics education that are of current priority and particular interest to the member institutions
- to suggest appropriate ways of gathering and retrieving information as well as the creation and extension of databases.

During the sharing of country experiences, the participants reported on (1) the infrastructure on information exchange existing in each country; (2) the type of information needed to be exchanged and how; (3) the information stored in existing databases; (4) the hardware and software currently used; (5) how individual teachers gain access to the system; and (6) the applications and uses of the data system.

The meeting proposed projects for improving information exchange in science technology and mathematics education at the national and regional levels, which will lead to greater cooperation among countries and enhance the quality of STME at all levels in the participating countries. The areas in STME which were selected as priorities for collaboration are:
- science technology and mathematics curricula
- teacher education
- teaching aids
- research and evaluation
- policy making and planning
- publications and journals
- high level manpower (consultants)
- teaching methods

The participants agreed that a pilot project should be considered in order to be able to exchange computerised information on STME, and that INISTE should expand and explore other ways of collaborating with other agencies, for example UNDP, ADB and others.

European Youth Science Network

EURYSN, the European Youth Science Network, is a new international framework for young people and organisations involved in youth science, the sciences and youth affairs.

The Network aims to encourage and promote Youth Science in Europe by:
- providing a forum within Europe for organisations and individuals dealing in the area of youth science.
- providing a framework within which common activities can take place.
- encouraging more youth organisations in Europe to have a science element to the personal and social development of young people through "Science in Society".

Activities include information exchange, meetings and receiving *Copernicus*, the EURYSN Journal.

The organisations and individuals from the following countries are currently participating in EURYSN - Belgium, Czechoslovakia, France, Greece, Ireland, Italy, Malta, Netherlands, Norway, Portugal, Spain, Sweden, United Kingdom, and Yugoslavia.

For further information, contact:

EURYSN

c/o IAYSG

37 North Great Georges Street
Dublin 1, Ireland
The principal goals of the Committee on Teaching of Science are:
• to develop and enhance, on an international scale, the teaching of science at all levels of education and training
• to cooperate with other organisations to further all aspects of the teaching of science
• to facilitate cooperation between the Teaching Commissions of the International Scientific Unions.

Seventeen scientific union members of ICUS have representation on and participate in the activities of CTS. COSTED and ICASE are affiliate organisations.

Scientific meetings
Representatives of CTS were participants and observers at a number of conferences sponsored by scientific unions. The Teaching Commissions of IUPAP, IUPAC, IGU, and the Secretary of CTS participated in the Workshop on Energy and the Environment as related to Chemistry Teaching, co-sponsored by Unesco, USDOE and IUPAC/CTC.

Education and training activities
The major workshop activity of CTS was the planning of the Zimbabwe Workshop on the Preparation of Innovative Teaching Materials for Science Education. The workshop, scheduled for January 1991, will include participants with responsibility for science education from a number of African countries. The workshop is being co-sponsored by The African Biosciences Network, Unesco, FASE, The British Council, and the Commonwealth Foundation.

CTS is co-sponsoring the ICUS-Unesco Project in University Science Teaching. The Project is developing science curricula in biology, chemistry and physics at university centres in Thailand. It is planned that the newly developed programs will provide prototypes for post-secondary educational institutions in other developing countries.

CTS and ICMI are collaborating on the Science and Mathematics Education of Future Elementary Teachers Project, sponsored by Unesco and ICMI.

Activities involving developing countries
The low-cost, locally-produced scientific equipment project by CTS focuses almost exclusively upon science education in the developing world. The project is developing specifications for the production of laboratory equipment and the training of science educators in the production of the equipment. Collaboration between CTS, WHO and IUB is being considered as a means to expand this project.

The CTS projects are concerned with and address problems associated with the production of scientifically sound, low cost materials for teachers and trainers of teachers in the developing world. CTS projects currently underway address the important elements of disseminating scientific information and methodology to the broadest range of constituents.

Publications
Several publications have been in preparation during the past year. The first is a handbook devoted to information processing, microprocessors and computers in science teaching, and is being prepared by a subcommittee of CTS. It will be made available free to science teachers and students worldwide.

Plans are underway to produce a volume that includes selected papers from the 1985 ICUS-CTS Bangalore Conference on "Science and Technology Education and Future Human Needs". The papers of the Conference were initially published as nine volumes. It is deemed important by CTS to extract the papers that meet particularly critical needs in science education and republish them in a single volume for greater access by science educators.

Special projects
The Education in Global Change Project is in its first phase of curriculum materials development. The Project will design and produce classroom materials for secondary science students that incorporate the most recent scientific data pertinent to global change research. Science educators and global change scientists are participating in the production and review of teaching units. The materials development team met in June 1990 to design and draft the initial four instructional units for classroom trials. Upon the successful completion of the first phase of the project, a second phase will occur in 1991. It is planned to initiate teacher training workshops in various parts of the world in 1992 as the second phase of materials development is underway.

Plans are being made for a workshop on teaching about ethical problems in science with the intention to reach a diverse, international audience. The team planning the workshop is made up of scientists and science educators who have a commitment to teaching about ethical issues in science. Pending the availability of funding, the workshop is tentatively scheduled for late in 1990.

New areas of interest
There are three areas that CTS is examining for possible future activities. The first is in conjunction with the ICUS-UNDP project entitled Strengthening Science Training and Research in the Third World. The CTS component of the project would involve the development of prototype teaching units for teaching interdisciplinary science at the tertiary level of education. The second is the preparation of instructional materials and sponsoring of teacher workshops addressing the scientific aspects of natural disasters. The third is the concern with the public understanding of scientific concepts. These projects, presently concept papers, if pursued, will take form over the next year.
SATIS 8-13
Placing science & technology in context for 8-13 year olds
by John Stringer, Project Director

The Early SATIS Project is moving from a phase where needs were explored, and structures established, into a time of active writing and materials development.

In response to teacher requests, SATIS 8-13 will chiefly comprise of short, stand-alone units, which are grouped thematically as far as possible. Individual units can be used sequentially or simultaneously, allowing a wide range of teaching strategies.

Some of the materials will address the issue of liaison between primary and secondary schools, facilitating good practice in continuity.

Central Television has offered us national, networked time during schools broadcasts to primary schools in 1992 for some specific SATIS programs; BBC School Radio is planning five SATIS programs for younger secondary pupils in the same term.

The first trial materials will be sent to schools shortly; on their reports, and the advice of reviewers, the units will be revised and edited.

There are 28 local groups developing around the country, including Scotland, Wales and Northern Ireland. Many of them will be making contact with industries in their locality. We are looking forward to the publication of an exciting and influential project.

Further information can be obtained from the Early SATIS Project, Barclays Venture Centre, University of Warwick Science Park, Sir William Lyons Road, Coventry CV4 7EZ, UK.

India: Children and Trees Project

The Children and Trees Project is an environmental education project designed to encourage environmental awareness among children.

The project materials consist of teachers' packs that help teachers to understand and teach environmental concepts related to the following books:

A child and a tree - about planting trees, the effects of soil erosion and the importance of maintaining tree cover.

Mala the mongoose - about water control, bunding, trees and land management.

Elephant and dragonfly - about the diminishing forests and the damaging effect on wildlife, especially on the Asian elephant.

The books are suitable for schools and village action programs and are produced using illustrations from the books.

The immediate aim of the project is to provide at least one copy of A child and a tree for each school in the local language of each major region. It is hoped that eventually ten copies of each book will be distributed to every school in India.

Cameroon Association for Science Education: to be or not to be?

by Augustin Kiteh
Government High School

The concern for and focus upon science is not confined to Cameroon, but is common to nations all over the world. The aim is to produce a new generation of citizens, scientifically literate and thus better prepared to function in a world that is increasingly influenced by science and technology.

School science today is socially controlled, being the product of particular sets of choices made by particular groups of people at particular times. In initiating reforms in science education in Cameroon, there is a need for concerted action by all groups such as the Physics Teachers Association, Natural Science Teachers Association, Mathematics Teachers Association, etc. The single key issue which science educators need to address in Cameroon is how a more appropriate set of expectations and structures in science education can be created.

There is an ongoing effort by The British Council to change the face of physics and mathematics education in anglophone Cameroon; it supports innovative programs in physics and mathematics, run very largely by teachers for teachers; and it conceives and designs professional development activities to expand the repertoire of teaching strategies.

The worldwide shift of focus from "Education about Science" and "Education in Science" to "Education through Science" has implications for the science curriculum. Science and technology education has experienced a revolution that has given birth to a variety of associations - both national and international - which are concerned with the improvement of science education in schools and the advancement of science and technology in people's culture.

This is the challenge for the Cameroon Association for Science Education (CASE) if it is to be; but, if it is not, Cameroon may well be down on the league table of educational innovations from a comparative point of view in the third world. How can Cameroon fight the development problems of today and tomorrow with the rusty and irrelevant weapons of yesterday - the methods, educational technologies and strategies designed for a past generation?

When a nation sees itself to be successful in international competition, it tends to regard its education system as one of the foundations of that success. This, in Cameroon, depends on administrative, technical and educational responsibility and the decision of planners, practitioners, researchers and educators.

Augustin Kiteh teaches at Government High School, Nkambe, NW Province, Cameroon.

MNU Conference Outcomes
8-12 April 1990

by Drs Erik Jongejan

The 99th conference of the West German MNU Association was held in Munich, the capital of the federal state of Bavaria. MNU is an association for teachers of mathematics, physics, chemistry, biology and information theory. Among the 2000 participants, 100 were from East Germany. There were also participants from the Soviet Union, France, Luxembourg, Switzerland, Austria, Belgium and the Netherlands.

One of the major speakers was Professor Gerd Binnig, 1986 Winner of the Nobel Prize in Physics. He spoke on the topic "Creativity of nature and man", describing how the order in material and social structures in both inanimate and animate nature, is similar to the order which characterises the world itself.

During the congress, the chairmen of associations of natural science in West Germany, France and the Netherlands met to consider the outcomes and declaration of the 1989 European Congress of Teachers of Biology and Geology (see page 17). The meeting clarified the general picture of biology instruction in the three countries - the level of final examinations, the content of biology instruction for 12-15 year olds and for 15-18 year olds, the amount of practical work included, class sizes, the availability of technical assistance in the laboratory, funding sources, and the amount of curriculum development occurring. In France, primary teacher training will involve a five year training course, three of which will be undertaken at a university, which will result in a financial improvement for primary teachers. Class sizes can be as many as 35, and sometimes up to 42 students, although for practical work the limit is 25 students. In the Netherlands, the maximum class size is 24 pupils for safety reasons. In Germany, the situation is that all states do not yet engage technical assistants in science laboratories. Sometimes the city, rather than the state, funds one assistant per four teachers.

As a result of this meeting, it is proposed to press for a maximum of 18 students in practical classes. Practical work is essential for instruction in biology and natural science. It is hoped that Britain will become involved in the followup talks. In October, the group will meet in Paris to plan a congress in order to produce a joint statement concerning biology education.

It is planned to present such a joint statement to the twelve EEC ministers of education. Members of associations of natural science in EEC countries who endorse such a European wide initiative are encouraged to contact the NVON Chairman:

Enhancing Student Creativity
by John E Penick

Creativity is the essence of science. Creative persons learn more and are more observant. It is no surprise that science teachers the world over say that enhancing student creativity is one of their goals. But, creativity does not happen by chance alone. Teachers wishing to teach for creativity must carefully and consistently structure the classroom to maximise opportunities for creative endeavour, paying special attention to time, teacher role, and expectations of and for students.

Teachers must provide students intellectual freedom to be spontaneous, to structure their time to some extent, and to decide on courses of action. Rushing to a judgement or product is the opposite of the creative process. Rather, we must ask questions and provide time for observation, contemplation, response, and reflection. Without this, rather than creativity we will foster conformity and dependence via quick answers and no thought.

The role of the teacher
Providing students with creative time enhances creativity regardless of the role of the teacher. And, teachers demonstrating appropriate classroom behaviours are even more likely to have desired results. Since much of creative thinking centres around observations, questions, and possibilities, too must the teacher’s behaviour.

Students need something to view if they are to make observations and we must teach them how. Typically, students are told to observe, observations are counted and commented on, and the lesson moves on. Instead, if your goal is better observations, you must follow observations with teaching the student strategies to observe more. If students exhaust their supply of simple observations, help them to focus on applications (the candle will burn string, will burn hair, etc), possession (her candle is burning, Megan’s candle is burning, Lucas’ candle is burning, etc), location (the candle burns on the table, on the floor, sideways, etc), or time (the candle is burning now, is burning at 9.07, at 10.00, etc). These are not trivial observations. Each, in a scientific context, could carry considerable meaning. But, students who do think of them may feel that they are not worthy because they are unconventional and few students will think in these terms. Increased creativity, however, allows students to stay from the norm, to take risks, to seek the unusual. The creative individual looks at one thing and sees another. And you, as teacher, must help them know their ideas have value.

The teacher is quite important in such creativity. Well-posed questions stimulate thinking, revealing alternate points of view and logic, and may be viewed as the embodiment of curiosity. But, to be a model of creative inquiry, a teacher must use questions which go beyond mere description. Questions to stimulate creativity must require and allow multiple possible answers and demand action. Questions model our thinking as we pursue a relevant problem. Questions act as windows on the phenomenon in question as we ask a question, select the best answer, and ask the next logical question, continuing the process until the desired evidence or explanation has been revealed.

We should ask questions to obtain information, not to test students. When we seek information, we don't ask questions if we already know the answer. In good adult conversation, adults ask each other questions to find out, not to examine. We wouldn't spend much time with an adult who continually quizzed us. Our students are not different except they are captives in our classroom. As a rule of thumb in the classroom, if you wish to stimulate student involvement and creativity, never ask if you already know. We should also seek opinions and points of view as "How would you design an experiment to...?"

To stimulate multiple answers we must accept all answers, regardless of how good they may be. To encourage students to tell us their thinking, we must show them that each of their ideas has value, that we are paying attention to them. And, since evaluation stifles creative thought and reduces thinking to imitation, we must avoid judgement. But, this doesn't mean we let everything pass by without comment.

Evaluation, rather than arising from the teacher's singular perspective, the norm, or tradition, must be based on causes and consequences. For instance, a student, using a two-pan balance asks "Is this balanced?" The teacher could easily say yes or no, and get on with the activity. But, such a response does...
little to help the student understand or be confident. Think how different is
the scenario where the teacher, instead, replies "What do you mean by
balanced?" The student is now forced into considering the meaning and the
teacher learns more of the student's thought process. In real science,
evaluation always comes from causes and consequences, not from authority
alone. Why should our science classes be any different?

Students may also become dependent on the teacher for the praise associated
with positive evaluation. And, the more dependent students become, the
less likely they are to stray from the conventional and the teacher's certain
praise. All scholars and practitioners who study creative thinking agree that
evaluation must be totally avoided in the early creative stages and, when
evaluation does appear, must arise from individuals as they analyse their
ideas, actions, and products in terms of personal needs, utility, prediction, or
logic.

In the classroom

Teachers can easily make a difference by the structure they provide and the
atmosphere they create. If you wish to see creativity flourish in your

- Provide opportunities for creative
  work (time, materials, expectations)
- Ask questions that demand answers
  (no "yes/no", recall, or answers you
  already know)
- Wait for responses (don't rush, if you
  really ask a question, wait for the
  answer, and wait for and encourage
  multiple responses)
- Accept unusual ideas, questions, or
  products (no judgement, just
  acknowledge and ask for more)
- Ask students to examine causes and
  consequences (if that's true, then . . . ?
  What may have caused that?)
- Allow students to make decisions
  (structure activities so that decisions
  must be made and allow students to do
  so)
- Model creative thinking, action, and
  decision-making (ask questions
  yourself, express curiosity, make your
  room stimulating)

As you model creative behaviour, ask
good questions, wait and expect
multiple responses, and seek
evaluation based on causes and
consequences, you will find you and
your students change. The change will
be in the direction of being more
creative, having more ideas, seeing
more possibilities. We will all be
better for it.

About the Author
Dr John E Penick is Professor and
Coordinator of Science Education,
Science Education Center, University
of Iowa, Iowa City, USA.
Professor Penick's interests include
teacher education, the nature of
excellence, interpreting research for
practitioners, instructional strategies,
and analysing classroom events. In
addition to his active involvement in
professional organisations including
NSTA, NABT, AETS, SCST, AERA
and NARST, Professor Penick has
made substantial contributions to
ICASE Projects.

ICASE AWARD SCHEME
for outstanding contributions to international science education

ICASE Distinguished Service Award
This award is made to individuals who have a career history of distinguished service to
international science education through their involvement in the international activities
of local, regional and global science education organisations

ICASE Regional Service Award
This award honours individuals who have made a significant contribution to
international science education through their involvement in international activities
at the local and regional levels

ICASE Association Award
This award recognises individuals who, within their science teacher association, have
made a significant contribution to the international activity of their association

Contact Dr Jack Holbrook, Executive Secretary ICASE
Department of Curriculum Studies, University of Hong Kong, Hong Kong
"All you need is imagination, action, and desire", says Evhan Uzwyshyn to one of the 2000 female students seeking career advice at the Women in Science and Non-traditional Careers Conference which he has been organising for the past eight years at the University of Winnipeg. The two day symposium with more than 100 female speakers is designed to destroy common conceptions about women's possible job roles in the twenty-first century, inviting female students to explore and enter the vastly male-dominated field of science and technology.

Since receiving the 1986 International Science Educator of the Year Award, Evhan has been involved in various activities. Evhan was presented with the YSF Distinguished Service Award in recognition for his participation and accomplishment in the development and success of the Manitoba Schools Science Symposium by David Hall, past Executive Director of the Youth Science Foundation. "Science education, properly understood, is the enthusiastic explanation of the free and beautiful catchings of a child" mused Evhan on receiving the award.

The MSSS is one of the most successful and largest science fairs in the world with over 700 projects entered each year, annually sending three students to both the London International Youth Science Fortnight and the Canada Wide Science Fair. In 1988, Evhan was the treasurer for the planning committee of the Canada Wide Science Fair held in Winnipeg. Over 100 regions of Canada were represented and the fair was very successful. Currently on the board of directors of the Youth Science Foundation promoting extracurricular activities for Canadian science students, Evhan also continues to be a treasurer and fundraiser for the Manitoba Schools Science Symposium, having held the position for ten years.

On the board of Meeting Planners International as Education Chairman, Evhan facilitates networking between different professional bodies in the science and business world; he edited a provincial newsletter for 1988, and attended an editors conference in Dallas, Texas. For the past four years, also in Texas, Evhan arranged, with ICASE President Bob Lepishak, the NASA-CASE Space Seminars for Canadian teachers at the Johnson Space Center in Houston, giving teachers a chance to update themselves on the latest aspects of space education and research.

Recently, Evhan attended the first Canadian (sponsored by ICASE, CASE, STAO and APSQ) science congress in Ottawa, organising a session on sustainable development strategies given by the Hon. Harry Enns, Minister of Natural Resources in the province of Manitoba. This sparked the idea for the World Environment Energy and Economic Conference to be held in Winnipeg in October this year. As organising secretary, Evhan is planning a pre-conference on sustainable development curriculum and a post-conference of Science Olympics for youth with teams from around the world. Fifty international science educators have been invited to design models on sustainable development, and international spokesmen such as Robert Bateman and Dr David Suzuki will give talks.

Evhan has recently returned from a conference in Moscow hosted by the Soviet Academy of Science on "Russia in the Twentieth Century". He has organised teacher seminars on the Human Genome Project, DNA Biotechnology and a workshop on Biodiversity. "The language of science is the human imagination" says Evhan, "and therefore, is international. We must strive towards a scientific literacy which is capable of carrying our planet through the twenty-first century."

---

**Pasteur and Microbes**

**A Teacher Resource Book**

**Commemorating the 100th Year of the Pasteur Institute 1888-1988**

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute.

It also contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few. These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation. Order by sending US$8.00 or £5.00 (add 25% postage & packing) to:

In-Service Teacher Education for Nigeria's National Primary Science and Mathematics Project

Duro Ajeyalemi

Although rudiments of science were introduced into the school curriculum in Nigeria as far back as 1859, very little of science, in any form - nature study, hygiene, general science or primary science - was taught in most of the primary schools even as late as 1980. The absence of a nationally uniform primary science curriculum in such a centrally controlled educational system before 1980, was indicative of the relative neglect of primary science education by policy-makers. Existing science programs were taught by teachers who were largely incompetent in science, and who emphasised the informational aspects of science, contrary to the inquiry teaching approaches.

Consequently, pupils were mainly trained to remember, but not to understand, think or apply (Yoloye 1983). The teaching of Mathematics at the primary level suffered a similar fate - only arithmetic was taught in most schools and most pupils were bored by the didactic teaching methods employed by most teachers.

The deplorable state of primary science and mathematics education was more than apparent by the late 1970s, and the Federal Government decided to intervene. Core Curricula on Primary Science and Mathematics (Nigeria 1980a,b) were developed and the Nigerian Educational Research Council (NERC) was funded to ensure nation-wide implementation. The core curriculum in each subject was first reviewed and enriched by a team of resource persons selected from universities, teachers' colleges, educational resource centres, and the NERC. A teaching curriculum, based on the report of each review panel, was then developed (NERC 1982). Emphasis was on student activity and direct exploration of the local environment. By 1982, the implementation of the National Primary Science and Mathematics Project (NPSMP) began.

Implementation strategy of NPSMP

It was recognised that nearly all primary school teachers were incompetent to teach science and that the majority had weak backgrounds in mathematics. It was therefore necessary to upgrade the teachers' knowledge of content in both subjects as well as expose them to the philosophy and teaching methodology of each.

As of 1983, 63% of all primary teachers were unqualified to teach any subject, let alone science or mathematics. The problems of implementing the NPSMP were therefore enormous, and caution was necessary. First, it was clear from the costs involved, that sophisticated and largely imported laboratory equipment or other teaching and learning aids could not be provided for all schools. Thus, most of the suggested equipment were low-cost, locally procured, and/or improvisable. This in turn mandated that teacher education for the project needed to emphasise improvisation and exploration of the local environment. Secondly, the two curricula were pilot-tested before nation-wide dissemination, to ensure an evaluation and necessary improvement of the curriculum materials, the equipment and other aids, as well as the suggested teaching and assessment methods. For this purpose, three pilot schools were selected from each of the 300 Local Government Areas (LGAs) in the 19 states of Nigeria existing in 1982 (there are now 449 LGAs and 21 states). Each school nominated at least two teachers for science and for mathematics (six teachers from each LGA and a total of 1800 for each subject). These pilot school teachers needed training, but first, their trainers had to be inducted into the project.

Training programs

Training programs were in three phases: a two-week orientation of teacher-trainers; a four-week training of the pilot school teachers; and similar training of other teachers in all primary schools in each LGA. The model of training was the same in each phase, except that the training personnel changed from one phase to the next. The first phase started at the end of 1982 and was completed by 1987; the second phase took place in 1988; while the last phase is still in progress.

Teacher-trainer's orientation

Teacher-trainers were selected from each state, but were trained on a zone basis (the country was divided into five zones). They were mainly experienced first degree graduate teachers of science and mathematics in secondary schools or teacher-training colleges; some held higher degrees, some were sub-degree certificated teachers, and some were science/mathematics graduate staff of the respective Ministries of Education. Induction into the project was in the form of an intensive two-week
workshops held in each zone. The workshops also served as models to the teacher-trainers, of strategies for pilot school teacher training. The first week involved presentations, group discussions, practical activities and reading/practical assignments directed by resource persons drawn from universities, colleges of education, polytechnics, teacher training colleges, science equipment centres, ministries of education or the NERC.

Presentations and discussions in science or mathematics were held during the morning sessions on such topics as the philosophy and objectives of the project; nature of science, and of mathematics; the curriculum materials and recommended teaching approach (guided discovery); the psychology of learning and the African child, the Nigerian learning environment and resources for teaching science or mathematics; process skill development and concept formation; assessment methods in the cognitive, psychomotor and affective domains; the science or mathematics content difficulty for the primary school teacher; improvisation techniques and development of relevant teaching aids.

Afternoon sessions were devoted to practical activities such as:
- Field trips to different sites - ponds, gardens, markets, local industries, auto mechanic or electrician workshops, etc - for purposes of identifying and locating different resources in the local environment for science and mathematics teaching.
- Development and/or improvisation of teaching aids and equipment using locally available materials.
- Trying out of activities suggested for pupils in the curricula to determine their feasibility, and to evaluate the suitability and effectiveness of equipment (developed by teacher trainers themselves or supplied).

Assignments at the end of the day included familiarisation with the curriculum materials in each subject; planning for lessons to be taught the next week; preparing for field trips; and evaluation of the curricula and teachers guides in terms of perceived difficulty of content for the average primary school teacher and/or pupil, process skills teachable to pupils through the suggested activities and content, and classification of the suggested assessment questions into different thinking levels.

The second week was spent on model and practice teaching by both the course tutors and the teacher trainers, many of whom had never taught in primary schools. The purpose was to familiarise them with the typical primary school classroom, pupils and available facilities, as well as field test the curriculum materials and improvised or supplied equipment. In the first two days, course tutors engaged in model teaching using the curriculum materials, and were each observed by groups of teacher trainers; this was to inspire the teacher trainers and demonstrate the workability of the recommended teaching approach. Each lesson was videotaped and later reviewed in group sessions. The time remaining each day was spent by teacher trainers on earlier assigned topics from the curriculum; each teacher trainer was observed by a group of other teacher trainers and some course tutors. Subsequently, each lesson was played back and critically evaluated in terms of teaching method, particularly on involvement of pupils in practical activities, use of equipment, difficulty of content for pupils vis-a-vis teacher's language, questioning techniques and achievement of lesson objectives as recommended in the curriculum. The review sessions were especially useful for evaluating the strengths and weaknesses of teacher trainers, and were helpful in selecting the final team for pilot school teacher training.

The final day was used for exhibiting equipment and other teaching aids constructed by teacher trainers. This was attended by members of the public, including top government functionaries and teachers in nearby primary schools.

Training of pilot school teachers

This was a four week program, which took place in all states of the country between March and April 1988. The workshops were directed by teams of course tutors and teacher trainers, and the format was essentially the same as that of the orientation of teacher trainers. However, the program included intensive presentations on content earlier identified as difficult for most primary school teachers, and much more time was spent by pilot school teachers on improvisation, development of teaching aids and practical teaching. Samples of equipment ordered from local manufacturers and textbooks developed for pupils under the project were used. Pilot school teachers took away to their school, all equipment and teaching aids developed in the workshop, as well as all curriculum material and teaching guides. Other equipment was supplied directly to each pilot school by the NERC, and pilot school teachers thereafter started implementing the curricula in their schools, with their progress being constantly monitored by NERC field staff, supported by course tutors.

Presently, the training of teachers in other schools of each LGA is in progress. The NPSMP is now widely adopted all over the country, but it is too early to evaluate it summatively. However, it can be reasonably concluded that the inservice program achieved its aims, judging by the commitment and enthusiasm displayed by the majority of pilot teachers.

Where is Science in the Primary School in the Year 1990?

by Alan Cross
Manchester University, UK

This article contains a number of personal reflections based on experience as a teacher of infants and juniors and latterly involved in both in-service and initial training of teachers.

The position of science in primary schools is changing. Politicians and educationalists have sought and increasingly seek to influence that change; however both parents and children are becoming more influential as a generation of teachers learn to accommodate a level of accountability unimagined by some and dreamt of by others.

The position has changed markedly over the last fifteen years and particularly since the Primary Survey of 1978 by Her Majesty's Inspectorate, which found science to be the area "most commonly found to be less well matched to the children's capabilities than work in any other aspect of the curriculum".

At that stage we had a position which had evolved, centred somewhat as it had been for years on the work of major curriculum initiatives like the Schools Council. The HMI report itself stimulated a change in the perception of a significant group in primary education but resulted in little immediate change in practice. Also that year the Department of Education and Science took a significant step publishing Science 5-16 A Statement of Policy. Now we had an official statement saying that science should be part of each child's education.

Discussion at this time was very much about content versus process. The DES document took us a step on from that debate focusing attention on breadth, balance and progression (the statutory orders for the National Curriculum have established a place for both content and process in the curriculum). In the mid eighties, government funds were made available through Educational Support Grants. This money was used by over 90% of LEAs in England and Wales to provide advisory teachers for science (and technology in many cases), recruited largely from the classroom, who focused on support work in school as part of programs of in-service training.

This shift of gear was followed by another in 1988 when the interim report of the National Curriculum Science Working Party was published. What has followed has been a recognition of the importance of science to the stage where primary schools are now implementing science in every age range from 3 year olds to children of 11. "Science was part of the curriculum in all the Year 1 (5-6 year olds) classes inspected" (HMI Report: The Implementation of the National Curriculum in Primary Schools, 1989, DES).

Research

This period has been marked by publication of research into teaching and learning science with young children. Examples include the DES funded APU and the Leeds University CLIS projects. These projects began to provide evidence of the need for considerable development in the teaching of science particularly in the early years of education. This research must be maintained; the SPACE project at Liverpool will undoubtedly make a significant contribution.

A place for science

Visiting schools as I continually do, I find that whole staffs have developed their use of topics and themes to include science and that often the bias towards science is heavy, perhaps too heavy in some cases. This situation was to be expected and will be affected in three ways:

- With familiarity - as science seemed new, teachers rightly gave extra

Figure 1 Six year old children investigating the arrangement of batteries in various torches
planning and curriculum time to it in order to accommodate it both as part of the curriculum but also within their own understanding of the curriculum.

- In broad curriculum balance - we have yet to receive final statutory orders for history and geography, creative arts, and movement. These areas will require further accommodation in terms of curricular time and emphasis.

- In increased integration - balance is only likely to be achieved when we have more experience 'jigsawing' science into the curriculum.

Rather than being one piece in a jigsaw, science may be seen to be made up of several pieces of jigsaw spread around the picture of the curriculum. It is also present in all other pieces of the picture as science offers a major contribution in all areas of the curriculum.

Challenges

Several elements of curriculum design present themselves as challenges for the end of the century. Cross curricular balance is certainly a major element as is Science 3-16. Science has historically in some cultures been viewed as something for older, academically minded males. In some measure the revolution is that science is for all, male and female, all abilities, ethnic and cultural groups, and that we in education must be clear about what science is and how it fits into the world.

Very practical issues occupy our time at present. How can we create time for all the science (and other areas)? How can we assess, record and communicate achievement? Answers to these questions lie in a range of strategies that focus on developed planning for matching science activities for children, for balance in the curriculum, and for communication amongst the participants - child, parent and teacher.

Undoubtedly science is now occurring in primary schools. The emphasis must now be on quality; judgement of this needs to be based on the level to which children are equipped with the skills and knowledge which will allow them to contribute to our society and to gain fulfilment in life (this may include nationally agreed criteria).

Stepping into Science Newsletter

Teachers actively involved in Stepping into Science are planning to compile and distribute a newsletter containing ideas to try and other information about Stepping into Science. If you would like to contribute, suggest ideas about format and frequency, or have your name added to the distribution list, contact:

Children and the Scientific Method

Reprinted from the
Newsletter of the Teachers Resource Centre, Vol II No 4
Karachi, Pakistan

The rapid development in technology to store, retrieve, and communicate information has led to changes in educational practice the world over. Teachers are no longer 'feeding' their pupils with a body of knowledge considered appropriate for their age/stage, but teaching them to discover for themselves what they may find useful or interesting.

In our context, a major problem with this approach is that most of us in the teaching profession were brought up on textbooks only. We associate 'study' and 'research' skills with higher levels of education and find it difficult to envisage school children involved in such an activity.

The second problem is our own perception of 'the teacher' as the omnipotent source of knowledge. It is difficult for us to say "I don't know" and to join the children in discovering new things.

Organising 'hands-on' investigation by children is not difficult, provided you are willing to experiment yourself. For instance, the topic 'Fruits' is ideal because, in Pakistan, it is relatively easy to provide children with samples of real fruit with which to begin their investigation.

Let us say that you have given a group of children a melon to investigate. They will need to handle it, look at it carefully, smell and taste it. They can make detailed (eg scientific) drawings of the inside and outside parts and label them. Other fruits may be introduced for similar investigations so that comparisons can be made. Children can begin to draw up charts and graphically record the information discovered (eg the number and shape of seeds, colour and texture of the skin and fleshy parts).

The gathering of information is only part of the activity. The recording can be used as a source for children to make verbal and written conclusions (eg Fruits may have one or two seeds). Thus considerable scientific skills such as observation, recording, hypothesising and concluding can be practised. Sometimes teachers will need to extend an investigation further by raising more questions (eg What happens to the fruit when left outside?). Teachers can encourage children to ask such questions themselves. Books can provide further information about the subject once children have carried out the initial practical investigation.

We hope this small example sparks ideas you can try out in your classroom, bearing in mind that children forget what they are told, may remember what they see, and understand what they do.

I. HYPOTHESIS:
Fruits have one or two seeds.

II. MATERIALS:
A knife, assorted fruits like a melon, some peaches, pears, grapes, bananas; a mango or two, a papaya or a coconut.

III. TEST:
Cut the fruits and find the seeds. Count how many each fruit has.

IV. RECORD:
Draw the fruits and write their names. Under each fruit record the correct size, shape, colour, and the number of seeds.

V. CONCLUSION:
Different fruits can have one or many seeds.

VI. REFLECTION
Have the children reflect on the experiment, and pose questions to them:

Was it a fair test?
"No, because we did not use all the fruits in the world."
"Yes, because we used fruits of different sizes and shapes."

What factors in your experiment should you change?
"Leave out the coconut because it was hard to cut and difficult to see the seed."
"Make sure you cut the fruit in the middle to find the seed(s)."

What might you do next?
"Find out from books about more kinds of fruits."
"Set up an investigation of fruits of the same species and see if they all have the same number of seeds (lemons, guavas, etc.)."
ENGAGING SCIENCE is a resource development project of the Australian Science Teachers Association, and was funded by the Commonwealth of Australia's Education of Girls in Mathematics and Science Project.

The project addresses the significant challenge of how teachers can provide stimulating Science Technology & Society related experiences that engage all students in meaningful and relevant learning.

Some of the guidelines developed by the project are indicated in Figure 2 below.

To engage all students, especially girls, in learning science, material should:

Address something students want to learn about. Therefore it should:
- look at the whole picture
- link science, technology and society
- show science in a human context
- consider social responsibility in science
- be related to 'real' people in 'real' situations
- be 'hands on'

Be considered important to learn. Therefore it should:
- be more than just 'add-ons'
- be assessed using a variety of methods
- illustrate societal concerns and technological concepts as well as scientific concepts
- be challenging to students

Be diverse in the teaching styles used. Therefore it should:
- be interactive
- include cooperative learning styles
- emphasise creativity and problem solving
- include process oriented material
- include open-ended activities
- take account of 'children's science'

Be able to show that physical science can be worthwhile to learn. Therefore it should:
- be achievable
- be fun
- point to career options
- ask - do students need to know this?
- be relevant

Figure 2 Engaging Science Project Guidelines
One of the key considerations was that the material should be
gender inclusive. Because girls in particular seem to lack
interest in the physics components of traditional science
courses, the project concentrated on providing innovative
student and teacher resource materials for two topics with
physical science components.

The first topic is ELECTRICITY. The second topic is
RADIO AND COMMUNICATION. Generally the materials
are aimed at the Year 9 level but can be readily adapted to
suit a variety of year or ability levels, time constraints or
other needs.

The resource materials are designed to go into the teacher’s
own folder (Figure 1) so that the order can be changed and
other materials easily added. This is a ‘mix and match’
philosophy. Possible pathways and lesson outlines are
presented, but these are only suggestions and teachers are
encouraged to modify and adapt the materials to suit the
needs of their students and schools. The resources have many
possible entry and exit points.

As well as being valuable resources in their own right, the
project materials and teachers guide aim to provide a model
that will help teachers to produce their own materials on
other topics.

A key premise of ENGAGING SCIENCE is that science
education can be made more relevant by approaching it from
the perspective of science, technology and society. This is
illustrated by the unit called MUSIC TO THE EARS which
is about noise and how it affects people (see Figure 3
opposite).

To engage all students in science learning requires use of a
wide range of teaching techniques and strategies. Open-ended
practical activities, problem solving, co-operative learning,
and techniques which foster creativity are particularly
encouraged whenever appropriate.

With these strategies teachers aim to set up non-threatening
situations in which students are more likely to take risks,
answer questions and become involved in hands-on activities.
Girls in particular are encouraged to participate in hands-on
activities such as tinkering (Figure 4).

Noise and how it affects people

The scene is set when the teacher asks students to
listen to a variety of sounds. Students then decide
whether each sound is an example of noise or not.
This leads on to groups of students designing a survey
to find out how noisy their school environment is and
the problem of reducing noise pollution.

Students then carry out a ‘jigsaw’ activity on a case
study on issues of noise pollution and the extension of
an airport. They form home groups and then each
member of the home group is involved in a different
expert group. For example, one expert group looks at
the social implications of extending the airport.
Students return to their home groups and develop
‘consequence maps’ for various possible decisions.
Students consider the nature of sound, and examine
amplitude and frequency and the difference between
noise and music. They consider the sensitivity of
animals and also careers in acoustics. From this
follows an examination of the structure of the ear and
causes of deafness. Consideration of the decibel scale
for measurement of loudness leads to work on
logarithmic scales.

Finally extension work is provided on investigating:
noise pollution regulations in the student’s home
state; a local factory or workplace for noise pollution;
how mufflers work; and how ultrasound is used in
medicine.

In the teachers guide, teachers are encouraged to set up
apparatus for testing the hearing of their students.
The study of this unit should:
• increase students’ awareness of the effects of noise
pollution
• increase students’ understanding of sound and its
transmission
• develop students’ communication skills through
debating
• heighten students’ awareness of their social
responsibilities
• provide opportunities for students to practise
information collection and interpretation
• illustrate the application of mathematics

Figure 3 Noise and how it affects people

Figure 4 (left)
In the unit INSIDE A RADIO students can tinker
individually with a transistor radio, exploring its insides.
They are also able to learn how to use a soldering iron and to
investigate any questions that arise from their tinkering.
The unit QUICK AS A FLASH considers lightning to explore aspects of electricity. It then leads to a problem solving activity in which students as a group have to decide the most appropriate action in the event of a lightning storm. The scene is set:

"Imagine you and three friends have been camping in the country. After lunch you fall asleep in the warm sunshine. You awake several hours later to the sound of a loud crash. The sun is hidden by a huge thundercloud. You see a flash of lightning . . . "

With the storm rapidly approaching from the East, pupils are asked to decide in a group their course of action (Figure 5). Their decisions can then be discussed and questions which are generated can be classified and investigated further.

ENGAGING SCIENCE aims to help make science education more effective and relevant, and lessons more enjoyable for students and teachers alike.

Further details

Further information is available from Elizabeth Dangerfield, 39 Webster Street, Hughes ACT 2605, Australia.

About the author

Elizabeth Dangerfield, Project Officer of the Engaging Science Project, is a Science Consultant for the ACT Department of Education. Elizabeth, active in the work of science teachers associations, has recently been elected as Secretary of the Australian Science Teachers Association.

AN EXERCISE IN SURVIVAL

You are in the middle of a large, flat paddock as shown below. A storm is approaching rapidly from the east. The lightning is very loud and bright. How much time have you got before the storm is overhead? What are you going to do?

1. In a group, decide upon the most sensible plan of action. Write down your plan, explaining the reasons behind your actions.

2. Did you have all the information you needed to make a sensible decision? What more would you have liked to know? Often we have to make decisions on incomplete evidence. The more background information you have, however, the more likely your decisions will be the best possible in the circumstances.

NEW ICASE PUBLICATION

Bibliography of Science and Mathematics Education Software

This bibliography (63 pages) has been created by ICASE based on information about software in science and mathematics in Asia and Australasia and sponsored by Unesco. It is a followup to a bibliography created in 1986 in conjunction with an Asian seminar on the use of microcomputers in science and mathematics teaching. The publication lists (1) institutions, by country, engaged in the production of computer assisted materials for the teaching of science; and (2) computer software categorised in the areas of biology, chemistry, earth science, environmental science, general, mathematics, physics, and (general) science.

Further details are available from:
Dr Jack Holbrook
Executive Secretary, ICASE
Department of Curriculum Studies
University of Hong Kong
Hong Kong

International Newsletter on Chemistry Education

The Committee on the Teaching of Chemistry of the International Union of Pure and Applied Chemistry (IUPAC) publishes International Newsletter on Chemical Education in co-operation with Unesco. The newsletter is published in English twice a year, in June and December.

It contains news of international events in chemistry education, and articles from a variety of countries. Further information is available from:
Mr P J Towe
Centre for Studies in Science and Mathematics Education
University of Leeds
Leeds LS2 9JT, UK

Science Leadership Trend Notes

The National Science Supervisors Association's LISE Center is initiating a new newsletter resource for subscribers. Science Leadership Trend Notes, to be published six times a year, will contain the latest initiatives, trends, facts, events and networking connections essential to developing effective science programs, and relevant to all those holding supervisory positions in science education.

Send a subscription request with US$12.00 to NSSA's LISE Center, Suite 227, Copernicus Hall, Central Connecticut State University, New Britain, CT 06050, USA.

Energy: Economic Awareness and Environmental Education

This resource pack encourages investigative, process-led approaches to environmental issues. The pack is based on nine units that have been developed in association with teachers and trialled in schools. It consists of:

• copyright-free student resource sheets suitable for the 11 to 16 age range
• teachers' notes with checklists and guidance on possible uses of the resource sheets and expected outcomes of the activities
• extracts from magazines and journals that relate to the energy issues raised in the student materials.

The resource pack, recently published by the World Wide Fund for Nature, is available, price £12.95, from:

World Wide Fund for Nature
Panda House
Weyside Park
Godalming
Surrey GU7 1XR, UK
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1990

September 5-7
ICASE European Symposium on Industry and Education
Location: Brussels, Belgium
Contact: Drs Jan Hendriks, ICASE European Representative, Konijenpad 3, 7921 BM Zuidwolde (DR), Netherlands
This Symposium involves education representatives from member associations of ICASE and industry representatives invited by Conseil European des Federations de l'Industrie Chimique (CEFIC). The Symposium will (1) provide opportunities for the exchange of information and experiences in schemes for industry-education liaison, (2) develop models for industry-education liaison, (3) establish a network for information exchange for future developments, and (4) publish a resource book for teachers and administrators on industry-education liaison.

September 10-20
Seminar on STS Education
Location: University of Oxford, Oxford, UK
Contact: The Director, Courses Department, The British Council, 65 Davies Street, London W1Y 2AA, UK
The British Council is conducting a seminar on "Science Technology and Society Education: Developing a Relevant Science Education for the Future". The seminar will consider a wide range of educational issues which arise when science and technology are taught in the context of their social interactions. The following topics will be considered - rationale for STS, developing new curriculum materials in schools, innovations in teaching STS, research into STS in the classroom, studying the environment, ethical and gender considerations, monitoring changes in new technology, media influence on our students' ideas, and the way forward.

This conference, endorsed by ICASE and the Canadian Association for Science Education, and hosted by the Science Teachers Association of Manitoba, will focus on the theme "Sustainable Development Strategies - The New World Agenda". The conference will enable participants to examine and discuss the links that must be fashioned so as to integrate environmental concerns with continued development on the energy, resource and economic fronts. The program will address the role that curriculum, teachers and schools can play in helping students understand the environmental realities which are the cornerstone of sustainable development. An International Symposium on Sustainable Development will precede the conference on October 15-17. Representatives from education, government and industry will meet to examine the implication of sustainable development upon the curriculum.

November 7-11
NABT Annual Meeting
Location: Westin Galleria & Westin Oaks Hotels, Houston, Texas, USA
Contact: National Association of Biology Teachers, 11250 Roger Bacon Drive, Reston, Virginia 20209, USA
The theme of this conference is Planet Earth in Crisis. A feature of this year's program will be contributions by international participants and an international reception.

December 12-14
ASPEN Meeting on Demonstration Experiments and Computer-Aided Learning in Physics
Location: Pune, India
Contact: Prof Arun Nigavekar, Physics Department, Poona University, Pune, India

December 27 - January 1
International Conference on Teaching of Physics
Location: Karachi, Pakistan
Contact: Mrs Aziz F Hasnain, Head, Department of Physics, APWA Government College for Women, F 'B' Area, Karachi, Pakistan
The theme is The changing face of physics education in developing countries. The conference aims to discuss techniques for conceptual teaching in physics, to create awareness among physics teachers about modern teaching methods including the use of computers and audiovisual aids, and to establish a research program in physics education.
1991

January 4-7
ASE Annual Meeting
Location: University of Birmingham, Birmingham, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated with the September issue of Education in Science, the journal of the Association for Science Education. A special feature of this meeting will be an ICASE Symposium. Non-members of ASE and those outside the UK who wish to receive details should write to the contact above.

March 27-30
NSTA National Convention
Location: Houston, Texas, USA
Contact: Linda Crow, Asst Professor, Baylor College of Medicine, One Baylor Plaza, Room 633E, Houston, Texas 77030, USA

March 29 - April 3
7th ICASE-Asian Symposium
Location: East China Normal University, Shanghai, China
Contact: Prof Mi Zihong, Department of Physics, East China Normal University, Shanghai 200062, China
The symposium will be conducted in English/Mandarin and will address the theme Making science education in schools more relevant. The program will focus on (1) the development of appropriate curricula, the issue of integrated science vs separate sciences, the introduction of STS in science courses; (2) innovations in teaching, the role of project work, the teaching of science communication skills, low cost equipment, fieldwork; (3) technology in education, the effective use of visual aids, visits to industry, the place of the computer; and (4) research in science education, children's learning in science, assessment techniques. The program will consist of presentations by internationally renown science educators; papers, workshop and discussion sessions; poster displays; and an exhibition. Write to the above address for the second circular. Titles and abstracts of contributed papers should be sent to Prof Mi Zihong by 31 October 1990.

July
GASAT 6 International Conference
Location: University of Melbourne, Victoria, Australia
Contact: Ms Gaell Hildebrand, School of Education, University of Melbourne, Parkville, Victoria 3052, Australia

August 4-9
ChemEd 91 Conference
Location: Oshkosh, Wisconsin, USA
Contact: Bruce G Smith, Co-Director, Appleton High School-West, Appleton, Wisconsin 54914, USA or Paul Kelter, University of Wisconsin, Oshkosh, Wisconsin 54901, USA
ChemEd 91 is a major chemical education conference of interest to university, college, secondary and elementary educators from North America and beyond. Throughout the weeklong conference, activities are planned for all members of the family including excursions, field trips, sports activities and social events - a feature of ChemEd conferences.

August 25-30
11th International Conference on Chemical Education
Location: University of York, York, UK
Contact: Dr John F Gibson, ICCE 11, Royal Society of Chemistry, Burlington House, Piccadilly, London W1V 0BN, UK
This biennial conference on the theme Bringing Chemistry to Life is being organised by the IUPAC Committee on Teaching of Chemistry in conjunction with UNESCO and the Association for Science Education. The conference will focus on (1) making chemistry accessible to all students (2) new curricula at primary, secondary and post-secondary levels (3) new teaching strategies at all levels (4) teaching and learning at a distance (5) new frontiers of chemistry and their impact on teaching, and (6) research in chemical education. The program will include plenary lectures, poster papers, symposia, workshops, exhibitions, times for participants to discuss aspects of chemical education of special interest, social events and local visits. A first circular detailing the broad program and how to contribute is available now. The second circular will be published in October 1990.

August 26-30
Fourth Asian Chemical Congress
Location: Beijing, China
Contact: Prof Dehe Zhang, Secretary General of 4ACC, Chinese Chemical Society, PO Box 2709, Beijing 100080, China
The 4th Asian Chemical Congress will be held under the sponsorship of the Federation of Asian Chemical Societies. The Congress will focus on the important role of chemistry in raising the health conditions and living standards for all people. The program of plenary lectures, invited papers and contributed papers will be conducted in English and will concern various topics including organic chemistry of natural products, analytical chemistry and instrumentation, environmental chemistry, agrochemistry, coordination chemistry and its applications in medicine and agriculture, polymer science, photochemistry, computers in chemistry, catalysis, and chemical education.

August 27 - September 1
5th International Environmental Education Conference
Location: Cusco, Peru
Contact: MSc Eduardo Gil Mora, National University of Cusco, Zaguanc del Cielo L-9, Cusco, Peru
The conference will focus on the relationship between the environment and development, and on the changes needed in today's behaviour for tomorrow's world. The program will enable participants to learn of developments, approaches and strategies in environmental education in different countries, and will cater for primary, secondary and tertiary educators; and for teacher trainers, curriculum developers, and policymakers.

ICASE Symposium on Industry-Education Liaison

by Dr Jack Holbrook
Executive Secretary, ICASE

This symposium, held in Brussels, Belgium during 5-7 September 1990, was attended by 54 participants from Europe, America and Australia. Support was provided by CEFIC (Conseil Europeen des Federations de l'Industrie Chimique) and EPCA (European Petro-Chemical Association).

The program featured presentations of different patterns and strategies involving liaison between education and industry. While most of the presentations were made by educationalists, ICASE was greatly encouraged by the support shown by delegates from industry, both in their joint presentations and in their comments on the various models proposed.

The Chemical Industry Education Centre at the University of York, UK, was presented as a useful mechanism in meeting the needs of school science teachers by providing both a bridge between science teachers and chemical industries, and a means by which appropriate resource materials can be developed for and disseminated to science teachers.

The Cologne model: Chemistry - Technology, Daily Life, Inservice Training and the Interplay of the Elements of Science, Technology and Everyday Routine in Schools is an inservice training project in Germany in which there is intensive cooperation between teachers and university and industry representatives, both in the planning and implementation of events and in the development of materials.

The Colorado Alliance for Science, now in its eighth year, is an action-oriented consortium of school districts, businesses, industries, colleges and universities, researchers, science-related associations, and government agencies in Colorado, USA. This is an effective way of bringing the community together, and examples of alliance activities include: Visiting Scientists Program; the RESETT (Retired Educators, Scientists and Engineering Task Team) Program; Hotline (a link for all teachers with government, university and private sector personnel); and the Summer Fellowship Program for science and maths teachers, providing opportunities for teachers to work in an industrial, university or government agency setting during the summer.

The Triangle Coalition for Science and Technology Education in the USA consists of 95 national organisations in the business/industry, science/engineering, and education areas. Activities include a National School Volunteer Project, and a Summer Industrial Fellowship for Teachers Project. It has become an umbrella organisation for community action groups.

In an Activity-Based Industrial Visit Program in Finland, students are divided into small groups to make minor investigations closely linked to the school syllabus. The industry link is carefully planned as the activities in the plant are run by its staff. Teacher education has had an essential role in creating the model, but drawbacks are the traditional cultures in schools and in industry.

Kemira, in Finland, has developed a more formal program of plant visits which involves young people in a totally different way. Before the visit, a company representative goes to the school and pupils undertake preparatory work. During the visits, students are involved in laboratory tasks in small groups under the supervision of professional personnel. After the visit, reports are written and then presented in a final session on the company premises to which parents are invited.

The French chemical industry has cooperated with secondary schools for many years by organising talks by engineers on chemical processes, by plant visits, and by twinning schools and companies. In 1984, French National Chemistry Olympiads, in which students compete, were initiated. At the first level, talks, laboratory work and plant visits were organised using one of the major application fields in chemistry as the theme. From each district, a representative was selected to compete in a national competition involving a general paper,
laboratory work and an oral debate. The olympiad is an initiative of Elf-Aquitaine (the French Chemistry Industry Union), Union des Physiciens (Association for Teachers of Physics and Chemistry), and personnel from universities and 'Grandes Ecoles'. Its objective is to offer an experimental component to chemistry teaching, and to develop a closer relationship with industry.

The ClI (Confederation of Irish Industry) Education College, set up in Ireland in 1984, is a trust channeling funds from industry into education projects. It supports activities such as teaching materials (booklets, posters, videotapes). The Irish Science Teachers Association has been instrumental in the setting up of the ClI Education College and in promoting cooperation between education and industry in general. The Schools Information Centre on the Irish Chemical Industry has produced a directory of the Irish chemical industry for teachers, and is collecting information on teaching resources available from chemical industries overseas.

A distinguishing feature of Swedish schools is their focus on working life. Instruction on local employment begins at the junior level when students can go on field trips to workplaces and visit their parents at work. During compulsory schooling, students must complete at least 6-10 weeks practical working life orientation. The students' choice of practical work experience must be combined in such a way that boys become acquainted with at least one occupation where women dominate. Many municipalities have begun to build up technical resource centres operated jointly by schools and industry.

The role of the Royal Society of Chemistry in the UK in promoting industry-education links can be illustrated by its various initiatives including project weeks, 'hands-on' symposia for teachers, chemistry at work exhibitions, and industry study tours.

The industry study tours are residential conferences for teachers - planned, organised and operated jointly by teachers and industrialists. The tours are approximately 4 days in length and include large and small group visits to several sites, talks and discussions led by both educationalists and industrialists, consideration of syllabus and curricula implementation, and workshops in which participants are required to produce the first draft of industry-based teaching material for possible use in their school or college.

Symposium proceedings, which will include a list of participants, will be published soon, and will be available from the ICASE Secretariat. Thank you to Drs Jan Hendriks, the European Representative for ICASE, for his work in organising a very successful symposium.

Extension of Due Date for
Who's Who in Science Education
Around the World

The deadline for entries in this new ICASE publication has been extended to 31 December 1990. This additional time will enable ICASE to invite more prominent science educators, particularly in developing countries, to complete a profile on themselves and their work.

The information in Who's Who in Science Education Around the World 1991 Edition will help you to contact colleagues in both developing and developed countries who may be working on projects of interest to you, who may be potential speakers at your next meeting, or who may be invited to work on collaborative projects.

New member of ICASE

The European Youth Science Network (EURYSN) has recently joined ICASE. This network is an international network which provides a forum within Europe for organisations and individuals involved in the area of youth science. Refer to the September issue of Science Education International for more details about EURYSN.

For further information, write to:
Mr Martin Brady
Coordinator, EURYSN
37 North Great Georges Street
Dublin 1, Ireland

Join us in Houston

The US National Science Teachers Association meets in Houston, Texas, 27-30 March 1991. You are invited to participate in the Fourth Annual International Round Table. Each country is provided one or more tables in a large room where you can display and present information on science education in your country. While NSTA cannot offer funding, an official letter can be provided inviting you to make a presentation. Contact:

Prof John Penick, Science Education Center
University of Iowa, Iowa City IA 52242, USA
Process-Based Learning for Pupils and Teachers
The Work of an International Project in Primary Science

by Wynne Harlen

The activities described in this paper involve a group of science educators from different countries working together intermittently to improve primary science teaching through teacher education. In a nutshell, what has been done is to gather together the best of the ideas of experienced teacher educators and to pass these on to other teacher educators. But it is the way in which this has been done which gives the project its unique character. It has taken seriously and acted upon the view that to improve learning opportunities in the classroom requires teachers to change practice, and this in turn requires change in teacher education, both pre-service and in-service. Furthermore, its view of learning with understanding as change in ideas and skills, which is brought about by the learner's own mental and physical activity, has been consistently applied to the learning of children, teachers and teacher educators. The idea of attempting to change teachers by simply telling them about approaches to classroom practice is regarded as unprofitable, and sometimes damaging, as expecting young children to learn science by straight transmission of facts and procedures.

The rationale for the project

In 1985, on the initiative of the Commonwealth Secretariat and Unesco, a small project was set up which had short, medium and long-term aims:
- In the short term to bring together a small group of educators with expertise in primary science to plan a training workshop for teacher trainers and prepare draft materials;
- In the medium term to bring together teacher trainers, mostly from Third World countries for workshops using the approach exemplified in the materials;
- In the long term to collect together and develop further workshop materials for use in pre-service and in-service courses and make them available to teachers and those providing courses for teachers.

The focus of the project on teacher education is not difficult to explain. It is not just in countries of the Third World that primary teachers lack confidence in themselves in teaching science and perceive themselves as not having enough background knowledge. This is an almost universal problem and one which can only be tackled through teacher education.

An international project could perhaps entertain the ambition of having an effect at this level and it was recognised that the target must be teacher educators rather than teachers.

The activity of scientists . . . is not all that different from the activity of children

A second focus of the project, process-based learning, perhaps needs more justification. It is important to give the reason since it is fundamental to the view of learning and of science from which the work developed. It stems from a view of science as being about understanding the physical and biological world around. The activity of scientists developing further understanding at the frontiers of knowledge is not all that different from the activity of children finding out about the world around them. Both the scientist and the child, in trying to make sense of new events or objects, begin from relevant existing knowledge and ideas, and test the extent to which new phenomena can be explained using these existing ideas. If predictions based on a related existing idea fit the new observations, then the range of applications of the idea is extended; if the evidence does not fit the prediction, however, this may mean that the idea has to be modified or rejected in the light of the new evidence.

The use and testing of existing ideas involves the processes of science. It is through processes such as observation, question raising and hypothesising that existing ideas are brought to bear in trying to explain new evidence; it is through processes such as prediction, planning, experimenting and interpreting that conclusions are drawn as to whether the ideas fit the evidence. But if these processes are not carried out in a rigorous and scientific manner, then the emerging ideas will not necessarily fit the evidence. Ideas may be accepted which ought to have been rejected, and vice versa. Thus development of ideas depends crucially on the processes used.

It is in the extent to which the process skills are scientifically rigorous that children's learning activities differ from those of scientists. We know that children often observe superficially, looking for confirmation of their ideas rather than being open-minded in using all the evidence available; we know that their first attempts at prediction are really based on what they already know to be the case, rather

It is not just in countries of the Third World that primary teachers lack confidence in themselves in teaching science . . .

In working to achieve these aims, the project drew on what was already being attempted in teacher education by a small sub-committee of the Committee on Teaching of Science (CTS) of the International Council of Scientific Unions (ICSU). What is described here owes much to Jos Elstgeest from the Netherlands who, with myself and Emmanuel Apea, has seen the project through from the beginning to the present.
than being true predictions; the tests they carry out are often far from being 'fair' or controlled; they rarely check or repeat observations or measurements. Just as their ideas or concepts are limited and immature, so are their process skills, and both are capable of development. The dependence of concept development on the way in which ideas are tested, that is, on the use of process skills, provides one part of the rationale for the importance of developing these skills. It is perhaps worth emphasizing that the case for attention to process skill development is in terms of the role of these skills in concept development. Concept development is being served and not ignored by this focus.

A second part of the rationale for giving attention to process skills is implicit in the type of learning just described. This is learning in which the learner collects the evidence and does the reasoning; makes the ideas his or her own. This is what we may call learning with understanding. Learning without understanding, as in rote memorization, does not require the use of process skills. We need not linger long on the faults of rote learning, but it is worth observing that much science was (and probably is) taught in a way which leaves pupils little option but to learn facts by heart. This leads to science being regarded as a mystery, as not making sense and as having nothing to do with understanding the world around - the opposite of our aim in science education. Moreover we want pupils and future citizens to feel at ease with science, to know its strengths and weaknesses, even if they are not practising or directly using science, and the best way of achieving this is through the experience of finding things out and the realisation of how ideas emerge from human activity.

The way of learning just described - developing one's own understanding by testing and modifying existing ideas in such a way as to engender 'ownership' of the new ideas - is appropriate to all kinds of learning and to all learners, not just to children. Education of teachers requires change in their ideas about teaching. If they are already practising it is often necessary to produce a quite radical change in their view of what teaching is and how children learn. This will not happen quickly and without some considerable effort on the part of those concerned. In the case of teachers in initial training, the position is not so different from that of practising teachers; these aspiring teachers will have spent up to 12 years in school through which they will have developed quite firm ideas about teaching and learning which may well have to be changed.

So in teacher education we are concerned with changing ideas, not just planting new ones on virgin soil. To do this in relation to the teaching of science for primary teachers encounters particular problems. Many, perhaps most primary teachers have received from their own education a legacy of failure or at least dissatisfaction in relation to science. Thus the over-riding requirements of teacher education are to develop confidence, an appreciation of the nature of scientific activity, and enthusiasm for teaching science. These pervading aims have profound implications, for they concern attributes which cannot be engendered through specific content but only in the way of dealing with that content (for example, by not lecturing to a large group of students as the predominant style of a course).
and improvisation of equipment;

- Ability to handle children's questions, to encourage and use children's interests;
- Ability to assess children's performance and to evaluate the success of teaching and learning.

Whilst all of these are important, some are more fundamental than others. It has been argued (Harlen & Osborne, 1985) that, given some freedom of action, teachers tend to teach according to their view of learning and of the subject. Thus a teacher who regards learning as resulting from clear exposition on the part of the teacher and science as a set of facts and procedures to be memorised, will teach in a way which maximises opportunities for children to attend to sources of accurate information. If the teacher's view of

However good a teacher is at class management, learning depends on what the teacher sees as being required for learning

learning is the one suggested earlier, where the learner is active in creating understanding, testing ideas on the evidence of materials and events around, then the classroom provision will clearly be very different. This argument leads to the conclusion that the first two ideas on the list above are pre-eminent. However good a teacher is at class management or at assessing children, the learning that is managed and assessed depends on the quality of the experiences provided and this depends on what the teacher sees as being required for learning. Moreover, it has to be admitted that taking account of children's own ideas and providing opportunities for them to be tested using process skills is very demanding, despite its rewards. Thus, only when teachers are convinced of the value of active, process-based learning, will they be prepared to make the effort to organise the class, the materials and the time for children to learn in this way.

For these reasons the project gave priority to ensuring that teachers have experiences which lead to the understanding of the nature of scientific enquiry and of active learning. The experience of active learning is the only way of understanding what it means and, moreover, invariably creates the excitement and enthusiasm for science which few teachers have managed to acquire from their own school education. To help children learn in this way it is necessary to understand, not just at an intellectual level but in terms of practice, what it means to carry out observation, to hypothesise, to make a prediction, to plan an investigation, and so on. This is a tall order for those who may never in their own education have had an opportunity to create and test a hypothesis based on their own ideas. So important experiences for teachers or student teachers involve them in doing some science activities, at their own level, but in the way in which it is hoped they will provide for their children.

After experiencing learning in this way, the adult learners can stand back and consider what they have been doing and how they have been learning. They are in a position to realise the advantages of this way of learning and to develop some commitment to making it available for children. This is the essence of what has been described as a 'worship' approach to teacher education, whose characteristics are (Unesco, 1984, Document 13, pp 8-9):

- The participants are active, both mentally and physically. They are involved in experiencing the kind of learning that is being advocated for children, in reflecting, in analysing, in creating;
- The messages that are conveyed are not transmitted by direct telling but through active involvement;
- Through handling materials for themselves the confidence is gained that is necessary to providing similar experiences for children;
- Understanding is achieved by each participant from within rather than from outside; it comes through reflecting on direct experiences and on new ideas which may be presented for discussion;
- The product is not knowledge of a set of specific activities for children to do but an appreciation of new kinds of learning and some of the many ways of bringing this about in children.

This way of learning does not have to be restricted to developing personal knowledge of science. It can, and should (to reinforce the value of learning this way) be applied to all the learning experiences which were listed earlier. It means starting from the ideas which are already present and working with the learner/teacher, making use of evidence (from previous experience and logical argument as well as direct observation, since we are dealing with adults) to change them. Working in this way has a double benefit, in bringing about re-education relating to the nature of learning and, at the same time, being the most effective way for teachers to

---

Who's Who in Science Education Around the World
1991 Edition

ICASE is compiling this valuable reference book containing profiles on prominent science educators and their work. In order to enhance the value of this reference work, it is important to include prominent women and men in the areas of primary, secondary and tertiary science education in many countries throughout the world. You are invited to recommend individuals for inclusion.

Please send names and addresses to:

The Editor, Who's Who in Science Education, 10 Hawken St, Monash ACT 2904, Australia
learn the skills and abilities required for effective science teaching.

The group context of the activity enables discussion to turn to analysing the role of process skills and concepts in their learning, to reflecting on the sorts of activities which encourage use of these skills and concepts, to considering the teacher's role in these activities, and to identifying the range of class organisation, strategies and resources which are required. Thus the other items on the list of teachers' needs are covered by further workshop activities.

As an example, ways of dealing with awkward questions from children (a situation which is at the heart of many teachers' lack of confidence) are addressed in the following activity. There is first a discussion of children's motives for asking questions and a rough categorisation of the kinds of questions they ask. Teachers working in groups then reflect on one of the science activities they have done previously and draw up questions which they consider 'difficult' for a teacher to answer. Each group then passes its difficult question onto another group who attempt to categorise it and to suggest how to respond to it. Usually there are several alternatives put forward within the group as a result of often heated discussion. In a plenary session, all groups in turn read the questions handed over to them, give their suggested responses and their justification for their preferred response. The group originating the question is asked to comment on how satisfied they are with the response and other groups join in. While no firm formulae for answering questions can be given, there emerge from the discussion guidelines for responding to different kinds of questions. Often the best response is not to provide an answer, but to turn the question so that it leads to further enquiry by the child. Thus the responses are termed ways of 'handling' questions rather than answering them. The important thing is that they are the product of the thinking and arguing of the teachers themselves and what emerges are their ideas (further discussion of handling questions can be found in Jelly, 1985).

Progress towards the project's aims

The project's activities have made progress towards all three aims listed at the beginning of the article. There was a small international seminar held in Liverpool in December 1986, which thrashed out the basic philosophy and planned the first workshop for teacher trainers. An international workshop, achieving the second aim, was held in Barbados in 1987, with the support of ICASE and the British Council as well as the Commonwealth Secretariat and Unesco. Several of the participants later ran workshops in their own countries. In addition there was a South East Asian Regional Workshop in 1989 and an African Regional Workshop in 1990. Achievement of the third aim is taking the form of a new Unesco Handbook, to be published in 1991.

It is well recognised that many Third World countries are a considerable distance from being able to implement the ideas in their intended form. For many, the project indicates the direction of progress even though they may be able to take only a small step in that direction at the present time. It is also realised that supporting materials, such as are being produced, are only part of the story. Teacher trainers in many countries will not have any experience of primary school teaching and will themselves require a good soaking in the workshop approach before they can effectively use the materials which are being made available.

There is resistance to a process-based approach to teaching science

Another pervading problem is the pressure of time; time in the training programs and time in the school programs for this way of working. Commonly there is resistance to a process-based approach to teaching science simply because of the type of syllabus which a teacher is required to cover. Perusal of these syllabuses generally shows the potential for reorganisation into far fewer items which focus on key concepts, rather than the multitude of separate facts often bearing little relationship to the children's immediate environment. It is possible to adjust syllabuses or curricula in ways which still meet statutory requirements but make room for children to take part in their learning.

To change assessment is perhaps the swiftest way of promoting change

Finally, the role of assessment - a factor often inhibiting change in schools and therefore in teacher education programs - must not pass unmentioned. Assessment methods and criteria have to be consistent with the aims of learning if there is to be any chance at all of implementing changes in children's learning experiences. It is no longer the case that process skills and understanding (as opposed to factual knowledge) cannot be reliably assessed. The techniques exist and examples are readily available. To change assessment is perhaps the swiftest way of promoting change, if those responsible for it are willing to do so.

About the author

Wynne Harlen is Director of the Scottish Council for Research in Education, 15 St John Street, Edinburgh EH8 8JR, Scotland, UK. Previously she was Professor of Science Education at the University of Liverpool. She is consultant to the Commonwealth Secretariat/Unesco project on process-based learning in primary science.
Trends in K-12 Science Education in West Africa

by Duro Ajeyalemi

Of the 15 countries in the Economic Community of West African States (ECOWAS) region, five (Nigeria, Ghana, Sierra Leone, Gambia and Liberia) are English-speaking. All except Liberia were colonies of Great Britain, and so share a common heritage of Western education from Britain. For example, all have a centrally controlled educational system with English as the language of instruction at all levels; uniform standards of curriculum content and assessment at the secondary level; and until recently, a 6-5-2-3 educational structure like Britain.

Illustrated mainly with data from Nigeria and Ghana (the two largest), this paper summarises trends in K-12 science education in the last decade in the British West African countries, drawing implications for the 1990s. Issues discussed include the objectives, curriculum content, the students, the teachers, classroom implementation, and assessment procedures. The trends in the French-speaking West African countries would likely resemble those in France; and those in Liberia were more American until recently, when Liberia harmonised its educational system with those of other English-speaking countries in the region by joining the West African Examinations Council (WAEC).

Background

From the late 1800s when formal science education became part of the school curriculum until the mid-1960s (even after independence), science education in British West Africa was totally patterned after that in Britain, except that little or no science was taught in elementary schools. For example, West African students studied the flora and fauna of Britain in biology instead of organisms in their own environment, and all secondary school subjects were assessed by either the London, Cambridge, or Oxford General Certificate of Education Examination Board. Even WAEC, established at the end of the 1950s to take over the functions of the British Examination Boards in the region, based its examinations on the syllabuses of the British boards until the mid-1960s.

The post-Sputnik science curriculum reforms in the Western world certainly influenced developments in West Africa. Mainly at the behest of science teacher associations in these countries (including the Science Teachers Association of Nigeria, and the Ghana Association of Science Teachers), many new elementary and junior secondary science programs similar to those in the West, but adapted to the local environment, were developed (eg the African Primary Science Project, and the Nigerian Integrated Science Project). For the senior classes of the secondary school, the WAEC developed new syllabuses in biology, chemistry, general science, health science, and physics. All these programs suffered the limitations of their counterparts in the West, including:

- Unsuitability of the secondary curricula for the majority of students not desiring a career in science or science-related occupations, due to emphasis on the structure of the disciplines;
- Incompetence of the teachers in the use of the recommended inquiry methods of teaching and learning.

Teaching emphasised information-giving, was textbook-bound, and was carried out essentially through the lecture method

In addition, most secondary students had weak backgrounds in elementary science and were not motivated to study science either through any government policy or their experience of science in schools. In all the countries, provision of laboratory facilities for science teaching at all levels was not only inadequate but what was provided was not used by teachers, either for reasons of incompetence, large class size, pressure to cover apparently over-crowded syllabuses, or other related reasons. Teaching emphasised information-giving, was textbook-bound, and was carried out essentially through the lecture method. Learning was through rote memorisation of presented information, and assessment through WAEC examinations encouraged more the recall and regurgitation of memorised knowledge. In summary, education in West Africa, particularly in science, was generally academic and elitist, emphasising and glorifying the acquisition of knowledge and certificates, yet totally unrelated to the world of work and/or the immediate needs of students and societies.

By the mid 1970s, the general dissatisfaction with that type of science education led to a review of the systems in four countries. A new structure and content of education was formulated in Ghana in 1974 (Republic of Ghana, 1974), and by 1977 Nigeria had launched a new policy on education (Nigeria, 1981). By these policies, the structure changed from the British 6-5-2-3 system to 6-3-3-4, similar to the American system where students spend six years in elementary school, three years in junior secondary (JS), three years in senior secondary (SS), and four years in higher education of varying types. Of greatest importance were the changes in curriculum objectives, content, and assessment methods. Attempts were made to make the curriculum more functional while continuous assessment in the three domains of educational objectives was introduced at all levels of education. For example, integrated science, introductory technology, and pre-vocational subjects (eg home economics, business studies) became essential components of basic education up to junior secondary, the terminus for a majority
of students, especially those who are not academically able. This is to prepare students, at least minimally, for the world of work.

Changes in the Curriculum

Both elementary and JS integrated science curricula now require students to acquire appropriate science process skills, attitudes and thinking skills, but not a great deal of knowledge. The rationale is that the majority of students do not develop as scientists, but require these skills and attitudes, more so than knowledge, for coping with and solving problems in everyday life. The suggested content, still an adequate foundation for students with ambitions in a science career, is derived from the students' local environment. Topics such as the human body, earth and sky, electricity, light, heat, air, health and safety, plants and animals, and water are now studied in a local context.

The curricular shift to scientific literacy embracing science, technology and mathematics and their impact on society is now noticeable in West African science education

Science at senior secondary is meant for the academically able who elect to study science subjects. Here, students prepare for advanced studies in science while developing their problem-solving skills and desirable attitudes. Science content is emphasised as much as process skills, stressing the application of both content and skills in problem-solving (Nigeria, 1985). Thus, the observed curricular shift from an emphasis on the structure of the disciplines to scientific literacy embracing science, technology and mathematics and their impact on society as found in most developed countries, is now noticeable in West African science education. What may be difficult to implement in West Africa (where curriculum content is specified and centrally controlled), is the recommended instructional approach, which most often demands that students' questions dictate the lesson content and presentation. Research on appropriate instructional strategies for achieving these objectives are needed in the West African region.

One clear difference between the K-12 science education systems in West Africa and that of the US is that the curriculum in West Africa (as in France, Japan, Australia, and recently the UK) is standard for all students while in the US there is a large degree of autonomy from one teacher to the other, one school district to the other, and from one state to the other in what is taught. Students in some US schools may even decide their own curriculum. Perhaps the poor performance of American students in the last IEA study is attributable to the unfettered freedom to choose what to teach and/or learn. On the other hand, a rigidly specified curriculum as found in West Africa puts the teacher under intense pressure to rush through the curriculum in time for the final examination, and leaves little room to manoeuvre or cater for students' real interests. Graduates from such a system may have only learned science as pure knowledge and not as thought, action and attitudes. Perhaps the approach of the AAAS in its Project 2061, of providing a framework of minimum knowledge, skills and attitudes required of all Americans to be scientifically-literate, and encouraging schools to develop their own curriculum based on the framework, is the needed mid-way between the two extremes.

West African children are as curious and intelligent as children anywhere in the world and so are capable of learning science right from kindergarten. However, certain factors in their environment militate against the full utilisation of these innate capabilities, particularly for learning science. These could be grouped into:

(1) cultural factors: language difficulties (both students and teachers are not mother-tongue speakers of English, the language of instruction); poor and non-supportive home environments for the majority; absence of needed facilities and absence of a scientific culture; prevalence of superstitious beliefs which inhibit scientific reasoning patterns; and an authoritarian culture which inhibits the development of students' questioning skills because children are most often forbidden to question the wisdom of an elder, the teacher in this case.

(2) school factors: inadequate provision of science teaching resources, both human and material, including textbooks; large number of unqualified teaching and support personnel; the prevalence of the lecture-recitation method of teaching; and ineffectiveness of monitoring of supervision systems.

(3) societal factors: inadequate public support manifested in the low prestige and reward system for professionals in science; and relatively low government investment in science education and society's indifference to this.

INTERNATIONAL ROCK & FOSSIL EXCHANGE

For the past year
Eunice Hefty and her 13-14 year old Earth Science students have been exchanging rocks and fossils across the United States

Eunice and her students are keen to make this project an international one. If you are interested in exchanging labelled rock and fossil specimens contact

Eunice Hefty
O. Henry Middle School
2610 West Tenth Street
Austin, Texas 78703
USA
Even though the number of students selecting optional science up to the end of secondary education is increasing every year as indicated by the number registering for the final West African School Certificate Examinations (WASCE), quality and success rate in the WASCE show a decreasing trend (Ajeyalemi, 1987). Generally students will learn by rote, in response to the didactic teaching methods commonly used by teachers. Although they continue to demonstrate favourable attitudes toward science in the face of all odds, their science educational experience may not be preparing them as real and functional scientists.

The increasing number of females choosing science is another noticeable trend, possibly resulting from conscious efforts made to remove gender-stereotypes from the new curricula. However, the majority of females continue to select biology, while the physical sciences and mathematics continue to attract more males. The fact that the majority of biology teachers are females may be reinforcing this situation.

**Teachers and Teaching**

At this point, it is fair to observe that West African teachers at any grade level are working under very adverse conditions which affect their quality of teaching. In Nigeria, which has many more teachers than the other countries combined, more than 60% of all elementary school teachers in the region are unqualified to teach (Nigeria, 1986). The most qualified are mainly secondary education graduates from a five year post-elementary teacher training course. All teachers, qualified or not, are generalist teachers who teach all subjects, although most of them are unqualified (and unwilling) to teach science. Thus, science is left untaught in many classrooms. And, even when taught, many of the teachers adhere rigidly to the recommended textbook, dictating notes instead of giving students the opportunity to explore their environments as envisioned in the curriculum. The result is that students graduate from elementary school with little or no knowledge or understanding of science, let alone minimal competence in science process skills. This weak background in elementary science compounds the problems of teaching science at the secondary level.

**Teachers teach only those aspects of the subject in which they have some competence and background**

Likewise, the majority of secondary science teachers are unqualified. For example, more than 60% of all secondary school teachers (science and non-science) in Nigeria were unqualified as recently as 1984 (Nigeria, 1986) and generally science teachers are in short supply, particularly physical science and mathematics teachers. The situation for integrated science at the JS level is worse because a majority of the teachers are specialists in only one science subject (usually biology), and often do not have a broad enough science base or training in the teaching of integrated science. Most often, such teachers teach only those aspects of the subject in which they have some competence and background. The majority of junior and senior secondary science teachers nearly always employ the lecture method, and emphasise mainly the informational aspects of science. Where laboratory work is done at all, it is usually the verification type which is most often accomplished by teacher demonstration. Thus, students learn passively, mainly by rote memorisation and, due to a shortage of qualified science teachers in secondary schools, the few available are often over-worked. It is not uncommon to find a specialist in biology, for example, unqualified but teaching other science subjects, or a teacher coping with more than 30 class periods per week. Little time is available for proper planning and presentation of lessons and teachers rarely meet with each other. Elementary science teaching is equally problematic since science is not a compulsory subject in teacher training colleges.

Science teacher associations in all the countries have been very active in organising workshops aimed at updating the knowledge and skills of their members

Making science compulsory in teachers colleges is the first vital step, which must be followed by other efforts at upgrading the qualifications of teachers such as the Associate Diploma in Education (ADE) program in Nigeria. In the ADE program, experienced qualified primary school teachers (with or without some science background) spend a full year on an intensive mathematics/science education course either at a university or a college of education. Nigeria's plans to make the National Certificate in Education (a three year post-secondary program) the minimal qualification for teaching in elementary schools could also be emulated by other countries in the region.

A research-supported strategy (Yager and Penick, 1990) that may be used to improve the performance of K-12 science teachers (no matter the grade level) in the region is the constant organisation of in-service workshops. Such workshops would involve participants in analysing their needs and focus on specific teaching strategies. To encourage participants, they should enjoy benefits, such as cash stipends or earned course credits as commonly done in the US and many other countries. Such workshops in West Africa have not made the necessary impact because participation, in addition to not immediately rewarding teachers, oftentimes, requires participants bearing the cost on their own (such as in Nigeria).

Science teacher associations in all the countries have been very active in organising workshops aimed at updating the knowledge and skills of their members. If science education is to be improved systematically, these initiatives must be supported by teachers' employers directly and continuously. Similarly, pre-service teacher education needs to be re-designed to emphasise practice as it relates to theory. Student teachers need to spend more time analysing teaching/learning behaviours, comparing theory to practice, and participating in multiple practical teacher experiences, even before student teaching. This may imply a delay of certification while extending the course duration but, such is the price of increased competence and professionalism.
Assessment

An end-of-course First School Leaving Certificate Examination is conducted by respective governments in the region at the end of elementary education in Grade 6. Often, science is not part of this examination, for obvious reasons. Thus, formal assessment in K-12 science is left to the secondary school. The final secondary course examination (WASCE) in each science subject comprises a theory, a multiple-choice, and a practical paper, based on a generally over-loaded syllabus. The theory and multiple-choice papers are generally criticised for concentrating on recall and other low cognitive level items. While this has changed with time and items are now fairly well distributed among the different thinking levels, the largest number still require little more than recall. The massive scope and emphasis on recall may be partly responsible for the preponderant use of the lecture method by teachers, as a measure of success in teaching is the number of students passing the examination. Teachers hardly venture out of the examination syllabus and much time is spent rehearsing past question papers with students. This observed pattern is expected to change with the adoption of continuous assessment as an evaluation strategy in the new educational policies currently being implemented in the region.

Practical skill assessment is often the verification type and a once-and-for-all affair in the three-hour practical examination. The continuous assessment policy should positively influence teaching and assessment in this, as well as in the affective domain. The fact that continuous assessment scores are expected for each student in these domains should encourage teachers to involve students more in laboratory activities. And if practical and other examination questions begin to include more thoughtful, higher cognitive level items, teachers will follow suit in their teaching.

Conclusion

The state of K-12 science education in the English-speaking West African sub-region, particularly in terms of curriculum objectives and content, has certainly improved with time, but there is still a great need for further improvement. Both pre-and in-service teacher education need drastic improvement, especially in providing appropriate science content and more focus on teaching strategies. Similarly, the provision of teaching/learning resources and teachers' welfare both need improvement. A continuous re-appraisal of the curriculum in the light of contemporary developments world-wide would contribute greatly to a more consistent improvement in West African education. For instance, more needs to be done to encourage the teaching of science in the context of technology and society, a contemporary trend (Harrison, 1985) which is appropriate and useful in the African context.

Science across Europe
by John Holman

Background
As the countries of Europe move closer together, it is important to raise the awareness of European citizens for one another’s societies.

It is common experience in most countries that the most effective way of introducing new educational topics is to tie them closely to the curriculum. It is therefore proposed that an area of the curriculum that is studied in all European countries, namely science, be used as a vehicle for introducing European awareness into schools.

Aims
The project Science across Europe plans to produce curriculum materials based on European science-related issues. The aims of the project are to:

• Introduce a European dimension into science education by showing the different national traditions within a common European culture.

• Raise students’ awareness of the perspectives and ways of life of students in other European countries.

• Raise students’ awareness of the ways in which science and technology interact with society, industry and the environment.

• Provide opportunities for students to develop skills in communication in its widest sense, including languages other than their own.

• Provide opportunities for schools in different countries to collaborate.

Intended outcomes
The project will produce a series of short units (lessons) for use in conjunction with the science curriculum for 14 to 17 year olds. The units will be translated and adapted to make them appropriate to each of a range of European countries. Each unit will be based on a science-related issue, selected according to the following criteria: (1) the extent to which the issue affects students throughout Europe, and (2) the extent to which it links to mainstream science curriculum topics.

Collaborators
The project has been initiated by the Association for Science Education (ASE) in collaboration with British Petroleum (BP). ASE has close links with science teaching associations in a number of European countries, and with the International Council of Associations for Science Education (ICASE).

The pilot phase
The pilot phase began with a small writing workshop in Bruges, 15-17 June 1990. A small group from schools and universities in six European countries met to draft the first units. The countries represented were France, the Netherlands, Switzerland, Sweden, Spain and Great Britain. A general strategy was agreed upon for the project, and the first two pilot units were drafted in English. Arrangements were made for subsequent translation and adaptation of the units into French, Dutch, German, Swedish and Spanish, and for trialling them in the countries represented at the workshop, with the likelihood of additional trials in Belgium, Norway and Portugal. The following timetable has been set for the project:

<table>
<thead>
<tr>
<th>Timeframe</th>
<th>Activity</th>
</tr>

<td>Evaluation of the trials</td>
</tr>
</tbody>
</table>

Outline of the pilot unit "Europe's Energy Sources"

“This unit is a comparison of domestic energy sources used in different countries. Students will survey their own uses of energy and the costs, particularly those for cooking and heating homes, and produce data for their class. Having completed the class analysis, they make contact with students in other European countries who have undertaken a similar survey, and receive the equivalent information in return.

Students will then evaluate all the data and answers to the questions in the survey, comparing usages, prices and opinions.

This will lead to a discussion of the interdependence of countries for their energy supplies (e.g. electricity, gas); how their use of energy affects other countries (e.g. air pollution); European measures to reduce energy use; future developments in the kind of energy sources used in Europe.

Outline of the pilot unit "Acid Rain"

This unit is a survey of the acid rain problem in different countries, and a comparison of different perspectives. Students collect, by direct contact, information on the nature of the acid rain problem in different countries, the measures being taken to counter it, and people’s perspectives on where the blame lies. Students then evaluate the subjective information they have collected by comparing it with a collection of factual data for different
countries on, for example, production of sulfur dioxide, prevailing winds and average pH of rainfall. They can thus get a view of differing perspectives and evaluate them on the basis of hard fact.

A major feature of both these pilot units is the need for students to collect information by direct contact with one another. In the trial stages of the project, we will limit the number of schools to help them make contact with one another. We are encouraging contact by all means available, but particularly by fax and electronic mail.

Trials and further development

Trials will be conducted through two networks. The first is a small and closely controlled group of schools identified by those involved in the initial writing workshop.

The second network is based around BP's European operations, and we are hoping to build partnerships between individual schools and BP centres, and enable the schools to use BP's communication network.

Following the evaluation of trials, decisions will be made on future developments. Future work may include:

- Revision and improvement of the existing pilot units in the light of feedback from trials.
- Production of further units; we have had many suggestions for possible topics, particularly on themes relating to energy, the environment, food and agriculture, and medicine.
- The extension of the project to include other countries.

Results of 1989/90 CASTME Awards

First Prize
Application of computers at the School for the Deaf in Cyprus by Mr Panteleimon Makris, Cyprus

This is a description of the introduction and development of computing facilities in a school for the deaf. It is a clear presentation of a careful program extending over several years.

Joint Second Prize
Use of scientific enquiry methods to teach advanced-level students science by Sujatha Gunaseeli Kankanige, Sri Lanka

A project on environmental issues aimed at developing skills. It uses a case study to introduce concepts connected with environmental pollution. The evaluation is in terms of student behaviour.

Measurement in real life by Miss Joy O’Jon and Mr Ian Blair, Guyana

A careful account of a remedial series of practical lessons with pre- and post-tests and samples of children’s work.

Joint Third Prize
Promoting scientific literacy through the publication of a student science magazine in Brunei Darussalam by Peck Yoke Oh, Brunei

This project aims to increase and spread scientific literacy through the publication of a science magazine for students. It highlights economic and social issues. The mechanics of publication are carefully considered.

Low cost heating source for use in secondary school science laboratories by Miss Cherri George and colleagues, Guyana

This team of teachers explores the use of alternative sources of energy for laboratory science experiments requiring heat. The project uses easily available materials and has a low cost implication allowing more experiments to be conducted.

A practical method of teaching mathematics through naturally available resources by Ms Bettadapur Venkatasubbiah Subhadra, India

This project uses leaves, fruits, etc to illustrate geometrical concepts thus avoiding too much abstraction in early mathematics. Examples of children’s work are included.

Commendations

An enrichment activity to encourage students to apply concepts/skills of measurement/perimeters to a recreational situation by Mr Kenneth Baisden, Trinidad & Tobago

A description of a game invented by the author to reinforce specific mathematical concepts.

A project to conserve top soil and fertility by Mr K V Rangaswamy, India

This is a project to teach students the dangers of soil erosion and ways of combating it through practical activities.

A comparative study of teaching mathematics to students of standard I by practical and non-practical teaching methods by Miss Kumudben Narmada Shanker Vyas, India

An account of a series of practical lessons in early number work, comparing their effect with that of a purely symbolic approach.

Have you entered for a CASTME Award?

The awards are intended to encourage teaching of the social aspects of science, technology and mathematics, with particular reference to developing countries of the Commonwealth. Teachers and officials (advisors, inspectors, etc) working in primary, secondary and tertiary education in Commonwealth countries are eligible to enter as individuals or syndicates.

Registration Forms (to be received by 30 November each year) are available from your local British Council office or Education and Science Division, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
The LMKF Conference 1990 was the 14th in the series of triennial Nordic meetings, and the first to be held in Iceland. There were more than 300 participants including delegations of approximately 100 from Finland, 100 from Sweden, and smaller numbers from Denmark, Norway, Iceland and the Faroes. Professor M Rubinstein, a specially invited speaker from the USA, and Dennis Chisman, representing ICASE and Unesco INISTE, also attended the Conference.

Main sessions comprised concurrent lectures, symposia, discussions and workshops. Most lectures were presented in various Scandinavian languages; a few were presented in English. Lecture and symposia topics were wide ranging, and included computer interfacing and modular programming; women in science and engineering; plate tectonics and earthquakes; and marine science.

Workshops and discussion sessions focused on the teaching of mathematics, physics and chemistry.

During the Conference, a special meeting was held to discuss the establishment of an Icelandic branch of INISTE. This meeting was convened by Halfor Gudjonsson who was the Icelandic representative at the 2nd Nordic Science Education meeting held in Finland, under Unesco INISTE auspices, in August 1989.

It was agreed to set up an INISTE, comprising representatives of the various national science education organisations in Iceland, including LMKF.

---

**Twin Teacher Trainer Project**

The Science Education Section of the Unesco Division of Science, Technical & Environmental Education is concerned with the problems in some teacher training institutions caused by their isolation due to geographical location, political barriers or lack of resources.

In many countries, cities or towns are paired with similar cities or towns in other countries in order to form twin cities or twin towns which exchange information of mutual interest and exchange visits.

Perhaps twin teacher training institutions could exchange handbooks, course materials, examples of trainee's work, photographs and new ideas to their mutual benefit.

The Science Education Division could identify isolated institutions in another country, provided that both institutions agree.

Unesco would not be in a position to provide funds to facilitate these exchanges, however the resources of Unesco could be used to assist in the contacting of isolated institutions.

Some institutions have already been contacted, and many positive responses have been received.

The Science Education Section would like to obtain from each country, address lists of teacher training institutions. These may already be compiled on a database or in a publication.

GHS Science Fair in Cameroon
by Augustine Kiteh
Government High School

In 1987 science teachers in Government High School, Nkambe decided to organise Cameroon's first science fair. The aim of this event was to encourage students to display their knowledge and skills in science, to enable students to see that science can be fun, and to entertain the largely illiterate public by staging a number of science demonstrations.

The science fair was conducted during 'Youth Week' so as to involve neighbouring schools, the local administration and the general public.

In order to gain maximum publicity, the teachers invited government administration officers, political party leaders, church dignitaries, primary school headteachers, school proprietors, and other local prominent people. These individuals were requested to donate a small prize for the display competition.

Since 1987, this practice has continued at GHS Nkambe, one of several schools in the North West Province of Cameroon. Science teachers at GHS Nkambe are keen to involve all schools in the province, and see this as an effective strategy toward "Science for All" in Cameroon. They would welcome suggestions on how to improve the science fair.

The education system in Cameroon tends to be preoccupied with two curriculum-related problems: The first involves the need to update, strengthen, and increase teacher effectiveness, especially in the areas of maths and science. The second and much more difficult problem, inherent in any mass educational system, is the need to adapt curriculum and teaching methods to cater for a diversified student body - slow and fast learners, less and more academically motivated students, a wide spectrum of interests and career aspirations among students, terminal students and college-bound students and the 'undecideds'.

Augustine Kiteh teaches at Government High School, Nkambe, NW Province, Cameroon.

International Symposium on Fieldwork
22-28 April 1990
by Jan Hendriks & Henk Lindeman

SISFIS (Foundation International Symposium on Fieldwork in the Sciences) was founded on the initiative of NVON (Dutch Association for Teachers in Science Education) in 1988, and undertook the planning and organisation of an International Symposium on Fieldwork in the Sciences.

For practical reasons it was decided to organise an International Symposium and a National Conference.

The International Symposium, held at Westerbork in the Dutch province of Drenthe during 22-27 April 1990, was coordinated by SLO, the National Institute for Curriculum Development. 51 participants from 16 countries attended the International Symposium chaired by Jacques van Trommel, the advisor for curriculum development in the Netherlands and secretary/treasurer of IOSTE.

The program included lectures on world trends in fieldwork, computers and field work, and implementing field work programs; discussion sessions; fieldwork sessions using programs developed by participants; and excursions to the National Park 'De Wierribben' and to Kampen.

Many lively discussions were shared, and it became obvious that there is a need for more meetings of this kind. There were distinct resemblances, as well as distinct differences in trends and approaches.

Participants focused more on the development of fieldwork, rather than its implementation. Strategies for involving whole classes in fieldwork are still poorly developed at the international level.

The National Conference, also held at Westerbork during 27-28 April 1990, was coordinated by the Orvelte Field Study Centre to coincide with the annual conference organised by NVON. The major purpose of this Conference was to offer secondary school teachers knowledge, understanding and experiences of fieldwork to encourage them to incorporate fieldwork in their teaching.

Nearly 300 teachers of geography, biology, physics, chemistry and integrated science took part in the National Conference. The varied program included lectures on fieldwork and many practical fieldwork assignments, many of which incorporated aspects of physics and chemistry. The National Conference was also very productive for participants, who completed practical experiences in fieldwork - an important prerequisite before involving students in fieldwork.

The organisers are grateful for the subsidies and assistance provided by the Dutch Ministry of Agriculture, Conservation and Fisheries, the National Institute for Curriculum Development, the Advisory Body for the Development of Curricula in the Sciences, the Dutch Province of Drenthe, the Dutch Petroleum Company, the Shell Oil Company, NVON, the Royal Dutch Geographical Society, the Dutch Society of Chemical Industry, and the World Wide Fund for Nature.

First International History Philosophy and Science Teaching Conference

A Report

The first conference of the International HPS and Science Teaching Group was held at Florida State University from 5-10 November 1989. It was attended by nearly 300 people from 20 different countries. It was generously supported by the American National Science Foundation.

A feature of the conference was that many of the 125 papers delivered were available beforehand so that nearly each session was a working session with maximum time for comment and deliberation. Four journals ran, and overprinted, special issues on the conference theme; these contained 40 papers and were available prior to the conference. Additionally papers were asked to be submitted on disk, and an attractive book of 37 of these was also published prior to the conference. Two post-conference journals are being published, as well as a second volume of Proceedings.

Many remarked that this pre-conference publication format could be profitably followed by other academic organisations.

There were 2-3 Plenary Sessions each day, and 3-4 concurrent sessions. Topics discussed included: rationality and science, science and moral education, history and philosophy in physics teaching, history in chemistry teaching, feminism and science, the textbook image of science, constructivism, HPS in science teacher preparation, science literacy, and many others.

Many examples of the successful implementation of HPS informed lessons, and curricula were provided. It was acknowledged that these need to be further developed, and that some mechanism needs to be provided so that scholars and teachers in different countries and different disciplines are not re-inventing the wheel. Much is being done, but it needs to be publicised. Fabio Bevilacqua of Pavia University spoke of the longstanding efforts of the European Physical Society to promote history of physics in physics teaching, and expressed the hope that greater contact could be arranged between the two groups.

It was agreed that conferences would be held on 3-4 yearly intervals.

Second International History Philosophy and Science Teaching Conference

The dates and venue for the Second International Conference on History, Philosophy and Science Teaching have now been finalised. It will occur at Queen's University, Kingston, Ontario, Canada, 11-15 May 1992.

The title and a 200 word synopsis of papers should be submitted by 12 October 1991. On receipt of this, full style guidelines and format advice will be sent. Papers should be between 4000-6000 words, and submitted on disk along with 3 copies by 12 January 1992. All conference papers will be printed in Proceedings that will be published in advance of the conference.

Further details are available from the Conference Secretary:

SciLINC Project

Launched to Improve K-12 Science Education

by Kenneth Russell Roy
ICASE North American Representative

The Science Leadership Institute Network Centers Project or SciLINC has been initiated this fall in the United States according to the NSSA's LISE Center Executive Director Dr Ken Roy. He noted that there is a high level of excitement about the potential of this project in that it establishes a national network of district level science centers committed to improving science education through leadership development training and resources. With a variety of reform movements to improve science education in the states, there needs to be a vehicle for bringing about change at the local level. This initiative serves to meet that need. The NSSA's LISE Center has developed this long term leadership training program to improve science education as a grass roots level initiative. SciLINC districts will specialise in elementary and/or secondary science.

How SciLINC works

Operationally, the LISE Center trains a cadre of regional and state directors. Each director then provides training through state leadership institutes for local SciLINC District supervisors. Programs are effected with support from locally developed business/education alliances. Once trained, local supervisors/teacher advocates serve as SciLINC District directors for their school or district's network center. Each level of training
is upgraded on an annual basis to keep
the director's skills sharp and
knowledge base current to improve
science education at the local level.

First training program

The first training program for new
state directors was conducted for three
days during September 1990. Seminar
topics focused on several areas
including supervisors/teacher advocates
as change agents, effecting long term
change, changing needs of students,
leading edge curricula reforms and
general issues and initiatives.

Implementation time line

Phase I (1990-91). During 1990-91,
State Network Center directors will be
selected and receive training in two
NSSA geographic regions or
approximately 17 states. Later in the
academic year, SciLINC Districts will
be selected and center directors will
receive training in each state.

Phase II (1991-93). During 1991-93,
the balance of the NSSA regions or 33
states will be introduced to SciLINC.

Australian Science Education Research Association

Report on 21st Annual Conference
Perth, Australia, 14-17 July 1990

by Dr David Tregast
Curtin University of Technology

Held on what turned out to be the
wettest weekend of the year, the 90
science educators who attended
ASERA 1990 could not be
convinced that Perth is the sunniest
capital in Australia. This was the
first time ASERA had been held in a
hotel and especially given the
inclement weather, this proved to be
an ideal location for the conference.

The 90 conference attended 54
sessions addressing a range of topics
in primary, secondary and tertiary
education. Sessions involved
empirical studies, descriptions of
research programs and discussion
papers. Topics included technology
education, computer education
related to science teaching,
evaluation of new and longstanding
curricula, methodological issues for
improving science education and
investigations into student learning.

Conferences attended from all states
and territories in Australia with a
small number of science educators
coming from Malaysia, the USA,
New Zealand, Papua New Guinea,
Israel and South Korea. There was
ample opportunity in the program
schedule for informal discussions
and science educators were engaged
in interesting debates throughout
the conference.

Next ASERA conference

Next year's conference will be held
in Brisbane in July 1991. For
further details, contact:
Dr Cam McRobbie
Kelvin Grove Campus
Queensland University of
Technology
Locked Bag No 2
Red Hill Qld 4059
Australia

CSIRO Women in Science Project

Australia's Commonwealth Scientific
Industrial Research Organisation
(CSIRO) has set up a project where
women, working in scientific research
and technical areas in CSIRO, are
visiting high schools to talk with
15-16 year-old girls.

By providing role models and
information on science careers, CSIRO
hopes to increase the participation of
girls in science and mathematics at
senior secondary level. This will
promote scientific literacy in the
community as a whole and will permit
more women to take an informed part
in current debates on issues such as
in-vitro fertilisation, nuclear power and
genetic engineering. In today's society
people also require technical
understanding for many other aspects
of life, as consumers of modern goods
and services.

Increased participation by girls in these
subjects also means expanded career
options. Many occupations, not just in
science, require a solid grounding in
science and mathematics. By dropping
these subjects at Year 10, girls restrict
the number of jobs for which they can
apply.

Australia needs talented and skilful
people to undertake research for
continued development. At present,
many able girls who could contribute
significantly in Science are not aiming
to fill these positions.

This project is a logical extension of
CSIRO's commitment to education
such as the Science Education Centres
around Australia.

Outline of the scheme

1. Interested schools are sent a
videotape entitled Women in Science
and a student activity sheet for use
with year 10 classes (both boys and
girls). The video consists of interviews
with seven women scientists about
their work and experiences as women
in the scientific field.

2. Approximately a week after the
video is shown, women scientists visit
the school to talk with Year 10 girls in
groups of less than 15 girls. Ideally a
professional scientist and a technician
each speak to the group in order to
demonstrate a range of possible careers
in science.

After a five minute introduction from
each woman on their day to day work
and how they entered their career, a
discussion is encouraged to cover
topics of interest to students.

The project has been operating for five
years, and has received positive
responses from the thousands of
students who have participated.
Field Work in Secondary Science

by Tom Schnoebele

The most effective learning takes place when connected to direct experiences (McNamara & Fowler, 1975; and others). Science outside the classroom, through the use of field trips, is an excellent way to accomplish this. Science students need to be reminded that the world itself is the real laboratory.

"Classroom experiences seldom carry the student beyond chalkboard living, and a chalkboard interpretation has only a superficial resemblance to reality. Laboratory activities may - but not always - come closer in a flyby to more complete understandings. For the learning of many important concepts, however, students can't become involved in direct experiences when confined in the classroom. Therefore, for these concepts it is important, whenever possible, to get students out of the classroom and into contact with the real thing." (Lisonbee 1986)

A rationale for field work

Many authors have described the benefits of field trips for teaching science at the secondary level. McNamara and Fowler (1975) studied 1200 junior high earth science students, one-half with laboratory investigations in an outdoor environment using pre-packaged materials and the other half with laboratory investigations in the outdoor environment using available natural resources. They concluded:

1. Concepts that are an integral part of the students' environment are best learned in the outdoor environment.

2. If parts of a concept can be related to the students' immediate environment, the concept has a better chance of being understood, whether the concept is concrete or abstract.

3. Critical thinking is enhanced in the outdoor environment, especially for the average to below-average student.

4. Investigations in the outdoor environment increase the students' desire for that environment.

5. Lower ability students tend to prefer the environment to which they are exposed.

Sorrentino and Bell (1970) reviewed articles presenting the values attributed to secondary school science field trips. They compared attributed values with empirically determined values and determined that field trips were beneficial in the teaching of secondary science. Mason (1980a) annotated 43 studies related to the use of field trips in elementary, secondary, and post-secondary education spanning a period from 1930-1977. His analysis shows field trips are an effective instructional technique as well as an important link between the classroom and the outside world.

Research suggests a positive link between field trips and knowledge gains (Benz, 1962). Riban and Koval (1971) reported that students who participated in extended field studies were found to gain significantly in use of scientific methodology. Motivational gains (Ignatius, 1978; Kern & Carpenter, 1984) have also been documented in the literature.

Harvey (1951) studied the effect of the field trip upon the development of scientific attitudes. Selecting two sections of ninth grade general science classes for the experiment and conservation as the unit of study, he concluded that students who participated in field trips had significantly more positive attitudes toward science than students who remained in regular classrooms.

Barriers

Unfortunately, teachers do not take advantage of field work. For instance, Keown (1986) surveyed the use of outdoor resources in the teaching of natural science in secondary schools and found that 16 percent of classes do not study science outdoors and the majority of classes use outdoor resources fewer than three times during the school year.

Results from several studies have identified certain problems or barriers that cause teachers to avoid using field trips. Muse and Davidman (1982) surveyed 300 elementary and secondary teachers and asked them what problems seemed to be most bothersome about field trips. Elementary teachers were concerned with costs associated with field trips, while secondary teachers listed students as a problem area. Three teachers specifically stated that "junior high kids are too squirelly to take on a field trip!" Thus, the issue of controlling student behaviour appeared to weigh more heavily on secondary teachers' minds than it does on elementary teachers'. Keown (1986) found that teachers rated financing travel and large class size as the main impediments to outdoor natural science. He added, however, that many teachers named class schedules and
time allotment for field trips as well. Mason (1980b) published results of a study that examined the status of field work in Virginia. He surveyed all full-time earth science teachers during the fall of 1975. The main hindrances perceived by teachers were: (1) lack of planning time; (2) lack of resource people for assistance; (3) failure of the school to assume trip risk; (4) lack of a satisfactory method of covering classes; (5) restrictions placed on field work by school regulations; (6) lack of administrative leadership, support and encouragement; (7) lack of funding; (8) limited available transportation; (9) too much "red tape"; and (10) excessive class size.

McKenzie and Lisowski (1986) point out that science teachers educated in lab-oriented sciences, with limited field experiences, are frequently unfamiliar with the organisation of field trips and therefore tend to avoid them.

Ideas to encourage effective field work

1. Communicate your rationale

If science teachers are going to use field trips in their curriculum, they must be prepared to explain why they are important. What are the educational values in field trips? How do they fit in with your classroom goals?

Questions such as these can be answered by preparing a rationale statement that substantiates the benefit of using field trips. Teachers should include supporting research in this rationale, and be able to communicate it to students, parents, fellow teachers, and the principal.

In addition, when planning a field trip, explain what the objectives are and why the trip is necessary. Researchers Muse and Davidman (1982) recommend that, if teachers are to make field trips more educative and effective in terms of learning outcomes, then field trips should provide unique outcomes that cannot be attained in the classroom setting or through the use of simulations of media such as film strips, slides, or movies. They suggest that dependence on field trips as a mere diversion or break from classroom instruction will probably not yield significant improvement in attainment of cognitive or affective outcomes. Thus, the rationale for a field trip, at minimum, should specify how the trip will benefit students in a way not possible in the classroom and how the trip fits into the curriculum.

2. Be informed

How can a science teacher with little experience in the use and organisation of field trips begin? The best answer is that they have to become aware and informed of available resources. Troy and Schwab (1981) offer recommendations to teachers who engage in field trips:

1. Be familiar with existing state laws and school district policies regarding field trip procedures.

2. Plan in advance. The ability to demonstrate that reasonable and cautious plans were made will be of immeasurable assistance in defending against any liability action.

3. Obtain approval for the field trip and authorisation for transportation from school officials. Do not use private vehicles. Be sure that proper insurance cover is effective.

4. Contact the authorities of the site to be visited and secure their permission to make the trip.

5. Provide parents with specific information about the trip and require written consent for the child to participate.

6. Visit the site prior to the trip and check for potential hazards.

7. Check out a first aid kit which has been inspected and approved by the school nurse. Review first aid procedures needed for the type of

Department of Curriculum Studies, University of Hong Kong, Hong Kong
accident which may occur.

8. Identify emergency procedures for treatment and reporting of accidents. Report any injuries which occur to proper school authorities.

9. Provide students with special safety equipment which may be appropriate for the planned activities. Be sure that the equipment is in proper working order.

10. Provide adequate supervision. At least one adult for every ten students is recommended.

Many journal articles and books describe effective field trips. Workshops or in-service courses offer practical teaching methods. Colleges and universities usually provide these workshops, but that should not stop a group of teachers from starting their own workshop. Teachers can share their experiences and ideas. They may want to compile a list of essential field trips and work out the details of each (that is, a list of potential hazards and safeguards, estimated costs, suggested ratio of chaperones to students, educational value to students at the designated grade level, and suggestions on how to integrate the trips with curriculum, both before and afterwards).

There are also many local services available to teachers that are free or very inexpensive. For instance, each state has a geological survey that often provides assistance in the location and proper use of suitable field trips.

Field trips are an excellent way to get people in the community involved and to improve relations between teacher, parents and students. Perhaps one of your students has a parent who is a professional conservationist. The teacher can get advice on how students can plant trees around their school and study them, or how to get students to do a survey of the school's soil. This person could also involve students in a field trip or at least be able to give the teacher some useful literature.

University students may be available to help out on field trips as well. They could work with the teacher to plan an effective team teaching experience outside of the classroom. None of these things will happen, of course, unless the teacher takes the initiative to become informed.

3. Start a field trip file

Science teachers can collect meaningful activities and information concerning field trips in a file. For each activity, the teacher should write personal notes concerning the purpose, timing and planning of the trip.

An organised field trip file will save time and headaches in the planning of field trips. Muse and Davidman (1982) suggest that field trips be preceded by a series of activities/experiences that will serve as advance organisers and focus student observations during the trip. The field trip file would be an excellent place to include these advance organisers, as well as post-trip activities.

After taking a field trip, evaluate the trip in terms of strengths and weaknesses. Make a note to repeat the worthwhile activities and indicate ideas for changing the situations which did not work. Again, all this can be saved and put into the field trip file for future use.

4. Begin with simple, inexpensive field trips

Nothing implies that field trips have to be expensive and time consuming. In fact, Harvey (1951) demonstrated that a worthwhile excursion can be conducted within a 55 minute class period. Teachers should begin with simple, inexpensive field trips close to school and work their way towards extended field trips. Also with these simple field trips, the students could more easily set the objectives, be involved in the planning, and evaluate the strengths and weaknesses. This would of course take some of the planning duties away from the teacher and allow for time to do other things.

Fitzsimmons (1983) says each school building and its grounds offer their own set of on-site field trips waiting to be discovered and used. He describes five successful field trip activities that have been used successfully with eighth grade earth science classes. These on-site field trips cost nothing, were completed in a single class period, and presented no scheduling problems. He also added that with field trips such as these, students become involved in the subject and are less likely to misbehave.

Eventually a teacher can begin implementing more complex field trips. Riban (1971) describes a program where the field trip is used not just for instruction, but for investigation. The problems to be investigated are initiated and defined by students during a four-day period.

5. Be positive

As a final suggestion, teachers should be positive and not become discouraged or be afraid of failure in taking a field trip. The field trip can pose teaching and learning challenges to the teacher, but with creative teaching, it can be a valuable source to help students understand how science relates to their everyday life. Sharp (1952) has this to say about teaching beyond the classroom walls.
"In the outdoor classroom the student stands beside the teacher; they are facing in the same direction, looking toward the object that is under observation, they are partners in learning . . . and . . . when they go back into the indoor classroom . . . much of the stiffnessthathas gone out of the educational process, to be replaced by a new kind of eagerness never before seen within these walls."

About the Author

A native of Iowa, Tom Schnoebelen will receive his B.S. (Honours) in Science Education in May 1991. He plans to teach chemistry and physics in a secondary school.

Who’s Who in Science Education Around the World

1991 Edition

This valuable reference book will contain brief profiles on prominent science educators and their work. Advance copies (E6 or US$10 or A$13) can be ordered from the Editor 10 Hawkens Street, Monash ACT 2904, Australia Cheques payable to "ICASE"

An ICASE Initiative
The Children & Youth Science Centre
China Association for Science & Technology

The China Association for Science & Technology (CAST) is a large organisation of scientists, engineers and technologists, and a federation of both the national natural science societies and local science & technology associations. In an era of rapid development of science and technology, CAST has been active in the task of improving the quality of science education for children and young people.

Following the setting up of the Department of Children and Youth Affairs in 1978, the Children and Youth Science Centre - a national institution for children's education - was formed. With the support of many national science societies, the Centre promotes a wide range of scientific activities for children.

Through practical work and experiments, children acquaint themselves with new scientific knowledge, stimulate their interest, expand their abilities to work independently, and foster their ideals. The CAST Children and Youth Science Centre liaises with other Children and Youth Science Centres in provinces and municipalities which are administered by the Central Government, and has formed a network for children's science education.

The many activities which have been jointly sponsored by the CAST Centre, government departments and other organisations, include exhibitions of science projects, creative invention contests, science seminars, camps and tours, contests relating to the natural science subjects, in-school and out-of-school scientific hobby groups, "Love Science Month", and science experiments in rural areas.

Hobby group activities have been carried out in many middle and primary schools in urban and rural areas throughout the country. Activities have ranged from monitoring city environments to farm planting and cultivation experiments, from constructing radios or models to computer programming, and from tests in physics and chemistry to astronomical observations.

Camps in science and technology are held during vacation periods, and enable hundreds of thousands of children to enjoy their holidays in the mountains or at the seaside, to broaden their knowledge and appreciation of their country's environment.

A national creative invention contest and science seminar is held every two years. Since 1982, more than 600 creative inventions and 300 seminar papers have been produced.

Thousands of children and youth take part in mathematics, physics, chemistry, computer and other contests each year. Those middle school students who win national contests travel to international olympiad competitions in mathematics, physics, chemistry, etc.

CAST also focuses attention on children's science activities in minority nationality regions, remote areas and rural areas. Several local Children and Youth Science Centres make use of mobile buses equipped with science exhibits, popular science lecture materials, scientific films, videos and books. Ten million children benefit from such programs each year.

The Children and Youth Science Centre of CAST liaises with the United Nations Children's Fund, Unesco, and several science education institutions in other countries and regions, and is keen to establish contact and an exchange of information with colleagues in other countries.
The John Gardiner Centre, which came into operation just over a year ago, provides a range of science, mathematics and technology activities for students, teachers and the community. In the first year:

- Over 1000 teachers have become members of the Centre and have been involved in professional development activities run by the Centre.
- The Centre has developed a wide-ranging program of activities, including teacher professional development courses focusing on 'hands on' science for primary teachers; science and technology 'hands on' classes for over 8000 primary children; and science and technology holiday programs for hundreds of primary children.

- The Saturday Afternoon Science for Families program, launched in April 1990 and held on the first Saturday of each month, has been extremely popular.

The aim of the activities is to provide students with opportunities to experience science 'hands on', and at the same time, to provide teachers with the confidence and experience to teach more science in their own classrooms. During the past year, the following activities have been available for primary students.

**Light and Colour (Grades P-6)**

This activity includes: filters, lenses and prisms; pigments and dyes; lighting in houses; photography; ultraviolet light and the skin.

**Electricity (Grades 3-6)**

Students construct electric circuits to switch on lights, ring alarm bells, work motors and household appliances; they determine what is in an electric puzzle box; they play a simulation game in which they are 'volt people' and 'electron people'; and they tinker with electric appliances to see how they work.

**Balancing Acts (Grades 4-6)**

Students examine the principles of balance and centre of gravity as they perform simple balancing acts, construct balancing toys and mobiles, and look at the science of high jumping, long jumping and tightrope walking.

**Flight (Grades 3-6)**

In this activity, students design and construct helicopters, unusual planes and gas-propelled rockets, as they learn the basic elements of aerodynamics.

**Metals and Magnets (Grades P-6)**

Students make magnets and electroplate coins; they look at some of the ways we use metals and magnets such as in household appliances, motors, buildings and sculpture.

**Supermarket Science (Grades 3-6)**

Using products which are easily available at the local supermarket, students experiment to analyse a number of white powders and determine what substances are in their 'mystery powder'.

**Bubbleology (Grades 3-6)**

Students investigate the intriguing nature of soap bubbles, how to use colour to predict when a soap bubble will pop, making square bubbles, and making bubbles in bubbles.

**Cabbages & Chemistry (3-6)**

The idea that chemistry only occurs in laboratories is dispelled as students use the chemicals in plants to conduct tests on soda water, aspirin and soap. They make a colourful array of solutions and discover which common household products are acids and which are bases.

**Budding Builders (Grades 3-6)**

Students test a range of shapes used in building, construct and testalsa roof trusses, and design and build simple structures such as bridges, towers and domes.

**Balloons under Pressure (3-6)**

Children complete a wide range of activities using balloons, as an introduction to the science of air and air pressure.

STS as a Development in Science Education

by Robert E Yager
University of Iowa

Science Technology Society (STS) has become a major movement in science education in the US since it emerged as one of the five focal points for Norris Harms' Project Synthesis (Harms, 1977). E Joseph Piel headed the STS task force for Project Synthesis where exemplary STS programs were envisioned as those with the following characteristics:

- Prepare individuals to use science for improving their own lives and for coping with an increasingly technological world;
- Prepare students to deal responsibly with technology - society issues;
- Identify a body of fundamental knowledge which students may need to master in order to deal intelligently with STS issues;
- Provide students an accurate picture of the requirements and opportunities involved in the multitude of careers available in the STS area.

After the Project Synthesis report in 1981 (Harms & Yager, 1981) NSTA initiated its Search for Excellence in Science Education (SESE) Program. STS was included as one of the initial search areas in 1982-83; STS criteria were updated and a second search for STS exemplars was undertaken in 1986. Since these beginning efforts, STS has flourished as a focus for school science, as an area for identifying new goals, new curriculum modules, new instructional strategies, and new forms for evaluation. STS has been a major focus for science education reform in Iowa since the initiation of the NSTA-NSF Chautauqua Program in 1984. Today over 1000 teachers have developed and introduced STS modules into their science classrooms, especially those in grades four through nine.

STS programs have developed in ways quite different from the early ones identified in the first NSTA Search for Excellence (Penick & Meinhard-Pellens, 1984). The following table permits a twelve point contrast between standard science programs (as revealed by the NSF state studies and Project Synthesis) and the situation found in STS experiments in Iowa.

<table>
<thead>
<tr>
<th>Standard Science Programs</th>
<th>S/T/S Programs</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Survey of major concepts found in standard textbooks</td>
<td>1. Identification of problems with local interest and impact</td>
</tr>
<tr>
<td>2. Use of laboratories and activities suggested in textbook and accompanying manual</td>
<td>2. Use of local resources (human and material) to locate information that can be used in problem resolution</td>
</tr>
<tr>
<td>3. Passive involvement of students assimilating information provided by teacher and textbook</td>
<td>3. Active involvement of students in seeking information that can be used</td>
</tr>
<tr>
<td>4. Science being contained in the science classroom for a series of periods over the school year</td>
<td>4. Science teaching going beyond a given series of class sessions, a given meeting room, or a given educational structure</td>
</tr>
<tr>
<td>5. A focus on information proclaimed important for students to master</td>
<td>5. A focus upon personal impact, perhaps starting with student curiosity and concern, not merely hoping to get to that level</td>
</tr>
<tr>
<td>6. A view that science is the information included and explained in textbooks and teacher lectures</td>
<td>6. A view that science content is not something that merely exists for student mastery, simply because it is recorded in print</td>
</tr>
<tr>
<td>Standard Science Programs (continued)</td>
<td>S/T/S Programs (continued)</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>7. Practice of basic process skills, but little attention to them in terms of evaluation</td>
<td>7. A de-emphasis upon process skills, just because they represent glamorised skills of practicing scientists</td>
</tr>
<tr>
<td>8. No attention to career awareness, other than an occasional reference to a scientist (most were deceased) and his/her discoveries</td>
<td>8. A focus upon career awareness, especially careers that students might expect to pursue as they relate to science and technology and not merely those related to scientific research, medicine, and engineering</td>
</tr>
<tr>
<td>9. Students concentrating on problems provided by teachers and text</td>
<td>9. Students performing in citizenship roles as they attempt to resolve issues they have identified</td>
</tr>
<tr>
<td>10. Science occurring only in the science classroom as a part of the school’s science department</td>
<td>10. Science study being visible in a given institution and in a specific community</td>
</tr>
<tr>
<td>11. Science being a study of information where teachers discern the degree students acquire it</td>
<td>11. Science being an experience students are encouraged to have</td>
</tr>
<tr>
<td>12. Science focusing upon current explanations and understandings; little or no concern for the use of information beyond the classroom and performance on tests</td>
<td>12. Science with a focus upon the future and what it may be like</td>
</tr>
</tbody>
</table>

Students are also found to be different as a result of major experiences with STS. Assessment has centred in five domains that are important in science teaching. Figure 1 is an attempt to depict the domains and to define STS in connection with them.

In regular science teaching nearly all attention is directed to the acquisition of information. (It probably should not be called knowledge very often since so few students can ever demonstrate that they can use the information that is seemingly learned.) It is common for school curricula and for teachers to embrace the importance of considering science processes. Nonetheless, there is little evidence that traditional science teaching is effective in helping students develop such skills, at least in a manner that they can be used in other situations in addition to the ones used to illustrate them in the classroom.

Positive student attitude and certain aspects of creativity are seen as necessary attributes for STS students, perhaps all students able to attain knowledge (useful information) and science skills/processes (useful in non-class settings). Positive attitudes and personal creativity are traits more easily attainable by dealing with issues in today’s society and technology which affect the lives of all. In traditional science courses, technology is often seen as irrelevant. (It was purposefully omitted from the pure science programs developed during the 1960s). And, current societal issues and topics that are readily related to responding to student needs and concerns are dismissed as health, psychology, or some other social study.

STS programs are defined as those starting with real world issues and concerns. Hopefully these are (or can become) student issues and not some other kind of information teachers wish to present to students.

When teachers begin with a topic from the existing course outline, a favourite topic or science concept, or information that they have been wanting to share with students, problems are often encountered. When STS is viewed as the same science concepts as those appearing in the textbooks, but with technological and societal dimensions “added on” in that order, the experience proves less successful.

Many teachers begin with frustration. What will their STS modules be? How should the task be approached? The most effective STS efforts have arisen from sharing the frustration with the students, including the choice of problem, the need for a student-based effort, the need to use applications immediately in daily living. The best STS efforts are those where the student chooses the problem to be investigated. The problem comes from unusual circumstances. Some of the best have been students who have reported problems with toilets plugging at home, a faucet which does not turn off at school, a power failure in a school with no windows, a problem with a polluted water well, and hundreds of other problems identified by students.

One of the greatest problems with school science seems to be the belief that there is essential information found in curriculum guides and textbooks which teachers must force students to go over. When real problems are internalised and the students are encouraged to work on their resolution, the power of information is soon realised. Students search out information and use it; and in the process new problems are
defined. STS means dynamic teaching and learning. Effective science classrooms cannot be passive ones where students merely go over information, information that will be used for examinations and/or activities that will verify its accuracy. In traditional science classrooms students are expected to remember, to get "the answer" on quizzes, and to make "correct" observations in the laboratory. Rarely is a real-life context provided.

STS means focusing on problems, on questions, on unknowns. It means searching for answers and explanations. However, this searching means that students encounter numerous new questions and problems. Sciencing is a never-ending process.

The best STS modules (and teacher experiences with STS) always result in teacher comments such as: "My STS module is not complete yet..."; "I just had to stop..."; "I never imagined that we would investigate so many questions..."; "I had no idea that STS would result in so much student initiative, enthusiasm, action..."; "The students did the work. They identified problems, proposed actions - they wouldn't let it stop!"

The place to begin new STS modules needs to reside with the students. They must see and buy into a problem. Real science learning cannot result from teachers "presenting" information or "announcing" the STS module. Students must have a hand in constructing the problem and determining their actions concerning it.

Students who experience science as STS are different from students who complete a traditional science program organised around the typical concepts found in most textbooks. A look at differences in each domain illustrated in Figure 1 may be helpful.

<table>
<thead>
<tr>
<th>Traditional Connections &amp; Applications</th>
<th>STS</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Students see no value and/or use of their science study to their living</td>
<td>1. Students can relate their science study to their daily living</td>
<td></td>
</tr>
<tr>
<td>2. Students see no value in their science study for resolving current societal problems</td>
<td>2. Students become involved in resolving social issues; they see the relativity of science study to fulfilling citizenship responsibilities</td>
<td></td>
</tr>
<tr>
<td>3. Students can recite information and concepts studied</td>
<td>3. Students seek out information and use it</td>
<td></td>
</tr>
<tr>
<td>4. Students cannot relate the science they study to any current technology</td>
<td>4. Students are engrossed in current technological developments and use them to see the importance and relevance of science concepts</td>
<td></td>
</tr>
</tbody>
</table>

**Creativity**

<table>
<thead>
<tr>
<th>Traditional</th>
<th>STS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Students decline in their ability to question; the questions they do raise are often ignored because they do not fit into the course outline</td>
<td>1. Students ask more questions; such questions are used to develop STS activities and materials</td>
</tr>
<tr>
<td>2. Students rarely ask unique questions</td>
<td>2. Students frequently ask unique questions that excite their own interests, that of other students, and that of the teacher</td>
</tr>
<tr>
<td>3. Students are ineffective in identifying possible causes and possible effects in specific situations</td>
<td>3. Students are skilled in suggesting possible causes and effects of certain observations and actions</td>
</tr>
<tr>
<td>4. Students have few original ideas</td>
<td>4. Students seem to effervesce with ideas</td>
</tr>
</tbody>
</table>

**Attitude**

<table>
<thead>
<tr>
<th>Traditional</th>
<th>STS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Student interest declines at a particular grade level and across grade levels</td>
<td>1. Student interest increases in specific courses and from grade to grade</td>
</tr>
<tr>
<td>2. Science seems to decrease curiosity</td>
<td>2. Students become more curious about their world</td>
</tr>
</tbody>
</table>
3. Students see teacher as a purveyor of information

4. Students see science as information to learn

3. Students see teacher as a facilitator/guide

4. Students see science as a way of dealing with problems

**Process**

1. Students see science processes as skills scientists possess

2. Students see processes as something to practice as a course requirement

3. Teacher concerns for process are not understood by students, especially since they rarely affect the course grades

4. Students see science processes as abstract, glorified, unattainable skills that are unapproachable for them

1. Students see science processes as skills they can use and develop more fully for themselves

2. Students see processes as skills they need to refine

3. Students readily see the relationship of science processes to their own actions

4. Students see processes as vital parts of what they do in science classes

**Knowledge**

1. Knowledge is really information mastered for a teacher test

2. Knowledge is seen as an outcome itself

3. Learning is principally for testing

4. Retention is very short-lived

1. Students see science knowledge as personally useful

2. Knowledge is seen as a needed commodity for dealing with problems

3. Learning occurs because of activity; it is an important happening but not a focus in and of itself

4. Students who learn by experience retain it and can often relate it to new situations

**Figure 1 Differences in traditional vs STS science in relation to domains**

STS efforts have moved forward with dramatic pace during the ten years since Project Synthesis. STS is becoming the megatrend that Rustum Roy proclaimed it to be. STS activities are exciting and innovative developments in every state. STS programs are affecting the entire school curriculum, not just the nature of science courses and teaching. Exemplary programs represent major efforts and successes with realising the priority needs identified ten years ago by the Project Synthesis research team. Perhaps it is time for a second Synthesis study to note with certainty the extent that STS programs have resolved the science education issues so clearly identified in 1978.

**About the author**

Robert E Yager is Professor of Science Education at the Science Education Center, University of Iowa, Iowa City, Iowa 52242, USA. Dr Yager, a past president of NABT, AETS, NARST and NSTA, was presented with the Presidential Award of the National Science Supervisors Association earlier this year. He is continuing to play a key role in the development of STS education.
Resources

Women Too in Science and Technology in Africa
by Jan Harding and Emmanuel Apea

This new resource book (140 pages), written by Jan Harding and Emmanuel Apea with contributions by Kabiru Kinyanjui and Eddah Gachukia, has just been published by the Commonwealth Secretariat.

Few girls and young women become skilled in science and technology; this means that girls and women are largely excluded from participating in many areas of development. The Commonwealth Secretariat has tried to raise awareness of gender biases in science, technology and mathematics education in Africa in a variety of ways.

This book is intended to be a resource book of information about women already working as scientists and technologists, so that they may serve as role models to girls in schools. It may challenge the stereotyped assumptions of their teachers and parents too.

In addition to interviews with eminent women, the book looks briefly at the Commonwealth Plan of Action on Women and Development, current thinking about women and development, the role of science and technology in development, and what needs to be done to enable women to participate in development in scientific and technological fields. However, it is primarily a resource book for educators and scientists, for schools and institutions not only in Africa but in other regions of the world as well.

WINDBOWS INTO SCIENCE CLASSROOMS

PROBLEMS ASSOCIATED WITH HIGHER-LEVEL COGNITIVE LEARNING

Edited by Kenneth Tobin, Jane Butler Kahle and Barry Fraser

Based on recent ethnographic research, this qualitative study records, interprets and analyses actual occurrences in the science classroom. In addition, the researchers place their results in a theoretical framework. Individually, they record and interpret observations, while collectively, they validate assertions and interpretations in order to build a theoretical base.

Chapter 1: Learning Science with Understanding: In Search of the Holy Grail?
Chapter 2: Methods and Background
Chapter 3: Teacher Mind Frames and Science Learning
Chapter 4: Real Students Take Chemistry and Physics: Gender Issues
Chapter 5: The Cognitive Level of Curriculum and Instruction: Teaching the Four R's
Chapter 6: Student Participation and Motivational Orientations: What Students do in Science
Chapter 7: Students' Perceptions of their Classroom Environments
Chapter 8: Conclusion: Barriers to Higher-Level Cognitive Learning in Science

Published by Falmer Press, 1990 (264 pages)
Paperback US$20 Hardcover US$40

Order from Falmer Press, 1900 Frost Road, Bristol PA 19007-1598, USA

Individualised Classroom Environment Questionnaire

The ICEQ assesses perceptions of five aspects of classroom climate which are salient in individualised or open settings - Personalisation, Participation, Independence, Investigation and Differentiation. There are several different forms of the questionnaire:
* actual form (what the classroom is like) or preferred form (what students would prefer the class to be like
* student or teacher forms
* long form (50 items) or short form (25 items)

Copyright exemptions permit the ICEQ, after initial purchase, to be reproduced for use within schools. The ICEQ can be used in many applications, including the evaluation of new curricula, practical attempts to improve classrooms and investigations of differences between students' and teachers' perceptions.

The comprehensive handbook includes the various forms of the ICEQ, answer sheets and information about development, scoring and applications. It is published by the Australian Council for Educational Research (40 pages, quarto size) at a cost of A$49.95.

Order from: ACER, PO Box 210, Hawthorn, Victoria 3122, Australia
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1990

December 27 - January 1
International Conference on Teaching of Physics
Location: Karachi, Pakistan
Contact: Mrs Aziz F Hasnain, Head, Department of Physics, APWA Government College for Women, F 'B' Area, Karachi, Pakistan
The theme is *The changing face of physics education in developing countries*. The conference aims to discuss techniques for conceptual teaching in physics, to create awareness among physics teachers about modern teaching methods including the use of computers and audiovisual aids, and to establish a research program in physics education.

1991

January 4-7
ASE Annual Meeting
Location: University of Birmingham, Birmingham, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
A special feature of this large international meeting will be an ICASE Symposium "Science Teachers Associations Worldwide".

March 18-28
Computer Science in Schools
Location: Homerton College, Cambridge, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This residential course will focus on the application of computers in business, commerce and industry. Teachers will have the opportunity to use software, develop teaching materials and strategies. Different approaches to computer science will be reviewed and there will be an opportunity to exchange personal experiences. Participants should be those involved in the teaching of computer science to school students aged from 11-18 years. Application forms are available from British Council offices or the address above.

March 27-30
NSTA National Convention
Location: Houston, Texas, USA
Contact: Linda Crow, Asst Professor, Baylor College of Medicine, One Baylor Plaza, Room 633E, Houston, Texas 77030, USA
International delegates are invited to participate in The Fourth International Round Table. Each country is provided one or more tables in a large room where delegates can display and present information on science education in their country. While NSTA cannot offer any funding, an official letter will be issued on request, inviting international delegates to contribute to the program. Contact Prof John Penick, Science Education Center, University of Iowa, 450 Van Allen Hall, Iowa City, IA 52242, USA prior to 15 January in order for your name to appear in the official program.

March 29 - April 3
7th ICASE-Asian Symposium
Location: East China Normal University, Shanghai, China
Contact: Prof Mi Zihong, Department of Physics, East China Normal University, Shanghai 200062, China
The symposium will be conducted in English/Mandarin and will address the theme *Making science education in schools more relevant*. The program will focus on (1) the development of appropriate curricula, the issue of integrated science vs separate sciences, the introduction of STS in science courses; (2) innovations in teaching, the role of project work, the teaching of science communication skills, low cost equipment, fieldwork; (3) technology in education, the effective use of visual aids, visits to industry, the place of the computer; and (4) research in science education, children's learning in science, assessment techniques. The program will consist of presentations by internationally renown science educators; papers, workshop and discussion sessions; poster displays; and an exhibition.

April 1-14
Edinburgh International Science Festival
Location: Edinburgh, Scotland, UK
Contact: Edinburgh Science Festival Ltd, 20 Torphichen Street, Edinburgh EH3 8JB, Scotland, UK
There is something of interest for everyone at the international science festival. Now in its third year, this lively celebration of all the sciences, from astronomy to
zooology, is geared as much for those who are merely curious
or concerned about the world as it is for the serious scientist.
The 1991 festival will focus on the human body, but many
other topics as diverse as wildlife and artificial intelligence,
and biotechnology and electronics will be covered in an
extensive program of demonstrations, debates, exhibitions,
films, workshops, walks and talks. A full program is
available from the contact above.

April 5-8
Chemistry and Developing Countries
Location: Imperial College, London, UK
Contact: Stanley S Langer, The Royal Society of Chemistry,
Burlington House, Piccadilly, London W1V 0BN, UK
This conference will be the second organised by The Royal
Society of Chemistry on the theme of chemistry and
development. The 1991 conference, to be organised as part of
the celebrations to mark the 150th Anniversary of the
Society, will focus on two themes: (1) chemistry for the
environment, and (2) organising science to benefit the third
world. Representatives of several chemical associations from
around the world will be invited to present their views of
problems and opportunities.

July
Annual Conference of ASERA
Location: Brisbane, Australia
Contact: Dr Cam McRobbie, Queensland University of
Technology - Kelvin Grove Campus, Locked Bag No 2, Red
Hill, Qld 4059, Australia
All those interested in science education research are invited
to attend the 22nd Annual Conference of the Australian
Science Education Research Association.

July 7-12
CONASTA 40
Location: Adelaide, Australia
Contact: Anthony Diercks, SASTA Office, 163A Greenhill
Road, Parkside, SA 5063, Australia
The Australian Science Teachers Association invites you to
participate in the fortieth annual conference of the Australian
Science Teachers Association.

July 14-19
GASAT 6 International Conference
Location: University of Melbourne, Victoria, Australia
Contact: Ms Gaell Hildebrand, School of Education,
University of Melbourne, Parkville, Victoria 3052, Australia
The conference theme is Action for Equity: The Second
Decade. During the past decade, the GASAT Community
has explored the nature of the interaction between gender and
science and technology, and debated a variety of explanations
and solutions. GASAT 6 will focus on reflections upon past
GASAT work, current initiatives relating to intervention and
research, and perspectives on the challenges of the future.

August 4-9
ChemEd 91 Conference
Location: Oshkosh, Wisconsin, USA
Contact: Bruce G Smith, Co-Director, Appleton High
School-West, Appleton, Wisconsin 54914, USA or Paul
Kelter, University of Wisconsin, Oshkosh, Wisconsin
54901, USA
ChemEd 91 is a major chemical education conference of
interest to university, college, secondary and elementary
educators from North America and beyond. Throughout the
weeklong conference, activities are planned for all members
of the family including excursions, field trips, sports
activities and social events - a feature of ChemEd
conferences.

August 25-30
11th International Conference on Chemical
Education
Location: University of York, York, UK
Contact: Dr John F Gibson, ICCE 11, Royal Society of
Chemistry, Burlington House, Piccadilly,
London W1V 0BN, UK
This biennial conference on the theme Bringing Chemistry
to Life is being organised by the IUPAC Committee on
Teaching of Chemistry in conjunction with UNESCO and
the Association for Science Education. The conference will
focus on (1) making chemistry accessible to all students (2)
new curricula at primary, secondary and post-secondary levels
(3) new teaching strategies at all levels (4) teaching and
learning at a distance (5) new frontiers of chemistry and their

impact on teaching, and (6) research in chemical education. The program will include plenary lectures, poster papers, symposia, workshops, exhibitions, times for participants to discuss aspects of chemical education of special interest, social events and local visits.

August 12-22
Sixth International Symposium of IOSTE
Location: Wyndham Palm Springs Hotel and Resort, Palm Springs, California, USA
Contact: Dr Herbert K Brunkhorst, Institute for Science Education, California State University, 5500 University Parkway, San Bernardino, California 92440-2397, USA
The theme of the 6th International Symposium on World Trends in Science and Technology Education is Science and Technology Education: Responsible Change for the 21st Century. Science and technology education will be related to responsible change with respect to the role of science educators, scientists, engineers, business/industry and government agencies in the global community. The symposium will provide a forum for dialogue to increase awareness of regional perspectives worldwide and develop closer cooperation in addressing mutual concerns. This dialogue will be held in the context of science education issues, environmental issues, technology issues and socio-cultural issues. The symposium will be presented in English. Proposals for papers, including a brief abstract, should be submitted by 1st January.

August 26-30
Fourth Asian Chemical Congress
Location: Beijing, China
Contact: Prof Dehe Zhang, Secretary General of 4ACC, Chinese Chemical Society, PO Box 2709, Beijing 100080, China
The 4th Asian Chemical Congress will be held under the sponsorship of the Federation of Asian Chemical Societies. The Congress will focus on the important role of chemistry in raising the health conditions and living standards for all people. The program of plenary lectures, invited papers and contributed papers will be conducted in English and will concern various topics including organic chemistry of natural products, analytical chemistry and instrumentation, environmental chemistry, agrochemistry, coordination chemistry and its applications in medicine and agriculture, polymer science, photochemistry, computers in chemistry, catalysis, and chemical education.

August 27 - September 1
5th International Environmental Education Conference
Location: Cusco, Peru
Contact: MSc Eduardo Gil Mora, National University of Cusco, Zaguan del Cielo L-9, Cusco, Peru
The conference will focus on the relationship between the environment and development, and on the changes needed in today's behaviour for tomorrow's world. The program will enable participants to learn of developments, approaches and strategies in environmental education in different countries, and will cater for primary, secondary and tertiary educators; and for teacher trainers, curriculum developers, and policymakers.

1992

April 22-29
Symposium on Technology Education
Location: University College of Education, Erfurt, Germany
Contact: Prof D Blandow, University College of Education, Nordhäuserstraße 63, 5064 Erfurt, Germany
This symposium will be the first pan-European meeting on technology education to be held in a unified Germany - at an institution in Erfurt renowned for initiatives and developments in technology education. The principal aim of the symposium, which is being organised in collaboration with a number of organisations including ICASE and INISTE, will be to discuss technological literacy and competence in technology education within a European dimension. The majority of participants will be from European countries, with a few key people from other regions of the world. The principal language of the symposium will be English.

May 11-15
Second International History Philosophy and Science Teaching Conference
Location: Queen's University, Kingston, Ontario, Canada
Contact: Prof Skip Hills, Faculty of Education, Queen's University, Kingston, Ontario, Canada K7L 3N6
This conference follows the very successful First International Conference on History, Philosophy and Science Teaching held at Florida State University in November 1989. All conference papers will be published in advance of the conference. Accounts of the application of history and philosophy of science in the science classroom are welcome, as are research papers on the issue.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

1990 ICASE Distinguished Service Award

This award was presented to Mrs Sheila Haggis on 6th January 1991 at the Association for Science Education Annual Meeting in Birmingham, UK.

The following is part of the citation made by the ICASE President, Mr Bob Lepischak at the Presentation Ceremony.

The award is reserved for individuals who have a career history of distinguished service to international science education. Such service is characterised by consistent involvement in the international activities of local, regional and global science teacher organisations.

Mrs Haggis, educated at the University of Cambridge, began her teaching career in Nigeria and Ghana as a missionary teacher. It was on her initiative that GAST, the Ghana Association for Science Teachers was established...the Association has completed 33 years of service to science teachers.

For the past 25 years, Mrs Haggis has served as a Unesco staff member in Paris, most of the time responsible for science education within Unesco as Chief of the Science Education Section.

As part of a forward looking group, Mrs Haggis was responsible for facilitating the Preliminary Meeting of Science Teacher Associations held in Singapore in 1972; and in April 1973 was largely responsible for the inaugural meeting of ICASE held in Maryland, USA.

Mrs Haggis has participated in ICASE sponsored and endorsed events and meetings around the world providing counsel and enhancing the ICASE network.

With this award, Mrs Haggis joins an exclusive alumni of like-minded educators extending from Australia to the Caribbean, and from Singapore and the Philippines to the United States and Canada. In 17 years, the award has been presented to only seven other individuals.

Colleagues of Mrs Haggis admire her for her efficiency and her “stick-to-it-iveness”...she is considered an exemplary colleague, an individual with vision, and a gracious person. ICASE, and indeed education in general, is richer for the contribution made by Mrs Haggis.

Who's Who in Science Education Around the World

At the ICASE Executive Meeting held in Birmingham, UK in January 1991, it was decided to postpone publication of the Who's Who in Science Education Around the World 1991 Edition until late 1991.

This valuable reference book will contain profiles on prominent science educators and their work. The Executive decided to enhance this biographical volume by including details of science teacher associations around the world, and a brief profile on the science education scene in countries around the world.

It is not too late to submit details of prominent women and men and their work in the areas of primary, secondary and tertiary science education. Your recommendations are welcome. Forms for completion are available from:

ICASE Executive Meets in Birmingham

by Brenton Honeyman
ICASE Journal Editor

Members of the ICASE Executive met from 31 December to 3 January 1991 in Birmingham, UK prior to the ASE Annual Meeting. Full minutes of this four day meeting will be sent to all ICASE members - some of the outcomes are summarised here.

World Conference 93
ICASE has commenced planning, in conjunction with UNESCO, a major world conference on Scientific and Technological Literacy: Forward to the Next Century, to be held in Paris, July 1993. A planning subgroup met during the executive meeting to prepare a detailed proposal for this event. It is hoped that the outcomes of a number of conferences being held in various places around the world during 1992, will provide a significant input into the agenda of the 1993 World Conference.

History of ICASE
In 1993, ICASE will celebrate its 20th anniversary. To commemorate this occasion, Dennis Chisman, Honorary Treasurer, is coordinating the publication of the history of ICASE.

Membership Dues Increase
ICASE Membership Dues are to increase by 10% from 1 July 1991. Member associations and bodies paying their 1991 dues prior to this date will avoid this increase.

Five Year Development Plan
A subgroup of the Executive Committee met to commence the development of a 5 year plan, involving development of five major areas - profile; financial base; services to members; human resources; policy development and operations.

Publications
The number of pages of Science Education International is to increase, but individual and library subscription rates will remain the same for 1991. Another new development will be the inclusion of some articles in French and other languages. Claude Gadbois, Special Projects Officer (French) has joined the Editorial Team to assist with this new initiative. Additional individual and library subscriptions will be encouraged during 1991. A scheme, where a local association can receive subscriptions to assist those who have difficulty in paying in other than their local currency, will be introduced during 1991.

The Executive Committee gave approval for the Proceedings of the ICASE European Symposium on Industry and Education (held in Brussels in 1990) to be published as the 1990 ICASE Yearbook.

An information folder ICASE: The People and the Organisation is being compiled. The folder will contain a profile of the Executive Committee and those working on ICASE projects; a profile of ICASE projects and accomplishments since its inception; the ICASE 5 Year Plan; the Annual Report; illustrated list of ICASE publications; ICASE brochure and membership list; ICASE Position Statement on Science Education; Position Statement on ICASE relationships with member organisations, corporate bodies and other organisations; ICASE Constitution. It is planned that documents within this folder will be available in English, and eventually in French and Spanish versions.

International Space Year
Four special International Space Year (ISY) activities involving ICASE were endorsed: (1) Publication of a set of space science resource materials for science teachers (a joint project with the ICSU Committee on Teaching of Science); (2) World Activity Day on Space Science, scheduled for October 1992 and to be promoted through ICASE member associations; (3) International Invited Conference Space Enough to Learn, to be held in Canberra, Australia, 13-17 July 1992; and (4) ICASE delegation to participate in the Space Science Seminar at Johnson Space Center, Houston, USA in 1992. Dr David Moore, UK, was appointed as the Project Officer coordinating ICASE involvement in these ISY Projects.
ICASE approaches 100 members
by Dr Jack Holbrook
Executive Secretary, ICASE

ICASE membership, as of January 1991, has reached 97, made up of 55 full members, 18 associate members, 19 institutional members, 1 foundation member, and 4 company members. In the past year, 10 new members have joined ICASE. The new members are:

- Quebec Science Teachers (QUEST), Canada
- European Youth Science Network (EURYSN)
- University College of Education, Erfurt, Germany
- Institute for the Promotion of Science Education, Pakistan
- Education Division of the Royal Society of Chemistry, UK
- The Zoological Society of London, Regent's Park, UK
- London International Youth Science Fortnight (LIYSF), UK
- Standing Conference on Schools' Science and Technology (SCSST), UK
- University of Toledo, USA
- Association of Biology and Agricultural Technology Teachers, Vietnam

London International Youth Science Fortnight

ICASE welcomes the LIYSF as an institutional member.

Each year, since 1959, the London International Youth Science Fortnight has brought together students of the Sciences of university entrance standard to share a program of lectures, seminars, discussions and debates, intermingled with visits to scientific, research and university establishments throughout southern England, in the London area and at Oxford and Cambridge.

In 1990, some 360 students - many of whom were award winners in Science Fairs and other competitions - from 50 countries took part in the meeting. The academic standards are high amongst the participants and are matched by those who give lectures and lead seminars - nobel laureates, university professors and eminent academics all contribute to the program.

Apart from the scientific program, the Science Fortnight offers a unique opportunity to live in an international community. Accommodation is arranged in University of London Halls of Residence, together with opportunities for social interchange at discos, international cabaret evenings and optional excursions to places of interest at weekends.

The Science Fortnight is the principal international youth meeting annually organised in Britain, and is the major international meeting of young scientists in the world.

Details of participation and the 1991 program are available from:

George McGowan
Director, LIYSF

Standing Conference on Schools' Science and Technology

The Standing Conference on Schools' Science and Technology is the newest associate member of the ICASE family. SCSST was established in 1971, at the instigation of HRH The Duke of Edinburgh, to promote and encourage the development of science and technology in schools with particular reference to their economic and industrial applications.

SCSST is an independent national organisation whose corporate membership includes the leading organisations in education, industry, science, engineering and government departments. Through its activities, SCSST aims to:

- influence public policy on science and technology education
- sponsor innovation in the teaching of science and technology
- provide local support to schools through the SATRO network

SCSST is an educational charity supported by DES (Department of Education and Science), DTI (Department of Trade and Industry), industry, the science and engineering professions, and its member organisations.
Stepping into Science
A Report from Muscat

by Yunus Sola
Science/Accessment Coordinator, British School Muscat

Stepping into Science is a very important tool for motivating pupils. The project was initiated by Sue Dale Tunnicliffe, who is now Head of Education at the Zoological Society of London and the ICASE Project Officer for this worldwide project.

The project targets primary/elementary schools. Until now, award projects have concentrated on middle and secondary schooling. Stepping into Science is the first truly international award project designed for primary and elementary schools. It involves pupils doing a number of science tasks and investigations for which they are awarded a certificate. Any school and any teacher in the world can become involved.

Although the project is in its early development stage, it has already been implemented in some schools in England and abroad.

Teachers and schools around the world are invited to register, and take a "Step into Science". There is no fee and, upon registering, teachers can obtain certificates free of charge by writing to Yunus Sola at the address below.

The suggested framework is that each child should participate in about 6 tasks or investigations per year. A certificate is awarded to each child either as soon as they have completed these activities or at the end of the year. Of course, children may complete more than 6 activities per year. In fact, science coordinators and class teachers may adapt the scheme and the awarding of certificates to best serve the needs of their school. For example, at the British School in Muscat, Oman, I am using the project to support the Science in the National Curriculum which the school has implemented in line with England and Wales.

The award scheme has been organised to encourage children to take steps in science each year during their primary school years. These steps are colour coded as follows:

- yellow for preschoolers
- green for grade 1 children
- blue for grade 2 children
- red for grade 3 children
- orange for grade 4 children
- grey for grade 5 children
- purple for grade 6 children

Using this scheme, children in class 1 take the green step (consisting of about 6 activities appropriate for that level); children in class 2 take the blue step; and so on. The philosophy of the project is to give teachers the professional responsibility to manage the award scheme. It is up to the teacher to ensure that children complete the prescribed number of science tasks. The certificate scheme should not be used in a pass/fail sense, but should be used to acknowledge participation in, and completion of science tasks.

At the British School Muscat, the response has been very positive. Pupils love the idea, and enjoy the thought of being awarded certificates as part of an international project. Parents are thrilled that the school is involved in such an international award scheme. By being involved in this project, the Science Department has enhanced its status in the school community.

Heads of Science please note - I have found that teachers are more willing to organise science activities when they know that their children will be awarded certificates.

All schools will benefit by becoming involved in the Stepping into Science project - remember that the award scheme can be adapted to meet the individual needs of schools.

BP Middle East (Oman) Ltd have been very generous in covering the cost of printing and posting certificates to schools. On behalf of the Project Coordinating Committee, my sincere thanks go to BP for sponsoring this project.

To register your school, or for more information, write to:

Yunus Sola is the Science/Accessment Coordinator at the British School Muscat in Oman. He is a member of the Project Coordinating Committee for the ICASE Stepping into Science Project, and the Coordinator for the International Science Award Scheme.
Curricular Rhetoric
Class Teaching and Examinations
A Study of the New Nigerian Science Curriculum

by Abdulla Uba Adamu
Department of Education
Bayoer University, Kano
PMB 3011
Kano State, Nigeria

Introduction
Like most developing countries, Nigeria sees rapid social and economic development through a systematic process of scientific manpower training and education, a view closely connected with the effects of the waves of science education reform movements in other countries of the early 1960s.

After political independence from Britain in 1960, dissatisfaction with the emphases of the then existing West African Examinations Council science curriculum designed in the 1950s set in rapidly in Nigeria. As a consequence, a new National Policy on Education was introduced in Nigeria in 1977 based on a 6-3-3-4 format which allocates six years in primary schools (starting from 1977), three years each for Junior Secondary Schools (from 1982) and Senior Secondary Schools (from 1985), and four years for a standard university degree (from 1988). However, the new policy is generally accepted to have started fully operating from 1982 with the Junior Secondary School phase.

The most distinctive characteristics of the new educational system are its orientation towards technical education in the Junior School, and an introduction of a new post-sputnik science curriculum in the Senior School advocating for a 'process' approach to teaching science subjects. These are all characteristics aimed at making secondary education in Nigeria consistent with self-reliance and national development (Nigeria, 1981).

This paper analyses the new Nigerian Senior Secondary School science curriculum against the background of the interpretation of the curriculum in schools by teachers and the abilities tested by new science examinations of the new system. This should enable judgments to be made about whether the examination encourages the development of abilities which the curriculum developers state should characterise science teaching and learning in Nigeria. The analysis should also provide an insight about the extent to which the new science curriculum could be used as an index for future social and economic development of Nigeria through science curriculum development.

Research Procedures
This paper is structured around the findings of the following research questions:

(1) What are the structural characteristics of the new Nigerian science curriculum?

(2) How are science subjects taught in secondary schools under the new curricular guidelines?

(3) What skills do the examination questions of the new curriculum encourage in children?

Three main data collection and analytical strategies were used in the course of the investigation. The first strategy was the analysis of the distribution of performance objectives in three science curricular guidelines (Biology, Chemistry and Physics) issued by the Nigerian government. This was to determine the emphasis of these curricula in terms of their statements of behavioural objectives for all the three science subjects.

The performance objectives in all the three subjects were analysed at the same time for comparative purposes, as well as to show the curriculum developers' relative expectations for each subject according to the three domains of learning - cognitive, psychomotor and affective. The strategy involved counting all the performance objectives stated for all the topics of the three subjects and categorising them according to the leading words used to state each in the domain that best suits the expectations of the objective.

The second research strategy involved classroom observations of science teaching in four Senior Secondary Schools in Kano State, one of the 21 states of Nigeria. This was done through a specially developed observation schedule (after Eggleston 1975, and Alexander, 1974) as part of the field work carried out for a larger study (Adamu, 1988). The aim of the observations was to determine science teachers' interpretation of the new curriculum in practice. A total of 15 teachers were observed teaching 28 Biology and Physics lessons in four senior classes (SS II, equivalent to Form V in the former system) in each school. The observations lasted six months during which 2455 minutes of classroom interactions between teachers and students were recorded.

Thirdly, using the statement of behavioural objectives in the three science curricular guidelines as a framework, the individual examination questions in theory papers of the newly introduced (June 1988) ordinary level Senior School Certificate Examination (SSCE) were categorised according to the skills and abilities the questions appeared to encourage and test. The analysis of the individual questions and sub-questions of the Nigerian SSCE yielded a picture of the general distribution of skills encouraged by the SSCE.

Key: K = Knowledge  C = Comprehension  A = Application  S = Synthesis

Structure of the Nigerian Science Curriculum

A quite striking feature of the new Nigerian science curriculum is its structure. This radically differs from what was used in the country prior to 1985 - which was actually an examination syllabus (WAEC, 1985). In providing the rationale for the structure of the new curriculum, the performance objectives of each topic in the three science subjects were stated in the three broad categories of cognitive, psychomotor and affective domains of Bloom's Taxonomy of Educational Objectives (Bloom et al, 1956). The analysis indicates that the overall distribution of the performance objectives is not even among the three clusters of objectives, as indicated in Table 1 above.

As Table 1 suggests, most of the performance objectives were stated in the cognitive domain, where 263 of the objectives were stated at the knowledge level. This is followed by 244 comprehension items. These two constituted the largest categories of objectives in the cognitive domain as stated in the Nigerian science curriculum. Fewer objectives were stated in the applications and synthesis levels.

Of all the three subjects, Physics appears to be the most practical science subject in Nigeria, since 38 performance objectives were stated with psychomotor achievement in mind. Chemistry turned out to be more descriptive than Biology because only 17 objectives tested the psychomotor domain as compared to 25 in Biology. This, however, is a reflection of the greater number of stated performance objectives in the Biology curricular guideline.

Classroom Teaching Strategies and Emphases

The second level of analysis of the science curriculum involves classroom observations during the teaching of Biology and Chemistry in four Senior Secondary Schools. This is to determine whether teaching science is consistent with the curriculum developers' expectations.

What makes judgment easier is the explicit statement of the suggested teaching approaches for all the science subjects in the curriculum. As further stated in the Physics curricular guidelines, as an example, teachers are strongly encouraged to employ the student-activity based and inquiry oriented mode of teaching (NERC, 1985).

The results of the six month observations of Biology and Physics teaching in four Senior Schools of Kano State in Table 2 below indicate the extent to which teachers interpret these guidelines during class teaching.

</tbody>
</table>
It is thus significant that the teachers' emphases during Biology and Physics teaching in the observed schools differ markedly from the advocated teaching methodology of the Nigerian science curriculum.

This is because, despite the urging of the science curriculum developers to the teachers to use what the developers see as 'inquiry oriented' techniques, about 54.7% of teaching time for the two science subjects was spent by the teachers expanding an explanation of a topic they started almost the moment they came into the classroom. And in all, about 73.3% of class time was dominated by teacher verbal behaviour. Actual student participation in the lessons accounted for less than 5% of the time spent during the lessons.

Emphasis of the new SSCE Examinations

The two stages of analyses done so far provide a framework around which the structure of the examination questions in the newly introduced SSCE could be better appreciated. The result of categorisation of the individual questions of Biology, Chemistry, and Physics theoretical papers of the SSCE into the learning behaviours encouraged by the question papers are indicated in Table 3 opposite.

Thus, although quite a few of the examination items were written to test comprehension, application and synthesis skills, nevertheless the largest category of skills the SSCE would seem to encourage in Nigerian students is knowledge of basic scientific information.

This is because 47.29% of the individual question items in the new Senior School Certificate Examination, which culminates the innovative nature of the new science curriculum in Nigeria, tended towards asking for items that would yield factual information, rather than testing reasoning skills.

Discussion

The analysis of the Nigerian science curriculum using three broad clusters of objectives (cognitive, psychomotor and affective) revealed a very surprising pattern of distribution. For a curriculum with general orientations towards active student participation, the Nigerian Science curriculum would appear to encourage the behaviours it sets out to eliminate during students' learning of science in Nigeria.

This is because the evidence from Table 1 suggests a prime emphasis towards stressing basic scientific knowledge in the curriculum, followed by comprehension skills. Other traits most commonly associated with learning science, and as declared in the rationale of the curriculum, such as the development of reasoning and psychomotor skills, as well as specific attitudes were either not emphasised, or found to a limited degree.

However, these emphases would seem to be recurrent in cases where attempts are made to make the science curriculum 'pupil oriented' - a character of the newer science curricula, especially in developing countries, where curricular attempts were aimed more at breaking the mould of the traditional world-view.

For instance, in an analysis of the Malaysian Integrated Science curriculum materials whose major intentions were to reduce emphasis on the recall of factual information in favour of encouraging the development of affective, psychomotor and higher order cognitive behaviours, Lewin discovered that despite this intention, "it is surprising to find that 53% of section objectives are specified at the knowledge level of the cognitive behaviour whilst only 18% of general objectives are." (Lewin, 1981)

Generally, the expectation that teachers could implement the curriculum they had had no hand in developing, assumes they are aware of, and agree with, the balance in the cognitive, psychomotor and affective expectations recommended by the science curriculum developers during their teaching. Not many Nigerian science teachers are capable of doing this due to the limited nature of their training. A typical response

Who's Who in Science Education Around the World

1991 Edition

ICASE is compiling this valuable reference book containing profiles on prominent science educators and their work. In order to enhance the value of this reference work, it is important to include prominent women and men in the areas of primary, secondary and tertiary science education in many countries throughout the world. You are invited to recommend individuals for inclusion.

Please send names and addresses to:

The Editor, Who's Who in Science Education, 10 Hawken St, Monash ACT 2904, Australia

8
from a teacher summarises the general situation in Kano State:

"Personally for me there is this question of lack of experience. Sometimes I lag behind as regards the rate at which I go which I know arises because of my lack of teaching experience." (Interview transcript in Adamu, 1988)

Further, many Ministry of Education officials in Kano were not convinced that instructing or requesting science teachers to teach science in a specific way (for example, as suggested in the new science curriculum) would be useful. As a government official stated, there would be quite a few problems:

"... if you recommend a particular technique (of teaching science) to the teachers, it may not be known to the teachers. You have to realise that in Nigeria today, it is not all teachers who are in the classroom who are actually teachers. They don't even have the basic qualification for teaching." (Interview transcript in Adamu, 1988)

But disparity between what the curriculum developer (or administrator) aims at, and what teachers do in the classroom in implementing the same curriculum is emerging as a standard feature of science education reform, in both developing countries (Lewin 1981; Maddock 1981) and interestingly, in some developed countries such as Canada (Aikenhead 1984; Ste-Marie 1982).

For instance the report of various case studies of observations of science teaching in many Canadian schools revealed that senior-year teachers view science as a precise method and as a system of exact numbers, highly organised bodies of information, and specialized terminology. Their concern is to provide students with the notes and with the practice in solving problems that will result in high marks on examinations and allow the student to move through high school to university (Orpwood and Souque, 1984).

Thus in Nigeria, as in some other parts of the world, the predominance of teacher behaviour reflected in Table 2 casts doubts on any science curricular advocacy that invests more learning independence on the students. This is because such suggested science teaching advocacy rarely takes into consideration the educational realities of the schools - lack of qualified teachers, or facilities or both - as well as the school authorities' concern with covering the syllabus guidelines in the shortest time possible before the all important examination; a strategy which is inconsistent with the new science curricular pedagogy.

Finally, for a new curriculum that advocates a revolutionary perception of science teaching with emphasis on the learner, it would seem that the skills derived from the new curriculum and tested in the learner, lean more towards the ability of the student to recall basic scientific knowledge, instead of encouraging the student to display an understanding of science as a function of greater personal awareness and intellectual development consistent with the stated overall aims of the science curriculum.

And yet one of the rationales given for the development of the new science curriculum in Nigeria is to de-emphasise the power of the examination system on curriculum interpretation by both teachers and students. This is, for instance, indicated in a critique of the former science curriculum in Nigeria (WAEC, 1985) by a member of the team that developed the new Physics curriculum who observed that, prior to 1985 when the new curricula were introduced:

"In upper classes of the schools, the topics taught were in obedience to the stipulation of the examination board... No proper scientific skills and attitudes were acquired by the students." (Ivori, 1982)

But although these remarks were aimed at what was considered a redundant curriculum in a rapidly changing society, the same could very well apply to the new science curriculum.

From this, it would seem that the new SSCE was not supportive of the philosophical orientations of the new Nigerian science curriculum. And possibly due to this, teaching science in Kano State Senior Secondary Schools has become rigid, and less imaginative. It also seemed aimed at providing learning experiences directly relevant to enabling the students to pass their examinations.

Conclusions

This study confirms that examinations can exert pressures, albeit hidden, on teachers' interpretation of the curriculum in the classrooms, no matter how innovative the curriculum claims to be. This is significant in the implications it suggests for curriculum reformers and policy makers.

For instance, if a curriculum based on the process/enquiry approach to science teaching is taught didactically, then whatever the students achieve cannot be attributed to the enquiry approach.

This has far reaching consequences. This is because curriculum development in science education usually has strong social and political bases. Consequently science education projects, especially curricular reforms, are expected to result in more people in society knowing more about science and having a better understanding of the nature of scientific work. Often, curriculum development is also expected to encourage more young people to enter scientific and technological occupations. This paper has raised possibilities that the expectations that curriculum development can influence broader social and educational matters in Nigeria may be an uphill task.

Thus it is not enough to merely improve the curriculum by changing its objectives and introducing words with social and developmental dimensions. A whole new range of integrated science curriculum development strategies has to be developed for Nigeria. This should see science education not merely as a list of impressive and politically significant objectives which policy makers and curriculum developers hope will be attained by students, but as a dynamic classroom process which reflects itself both in its statements of intent and in the examination system.

Communique of the 31st Annual Conference
Science Teachers Association of Nigeria
27 August - 1 September 1990

At its 31st Annual Conference, STAN formulated the following recommendations:

- Nigeria should embark on programs designed to achieve scientific literacy for all by the year 2000.
- Computer education should be introduced at all levels of education as soon as possible after necessary planning. In this connection, appropriate curricula should be drawn up, teachers should be trained and the necessary infrastructure and learning materials should be provided.
- Teachers should adopt a humanistic approach to teaching that will make the learning of STM attractive to the learner.
- STM curricula should be reviewed to ensure that they are based on the environment. STM teachers should also draw examples from their local environment. This will help to improve learning and also demystify science. The use of low cost equipment should also be emphasised.
- A well articulated integrated science program should form the foundation for achievement of scientific and technological literacy for all.
- The pre-service preparation of science teachers should be approached with a greater degree of seriousness than in the past. Serving teachers, inspectors and policy makers should be given in-service training so as to update them.
- All university faculties of education are urged to introduce degree programs in integrated science.
- Education research in STM should be directed towards strategies for improving the quality of lesson delivery as well as strategies for improving learning through problem solving.
- Since the primary school is the foundation level of education, the teaching of science at this level should be strengthened. In this connection, selected primary schools should be provided with good science facilities for the study of STM. JETS Clubs should be introduced in primary schools. Furthermore, JETS production centres should be set up in each local government area, where pupils can carry out projects, fabrications and copy technology.
- Specialist teachers should be allowed to teach science in the primary schools.
- Universities should strive to maintain the 60:40 ratio in the admission of candidates into science and non-science courses.
- A survey of the human and material resources required to attain the targets set for the 1990s should be undertaken within the next year.
- Federal and State governments should speed up the procurement, installation and maintenance of equipment for Introductory Technology.

Incentives in the form of inducement allowances should be given to STM teachers.

- To attain scientific literacy for all by the year 2000, STAN should write simple science supplementary readers and produce the same in the three major Nigerian languages.

Learning to Manage our Thinking

by Douglas M Hill and Juhani E Tuovinen
Charles Sturt University - Riverina
Wagga Wagga, Australia

Anderson (1983) distinguished between knowing that (declarative knowledge) and knowing how (procedural knowledge) and suggested that both types of knowledge interacted in intellectual functioning. For example, domain specific knowledge and general thinking skills or cognitive strategies are needed to solve specific problems. Cognitive strategies are general intellectual skills such as "working out alternatives, judging the likelihood of success, reflecting on the meaning of new knowledge, searching out associations between the elements of knowledge, generalising and deducing." (White, 1988, p40). They also include other powerful procedures which are learned, such as:

"... keeping (one's) mind on the task, determining the goal, reflecting, weighing alternatives, and so on. These cognitive strategies determine the quality of performance in learning, in problem-solving and in day-to-day living. Of course, they operate in conjunction with specific knowledge there has to be a task, some information to absorb, a problem to solve, on which the strategies can be applied." (White, 1988, p83)

Problem-simplification (reduction) is a strategy which has been widely used in science. Mendel's seminal work on genetics provides a good example. Instead of trying to follow the inheritance of multiple characteristics be focused on single factors to identify a pattern. The same strategy was employed by Le Bel in developing the concept of structural isomers. He investigated the simplest organic compounds which existed in two forms and built models to show how such differences might be explained in terms of the possible spatial arrangements of components. Crick and Watson used similar techniques in deciphering the structure of DNA.

In our haste we often fail to draw students' attention to the way in which scientists have used this reductionist strategy, and its limitations. It provides the rationale for the development of skill in controlling variables in science at the secondary level.

The teacher training workshop activities which follow are designed to develop the simplification strategy. This strategy involves simplifying a problem situation, finding a pattern in the way the simplified problem can be solved and then trying out that pattern with the problem in its complex form. The workshop's set of three tasks can be run as follows:

Task 1 - 15 minutes
Refer to Task 1 on page 12. Few, if any, will be successful in the given time. The tutor should raise the issue of looking for a suitable strategy to tackle this type of problem - simplification will usually be suggested.

Task 2 - 20 minutes or more
Refer to Task 2 on page 13. The tutor should check to see if the simplification strategy is being used - if not, the tutor could ask about the similarities between tasks 1 and 2.

Task 3 - 40 minutes
The tutor sets the task of designing a problem which uses the simplification strategy. It may be framed in the LEGO TC context, for example to build a computer controlled merry-go-round. In such a problem, the development of modular programming technique would be developed, where a large complex problem is broken down into smaller manageable tasks which may be completed in a suitable sequence to carry out the larger enterprise. This could lead to the solution of a complex LOGO problem by building up the total solution from a number of simpler modules or procedures.

A complex problem could be considered, such as the behaviour of pourable solids when they pass through a suitable funnel and form a pile on a flat, level surface. A range of solids could be investigated including sand, tapioca, split peas, coffee crystals, table sugar, flour, rice, talcum powder, fine sawdust, soap flakes, polystyrene beads, etc. To solve this problem requires the use of the simplification strategy in the process of making decisions about what variables will be manipulated and which will be controlled.

Simplification strategies can also be developed by using suitable computer programs. A good example for primary and lower secondary levels is the Collamore Castle: Strategies for Problem Solving (Bradshaw & Boesch & Co, 1987). It is designed to cultivate strategies such as simplification and working backwards, and forms a useful illustrative and developmental component of a course dealing with problem solving techniques in science.

Australia
Task 1

Shade in 4 of the 8 small squares

Cut out the 8 small squares

Turn the uncut grid of larger squares horizontally and place one of the shaded squares on each of the 4 squares on the left-hand side of the playing space (9 larger squares)

Place one of the unshaded squares on each of the 4 squares on the right-hand side of the playing space

You are now ready to play! The aim of the game is to get the shaded and unshaded squares to the opposite end of the playing space. Here are the rules:

- Squares can only move in one direction - shaded to the right, unshaded to the left

- Two squares cannot occupy the same playing space

- One square may jump another if there is an empty space on the other side

- Only one small square can be moved at a time
Task 2

Cut out the 5 squares of different sizes

Turn the remaining column of 3 large squares horizontally and place the largest square on the first left-hand playing space

Place the second largest square on top of the largest, and so on until there is a 'tower' of 5 squares. You are now ready to play the game!

The aim of the game is to transfer the tower from one end of the playing space to the other in as few moves as possible

The rules are that only one square can be moved at a time; and a smaller square must always be on top of a larger one

Find out the minimum number of moves needed to transfer the tower from end to end
Greek Primary Science Education
New Textbooks and the National Curriculum

by Dr Zoe Zoni Kavogi, Research Student
King's College London, University of London

Educational changes in Greece have been limited to the 'extrinsic re-arrangement' of Education (legislation, establishment of new types of schools, structure of schools, etc). They have not concentrated on the core of educational reality (intrinsic re-arrangement) - methodology, curriculum, books, teacher-training, etc. (Terzis, 1981) The new Greek National Curriculum includes four basic structural elements (Xohellis, 1981):

- Objective didactic targets
- Content
- Methods of teaching
- Testing

Changes in all the above elements may influence the qualitative results of classwork and, later on, Greek education as a whole.

Such viewpoints arose on the horizon of Greek Education at the time of the 'Educational Renaissance of 1976'. However, daily educational practice has shown that the ideology of technocracy exists - a new kind of control being established in education, and narrow limits on teachers' involvement.

The new National Curriculum was introduced gradually, starting in 1982, and applied by new textbooks. The new textbooks, which have been gradually introduced for the first time in primary education, cover the areas of Greek Language, Mathematics, Study of the Environment, Discovering the Natural World, and Social and Political Education.Already, there is considerable experience in their use and application in schools.

The new National Curriculum was written by the Department of Primary Education of the Pedagogic Institute - an important department of the Ministry of Education.

It was in 1964-65 that the first steps were taken to change educational policy and impose a new National Curriculum (Kazamias, 1983), only to be stopped by the 1967 dictatorship. Years later, a new attempt to change educational policy began - the 'Educational Renaissance of 1976'. However, it was not until 1982 that this policy was implemented in schools through a new National Curriculum and new textbooks.

The 1982 National Curriculum

The new law for the structure and function of Primary and Secondary Education is known as 'anti-309'. It is based on Bruner's theory for the structure of knowledge, and considers this theory to be the only acceptable one. The methodology for organising knowledge in the National Curriculum and new textbooks follows the prototypes of the USA and European countries but, while it emphasises the detailed planning of daily lessons, it ignores many other problems including social differences, school failure, the short time pupils spend in school - 25 to 30 hours per week - because of lack of buildings, etc.

The New Textbooks for Primary Education

These include programmed material for learning and methods of teaching in detail (quality, quantity, didactic actions and student activities, available time, evaluation of the success of learning targets, etc).

There is also a teacher's book for each subject and grade - a resource which all teachers had been waiting for. Each teacher's and pupil's book is the result of the work of groups of specialists - members of the Pedagogic Institute - organised under the guidance of the Ministry of Education. The new books include what teachers need to know and what pupils need to learn. For instance, the book for the pupil contains all student activities, exercises and questions in a pre-defined format. The book is a part of the didactic operation which is suggested by the teacher's book. (Pedagogic Institute, Ministry of Education, 1982). Demaras (1979) contends that "under the excuse of a qualitative improvement of the school book and the protection of pupils and parents from the high-handed acts of some editors, as also the excuse of student's release for the purpose of University and College books, the total control of educational books is under the National Authority". Hence, a common and compulsory book is imposed on all students at no cost to them. Its use is compulsory and exclusive if we bear in mind the prohibition against introducing other books and educational aids in schools (Pedagogic Institute, 1984).

Education legislation obliges teachers to comply with the guidelines of the Pedagogic Institute as expressed in the teacher's handbook.

Teachers' opinions are reflected in the research of M Danilidou (1984:87). To a certain extent the textbooks help them save time in preparing to teach. However, on many occasions they have found themselves incompletely prepared or lacking in knowledge, time or confidence to handle a new subject. Members of the Pedagogic Institute who have designed and written these textbooks claim that "they aim to protect the teacher from sketchy improvisation and insecurity" (Pedagogic Institute 1983:6).

Study of Environment

The new textbooks (four pupil's and teacher's texts for grades 1 to 4) should be examined from three different viewpoints:

1. From the viewpoint of their content

The textbook content in relation to the pupil's level of knowledge is critical. With regard to the scientific content there has been an improvement in the textbooks for primary
science education, and therefore are quite adequate, progressive and modern compared to the previous ones. However, they maintain similar frames of values and prototypes of behaviour.

Both "Study of Environment" and "Discovering the Natural World" have an integrated science structure. Both contain Physics, Chemistry, Biology, Environmental Studies, Geography, etc. Systematic educational research is required so that the level, the extension and the quality of the changes can be defined.

2. From the viewpoint of the new didactic methodology which is suggested

Research is indispensable in this direction. The first important study of both the above mentioned viewpoints has been done by M Danilidiou for the textbook 'Study of the Environment' for the first grade of Primary School. Included in it is an evaluation by twenty teachers. Having assessed content, vocabulary and terminology, pictures, etc. of the book, they have generally concluded that the content is more scientific and progressive, and that the suggested methodology seems to be accepted by many teachers (1984: 45).

3. From the viewpoint of the organisation of daily teaching practice as introduced by the new textbooks

More practical work is needed but is practically impossible because of lack of time, equipment, organisation of classroom, and teacher training. Although a seemingly neutral condition of the teaching operation is presented, in reality both the teaching process and pupil's learning are controlled by the predefined and detailed operations in the textbooks, which must be followed by both teachers and pupils.

The texts are full of encyclopaedic knowledge. They contain modern aspects of life, pollution of the environment, development of human conditions of life, peace, etc.

Some examples serve to illustrate what pupils learn about their world as they study this subject. In the chapter on 'family', children learn that man and woman are married for procreation of mankind without any personal choice. This idea is supported by the parallel presentation of animals' families. A similar example occurs in the chapter 'how people communicate'; an analogy is suggested - animals also communicate. The teacher's guide refers to the kinds of communications among deaf and mute people, and people who speak different languages. The authors do not consider human thinking as a higher mental operation which does not exist in animals. Furthermore, they do not consider that deaf and mute people, or speakers of different languages think during communication. In another chapter we find that all living beings have the same needs - food, water, housing and sleep; hence children are not able to understand the existence of other basic needs such as education and peace, nor that humans think at higher levels than animals. Also the topic concerning the destruction of nature from pollution is not presented seriously and in depth.

Finally, pupils can become confused about their surrounding world because of the learning approach used. Children have no 'live' contact with the object or situation they learn about, even though this is necessary in view of their young age. There is a lack of suitable equipment in schools (garden with flowers and animals, laboratory of physics and arts, viewing hall, etc). Opportunities for learning outside the classroom do not exist. There are pictures in the textbook and a teacher relies upon these pictures to supplement the written text. Observations, comparisons and associations are made by the children on the basis of the pictures - a mental exercise; first hand, accurate knowledge of the environment is not undertaken. Many educators and parents object to this approach to knowledge, where textbooks look like 'comics'.

Discovering the Natural World

The Pedagogic Institute holds the view that a critical analysis of these new textbooks - pupil's and teacher's texts for 5th and 6th grades - at the time of reception is untimely, since the books have not been evaluated in practical use. The specialists of the Pedagogic Institute advise that teachers use the textbook in the suggested way and make criticisms later on. This means that the responsibility for obtaining good results from the use of the new books is left on the shoulders of teachers.

Conferences and discussions within the Department of Education, the School of Postgraduate Studies for Primary Teachers and other educational bodies contend that research for evaluation and improvement of this book is imperative, and that special training is needed to enable teachers to cope with the problems in the use of the book, particularly in the area of scientific knowledge rather than the organisation and control of classroom activities. Experience so far is indicating that this textbook does not work in school practice.

Many concerns from teachers, parents and students have been raised about the content of these textbooks. Considerable scientific knowledge is required by teachers, but no inservice help is provided. Primary teachers' lack of scientific knowledge in the areas of Physics, Chemistry and Biology handicaps them as they try to teach the content in the right way. Both texts include too much material. A prescribed lesson for one teaching hour is often impossible to complete in one hour. The teacher often needs twice that time. In the teacher's text one finds only the organisation of the teaching process, without the additional information needed by teachers. Teachers need considerable preparation information and background explanations in order to teach a good lesson. They also need suitable equipment and material for the experiments.

Although both textbooks are attractive, many chapters do not follow a meaningful sequence. Teachers often are obliged to give more information for a chapter to be comprehended. Many mistakes can be found in the expression and formulation of physical meanings. The new textbooks include simple and attractive experiments, but these require suitable equipment and their formulation is not simple, so pupils are often not able to carry them out. Another disadvantage is that there is a great number of events for every lesson, all of which must be carried out during one lesson - an impossible task. Another negative point is the lack of writing space for pupils' observations and data during an event or experiment. These would give teachers the
opportunity to understand if pupils have gained anything during their experimenting, and to criticise their answers. The teaching process could then be improved.

Textbooks and Parents

The Ministry of Education has abolished home study for pupils at primary school. Study at home refers to various activities involving the collection of information from sources such as books, magazines, etc. From a young age, children learn to search, to express ideas correctly, and to conceive basic meanings of science - an important foundation for future learning.

The Pedagogic Institute advises teachers to rarely give, as homework, a passage from the textbook to be learnt by heart and 1-2 sentences for spelling (Pedagogic Institute 1984). This type of homework is useless and boring, is not accepted by teachers and pupils, and has a negative influence on children's learning, in particular the quality of their learning, their reaction to learning, and the availability of free time to be used in creative activities.

On the other hand, the abolition of homework takes away parents' opportunity to contribute to children's learning and to improve it or to correct children's mistakes. Parents have no chance to assess the quality of school education and, if necessary, to request improvement.

Many parents and teachers claim that the education offered by Greek schools is not appropriate for all pupils. The application of the new textbooks and National Curriculum, especially in the subjects of Mathematics, Discovering the Natural World, Study of the Environment, and Greek Language, has resulted in a great number of weak pupils. This is compounded by the less time pupils remain in school; teachers do not have enough time for explanations and parents need to offer further help at home through private paid lessons.

The Results

The content renewal of the subjects 'Study of Environment' and 'Discovering the Natural World' has produced the following results in school practice:

The time for teaching has not increased in proportion to the increased amount of content. This problem becomes larger in the case of certain types of schools. In remote rural areas in Greece there are (1) primary schools of six grades in one class, (2) primary schools of six grades in three classes where every class includes pupils of two grades. In these types of Primary Schools, the time available for each grade is shorter than in the usual Primary School class.

A trial period did not precede the wide application of the new National Curriculum. The benefits of pilot studies would have included improving the content of daily lessons, methodology, and number of exercises, and would have indicated the need for an additional hour of teaching time in order to complete the content in each lesson. As it is now, pupils are flooded every day with a large amount of knowledge - too much for them to assimilate. The fact that many lessons do not follow a logical sequence does not help either. If the teacher follows the guidance of the teacher's textbook, he/she ought to use some time from other activities (music, athletics, arts) to complete the lesson. In summary, these are the outcomes:

(1) The teaching rhythm of the two subjects is intensive producing anxiety in teachers and pupils, cognitive gaps and a lack of real learning according to teachers' reports. (2) Although the content theoretically corresponds to an ordinary pupil, in practice only high ability pupils can complete all the exercises; many pupils do not cope comfortably. (3) Serious research and evaluation of the new National Curriculum in Primary Science Education must be undertaken.

Report on the 3rd Annual General Meeting
Galician Science Teachers Association
by Frutos Fernández González
President, ENCIGA

300 Galician science teachers attended the third Annual General Meeting of ENCIGA (Galician Science Teachers Association), held at the F.P. Institute of "A Pinguela" in Monforte de Lemos, Galicia, Spain, 8-10 November 1990.

The broad and diverse program involved more than 40 talks, workshops, experimental demonstrations, as well as poster sessions on physics, chemistry, natural sciences, mathematics and integrated science.

A subject which raised great interest was that of teacher training, since we are undergoing the introduction of a new educational system in Spain. Dominguez Castilleiras, Garcia Rodeja, Jimenez Aleixandre and Lorenzo Barral addressed the topic of initial training of future science teachers, and Grafa Carrodegus and Fernandez Fonticoba addressed the topic of inservice training of teachers.

Another recurring theme was about using students' social and cultural environment to increase student motivation and to enhance the social and cultural aspects of Science. Adela Vázquez talked about the importance of the environment as a material resource in developing a science curriculum, and shared her experiences, including activities with her students in hatcheries, greenhouses and hydroelectric stations.

Other sessions included Environmental Science Education by Tajes Gómez, teacher of IESP at La Coruña and the science staff of "Otero Pedrayo" High School, Orense; Astronomy by teachers of the group Antares; and Assessment.

The meeting also attracted many mathematics teachers, and there were a number of sessions focusing on mathematics topics. The Lua group from Lugo presented a session which exemplified mathematics games as hands-on experiences in teaching materials. Other topics addressed were the cultural value of mathematics (mathematics for all) by Antón Labrada; and assessment.

José María Pérez, nationally recognised expert in the computerisation of science teaching, spoke about semantic fields, semantic trees, automation and grammars in physics language, and about the computerisation of a syllabus.

The exhibition "Mathematical Horizons" which was featured throughout the 3 day meeting, will also tour three cities of Galicia. This event, organised by ENCIGA, will be visited by over 10000 students. The broad program which included social events, excursions, and visits to museums ensured that the Annual General Meeting was an enjoyable event - we're looking forward to the next meeting.

New York University
Science Education
Summer School
London, UK

Participants will visit British schools, meet with teachers and students, learn about current innovations in science and technology education, and complete a 6 credit graduate course in science education at the same time. This unique residential course takes place July 1-19 at the Roehampton Institute, Wimbledon, London, with senior faculty from both Britain and the United States providing the instruction.

For further information and application forms, contact Professor Graham Orwood, 200 East Building, New York University, New York, NY 10003, USA.

Canadians may write to 131 Bloor Street West, Suite 200, Box 326, Toronto, Ontario, Canada M5S 1R8.

Have you entered for a 1991 CASTME Award?

The awards of the Commonwealth Association of Science Technology and Mathematics Educators (CASTME) are intended to encourage teaching of the social aspects of science, technology and mathematics, with particular reference to developing countries of the Commonwealth. The scope of the awards is interpreted broadly, and social aspects includes the relevance of science, technology and mathematics curricula to local needs and conditions, and to the impact of technology, industry and agriculture on the local community. For entry forms, contact your local British Council office, or The British Council, 10 Spring Gardens, London SW1A 2BN.
Sustainable development - the new world agenda

Of concern to all of us are the pressing environmental and economic opportunities and challenges facing us today and influencing future generations. Sustainable development is a mind set which developed during the latter part of the last decade. It is a means by which our environment can be protected, our economy can grow and our society can be enhanced. Sustainable development depends on active involvement and participation by all sectors of the economy and society. As pro-active participants, citizens find solutions to problems, identify opportunities and mould the type of society that meets our needs and those of future generations.

The mandate of the World '90 Congress, held in Winnipeg, was multi-faceted. The conference was designed to attract a multi-sectoral audience representing government, industry, business, education, the general public, and youth. The congress was provincial, national and international in scope.

Curriculum model for sustainable development education

Education is the key to the success of a sustainable development agenda. To this end, the pre-conference focused on examining the application of sustainable development in formal curriculum. The pre-conference proceedings document will outline a curriculum model embracing sustainable development strategies as an integral component of K-12 education. The Canadian Association for Science Education (CASE)

President, Paul Barron, served as host/facilitator for the pre-conference event. Milton McClaren addressed the "state of the art of sustainable development in Canada". Joseph Sanders, President of Southern California Association of Science Specialists, presented conceptual dimensions of an integrated environmental education model. Anthea Maton presented the NSTA Scope, Sequence and Coordination Project - a restructuring of science education in the United States. Frank Allan, Curriculum Coordinator for the Ottawa Board of Education, provided an insight into "Global environmental issues and the school curriculum". The ten presentations provided substance for the Breakaway/Seminar Sessions where the "real work" of the pre-conference was done.

International scope of pre-conference

The pre-conference proceedings are being edited by Dennis Chisman, ICASE Honorary Treasurer, and Dr Jack Holbrook, ICASE Executive Secretary. The planning committee feels that the writing and editing by ICASE officers will help to eliminate a provincial or national bias.

Main Congress Event

The main congress event was a two and a half day conference offering to 2800 delegates, some 230 lectures, workshop sessions, forums and debates. The purpose was to provide an arena for information sharing, discussion, and cross-pollination of ideas. At the conclusion of each conference day, delegates were afforded an opportunity to participate in stakeholders sessions, which added suggestions, concerns, and resolutions to the fabric of the Manitoba Protocol, the main conference proceedings document.

International contributions to Manitoba Protocol

A truly national and international cast contributed to the main congress event. Dr Ghafoor-Ghaznawi, Chief of the Unesco Environmental Education Section, Paris, provided an overview of "Environmental education from 1977-1982". Professor Chris Baines of Birmingham, UK, examined a "Landscape full of life".

Robert Bateman, famous Canadian wildlife artist and conservationist, reminded us that "The best things in life aren't free anymore". Dr Amory Lovins of Colorado, USA, addressed the topic "Energy efficiency, environment and development". Ralph Winrich, NASA Aerospace Specialist from Ohio, USA, focused on "Global environmental concerns".

Dr Anatoly Shidlovsky, Director of the Institute for Electrodynamics in the Ukraine, explored the topic of "How ecological and economic factors influence energy resource development in the Ukraine". Dr Edgar Faust, Manager, Strategies Planning, Fungicides/Insecticides, Frankfurt, Germany, discussed "Staying alive in the 21st century".

World '90 was an event at the leading edge of a revolution in thought regarding our environment and future economic development. Its success will not be measured by the event but rather by those deliberations and events which will be facilitated by the Manitoba meeting.
Education for All
Meeting Basic Learning Needs
by Sheila M Haggis
Paris, France

It is now a year since the World Conference on Education for All was held in Jomtien, Thailand. Jointly sponsored by Unesco, the United Nations Development Program, Unicef and the World Bank, as well as 18 co-sponsors (governments and organisations), the Conference was spectacular by any standard. There were some 1500 participants, including delegates from 155 governments, and from a number of major governmental organisations. It was addressed by Heads of State and Ministers of Education as well as by many key policy-makers and specialists in education and other sectors of social and economic life.

At its closing session on 9 March, the Conference adopted by acclamation a "World Declaration on Education for All" and a "Framework for Action to Meet Basic Learning Needs". The texts were the product of a wide and systematic process of consultation during the year before the Conference, which included no less than 9 regional consultations. The Declaration states that every person - child, youth, adult - should benefit from educational opportunities to meet their basic learning needs. The Framework for Action is designed to help countries develop their own specific plans of action to meet this goal.

The "basic learning needs" as outlined at Jomtien call for educational opportunities not only to read and write but also to develop basic learning skills such as numeracy, problem solving and oral expression. There is, moreover, the need to acquire learning content - not only knowledge, but also the attitudes and values without which human beings can neither survive and live and work in dignity, nor make informed decisions and continue learning. It is here that scientific literacy, health and population education are indispensable. A series of Round Tables on these themes discussed the importance of broadening the concept of basic education to cover the corresponding content areas and the relevant skills. They affirmed that science and technology education must form part of education for all.

The Jomtien Conference has an important message for ICASE and for associations for science education world-wide. It is imperative for science and technology to form part of basic education in all countries and for the methodology used to be a practical one based on the learners' environment and placing a premium on their curiosity and creativity. For this to become a reality, teachers need support systems. There must be opportunities for them to communicate with colleagues - and what better forum for this than a professional association! There is also a need for their associations to act in concert as pressure groups to ensure that the curricula, the examinations and the text-books do not become fossilised, for then the very notion of "education for change" will wither.

The Conference also focused attention on the need for a "gravitational movement" causing the whole educational system to become more aware of and more sensitive to the ways in which scientific and technological innovations are changing the nature of work. As a consequence, workers need new skills, and the education and training they receive must be transformed. School curricula are often out of touch with the real needs of the world of work. Closer links with industry, the use of educational technology in more appropriate ways, and greater emphasis on design and technology in the curriculum all form part of the "sea change" that is needed.

Follow-up activities to Jomtien have already begun and will continue throughout the world. Non-governmental organisations of many kinds are involved. Associations for science and technology education must be particularly vigilant in ensuring that their voice is heard and that their members are actively involved in the sweeping changes in education which, hopefully, will follow the implementation of the Jomtien Declaration.

---

Wanted: Acid Rain Partners For Project TARP-IT
by Michael Demchik

The co-directors of Project TARP-IT (The Acid Rain Project - International Twinning), Dr Michael J Demchik, Chemistry-Physics teacher, Jefferson High School, West Virginia and Dr Neil McKenzie of Nottingham Polytechnic, UK, are currently looking for further schools to participate in a month-long acid rain investigation. The earliest start is likely to be April or May this year with follow-up in October or November.

We have run three acid rain programs since 1988 involving schools in New Jersey, West Virginia, Florida and UK with excellent exchanges of information between participating students. This year we propose a two pronged strategy. In the first stage, students collect acid rain for one month according to an agreed methodology which we have tested in previous programs. Guidelines will be provided to help achieve common standards and methodology. In the second stage schools will pursue an extended investigation of the effects of different patterns of acid precipitation on plant growth. The rain data obtained in the first stage will be used to produce lab simulations of a range of climates under which the growth of wheat can be studied. In this way, the importance of acid rain on cereal production can be explored. Schools can participate in one or both stages. We expect to work
at two levels. Level 1 is for junior high/middle school students typically aged 12-14 years. Level 2 is aimed at 15-18 year old high school students. The benefits of Project TARP-IT are many, for example: multiple packets of data received from schools thousands of miles apart; valuable experience of collaboration in an international scientific research project; increased competence in carrying out reliable extended experimental research.

Interested teachers in the USA may contact Michael Demchik, Box 1420, Shepherdstown, West Virginia 25443, Tel. 304-267-9736 (home), Tel. 304-725-8491 (school). Teachers in the UK may contact Neil McKenzie, Department of Chemistry and Physics, Nottingham Polytechnic, Clifton Lane, Nottingham NG11 8NS, Tel. 0602-418418, extension 3184.

Annual Science for Educators Seminar

18-20 April 1991

Educators visiting Canada from member associations of ICASE are invited to participate in this annual seminar program which is spread over three days at the Chalk River Nuclear Laboratories in Ontario, Canada. While some sessions focus on nuclear reactor technology, including the Canadian CANU reactor, most sessions relate to areas that are at the basis of many different science and technology activities of our day.

On Day 1, teachers are given the opportunity to share an afternoon with a researcher. Here, teachers enter a laboratory, often on a one-to-one basis, and learn first hand what research is all about, and the personal views of the researchers and what motivates them. Teachers are able to select the disciplines of their choice, subject to space restrictions. The program on Days 2 and 3 consists of opening and closing plenary sessions, lectures and laboratory visits. This year’s seminar features sessions on fusion, new types of fission reactors, nuclear waste, corrosion, an environmental field trip, cancer and health sciences research, basic condensed matter and nuclear physics, glassblowing for science research, accelerators for both basic science and industrial use, and many others. The seminar is aimed at all educators - not just science teachers. AECL Research believes that it is important for all educators to become acquainted with current science and technology issues at the grass roots level. Teachers travelling to Canada and interested in participating in this seminar, are invited to write to Dr Malcolm Harvey, Director of Physics, AECL Research, Chalk River Laboratories, Chalk River Ontario, Canada K0J 1J0, Fax (613) 584-4024. Visitors are of course subject to security scrutiny associated with access to a Canadian nuclear laboratory.
The Harare Generator
University of Zimbabwe
21 January - 2 February 1991

by Sue Dale Tunnicliffe
Member of the Resource Team

The Harare Generator, a major initiative of the Committee on Teaching Science of the International Council of Scientific Unions (ICSU-CTS), was planned as a follow-on to the successful Bangalore Conference on "Science and Technology Education and Future Human Needs" which involved over 300 participants from all regions of the world and which examined ways in which science and technology education can be made more relevant to the needs of society in eight areas of concern. Although the books published as a result of the Bangalore Conference had made a major contribution to shaping science education, many felt that there was a need to directly involve teachers in applying the contents to local teaching situations. The Harare Generator was planned as an event to actively involve teachers and teacher educators in the production of tangible products.

Keynote presentations included: What was the Bangalore Conference?; Low Cost Equipment; The School Technology Movement; Audiovisual Techniques; Preparing Project Proposals.

A series of Sundown Seminars, to which local teachers were also invited, included: The microcomputer in education; Developments in primary school science; Science and technology in society; Popular science publishing; and Science education beyond the classroom.

Menu sessions provided yet another feature of the Generator, where Sundown Seminar speakers and Parallel Study Group leaders presented a synopsis of their sessions in order to help participants select the Project Planning Group or Parallel Study Group they wished to attend.

Project Planning Groups included: (1) Think and do, primary science; (2) Low cost practical exams; (3) Tree planting day; (4) Low cost electronics; (5) Microcomputer lab; (6) Computer simulations; (7) University/school liaison; (8) Aerial photography; (9) Discussion techniques; (10) The great egg race; (11) Expeditions; (12) Problem solving and decision making; (13) Games; (14) Using case studies; (15) Collecting and interpreting data; (16) Global laboratory; (17) School technology; and (18) Popular publishing.

A number of resource people from African countries, UK and USA were invited to assist with these Project Planning Groups. Each participant selected two Project Planning Groups, analysed the ideas presented by the speakers, and adapted them to the African teaching situation. They planned a program of work which was trialled with children in a school. The second phase of the generator was to produce teaching materials, and to script a short video of their school presentation so that this could be used throughout Africa. Resource people were encouraged to leave their groups so that the end product was the participants' work and not that of the resource people.

As the Generator came to an end, groups were suggesting possible sources of funding to enable further action to develop. For example, the primary science group proposed that a primary science newsletter, similar to *Fied Crow* in Kenya, be produced for teachers and children in cartoon strip form. This could be the African link with the ICASE Stepping into Science Project.

For further information about the Harare Generator and its outcomes, write to:

Mike Robson, Harare Generator Organising Committee, Faculty of Science, University of Zimbabwe, Box MP167, Harare, Zimbabwe

RSC Celebrates 150th Year

ICASE congratulates the Royal Society of Chemistry, UK on the occasion of its 150th anniversary. Today, the Society is active in a wide range of educational activities, for example:

The RSC produces a variety of careers information literature aimed at pupils from the age of 13 upwards.

The Society administers financial support to Chemistry Teachers Centres or to individual chemistry teachers who have specific projects they want to get started.

*Education in Chemistry* is the only journal which covers chemical education from secondary schools to universities. It provides a forum for school curriculum discussions.

By subscription to the Schools Publication Service, schools receive quality resource material generated from around the world and relevant to the teaching of chemistry. In addition to *Education in Chemistry*, it includes *Chemistry in Action* from Ireland, *Chem matters* from the USA, and *Chem 13 News* from Canada.

The RSC runs a number of awareness raising, one day symposia, focusing on topical issues relating to the teaching of chemistry in schools.

The Society's successful Industry Study Tours bring industrialists and educationalists together. Over a short residential period, teachers see chemical processes in action and are able to discuss the nature of industrial problems with those employed in the field. Teachers often produce curriculum materials suitable for use in the classroom.

The RSC hosts Chemistry Project Weeks, which bring together sixth form chemistry students, their teachers, higher education lecturers and industrial scientists, enabling students to tackle real industrial problems.

For more information on these and other projects, contact Dr A D Ashmore, Education Department, The Royal Society of Chemistry, Burlington House, Piccadilly, London W1V 0BN, UK
The Power of Cooperative Learning

by Alan Colburn & John E Penick

"Where's the teacher?" asks the school's secretary as she enters the classroom. She had instinctively looked to the front of the room.

"Over there," says a student pointing to the teacher in the midst of a group of four students. The secretary sees other small clusters of students dispersed throughout the room. Students are talking quietly, some tutoring each other, while others are working out a presentation strategy. Almost everyone seems to be purposefully involved in something.

In this type of classroom - the cooperatively structured classroom - small groups of students work together toward a common goal. The cooperative classroom offers distinct contrasts with the common competitive and individually structured classrooms. In contrast, in a competitively structured classroom, students are working against one another. One student can only "win" if another "loses". The individually structured classroom features students working by themselves - independent of what happens to their classmates.

All three provide effective teaching, but cooperative learning offers several unique advantages.

Cooperative learning represents powerful classroom instructional strategies that are defensible from both philosophical and extensive research bases. Indeed, humans have survived this long because of our ability to cooperate for the good of the group. Johnson et al (1984) point out that:

"At a time when being able to interact effectively with other people is so vital in marriages, in families, on jobs, and in committees, schools insist that students don't talk to each other, don't work together, don't pay attention to or care about the work of other students - students are encouraged not to care about other students' learning in the classroom." (p 7)

Learning in cooperative small groups builds constructive relationships, overcomes prejudices, and prevents behaviours like delinquency and drug abuse. Cooperative learning builds positive relationships between difficult children and others with more constructive behaviours.

However, cooperative learning is not merely students working in groups. The essential feature of cooperative learning is that the success of one student helps other students to be successful (Slavin, 1987).

In a cooperative learning group, students are concerned about the performance of all the group members. At the same time, students are held individually accountable for their learning and given feedback on their performance. This helps other group members know who to help and encourage.

**Figure 1**

**Characteristics of Cooperative and Traditional Learning Groups**

<table>
<thead>
<tr>
<th>Cooperative Learning Groups</th>
<th>Traditional Learning Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive interdependence</td>
<td>No interdependence</td>
</tr>
<tr>
<td>Individual accountability</td>
<td>No individual accountability</td>
</tr>
<tr>
<td>Heterogeneous</td>
<td>Homogeneous</td>
</tr>
<tr>
<td>Shared leadership</td>
<td>One appointed leader</td>
</tr>
<tr>
<td>Shared responsibility for each other</td>
<td>Responsibility only for self</td>
</tr>
<tr>
<td>Task and group maintenance emphasised</td>
<td>Only task emphasised</td>
</tr>
<tr>
<td>Social skills directly taught</td>
<td>Social skills assumed and ignored</td>
</tr>
<tr>
<td>Teacher observes and intervenes</td>
<td>Teacher ignores group functioning</td>
</tr>
<tr>
<td>Groups process their effectiveness</td>
<td>No group processing</td>
</tr>
</tbody>
</table>
These two features of cooperative learning groups, positive interdependence among members and individual accountability, contrasts with more traditional learning groups in which there is no interdependence, individual accountability, or incentive for students to work together (see Figure 1).

Aronson’s (1978) Jigsaw method provides one example of a cooperatively structured classroom. Students in a biology class are assigned to three member teams to learn about digestion. The academic material has been broken down into sections about digestion of proteins, carbohydrates, and lipids—each team member is responsible for learning only one section. Next, members of different teams who studied the same topic (e.g., protein digestion), meet in ‘expert groups’ to discuss their section. Then the students return to their original teams and teach their teammates about their section. The only way students can learn about sections other than their own, is to work with their teammates. Later, all of the students will have to demonstrate their knowledge of digestion via a teacher-generated quiz, a practical examination, or project work. Although every student’s individual scores are recorded, each member of a team can receive extra-credit ‘bonus’ points if the group’s average score is above 85%.

Notice that the students are dependent upon one another. This is a hallmark of real cooperative learning. At the same time, each student is still held accountable for all of the requisite learning. Additionally, the teacher’s role would include not only helping students learn about digestion, but how to teach others while helping the students develop social skills for working together.

Research about cooperative learning and academic achievement

Slavin (1987) summarises the results of 63 studies on the achievement effects of cooperative learning. Fifty seven percent of the studies found significantly greater achievement for cooperative groups over control groups; 41% found no differences. Johnson et al’s 1984 meta-analyses of 122 studies showed that cooperatively structured learning experiences promote higher student achievement than other ways of classroom structuring.

To produce increased achievement there should be some sort of group reward such as recognition, extra credit or certificates (Good & Brophy, 1987). Slavin (1987) suggests that when the group’s job is to be sure that every group member has learned something, it is in the interest of every member to spend time explaining concepts to other group members.

He points out that other studies have consistently found that the students who gain the most from cooperative work are those who give and receive the most elaborate explanations.

Good & Brophy (1987) mention the importance of methods that ensure individual accountability of group members. No study in which group members work together solely to produce a single worksheet or group product has yielded positive achievement affects.

In these situations, there is little incentive for the more able group members to explain things or to ask the opinions of the less able members, or for less able members to seek assistance.

In a study of specific factors that contribute most to successful implementation of cooperative learning strategies, Prescott (1990) found that elementary teachers selected ‘reward system’ more than any other factor. Among secondary teachers, only ‘teaching/management skills’ was selected more often.

ICASE AWARD SCHEME
for outstanding contributions to international science education

ICASE Distinguished Service Award
This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations

ICASE Regional Service Award
This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

ICASE Association Award
This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Contact Dr Jack Holbrook, Executive Secretary ICASE
Royal Society of Chemistry, Burlington House, Piccadilly, London W1V 0BN, UK
Research about cooperative learning and social skills
People who cooperate learn to like each other. This conclusion holds true for students with different ethnic backgrounds, ability levels, social class differences and in mainstreamed classrooms (children with physical or mental handicaps in "regular" classrooms). (Slavin, 1987)

Because students benefit from helping each other, they assist and encourage more in cooperative groups than in competitive or individually structured classrooms. Cooperative learning experiences also promote stronger beliefs that a student is accepted by others. These experiences increase the ability to understand how a situation appears to another person and how that person is reacting to the situation. Not surprisingly then, cooperative learning experiences tend to decrease negative stereotypical views among students (Johnson et al, 1984).

Several researchers have found that cooperative group work may increase student's self-esteem. Students in cooperative groups tend to have more positive feelings about themselves; they like others and feel liked by others more often than those in control groups. They may also feel more successful in their school work, which could also contribute to increased self-esteem (Salvin, 1987).

Johnson et al (1984) also point to evidence that students working together in cooperative learning groups develop better collaborative skills than students in other types of classrooms; are more motivated with better attitudes toward a subject; and are more likely to grow in the use of higher order thinking skills. And, while not researched yet, logic would suggest that students who study science together - discussing, arguing, debating, and explaining - would learn more of the processes, applications and true nature of science.

Some final thoughts
We all want our students to be more cooperative, more accepting of others, and to feel better about themselves. But, we also want them to learn the content, processes, and nature of their subject. Here is where cooperatively structured classrooms are at their best. Students learn as much or more content as in more traditional classes and, as an added benefit, they develop powerful social skills and attitudes necessary for successful adult life.

Only one real question remains - why aren't all classes structured for cooperative learning? The next issue will focus on tips for implementing a cooperative class.

Science Teacher Education

Some Recommended Ways for Including Multicultural Education in a Preservice Science Methods Course

George E. O'Brien

An important component of preservice elementary teacher preparation programs which is often ignored by science educators, is multicultural education. The US National Council for Accreditation of Teacher Education (NCATE), which has high standards for multicultural education, has defined multicultural education as:

The preparation of the social, political, and economic realities that individuals experience in culturally diverse and complex human encounters. This preparation provides a process by which an individual develops competencies for perceiving, believing, evaluating and behaving in different cultural settings. (NCTA, 1980)

Encouraging preservice teachers to develop realistic perspectives of cultural diversity, women's concerns, the rights of children, and issues important to other groups in society, should be a function of the entire elementary program's curriculum and instruction. Therefore, instructors of science methods' courses should contribute to the preservice teacher's overall development in multicultural education.

Atwater (1989) has identified a list of multicultural competencies which teachers of science should possess. These competencies are:

1. Create a classroom environment and help create a school environment representing a multicultural approach to education.
2. Develop science curricula and curriculum materials, and teach science lessons appropriate to the students, taking into account the cultural diversity of the students.
3. Detect biases and deficiencies in commercial and teacher-made curriculum materials.

This section focuses on the pre-service and in-service education of science teachers, and aims to communicate ideas and strategies which will assist science teacher educators to enhance and enrich their pre-service and in-service programs.

4. Assess inclusion models that are relevant and feasible for ethnic minority groups to use in classrooms and schools.
5. Show a basic knowledge of the contributions of minority groups to society, especially in science and technology.
6. Perceive linguistic and cultural biases in assessment and evaluative instruments, and in the prescription of a testing program.
7. Develop a philosophy on bilingual education when necessary.
8. Possess a knowledge of the cultural experience in both a contemporary and historical setting of any two ethnic, racial, or cultural groups.

This list of competencies is helpful to instructors creating and selecting activities for multicultural education in a preservice science methods course.

There are numerous opportunities and ways that a science methods course might be structured to help focus on stereotyping, racism, classroom environment, and characteristics of a multicultural science teacher. The following description of ways to incorporate multicultural education in a science methods course more specifically addresses competencies 1 to 4 listed above. I have found the following instructional strategies, activities, and assignments valuable in helping preservice teachers develop these multicultural competencies.

IN-CLASS WORK AND ASSIGNMENTS

1. Competencies and course objectives

Instructors should state course goals, objectives, and required competencies in relation to multicultural education in the course overview and syllabus, not present them as an afterthought, or in an inconspicuous manner.

2. The role of the instructor - the teacher as a model

The first and possibly most obvious place to start instruction of multicultural educational concepts in a methods course is by modelling appropriate behaviour and language in the classroom. Tiedt and Tiedt (1989) have pointed out that instructors can show preservice teachers how to (1) use language that is free of racist and sexist terms or labels; (2) recognise careless use of language and stereotyped perceptions of people that can hurt human beings and limit their potential; and (3) talk about people as individual human beings who have varied characteristics not limited by sex, race, class, or ethnic background.

Every instructor can lead preservice teachers to greater awareness by (1) modelling appropriate behaviour and usage of language; (2) initiating discussion of questionable practices and uses of language; (3) planning lessons designed to break down stereotyped thinking; and (4) selecting non-stereotyped text materials.
3. Make available excellent classroom materials
In addition to evaluating course texts and materials for appropriateness in a multicultural context, instructors should make available to preservice teachers samples of excellent science textbooks and associated resource materials, children's trade books, games, and audiovisual materials. These will serve the purpose of allowing preservice teachers the opportunities of comparisons with school resources during science teaching practice.

4. Local teacher with expertise
Invite a local teacher with expertise in multicultural education to share philosophy, practical teaching tips, and relevant experiences of teaching science. Arrange to videotape such an expert in various teaching environments and have the preservice teachers utilise the videotapes for analyses of instructional behaviours when studying topics including management, language, exceptional needs, school environment, and cooperative learning.

5. Small group discussions - share feelings, experiences
Arrange for small group discussions at least 3 to 4 times during the semester so that preservice teachers might share personal feelings and experiences, science teaching practice observations and comparisons of exemplary models of curriculum and instruction versus poor models. Arrange these sessions at strategic points in the curriculum. Good times might be immediately after certain preservice teachers' activities (that is, interviews of cooperating teachers and school administrators, observations of cooperating teachers, evaluations of school science materials) and during the time immediately preceding the preparation of learning/inquiry centres.

SCIENCE TEACHING PRACTICE WORK AND ASSIGNMENTS
Concurrent with the work in the science methods classroom, preservice teachers should be given several science teaching practice assignments that include components of multicultural education. These assignments, which are consistently evaluated highly by the preservice teachers, provide the preservice teachers with opportunities to enhance understanding of concepts and develop instructional skills.

1. Interviews
Have the preservice teachers discover as much as possible about the science program and science curricula at the practica schools by scheduling interviews with key personnel including the cooperating teachers, assistant principal and principal. Have them include in their inquiries questions focusing on elements in multicultural education.

2. Evaluating resources available in schools
Have the preservice teachers analyse student textbooks and any other print and nonprint materials for multicultural education content.

3. Observations of cooperating teachers and students
Have preservice teachers include criteria for multicultural education in their analyses of observations of science lessons.

4. Lesson plans
Include in the lesson plan format a category for multicultural education in addition to traditional categories such as instructional objectives, materials, induction, transition, sequence of activities, closure, evaluation of students, and lesson analysis.

5. Teaching lessons
Have the preservice teacher plan, prepare, and teach two or more lessons which include instructional strategies for multicultural education. Lessons should be audiotaped or videotaped.

6. Lesson evaluation
Have the preservice teachers self-evaluate and write critiques of instructional performances including analyses of instructional strategies involving skills and concepts in multicultural education.

7. Developing and implementing learning inquiry centres
Have the preservice teachers develop and implement learning inquiry centres that focus upon cultural and science aspects.

SUPPORTING SCIENCE IN SCHOOLS

IDEAS, ACTIVITIES AND RESOURCES FOR PROFESSIONAL DEVELOPMENT

By Stuart Naylor & Alan McMurdro

"Those that can, do; those that can't, teach. Those that can't teach, teach teachers."

Few teachers would agree with the first part of this statement, even if some of the leader writers in the newspapers prefer to believe it. Those who make the claim are often speaking from a position of ignorance, with little knowledge of the realities of classroom life or of the range of skills needed to survive for more than 10 minutes in the classroom.

As well as teaching children many teachers now also have a responsibility for teaching teachers, by providing professional development opportunities for their colleagues. Why is it then that teachers who are quick to defend the learning opportunities offered to children, will often be critical of much of what is offered by their colleagues for their own professional development?

Perhaps we should not be surprised. Teachers who are asked to put on an inservice day for their colleagues will generally have no extra preparation time; they may have had little previous experience as INSET providers; and they will probably have few resources to support them. When providing learning opportunities for teachers is at least as demanding as providing them for children, it is not surprising that so many teachers have often been dissatisfied with school-based inservice.

Supporting Science in Schools breaks new ground in providing useful ideas, suitable activities and appropriate resources for school-based professional development. The photocopiable loose-leaf format makes this publication very user-friendly. Structured activities, role plays, simulations and workshops can be used off the shelf, with very little advance preparation. Briefings for organisers (covering timing, groupings, taking feedback, etc) provide all the details needed for getting it right.

Wherever possible the activities take everyday situations as their starting point, rather than starting with general principles which may not always seem immediately relevant. Another unique feature is the way that it is designed for primary and secondary classroom teachers as well as for teacher educators. Even for experienced INSET providers, this pack provides a set of ideas and resources which offer fresh perspectives on familiar situations and some insights into unfamiliar areas. The structure also provides for departmental or whole school development which goes far beyond science. Any school will find that having their own copy is highly cost effective.

Visits to animal collections can be interactive in a number of ways. Silvia Wirth-Hirch, Education Officer at Alpenzoo in Austria, has developed interactive programs for children of 8 years upwards. Here she shares an account of behaviour studies carried out by pupils.

Humans are very tactile - we like to get an impression of things by feeling their surface, their temperature, etc. The German word "begreifen", which means "to comprehend by touching", represents one educational method by which we can learn about animals in a zoo. However, it is not appropriate to use this method with all animals; hence I have changed the methods of the educational programs at Alpenzoo by using three other senses - hearing, smelling and seeing; and I have stopped describing the life and needs of the animals - it is now up to the students to discover these things about the animals.

With pupils, the following behavioural study methods can be used - they are no different from those taught at university level: (1) Qualitative behaviour descriptions to compare the same behaviour pattern in different age groups or individual animals; (2) Quantitative behaviour descriptions such as scan sampling, sequence sampling, sampling occurrences of some behaviours and the nearest neighbour method.

With younger children, data sheets need to be simplified, and the tasks of observing and recording shared. Older children, after an explanation, will be able to design their own data sheets and manage the tasks of both observing and recording.

These are some examples of behavioural studies carried out at Alpenzoo.

Birds provide an excellent opportunity for observing habitat-specific behaviour. The aviary for small birds at Alpenzoo is structured so that birds can change compartments. Each compartment has a different plant growth. With a data sheet divided into columns with headings Conifers, Deciduous Trees, Wall, Fence, and Floor, pupils can find out which plant or structure is preferred by various bird species.

Using a second table with columns headed Flying, Climbing, Going, Jumping, and Other Locomotions, pupils can find out the mode of locomotion used by different bird species.

Because small birds are very active, pupils have sufficient data after 20 minutes of observation, to attempt a description of the habitat for each bird species.

A further activity involves studying food choice and feeding strategies for different species. For example, the nutcracker feeds on the seeds of a pine species, Pinus cembra. Mainly in autumn, the nutcracker collects these seeds, transports them in its throat and hides them in order to have a food reserve during winter. If there are insufficient pine seeds, the bird comes down into the valleys and collects hazelnuts, walnuts, beechnuts and acorns. With a simple data sheet with columns headed Pinus Seed, Walnut, and Hazelnut, young children can easily collect data about the food choice of the nutcracker. Older children can use a more complex data sheet with additional columns to record the feeding strategy, noting duration, place, and feeding, picking, hiding behaviours.

Here is a description of how pupils can investigate social hierarchy, dominance and space utilisation, using a simple scanning method. The first step involves each pupil sketching the layout of an enclosure. While one
student acts as a timer by calling out "now" every 30 seconds, each pupil notes on the sketch where his/her assigned animal is at that moment. After 30 minutes, students have sufficient data to determine which part of the enclosure is most used by the animals. Normally, higher ranking animals are near important places such as food boxes and viewing points; lower ranking animals are relegated to the periphery of the enclosure. This method is not reliable during mating season or at other times when normal behaviour patterns are disturbed.

Other examples of animal behaviour studies at Alpenzoo include:

- Interaction between brown bears during mating season
- Interaction between two species within the one enclosure
- Contact between mother and young
- Playing behaviour
- Which is the dominant species at the duck pond?

These programs aim to interest pupils in nature without the need to touch or to manipulate; they generate an excitement as pupils become nature detectives, finding out what they can about nature - the strategies, the adaptations, the behaviour patterns - and they instil a respect for the gigantic network of nature as they interact with their minds, instead of with their hands.

Stepping into Science Newsletter
Teachers actively involved in Stepping into Science are planning to compile and distribute a newsletter containing ideas to try and other information about Stepping into Science. If you would like to contribute, or have your name added to the distribution list, contact:

Sue Dale Tunnicliffe, Education Department
Zoological Society, Regent's Park
London NW1 4RY, UK
Tel 44-71-722-3333, Fax 44-71-483-4436

Making Music
An activity with straws
Based on CESI File Sheet #17

The materials for this activity are simple - drinking straws and scissors!

The goal of this activity is to investigate the sound-producing capabilities of drinking straws.

Start by cutting one end of a straw like this:

Then place it in your mouth and blow. Experiment until you get the correct placement of the straw between your lips and teeth.

How can you vary the sound? Try changing the shape of the point. Try changing the length of the straw.

Science Activities Re-Using Used Materials
These ideas for making a wind-vane or wind-powered rotor appeared in Investigating, the Australian Primary Science Journal Vol 6 No 3 August 1990

Illustrations of wind vanes by Charlotte Pocock
Greenhouse Teaching Resources

STS (Science Technology Society) courses have different aims and include topics which are different to those of traditional science courses. New aims and topics, however, are insufficient by themselves to bring about desirable changes in schools. If we are to motivate all of our students and help them to develop genuine understanding and relevant attitudes about science, technology and society, we also need to change our teaching approaches. Many teachers accept this need and are actively seeking and trying out new ideas for better learning and teaching.

An excellent "Greenhouse Education Kit" produced in South Australia contains more than 30 activity sheets suggesting a wide range of activities (refer to Figure 1).

Many of these activities are of a kind which I shall call "non-traditional" because they are not frequently used by science teachers. The importance of combining such non-traditional activities with traditional ones to produce a more meaningful program for students has been discussed in a number of publications. A book edited by Bentley and Watts (1989) and another by Gianello (1988) are particularly valuable for science teachers because they include many practical suggestions, case studies and examples to help teachers explore new ways of teaching.

Gianello (1988) also emphasises the importance of non-traditional activities in science courses to encourage girls as well as boys in science.

The Greenhouse Education Kit has been produced by the Energy Information Centre and the South Australian Energy Forum. The materials are flexible to use. They have been written for students in Years 6-9, but can be modified by teachers for use at other levels in elementary and secondary schools. Four worksheets have been reproduced on the following pages.

As well as worksheets, the kit contains information sheets that are basic and easy to follow. Additional information, where necessary, would need to be obtained from other sources such as newspapers, libraries and government departments.

Further information about the kit can be obtained from:

Dr Jill Kerby
The South Australian Energy Forum
Level 19, 30 Wakefield Street
Adelaide SA 5000, Australia

WRITING LETTERS

This activity introduces letter writing as a form of social action to increase public awareness of environmental risks.

REQUIREMENTS:
Pencil or pen, paper for each student
Examples of letters written to a newspaper

PROCESS:
Find and read some examples of letters written to a newspaper.
Select an issue related to climate change.
Decide the type of reader to whom the letter is addressed.
Write a brief letter of no more than 100 words about the issue. The letter should include the following points:

- who you are and what your position is e.g. student
- what you are writing about
- why it concerns you
- what will be the consequences if no changes are made
- what should be done
- who should do it
- what benefits will be gained from the changes

Share your letter with others in the class and display it on a greenhouse notice board (See Activity Sheet 1).

DISCUSSION:
Why should your letter be brief?
What kinds of people write letters to newspapers?
Who is likely to read newspaper letters?
Are newspaper letters effective in changing attitudes?
Can you identify some other people, industries or organisations to whom letters could be written?
SUPERMARKET SURVEY

In this activity you can examine a range of goods sold in supermarkets or stores which may be contributing to climate change. Make sure that you obtain prior approval from the store concerned if this activity is to be done by school group visits. Alternatives to school group visits could be individuals collecting data while shopping with parents, or working in class from advertising brochures and catalogues.

REQUIREMENTS:
Pencil or pen and paper for each group
Survey record sheets, made up by students
Advertising brochures, or access to a supermarket

PROCESS:
Work in small groups of up to four students.
Prepare a survey sheet with the following columns:
Product Name, Product Use, Cost, Type of Packaging,
Environmental Effects, Necessity, Alternatives.
Examine as many products as you have time for, and fill in on the survey sheet the first four columns as you go.
Back at School discuss with others in the group what should go into columns 5, 6, 7 for each product.
Share your survey findings with others in the class.

DISCUSSION:
Which products are likely to harm the environment?
Which products are unnecessary?
Why are there so many choices?
How much packaging is necessary?
How does advertising affect sales?
How does advertising affect the environment?
Plan a campaign to educate the public about the effects on the environment of having such a large range of consumer products.
Identify some areas in which you could reduce your personal consumption of such products.
THE GREENHOUSE GAME

In this activity you make up your own board game about greenhouse and play it. At the same time you will be learning about some of the factors affecting our earth.

REQUIREMENTS:
Large sheet of cardboard or paper per group
Cardboard to make game cards
Glue, scissors and coloured pencils
Counters and dice to play

PROCESS:
Mark out the board with squares (as many as you like, up to 100).
Make up a set of cards with positive and negative statements about the environment (the more cards the better).
For example: "You were driven to school today because you didn’t feel like walking. GO BACK 3 SQUARES".
"At home you sort your rubbish into groups for recycling. GO FORWARD 4 SQUARES."
Illustrate the cards.
Illustrate and decorate your board.
Play your board game to see if it works well, then make any improvements, e.g. more squares, more cards, different penalties.

DISCUSSION:
Play another group’s board game and tell them what you like about their game.
Do you think games like this are an effective way of getting the greenhouse message across?
Can you adopt your game so it can be played in the schoolyard, with squares marked out and using giant dice (cardboard box) and people as counters?
MELTING ICE

This activity examines the way in which a greenhouse alters the rate at which ice melts.

REQUIREMENTS:
2 ice cubes per group
1 large glass or jar per group

PROCESS:
Place the two ice cubes near one another on a tray or somewhere that water won’t cause damage.
Place the glass upside down over one ice cube.
Observe over a period of time. Try some pairs of cubes in full sunlight, others in shaded areas and others inside.

DISCUSSION:
Which ice cube melted first in each case?
Were there any water droplets on the inside of the jar?
Where did they come from?
NEW ICASE PUBLICATION

Empirical Research
in Mathematics and Science Education

Proceedings of the International Seminar
6-8 June 1990
University of Dortmund, Germany

The proceedings (221 pages) includes the following papers: Using an expert system to analyse students’ ability to process information in the area of basic electricity, Christoph von Rhöneck; Commonsense understandings of causes of motion, Denise Whitelock; Assessment of performance unit: a longitudinal study of science performance at ages 12 and 14 in the UK, Martin Braund; A label as hidden persuader: chemists’ neutralisation concept, Hans-Jürgen Schmidt; Student’s understanding of the particle nature of matter and its relation to problem solving, Dorothy L Gabel; Towards a more effective methodology of research on teaching and learning chemical equations, Onno de Jong; Learning, hierarchies in mathematics: a critique, Elisabeth Sander; Introduction to the study of interdependence between selected traits and the use of the question-answer technique in problem solving, Matthias Ehrsam; On the methodology of the investigation of the pupils’ structures of knowledge, acquired in the lessons of chemistry, Rolf Lämmer; Concept learning in biology teaching, Dittmar Graf; Two decades of research in science education: an American perspective, Anne C Howe; and other articles.

Copies, at a cost of US$8.75 including postage, can be ordered from:
Dennis Chisman, Honorary Treasurer, ICASE
Knapp Hill, South Harting, Petersfield GU31 5LJ, UK

Most articles discuss the use of the computer in conjunction with experiments - not only for on-line data acquisition, but also for simulating or modelling phenomena. This is an educational strategy advocated by AIF, for example:
The article dealing with simulations describes instructional strategies to be used in conjunction with laboratory activities, to increase students' comprehension of phenomenological aspects before arriving at a formal description.

Two approaches are apparent in articles describing actual classroom experiences. The first approach goes from the experiment to the construction of a computer model (usually a dynamic type) in which the experimental pattern is reproduced and recognised. The second goes from studying a typical mathematical function to performing experiments on phenomena exhibiting the same behaviour (for example, capacitors during an electric transient in connection with the differential equation leading to exponential behaviour). The issue is published in Italian, and is available at a cost of Lit 10000.

Another AIF special issue on the didactics of physics is Teaching the Second Law of Thermodynamics in the School Vol XXII No 2, 160 pages, Lit 10000. The issue contains materials produced by an AIF inservice course for teachers. This issue is also published in Italian. Address your request for these issues and prepayment in Italian lira to:

The Teaching of Science and Technology in an Interdisciplinary Context
Vol II
Unesco, Paris 1990

This publication, No 38 in the Unesco Science and Technology Education Document Series, is a summary of the Pilot Project and Proceedings of the Concluding Consultation held in Plovdiv, Bulgaria, 25-29 May 1987.

The Pilot Project on the Teaching of Science and Technology in an Interdisciplinary Context was part of a series of 10 pilot projects on various aspects of the teaching of science and technology at the primary and secondary school levels undertaken by Unesco's Division of Science, Technical and Environmental Education in a total of approximately 50 countries from 1981 through 1987.

The objectives of the Pilot Project on the Teaching of Science and Technology in an Interdisciplinary Context were to develop and test ways in which the concepts, processes and skills of science and technology could be linked with or incorporated into the teaching of other areas in the school curriculum at both the primary and secondary school levels.

Emphasis was placed on teaching methods and activities that promote understanding through active learning techniques, on efforts to link classroom learning with real-life experiences and on extending this teaching beyond the classroom.

The project, launched in 1984 and completed in 1987, had two aspects - one concerned with education in the basic sciences and mathematics, the other with nutrition and health education.

Five countries were officially involved in the project - Bulgaria, Denmark and the United Kingdom for the first aspect, Thailand and Indonesia for the second; other countries which became involved unofficially before the conclusion of the project were Germany, Norway, Sweden, USSR and USA. The official conclusion of the project was the consultation held in Bulgaria, the proceedings of which constitute this document, edited by Harold Foecke.

The contents include: Objectives and achievements of the pilot project, Harold A Foecke; The pilot project and the consultation in perspective, Sheila M Haggis; and a number of papers by attendees from countries participating in the pilot project.

Papers include: Teaching science in an interdisciplinary context: the Scottish experience, Sinclair MacLeod; Bees and their mathematics: a project integrating math and science, Otto B Bekken; The primary science project in Norway, Doris Jorde; The school and healthier living, Soetirso Kusumohadi; Why teach science in primary schools? Helene Srenson; Man, nature and polarised light, Erik W Thulstrup; Project work in environmental protection in the natural science branch of the upper secondary school in Sweden, Aina Tullberg; Project work in chemistry and scientific writing in the upper secondary school in Sweden, Aina Tullberg & Marianne Lindgren; The integrated course NATURE in the curricular structure of BARGE, D Lazarov & E Golovinsky; Applying informatics in science teaching: some examples, Polexenia Sarkissyan & Evgenia Sendova.

Papers by attendees from other countries include: Dimensions of integration, Donna F Berlin; Computer simulations in science teaching: aspects of didactics and software ergonomics, Peter Gorny; Consequences of the history of science in regard to the learning process in science education, von Alfrid Gramm; Computer-assisted learning (CAL) in science, Alison Rose; A basis for a triple integration: language-mathematics-informatics, A.L. Semonov.

Basic Concepts in Scientific Research
by Y Friedler & P Tamir
The Amos De-Shalit Science Teaching Centre, Israel

Evaluation studies all over the world have shown that for many students the laboratory experiences in school are not meaningful and learning by inquiry has failed to achieve its aims. We have developed a module entitled Basic Concepts of Scientific Research (BCSR) which has been successfully used in Israel from Grade 9 up to teacher education levels. The English version of BCSR has just been published. The materials cover:

- Historical introduction
- The research problem
- The research hypothesis
- Deduction: a stage in testing the hypothesis
- Designing the experiment
- The research process in its entirety
- An interesting story

The student text (68 pages) costs US$4.00 including postage. The teachers guide (27 pages) costs US$3.00 including postage.

ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1991

March 27-30
NSTA National Convention
Location: Houston, Texas, USA
Contact: Linda Crow, Asst Professor, Baylor College of Medicine, One Baylor Plaza, Room 633E, Houston, Texas 77030, USA
International delegates are invited to participate in the Fourth International Round Table - just one of the many features of this convention which plans to cater for almost 20000 science educators, including a large number of science educators from other countries! Each country is provided one or more tables in a large room where delegates can display and present information on science education in their country.

March 29 - April 3
7th ICASE-Asian Symposium
Location: East China Normal University, Shanghai, China
Contact: Prof Mi Zhong, Department of Physics, East China Normal University, Shanghai 200062, China
The symposium will be conducted in English/Chinese and will address the theme Making science education in schools more relevant. The program will focus on (1) the development of appropriate curricula, the issue of integrated science vs separate sciences, the introduction of STS in science courses; (2) innovations in teaching, the role of project work, the teaching of science communication skills, low cost equipment, fieldwork; (3) technology in education, the effective use of visual aids, visits to industry, the place of the computer; and (4) research in science education, children’s learning in science, assessment techniques. The program will consist of presentations by internationally renown science educators; papers, workshop and discussion sessions; poster displays; and an exhibition. The second circular is available from the address above, and details arrangements concerning registration ($US50 for members of science teacher associations), accommodation, program, and the obtaining of visas to visit the Peoples Republic of China.

April 1-14
Edinburgh International Science Festival
Location: Edinburgh, Scotland, UK
Contact: Edinburgh Science Festival Ltd, 20 Torphichen Street, Edinburgh EH3 8JB, Scotland, UK
There is something of interest for everyone at the international science festival. Now in its third year, this lively celebration of all the sciences, from astronomy to zoology, is geared as much for those who are merely curious or concerned about the world as it is for the serious scientist. The 1991 festival will focus on the human body, but many other topics as diverse as wildlife and artificial intelligence, and biotechnology and electronics will be covered in an extensive program of demonstrations, debates, exhibitions, films, workshops, walks and talks. A full program is available from the contact above.

April 5-8
Chemistry and Developing Countries
Location: Imperial College, London, UK
Contact: Stanley S Langer, The Royal Society of Chemistry, Burlington House, Piccadilly, London W1V 0BN, UK
This conference will be the second organised by The Royal Society of Chemistry on the theme of chemistry and development. The 1991 conference, to be organised as part of the celebrations to mark the 150th Anniversary of the Society, will focus on two themes: (1) chemistry for the environment, and (2) organising science to benefit the third world. Representatives of several chemical associations from around the world will be invited to present their views of problems and opportunities.

April 15-17
CASTME Plenary Meeting and Conference
Location: Vancouver, British Columbia, Canada
Contact: Mrs V Salisbury, 42 Bluebell Road, Norwich NR4 7LG, UK
CASTME, the Commonwealth Association of Science Technology and Mathematics Educators, is holding this conference in conjunction with the Commonwealth of Learning. The themes of the meeting are Quality, Assessment and Distance Learning in Science Technology and Mathematics Education.
educators from North America and beyond. Throughout the weeklong conference, activities are planned for all members of the family including excursions, field trips, sports activities and social events - a feature of ChemEd conferences.

August 19-24
32nd Annual Conference of STAN
Location: Yola, Gongola State, Nigeria
Contact: Mr Ben B Akpan, National Secretariat, Government College Campus, PMB 5075, Ibadan, Nigeria
The Science Teachers Association of Nigeria invites you to participate in their 32nd Annual Conference. The theme of Teaching Science Technology and Mathematics in the Mother Tongue will include subthemes on philosophical implications, curricula implications, implications for the learner, and implications for the teacher.

August 25-30
11th International Conference on Chemical Education
Location: University of York, York, UK
Contact: Dr John F Gibson, ICCE 11, Royal Society of Chemistry, Burlington House, Piccadilly, London W1V 0BN, UK
This biennial conference on the theme Bringing Chemistry to Life is being organised by the IUPAC Committee on Teaching of Chemistry in conjunction with UNESCO and the Association for Science Education. The conference will focus on (1) making chemistry accessible to all students (2) new curricula at primary, secondary and post-secondary levels (3) new teaching strategies at all levels (4) teaching and learning at a distance (5) new frontiers of chemistry and their impact on teaching, and (6) research in chemical education. The program will include plenary lectures, poster papers, symposia, workshops, exhibitions, times for participants to discuss aspects of chemical education of special interest, social events and local visits. Responses to the first circular have been received from over 70 countries. The second circular and registration form is now available from the above address.

August 12-22
Sixth International Symposium of IOSTE
Location: Wyndham Palm Springs Hotel and Resort, Palm Springs, California, USA
Contact: Dr Herbert K Brunkhorst, Institute for Science Education, California State University, 5500 University Parkway, San Bernardino, California 92407-2397, USA
The theme of the 6th International Symposium on World Trends in Science and Technology Education is Science and Technology Education: Responsible Change for the 21st Century. Science and technology education will be related to responsible change with respect to the role of science educators, scientists, engineers, business/industry and government agencies in the global community. The symposium will provide a forum for dialogue to increase awareness of regional perspectives worldwide and develop closer cooperation in addressing mutual concerns. This dialogue will be held in the context of science education
issues, environmental issues, technology issues and socio-cultural issues. The symposium will be presented in English.

**August 26-30**

**Fourth Asian Chemical Congress**
Location: Beijing, China
Contact: Prof Dehe Zhang, Secretary General of AACC, Chinese Chemical Society, PO Box 2709, Beijing 100080, China
The 4th Asian Chemical Congress will be held under the sponsorship of the Federation of Asian Chemical Societies. The Congress will focus on the important role of chemistry in raising the health conditions and living standards for all people. The program of plenary lectures, invited papers and contributed papers will be conducted in English and will concern various topics including organic chemistry of natural products, analytical chemistry and instrumentation, environmental chemistry, agrochemistry, coordination chemistry and its applications in medicine and agriculture, polymer science, photochemistry, computers in chemistry, catalysis, and chemical education.

**August 27 - September 1**

**5th International Environmental Education Conference**
Location: Cusco, Peru
Contact: MSc Eduardo Gil Mora, National University of Cusco, Zaguán del Cielo L-9, Cusco, Peru
The conference will focus on the relationship between the environment and development, and on the changes needed in today's behaviour for tomorrow's world. The program will enable participants to learn of developments, approaches and strategies in environmental education in different countries, and will cater for primary, secondary and tertiary educators; and for teacher trainers, curriculum developers, and policymakers.

**November 6-10**

**NABT Annual Convention**
Location: Souther Hotel, Nashville, Tennessee, USA
Contact: Patricia J McWethy, Executive Director, National Association of Biology Teachers, 11250 Roger Bacon Drive, #19, Reston, Virginia 22090, USA
The next annual convention of the National Association of Biology Teachers will focus on the theme Form and Function: How Should They Be Taught. Applications for program space are due on 15 March 1991.

**1992**

**January 3-6**

**ASE Annual Meeting**
Location: University of Sheffield, Sheffield, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated in *Education in Science*, a journal of the Association for Science Education.

**March 26-29**

**NSTA National Convention**
Location: Boston, MA, USA
International delegates are invited to participate in the International Round Table - one of the many features of this large convention. Each country is provided one or more tables in a large room where delegates can display and present information on science education in their country. Visitors move from table to table, talking with the various representatives. If you require an invitation to participate, write to John E Penick, Professor and Coordinator, Science Education Center, The University of Iowa, Iowa City, Iowa 52242, USA.

**March 29 - April 10**

**Science Teacher Education**
Location: London, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This British Council International Seminar will be directed by John Head and John May of King's College Centre for Educational Studies, University of London, and will focus on secondary level teacher education, although some aspects will be of interest to those involved in primary science teaching. There are vacancies for 30 international participants - practising teacher trainers, advisers, inspectors, organisers of professional development programs and policy maker.

**April 22-29**

**Symposium on Technology Education**
Location: University College of Education, Erfurt, Germany
Contact: Prof D Blandow, University College of Education, Nordhäuserstraße 63, 5064 Erfurt, Germany
This symposium will be the first pan-European meeting on technology education to be held in a unified Germany - at an institution in Erfurt renowned for initiatives and developments in technology education. The principal aim of the symposium, which is being organised in collaboration with a number of organisations including ICASE and INSITE, will be to discuss technological literacy and competence in technology education within a European dimension. The majority of participants will be from European countries, with a few key people from other regions of the world. The principal language of the symposium will be English.

**May 11-15**

**Second International History Philosophy and Science Teaching Conference**
Location: Queen's University, Kingston, Ontario, Canada
Contact: Prof Skip Hills, Faculty of Education, Queen's University, Kingston, Ontario, Canada K7L 3N6
This conference follows the very successful First International Conference on History, Philosophy and Science Teaching held at Florida State University in November 1989. All conference papers will be published in advance of the conference. Accounts of the application of history and philosophy of science in the science classroom are welcome, as are research papers on the issue.
Extending and improving education in science for all children and youth by assisting member associations throughout the world

5. Strengthen international exchanges

Appropriate curricula

One area which should be considered in developing a more appropriate science curriculum is biotechnology. This was proposed by the first plenary speaker. New areas of research, such as biotechnology, have had a profound impact on the world at large and thus needs to be seriously considered as part of the school science curriculum. Areas of appropriate biotechnology (and selecting biotechnology that is appropriate to the country is important) may include (1) the production of energy using biomass; (2) the production of medicines using herbs; (3) food preservation; (4) food production; and (5) agricultural industries such as tea and rubber.

Innovations in teaching

One innovation in science education suggested by the speaker from Thailand was the inclusion of project work. This has a role to play in making science education more relevant by allowing for more student involvement in the thinking, design and planning stages, and it allows the teacher to adopt the role of 'guider' rather than

---

Eighth ICASE Asian Symposium

Colombo, Sri Lanka

2-10 August 1992

THEME

Science Education for a changing world

The Symposium aims to identify some of the changes affecting our daily lives and to discuss ways by which science education can respond to these changes.

Subthemes include (1) technology, (2) appropriate technology (3) environment, and (4) scientific literacy.

Award Scheme
An ICASE Primary Science Project

The Stepping into Science Award Scheme has been organised to encourage children to take steps in science each year during their elementary/primary years. The steps are colour coded as follows:

Yellow for preschoolers
Green for grade 1 children
Blue for grade 2 children
Red for grade 3 children
Orange for grade 4 children
Grey for grade 5 children
Purple for grade 6 children

For further information about the scheme and how to order certificates contact the Project Officer: Sue Dale Tunncliffe
18 Octavia, Bracknell, Berkshire, RG12 4Yl, UK

'giver'. Four types of project work in science education were suggested:
1. Exploration and survey
2. Experimentation
3. Inventions
4. Theory formation

Technology in education
The presentation on technology in education proposed that technology education is a vital component of teaching if science education is to be relevant. However, teachers have generally experienced difficulty in teaching technology education because teachers do not understand the meaning of technology education, and teachers fail to cover the full range of learning skills when teaching their students.

Teaching strategies play a very critical role in science education (irrespective of the syllabus content) and more emphasis is needed on the process of learning rather than only considering the final knowledge outcomes.

Technology products such as locally produced apparatus can aid the teaching and learning process but, in most situations, the computer has yet to become an effective technological product for science teaching because of the lack of good software.

Research in science education
The plenary speaker considering research in science education suggested that, if student achievement is to be increased, the following outcomes of research need to be addressed:
1. The need for professional training of teachers is important.
2. Teachers' subject knowledge is important (not only knowledge of the topic in the textbook, but also knowledge of the associated technology in society).
3. Examination-centred teaching strategies are not the most appropriate for effective learning.
4. The type/mode of teaching instruction and the teacher's enthusiasm affect student achievement.

Conclusion
This symposium was a first for ICASE, involving instantaneous translation between Chinese and English. It is planned to produce the proceedings in English in the near future. For further details, write to:

Prof Mi Zihong
Department of Physics
East China Normal University
Shanghai 200062, China

Individual or Group Work
Where will pupils learn better science?

by Maria Mamalinga
Department of Education
University of the Aegean
Greece

The suggestion that groupwork causes pupils to focus on superficial, less abstract aspects of learning tasks and to be dominated by a need to agree within the group at the expense of a need to be logical was investigated. A sample of forty four 15 year old Greek pupils were given the same test items in two different social contexts. In the first context, pupils were tested in a conventional classroom manner, each filling in their own answers with no inter-pupil cooperation. In the second context, pupils were divided into groups of four and asked to fill in just one set of test questions communally. They were encouraged to talk amongst themselves during the work and the conversations were recorded. The explanations produced in the individual tests and the conversation and explanations from the group contexts were both analysed for the nature and quality of ideas used. The working hypothesis that the group context would produce more superficial ideas was not supported. The ideas raised and used were more or less the same in each case. Also, and again contrary to expectations, the group context produced fewer incorrect ideas than the individual situation. The reasons for these findings and the implications for science teaching are discussed.

Introduction

Science pupils working together in small groups is common in schools and, over the years, there have been studies which have investigated or argued the good or bad effect of group and individualised teaching methods on science learning. Johnson and Johnson (1979) for example suggested that cooperative learning might produce better academic performance than individualised instruction.

However, in her wide ranging review Solomon (1987) makes a number of specific suggestions which follow from the ideas of sociology of knowledge being applied to science lessons. Among other things she argues that:

"Both sociological theory and classroom evidence suggest that in socially acquired knowledge, exchange of meaning and consensus take the place of logical testing and typification by context replaces abstraction and conceptualisation."

(Solomon, 1987)

After translation, the suggestion here seems to be that, when pupils are working in groups, they may find the need to agree amongst themselves stronger than the need to be logical. Similarly, they could find that superficial and obvious features of the problem context are easier to agree on than abstract constructions. Pupils working alone (in apparently less constrained social contexts) may not have their thinking restricted in the same way. These ideas seem to contradict the argument that group learning encourages better problem-solving learning. It is important to look carefully at these conflicting possibilities. Recent experimental studies of these issues have been somewhat ambiguous. Sherman (1988) and Lazarowitz et al (1988), in different educational contexts, both obtained results which did not indicate any clear benefit of group over individualised instruction. The likely advantages and disadvantages of pupils working together or individually is not sufficiently well understood.

The social context of learning must influence the nature of what is learned (see the review by Solomon (1987) for many interesting references). Social context here means more than the obvious notion of pupil discipline and classroom manners. The social complexities of what, why and how pupils learn science, when they are put into the socially artificial situations of even the best run classroom, need to be probed in order to throw some light on the questions raised.

The concern of science teachers is to develop meaningful learning in the classroom by interacting with the pupils, though the interaction between teacher and learner is not the only one which is taking place. Interactions between pupils are a strong factor which must also affect learning and the presumption that these effects are beneficial has prompted the arguments for group learning. In a recent paper Kutnick (1990) argues persuasively that the social act of cooperation in learning science may be a key factor which has not been considered in the attempts to apply psychological principles such as those of Piaget to science curriculum development. Kutnick pleads for small group learning situations so that pupils can "come to their resolutions without the domination of specific control of teachers or authoritarian peers."

(Kutnick, 1990)

More general theories of the role of the social context on the development of knowledge have had a chequered history (Mulkay, 1979) especially when applied to science knowledge. Until recently science knowledge, unlike other kinds, was accepted to be objective and independent of the social context (Stark, 1958). This suited scientists very well since it gave their work a special status. Recently this view of science knowledge has been challenged (Knorr-Cetina,
1981) and the nature of the social pressures on science knowledge development are now being studied. The focus of the social context in question is usually the relationships between scientists working together, between competing research groups, between peer scientists and between scientists and society at large. Unfortunately, none of this directly relates to the sociology of the classroom, where a very different set of social pressures create the setting in which pupils' science knowledge is expected to develop. Since science classrooms are the places where budding scientists may be set on the road to professionalism, the study of the social influences on the context of science learning is overdue. Teachers and curriculum developers really do need to know when group or individualised work is appropriate for what has to be learned.

Aims of the Study

The aim of this study is to investigate how the social context might affect 'thinking' about school chemistry in class. Specifically it was decided to investigate whether the kinds of ideas used in a group problem solving situation, in which groups of pupils were made to cooperate and therefore negotiate with each other, differ from the ideas used in solving the same problems in an individualised test situation. If Solomon's (1987) suggestions are correct then pupils working without interfering social pressures should produce results which are more logical and more focused on the abstract nature of the task. If, on the other hand, the suggestions of Kutnick (1990) and Johnson and Johnson (1979) are correct then the group context should produce better results.

Research Method

As part of a larger test of science learning, the Assessment of Performance Unit (Driver et al, 1984) used written questions to investigate the conceptualisations held by 15 year old pupils in the UK of ideas about elements, mixtures, compounds and chemical change. The written questions were designed for and used in individualised test situations with no student-student interaction. Four of the problems investigated the following questions: (1) What ideas do students have about 'element', 'mixture' and 'compound'? (2) How do students interpret commonly used diagrams representing elements, compounds and mixtures? (3) What observations do students consider as evidence for chemical change? (4) How do students perceive the role of the relative masses of the reactants in a chemical reaction? The problems required decisions about a problem situation and also required extended written explanations. An example of one problem is presented in Figure 1.

For these established problems to be used in the present experiment a group testing technique was required based on the same main test. It was not clear at the outset just what evidence we should be looking for concerning the hypothesis. Consensus requires agreement within a social group. Solomon's (1987) suggestion implies that this will be easier to achieve when 'attractive' superficial ideas (correct or incorrect) are the focus of attention in the group. In other words, the pressure on the individuals of the group is to focus on what they can all agree on rather than on what the logic of the task may actually require, especially if the problem has abstract requirements as in these chemistry tasks. Thus the hypothesis became that if group problem solving is 'consensus' (rather than 'task-logic') driven, then the ideas raised in the group tests would be less rich, less abstract and more related to the superficial features of the task as given. It was necessary to look for 'features' which the groups attended to and to compare these with what the individuals attended to.

The four problems used required explanations by the pupils of their answers and these, rather than the correct/incorrect nature of the answers, were analysed for their contained ideas in order to build a rough picture of the 'individual's ideas'. Groups of students were asked to solve the problems communally and the ensuing discussions were recorded. Analysis of these discussions allowed the 'group's ideas' to be characterised in a similar way.

Two is the minimum number for a group. Barnes and Todd (1977) suggested that to have more than four children in a group is not advisable as there is a risk that one or more members will remain silent. Also, when the time available for group discussion is limited, each extra person in the group means less time available for individuals to talk. Furthermore, to have more than four children in a group may restrain the social organisation of the group and possibly divert the students (who are used to being controlled by the teacher) from their main task. For these reasons it was decided to use groups of four pupils. One test booklet containing exactly the same five-item test as used on an individual basis was given to each group. The members of

A pupil was studying the properties of an unknown chemical X.

Here are the results of some of his tests:

- At room temperature X is a white solid.
- It has a melting point above 200°C
- It dissolves in water to give a colourless solution.
- When it is melted it gives more than one product on electrolysis.
- When it is heated in air it forms a white oxide.

As a result of these tests, the pupil claimed that X was not an element.

Do the results support this claim or not?

Explain your reasons:

Figure 1
the group were instructed to discuss the problems in order to
write down test answers with which they all agreed. In this
way they were forced to cooperate and discuss openly what
they separately thought.

There was a problem of how to choose the members of each
group. On the one hand, if the criterion is friendship, this
may make the discussion more comfortable. We share our
ideas more openly with people we trust. On the other hand,
in arbitrarily chosen groups, there is more challenge to
express ideas explicitly and to explain them more clearly.
Overall, it was decided that self-selected groups, probably
containing friendship groups, would minimise the working
problems since there was only a very limited time for pupils
to solve the problems. Time would be wasted while the
pupils got to know each other in non-friendship groups. No
attempt was made to control the sex or ability composition
of the groups. The group discussions were tape recorded.

The experiment was carried out on the Greek island of
Rhodos. A sample of pupils was chosen from all the first
year (age 15) general lyceum classes of Rhodos and from the
first year class of the technical/vocational lyceum. All eight
lyceum of the island cooperated and eleven intact classes of
pupils completed the individualised written test. The urban
lyceum were much bigger schools than the village lyceas.
Therefore, two classes of pupils from each urban and one
class of pupils from each village general lyceum were tested.
All the classes were taught by different teachers. The way the
classes were chosen from within the schools was random.
Though this was not a strictly random sample, the pupils
tested should be a representative sample of the children in the
age range on Rhodos island. The sample for the present
investigation was a subset of this overall sample.

The four questions used were Greek translations of the items
used in the Assessment of Performance Unit test described
above. All of the data and the analyses were in the Greek
language.

After careful thought it was decided to test the sample of
pupils first as individuals and then divided up into groups of
four without the pupils being told the results of their
individual tests. Since the pupils will be the same in both
test contexts, and no new learning will have taken place
between tests, any differences in the nature of the ideas must
be due to the nature of the test context in each case. The
reverse order of tests, even as a control group, could not be
used because the pupils will learn from each other in the

Thus it was decided to have all the pupils in the sample do
the individual test first. Volunteer groups of four pupils, one
group from each class (eleven groups, 44 pupils), were then
taken to separate rooms, given one group-test booklet each
and left to get on with producing agreed group answers. This
organisation was chosen to ensure that the pupils could start
talking about the problems straight away, having just
answered them individually. The discussions took place with
no interference from the experimenter or from the class
teachers. The test-booklets produced by each group (eleven
booklets), the recordings of the group discussions (eleven
transcripts) and the individually answered tests (44 booklets)
by the same 44 pupils provided the raw data for the
experiment. The testing was started and completed within

Unlike previous studies, the purpose of the investigation was
not to see whether the group answers were simply more or
less correct than the individual tests using conventional
academic criteria. The purpose was to probe the nature, the
range and quality, of the ideas employed in the two test
situations. The explanations given to each question by the
pupils when working individually were first examined
carefully to identify and list the whole range of ideas
expressed. Statements which could be interpreted to imply
substantive concepts related to the test topic were extracted
from the pupils' written explanations and listed. The group
written explanations and the group discussion transcriptions

**Who's Who in Science Education**

**Around the World**

**1991 Edition**

ICASE is compiling this valuable reference book containing profiles on prominent science educators and their work. In order to enhance the value of this reference work, it is important to include prominent women and men in the areas of primary, secondary and tertiary science education in many countries throughout the world. You are invited to recommend individuals for inclusion.

Please send names and addresses to:

The Editor, Who's Who in Science Education, 10 Hawken St, Monash ACT 2904, Australia
were then treated in the same way. Concept inventories were formed of the ideas which pupils used to produce answers. As the test contained four questions, eight overall concept inventories were produced, four from the combined group discussions of each question and four from the total individual responses. Also, two concept inventories were produced for each separate group of four pupils for each question, one from their group discussion data and one from their individual tests. This produced 88 smaller concept inventories.

Three analyses were carried out. Firstly, the substantive statements in the group and in the individual data sets were analysed question by question for the range and nature of ideas present. Secondly, the substantive statements in the total individual and total group test data were categorised, where possible, as representing abstract or superficial ideas (in many cases a judgement could not be made). Thirdly, the joint explanations and discussions by each sub-group of four pupils were separately categorised using a rough judgement of the pupils' performances, group by group and question by question.

Results and Discussion

1. The nature and range of ideas in the two contexts

In problem 1 the pupils were presented with descriptions of five substances and had to use their knowledge of what an element is to decide which, if any, of the substances could be elements. The five alternatives contained a number of physical and chemical properties (eg colour, physical state, reacts to give, etc) which provide attractive, salient though incomplete criteria for decision making. Analysis showed that the range of ideas expressed in the group responses was more or less the same as the range of ideas expressed in the individual responses. Also, the nature of the responses was broadly similar, mostly reflecting the words and ideas raised in the test items, as was to be expected. The pupils mostly thought of elements as 'being made up of one component only', using this idea to solve the problems. There was not much evidence of the abstract particulate model in either context.

Problem 2 was similar to problem 1. The pupils were given descriptions of a 'substance X' (eg at room temperature it is a white solid) and were asked to decide which if any of the evidence supported the view that the substance was an element. The key information in the item was that the chemical 'gives more than one product on electrolysis'. This became the focus of attention in both contexts. Overall the only evident difference was that there were considerably more references to the same ideas in the individual tests than in the group recordings. This is because one statement of an agreed idea suffices in the group context whereas all four students may write the same idea as individuals.

Question 3 required the pupils to think about their idea of a chemical reaction. A before-and-after situation was presented and the pupils had to decide whether a reaction had taken place using criteria such as colour change and change of density of a substance that had been heated. Not enough evidence was given for the pupils to make a certain answer. Changes in mass, colour and density are all indicative of a reaction but not conclusive on the basis of the data given. In both individual and group contexts there was a focus on these changes but very little evidence in either context of discussions about whether a new substance had been formed. Only two pupils, in separate groups, raised the idea of molecular rearrangements. They also raised them in their written explanations. Once again the overall data are more or less the same in the two contexts.

Question 4 investigated the pupils' ideas of stoichiometry in reactions. They were presented with a description of a quantitative process and asked to think about the consequences of doubling one of the reactants on the quantity of product. If the pupils knew a descriptive law of constant composition then they could answer this question. The discussion in the group and the comments in the individual tests both focused on getting a clear idea of the law to use in this problem. The ideas raised seem to be similar in both contexts.

Taken all together these analyses show that there is not a lot of difference in the range and quality of ideas raised and used by the pupils in the individual and in the group contexts. There is nothing in this evidence to suggest that the social context of the group situation restricts the students ability or tendency to attend to the ideas which usefully contribute to the problem at hand as Solomon (1987) anticipated.

2. The abstract/concrete nature of the ideas used

In the context of these problems, 'abstract' was judged to be the spontaneous and clear use of the particulate model (ie thinking about atoms and molecules). 'Concrete' was used to categorise responses which were obviously either related to real objects and events or to words in the statement of the given question. For pupils at this level the particulate model is known to be difficult and this probably relates to its abstract nature. The items all required the pupils to think about their ideas of reactions, elements and compounds and this could be done with or without the particulate model. The twenty most frequently used ideas in all the individual and the group data put separately together are listed in Table 1:

% use is the occurrence frequency of the idea divided by the number of pupils (44) multiplied by 100
The most striking feature of these data, apart from the similarity of the two lists, is the lack of abstract ideas other than the notion of ratio, which is normally thought of as abstract. The rest of the list of ideas can be adequately thought of as representing concrete and real phenomena. In fact, the ideas of atoms and molecules hardly show up at all in the ideas considered by the pupils in either context. On the basis of these data, it is not possible to conclude that the group context inhibits abstract thought relative to the individual context.

3. The quality of the answers individually and in groups

This analysis showed a clear and important difference between the two contexts. The analyses presented above did not look at whether pupils used ideas correctly; 'molecules are made up of atoms' would produce the same data as 'atoms are made up of molecules'. In this analysis, the pupil comments, written or spoken, were analysed for their correctness. The aggregated ideas used by pupils working as individuals were compared with the ideas produced when discussed together in groups of four. The ideas in both cases were categorised using a scheme similar to that developed by Briggs and Holding (1986). The categories were (1) acceptable ideas about the topic under investigation, with reasoning given; (2) acceptable ideas used inappropriately with no, or wrong, reasoning; and (3) formally unacceptable ideas. The results are shown in Table 2.

Table 2
The quality of the ideas used in individual and group contexts
(% of total for each question in each context)
majority of the group. It is necessary to be cautious making
suggestions such as this since the data here is very limited
and was obtained in a test situation rather than a teaching
situation, though the two may not be so different. In both,
most of the pupils are endeavouring to build on their
knowledge by using new, difficult and probably ill
understood ideas. The confidence from sharing difficulties
may have a beneficial effect, apart from reducing the exposure
of incorrect ideas.

Conclusions and Implications

Generally, the group answers contained better reasoning than
the individual ones with fewer mistakes and better ideas.
There was no evidence that the range of ideas was reduced in the
group context or that the ideas were more superficial.
Abstract ideas were few and far between in either context.

It may be possible to conclude that the group situation was a
better learning situation since wrong ideas seemed to be
suppressed. Maybe, in the individualised context, some
pupils knew that their written statements were wrong or else
did not know an answer at all, but were obliged to write
something. It may be that the individualised situation, which
must appear more threatening to the pupils because of this
need to get an answer which the teacher will judge, is a poor
learning situation because it allows, even necessitates, pupils
to think and use wrong ideas. Perhaps freedom from this
pressure allows the exchange of opinions which takes place
in a group, with the variety of spoken ideas, to offer to
pupils a more integrated and productive perception of
problems.

No evidence for a greater dominance of consensus over logic
or concrete over abstract ideas in group discussion was
diagnosed in the experiment. On the contrary, the group
performances contained more formally correct ideas than the
individual explanations. This probably means that the
reasoning was more logical in the groups which, again,
probably makes it a better learning context for the majority
of pupils in these difficult problem solving topics. This
suggestion rationalises the results of Lazarowitz et al (1988)
who found a positive advantage with group learning
compared with individual instruction in a topic requiring high
level thinking but found a negative advantage when the topic
was more to do with information gathering.

An unquestionable feature of small group learning activity is
that it necessarily presents learners with other opinions other
than their own. Furthermore the learners have to make their
own ideas explicit to others who may not agree with them.
This necessitates a self-conscious consideration of personal
knowledge. It is likely that the use of small group discussion
as a part of a larger teaching strategy would be advantageous
for these and maybe other reasons.

Though Solomon’s (1987) prediction that group learning will
constrain the ideas that pupils use in learning seems, in this
particular case at least, not to be evident, her main point that
social influences are a central factor is undoubtedly true. It is
very important that science educators start to look seriously
at the relation between learning and the social context in
classrooms so that correct advice can be given to teachers,
curriculum developers and testers.

A Report on the Secondary Science Education Project

by Dr A M Sharafuddin & Dr A K M Shamsudduha
Secondary Science Education Project
Ministry of Education, Bangladesh

Background

In today's world, science has a decisive role in meeting the requirements of mankind and in bringing about economic development and social transformation. Hence in the education systems of both the developed and developing countries, science is being given an increasingly greater role. "Science For All" has become an accepted maxim, and a minimum scientific literacy of the entire population is considered an essential pre-requisite for development.

In Bangladesh, during the 1980s the improvement of science teaching at the secondary stage has been particularly emphasised because it is terminal for a large number of pupils and also because it forms the foundation of higher education for others. Consequently, efforts are being made to make science teaching more effective and meaningful.

In 1982-83, the Directorate of Secondary and Higher Education (DSHE) of the Ministry of Education (MOE) launched two schemes for science teaching - one for improving science facilities in 1200 non-government secondary schools, and the other for improving such facilities in 150 non-government madrasahs. The schemes included construction of science laboratories, provision of furniture, equipment, chemicals, books and teaching aids, and in-service training for science teachers.

Meanwhile, the Asian Development Bank (ADB) showed interest in providing financial assistance to Education Sector projects concerned with science and vocational education. Consequently, the implementation of the two schemes was suspended and, at the request of the Government, the ADB provided a technical assistance grant and engaged a four member team from Unesco to make a study which was completed in September 1983.

After a series of meetings between representatives of the GOB and the ADB Fact Finding Mission (November 1983), the Pre-Appraisal Mission (February-March 1984) and the Appraisal Mission (May 1984), it was decided that the two schemes would be combined. Accordingly, a Memorandum of Understanding between the GOB and ADB was signed in May 1984, followed by a Loan Agreement between the GOB and the ADB in November 1984.

The revised scheme entitled "Secondary Schools Development Project with Emphasis on Science Education" (commonly known as the Secondary Science Education Project) has been under implementation since April 1985, the date the loan became effective.

Objectives

The main objective of the project is to improve the quality of secondary education in Bangladesh with particular emphasis on science education. This is expected to lead to the establishment of science as a basic component of the school curriculum, increased supply of science-oriented manpower, and introduction of integrated science for all as a part of the core curriculum in grades 9 and 10. The specific objectives of the project are as follows:

1. To improve the quality of secondary science education and secondary education through upgrading education facilities and the professional competence of teachers, teacher trainers and administrators.

Photo: Pupils doing an experiment in a science class in a rural Project school
2. To make access to secondary science education more equitable and to reduce the gap in educational facilities between the urban and the rural areas.

3. To institutionalise inservice training and strengthen preservice training of secondary teachers, particularly science teachers.

4. To provide fellowships for staff development of Secondary Education and Science Development Centres (SESDCs), training colleges and supervisory personnel.

5. To promote and strengthen academic supervision of secondary schools, educational research, innovation and development of instructional materials.

6. To strengthen the capability of the Directorate of Secondary and Higher Education to plan, manage, monitor and evaluate secondary education through institution building and organisational reforms.

**Project Components**

The major components of the project are the following:

A. Project Implementation Unit (PIU)

The PIU, consisting of 12 officials and supporting staff, has been established on the fifth floor of DSHE at an estimated cost of Tk 2,316 million (US$1 is approximately equivalent to 35 Taka, the Bangladesh monetary unit).

B. Classrooms and laboratories

The Project provides for the construction of laboratories and multipurpose rooms, and for repairs and renovations in 1700 institutions which are most deficient in respect of science facilities. Construction work to be completed includes (1) one laboratory and one multipurpose room, measuring 111.60 sq m at an estimated cost of Tk 300,000, in 1200 high schools and 138 Dakhil Madrasahs (for teaching SSC-level science); (2) one multipurpose room (measuring 69.75 sq m at an estimated cost of Tk 187,000) in 300 high schools and 50 Dakhil Madrasahs ; (3) two laboratories and one multipurpose room (measuring 192.50 sq m at an estimated cost of Tk 516,000) in 12 Alim Madrasahs (for teaching HSC-level science; (4) repair and renovation of the 1700 institutions mentioned above at a cost of Tk 20,000 each.

C. Secondary Education and Science Development Centres

A National Secondary Education and Science Development Centre (N-SESDC) has been set up on the campus of the Teachers' Training College (TTC), Dhaka at an estimated cost of Tk 17.972 million. In addition, eight Secondary Education and Science Development Centres (SESDCs) have been set up on the campuses of eight other TTCs at a total estimated cost of Tk 87.648 million. The N-SESDC and SEDSCs will provide inservice training to teachers, supervision of classroom teaching in nearby Project schools, and function as resource centres for the improvement of classroom instruction. On completion of the Project, about 10,000 teachers will receive inservice training at the 9 centres each year.

D. Science Equipment and Teaching Aids

An estimated amount of Tk 172.804 million is being spent on the provision of essential science equipment, chemicals and teaching aids to 4000 institutions. This includes (1) Tk 55000 to each of the 1338 institutions with two rooms; (2) Tk 37000 to each of the 350 institutions with one room and 2300 institutions not having construction; and (3) Tk 97000 to each of the 12 madrasahs with three rooms.

E. Furniture

Each of the 1700 institutions with construction work, the 21 Zonal Project Offices, the 9 SEDSCs and the PIU are being provided with necessary furniture at a total estimated cost of Tk 54.635 million.

F. Books and Reference Materials

There is a provision of Tk 11.00 million for books and reference materials. Each of the 4000 institutions included in the project has been given books worth Tk 1300. The allocations for the N-SESDC and the SEDSCs are Tk 1.550 million and Tk 4.00 million respectively.

H. Fellowships

There is a provision for 368 man-months of overseas training for staff development for the PIU, N-SESDC, SEDSCs, Zonal Project Offices and selected teachers of project institutions.
I. Consultancy

There is a provision for 6 Consultants (for a total of 137 man-months) for assisting the PIU in project implementation, particularly in planning and organising the training programs. The UNDP made a Technical Assistance Grant of US$2.0275 million for financing the Consultancy and Fellowship components.

Management and Administration

The overall responsibility for implementation of the project lies with the Director General, Secondary and Higher Education, Bangladesh. The day-to-day management is left to a Project Implementation Unit (PIU) headed by a Project Director (PD). The PD is assisted by 2 Deputy Project Directors, 2 Assistant Project Directors, 2 Engineers, 1 Procurement Officer, 2 Research Officers, 1 Administrative Officer, 1 Accounts Officer and a supporting staff of 30.

At the field level, 21 Zonal Project Implementation Offices (ZPIOs) have been established at 21 old district headquarters for close monitoring and ensuring project implementation. The ZPIOs are attached to the existing District Education Offices and headed by a Zonal Project Officer (ZPO). The ZPO coordinates with other agencies responsible for implementation of the Project such as the Facilities Department and the managing committees of the institutions. The ZPO is also responsible for the academic supervision of the Project institutions.

Other Cooperating Agencies

In addition to the PIU, three agencies are taking a major share in the implementation of the Project. These are the Facilities Department, the Bangladesh Educational Equipment Board (BEEB) and the Teachers' Training Colleges (TTC). The Facilities Department, with its Zonal and District Offices throughout the country, has been entrusted with the construction of science classroom-laboratories in the Project schools, the office of the PIU and the SESCDs. BEEB has taken the procurement and distribution of science equipment to the schools. The TTCs have assisted with the organisation of short in-service courses on their campuses, particularly during vacation periods. In addition, the National Curriculum and Textbook Board (NCTB), Bangladesh Bureau of Educational Information and Statistics (BANBEIS) and the National Institute of Educational Administration, Extension and Research (NIEAER) have been cooperating in various aspects of implementation of the Project.

Project Coordination Committee

A Project Coordination Committee (PCC) consisting of representatives of (MOE), DSHE, the Facilities Department, BEEB, NIEAER, NCTB, N-SESDC, Dhaka and others as needed, has been set up to coordinate the Project. The Education Secretary, or his representative, chairs the PCC with the Project Director as Member-Secretary. There is also provision for the creation of Project Implementation Committees (PICs) at the divisional and institutional levels, as necessary.

Project Financing

In the revised Project Proforma, the estimated investment cost of the Project has been shown as Tk 1122.389 million. The major share of the cost is being borne out of the loan from the ADB (79.9%). The Consultancy Services and Overseas Fellowships are being provided out of the Technical Assistance grant of the UNDP (5.69%). The Government of Bangladesh is funding the remainder (14.39%) of the cost.

Project Implementation

The physical progress of implementation as of June 1990 is as follows:

- Out of 1700 schools and madrasahs, construction work has been completed in 1679 and the remaining ones are at various stages of completion.
- Construction of all the 9 SESDC buildings has been completed.
- The PIU building on top of the Shikkha Bhaban has been completed.
- Furniture has been provided to all institutions where construction has occurred. Office furniture for the PIU and the N-SESDC has also been procured.
- Imported science equipment and chemicals have been delivered to all Project institutions to the extent of about 80% of allocation.
• Funds have been placed at the disposal of all Project institutions (Tk 1300 per institution) for the purchase of books as supplementary reading materials.

**Inservice Training**

A total of 11,172 secondary school teachers and administrators have been provided inservice training - mostly of 2-week and 3-week duration. The subject-wise breakdown of the trainees is: 2848 in biological science, 2587 in physical science, 1523 in mathematics, 3086 in social science, 757 in Bengali and 371 in educational administration, including orientation courses (4-7 days) highlighting educational management for 171 teacher trainers and ZPOs.

**Overseas Fellowships**

Out of a provision of 368 man-months of overseas fellowships, 75 fellowships totalling 115.5 man-months have been utilised. Three short term courses in Academic Supervision, of 2-week duration each, were organised for the ZPOs and other staff of the Project (including 20 school science teachers) at The University of the Philippines. Two courses, of 4-month and 9-month duration respectively, for Project staff were organised at the University of Queensland in Brisbane, Australia. In July 1988, two officials of the Project attended the ICASE World Conference and the Unesco Seminar on Worldwide Developments in Integrated Science Education 1978-88, held in Canberra, Australia and also visited a number of institutions in Brisbane, Manila and Hong Kong on a Project Fellowship.

**Consultancy**

The full complement of 6 Consultants has been fielded. Their names and dates of joining are as follows: Dr A M Sharafuddin (February 1987), Team Leader and Science Education Development and Teacher Training Expert; Mr John E Reeves (March 1987), Physical Science Education Expert; Dr John W Ellick (March 1987), Biological Science Education Expert; Dr Orlando B Claveria (April 1987), Educational Management and Finance Expert; Dr Lourdes S Sumagaysay (September 1987), Mathematics Education Expert; and Dr Jasmin E Acuna (August 1988), Examination, Monitoring and Evaluation Expert.

The Consultants have made extensive visits to the Project schools, along with Project staff, to determine the needs of teachers and pupils, monitor the construction program and use of science laboratories and equipment, observe teaching methods and help teachers. They have also provided technical assistance in various Project implementation activities including the planning and preparation of training materials, conducting inservice courses, undertaking surveys on needs for training of teachers and problems of management of DSHE field offices and schools and on funding sources to support these schools.

The Consultants have worked in close cooperation with the N-SESDC staff and the PIU in preparing and testing self-teaching and inter-teaching modules (units) based on the new science textbooks and Teachers' Guides. Similarly, an instructional system for mathematics teacher training consisting of modules and lectures was developed. Procedures for monitoring and evaluating outcomes of in-service courses have also been designed and incorporated in the courses. Recommendations have also been made on enhancing the effectiveness of administration and management of secondary education and on reforming the examination system in Bangladesh.

**Project Benefit**

A pilot study was conducted during July-September 1990 to determine the impact of the Project after five years of operation. Questionnaires were administered through the ZPOs in 204 Project schools distributed all over the country and in 99 'comparable' non-Project schools as a control group. Data were gathered for 1985 and 1990 in respect of the schools' physical facilities and enrolment, and the assessment of headmasters and trained teachers on the impact of the Project inputs.

It was found that among the Project schools, 67% were co-educational, 25% only for girls and 8% only for boys. Among the non-Project schools, the proportions were 74%, 19% and 6% respectively. Of the Project and non-Project schools, 64% and 62% respectively, had electricity. These facts indicate that the Project and non-Project schools were, in fact, comparable.
The average number of teachers is 12.1 in Project schools and 13.3 in non-Project schools. On an average, 3 teachers of each Project school have so far been trained by the Project.

The Project schools in the villages show a 39% increase in enrolment over the 5-year period; those in towns show 37% increase. The comparable figures for non-Project schools are 37% and 21% respectively. In the cities, however, the Project schools show an increase of 27% but the non-Project schools 38%. In respect of science enrolment, the Project and non-Project schools show a similar increase in villages and towns; but in the cities, the Project schools show a much greater increase than non-Project schools - 41% versus 17%.

In terms of number of candidates appearing in the science group of the SSC examination, there is a marked increase between 1985 and 1989 among the Project schools; such increase is less marked for the non-Project schools. The Project schools, in general, report greater use of science equipment in their teaching compared to non-Project schools. This, obviously, is a reflection of the substantial input of equipment and teacher training to the schools by the Project.

In response to a separate questionnaire, the headmasters of Project schools view the major impact as improved physical facilities for science teaching, increased student interest and improved SSC performance, improved teaching skills of teachers and improved teaching climate. The trained teachers consider the most useful aspect of the training received by them to be the planning and organizing of practical work and teaching methods. Next in importance, in their view, are the laboratory skills and new science concepts.

Other Impact

With a view to keeping the teachers of Project schools abreast of the recent developments in educational thought, the N-SESDC has been putting out a Quarterly Project Bulletin named *Shikhaka O Biggan* since April 1988. Eight issues of the Bulletin have been published up to June 1990.

Largely as an outgrowth of the Project, a Bangladesh Association for Science Education (BASE) was formed in February 1988 by the professional staff of the Project and other concerned persons. The Association has since organised a number of seminars and sponsored annual national awards for two Best Science Teachers of Secondary Schools. A National Workshop on "New Directions in Secondary Science Education" was organised by the Association in cooperation with the Secondary Science Education Project during 9-17 May 1990. The Workshop was also sponsored by Unesco and UNDP. BASE has already been affiliated with the International Council of Associations for Science Education (ICASE). Some members of BASE have attended various international and regional meetings sponsored by ICASE.

Another indirect impact of the Project is the support it has been providing, along with BASE, to the promotion of various science club activities in the Project schools and other schools throughout the country. The Project organised a National Workshop on "Improvement of Science and Technology Education through Museums, Science Clubs and Science Fairs in Bangladesh" during 21-28 November 1989, in cooperation with the National Museum of Science and Technology, under the sponsorship of Unesco.

The impact of the Project is likely to gather momentum as all the Project inputs are completed, the N-SESDC network is fully operational and the provision of inservice training for teachers becomes a regular and systematic feature.

About the Authors

Dr A M Sharafuddin is the Chief Consultant to the Secondary Science Education Project. Dr Sharafuddin is also the Asian Representative for ICASE. Dr A K M Shamsudduha is the Project Director for the Secondary Science Education Project.

Using the JETS Program to 'catch the girls young' for Science and Technology in Nigeria

by Peter A Okebukola & Rosy N Agholor

The Junior Engineers, Technicians and Scientists (JETS) program was introduced into the school system in Nigeria in 1987, primarily to foster the development of science and technology culture among youth. This paper reviews the contributions of the program to the improvement of the interest level of girls in Nigeria in science and technology, and the bolstering of the achievement levels of girls in science and mathematics. Four factors were identified as being components of the JETS program that have demonstrated great potential for the attainment of this objective. These are the institutionalisation of the Best Female JETS of the Year Award, the nature of JETS projects, the all-year-round national radio and TV airing of the National JETS Project and Quiz Competition, and the institutional-level JETS activities that are slanted towards female participation. Strategies mapped out for sustaining the interest of girls in JETS are also discussed.

The development to full potential of over 100 million citizens has been the core goal of education in Nigeria. This philosophical basis of the 1981 National Policy on Education has led the way to greater access of women to formal education. The Better Life for Rural Women and Adult Literacy Programs, among others, have combined to melt part of the pervasive cultural (especially religious) barriers to the education of women. A conservative estimate from data obtained from the Federal Office of Statistics indicates that a 3% annual growth rate in the enrolment of girls in schools has been recorded in the past five years. Unfortunately, a corresponding increase in enrolment in science, engineering and technology has hardly been observed. Reviews by Okeke (1989) and Bozimo (1989) show imperceptible spurts of growth in female enrolment in a few science-related disciplines. The goal of winning more women for science and technology, therefore, needs to be more vigorously sought after.

The Junior Engineers, Technicians and Scientists (JETS) program appears to be poised to join possible potent strategies for winning more girls for science and technology in Nigeria. The JETS concept was introduced into the educational system in 1987, primarily to encourage the development of science and technology culture among youth. The idea of JETS of Nigeria was first mooted by the second author and crystallised, with the help of her colleagues in the Popularisation of Technology and Science (PTS) Branch of the Federal Ministry of Education and some consultants, into a proposal which was submitted to government in June 1987. The accent of government to the introduction of this innovation was premised on the notion that today's youth will be spending half their adult lives in the science and technology dominated world of the 21st Century. The need to prepare and tool them for the future was considered a priority by government, and the JETS concept was seen as being in alignment with this goal. A JETS Planning and Implementation Committee (JETSPIC) was established to prepare the necessary groundwork for the effective take-off of the JETS program.

JETS seeks to encourage Nigerian youths to adopt the problem-solving behaviour of engineers, technicians and scientists. It encourages fabrication and copy technology. It strives to promote the development of creativity and the channelling of such talents to solving everyday problems in the immediate environment. The forum for the pursuit of these objectives is the JETS Club. Over 6000 such clubs, enrolling an average of 120 students, have been formed in schools and colleges in the 21 states of the country and the Federal Capital Territory of Abuja. About 30% of JETS Club members are girls.

Before the introduction of the JETS concept into the educational system, there existed science clubs which were extra-curricular outfits that focused on promoting students' interest in biology, chemistry and physics. These clubs had been on the scene for the great part of the fourteen-decade history of formal science teaching in Nigeria. The replacement of science clubs by JETS Clubs came about as a spin-off from the introduction of the JETS concept and also as a response to the provisions of the National Policy on Education of 1981, which injected introductory technology into the secondary school curriculum. JETS Club activities accommodate science, engineering and technology whereas Science Clubs looked narrowly at the three major component disciplines of science which to all intents and purposes was out of tune with the spirit of the National Policy.

JETS activities as 'bait' for girls

It has been observed that many girls are now signing up to be members of JETS Clubs in Nigerian secondary schools, a trend which has implications for swelling the ranks of the female scientists and engineers in the Nigeria of tomorrow. Data available in the Popularisation of Technology and Science (PTS) Branch, the National Secretariat of JETS, indicate that the proportion of girls to boys observed a 2% increase in 1990. There are high hopes that further increases will be recorded in the coming years. The question worthy of being addressed next is: "What is girl friendly about JETS activities that accounts for the increased enrolment of girls?"

Four issues stand out for mention. First is the institutionalisation of the Best Female JETS of the Year Award. This is a national award that goes with the elegant and prestigious Francis Gana Trophy, and which was presented by the President and Commander in Chief of the
Armed Forces of Nigeria on November 28, 1990. The award is made to the best female student enrolled in a pre-university institution that earns the highest aggregate points in the highly competitive National JETS Competition. The contest is conducted in three phases: Theory, Practicals and Oral. Six subjects are involved: Agricultural Science, Biology, Chemistry, Mathematics, Physics and Technology. The second, third and fourth position winners also receive prizes and honourable mention at the national level.

The selective recognition of girls is seen to be a strong factor of encouragement for girls all over the nation to join JETS Clubs. Bunmi Ogunedeji, a female JETS from Federal Government College, Calabar, who received an honourable mention, wrote to the National JETS Secretariat on her return to school that:

"... for the fact that we went to Yola (for the JETS Competition) and later Lagos, every girl in my school wants to join the JETS Club. When the students saw our JETS badges, they fell in love with it and were asking where it could be bought. Well, I was quite happy to tell them that the JETS badges are not for sale, but worked for by us."

Another factor of attraction is the nature of the projects that JETS are encouraged to undertake. These projects have their spectrum of focus on a range of topics that have relevance to solving domestic problems. For instance in 1990, the national theme for the project was "Indigenous Food Preservation Techniques". The girls were on excellent terrain here as the traditional Nigerian homes feature such techniques that have more or less been perfected by women. Consequently, many girls exhibited projects (more than in previous years). Projects on the design of equipment for preserving local foodstuffs, especially grains and vegetables, and improved methods of slaughtering, drying, smoking and canning food materials were displayed by girls. The boys also put up a good show.

The third factor is the motivating effect of the all-year-round national radio and television airing of the National JETS Project and Quiz Competitions. Every Monday at 6.30 pm, there is a network transmission of the competition by the Nigerian Television Authority to more than 30 million viewers. On Tuesdays and Saturdays at 2.30 pm, the Federal Radio Corporation of Nigeria (FRCN) broadcasts the quiz competition nationwide.

It is believed that the excellent performance of girls in the preliminary finals, quarter finals, semi finals, and the final stages of the competition is challenging other school girls and providing them with an impetus to elect to study science and join JETS Clubs in their schools. Noteworthy in this connection, is the performance of the all-girls team from Ogun State, winning the National Young Scientists Competition in 1987 and, in 1988, the girls went ahead to knock out highly rated teams in the preliminary and quarter finals. In 1990, all girls in teams from different states, especially Imo and Lagos, gave a good account of themselves, particularly in Maths and Physics. The weekly national airing of such wonderful performances by female JETS is a source of inspiration for female viewers at home. The winning of the national award by the female JETS from Cross River State for her project on the making of paper from Guinea grass also attracted good media coverage in October 1990. Taken together, these achievements by female JETS present a source of reassurance that girls in Nigeria can quite effectively hold their own in science and technology.

The fourth factor is the next to be mentioned. At the institutional level, JETS Club activities include symposia, fairs, study tours and field trips, quiz and project competitions, science and technology debates and essay competitions. In some schools, these activities are purposely designed to encourage female participation. Guest lectures presented by female scientists, career talks and counselling for JETS Club members given by female scientists, study tours or visits to industries where female scientists work, talks on the world's great female scientists, and the inter-school JETS debates between female and male club members, are among the many 'girl-friendly' activities that have presumably helped to win more girls for JETS.

Nurturing the 'captured' girls

Having won the girls over through JETS, sustaining their interest in science and technology is a major goal of the PTS Branch as well as the soon to be established JETS of Nigeria Implementation Committee (JETSONIC). Proposals are being prepared for the production of literature to provide enrichment materials in science and technology topics for JETS. Seasoned science educators and teachers are expected to prepare such materials, especially in those topics that are rated as very difficult to learn in Agricultural Science, Biology, Chemistry, Mathematics, Physics and Technology. It is envisaged that these enrichment materials will help to make the learning of science, technology and mathematics more meaningful and a lot more fun.

The JETS Forum is another avenue for providing further motivation for all JETS generally and female JETS in particular, to continue being in JETS and aspire towards science and technology based careers. This magazine is expected to go into circulation by the middle of 1991. A number of other proposals are on the drawing board for sustaining the interest of female JETS, as well as assisting them to do well in their school examinations in the sciences and mathematics.

Conclusion

This paper has broadly looked at ways in which the JETS program has been of value in winning more girls for science and technology in Nigeria. Although the program is new, and its effectiveness has not been formally evaluated, the indications are that it is serving the useful purpose of promoting scientific literacy for women, and much more. It is, for instance, building up a pool of young female engineers, technicians and scientists that will be in the forefront of accelerating science and technology development in Nigeria. It appears that the newly formed National Association for Women in Science, Technology and Mathematics (NAWSTEM) will, in the near future, record a phenomenal membership as a result of the introduction of the JETS concept into the school system.

It should be mentioned in conclusion that JETS is a program for all youths in Nigeria, male and female alike. The impact of the program to the 'world of the boys' is not being
subordinated, and a deliberate position is not taken to diminish their efforts. Our findings show the remarkable effects the program has had on the attitude of boys toward science and technology. We have noticed, however, that the female JETS are benefitting from the program in an outstanding way, and we unequivocally conclude in favour of the position that JETS is a potent tool for winning more girls for science and technology in Nigeria.

Catalyst
A New Quarterly Science Magazine for Students

Catalyst is a new Science magazine written for GCSE and Standard Grade students in order to enhance their enjoyment and understanding of the world of Science . . . and, in the process, to improve their examination prospects!

Each issue contains articles written by teachers, examiners and scientists on key areas of Science. Coverage of biology, chemistry, physics and other sciences is carefully balanced throughout, and there are questions and activities for students to try.

In addition, there are a number of regular features: Profile describes the work of scientists, past and present; Improving Your Grade offers advice on assessment, coursework and examinations; Science Watch looks at Science in the news; and Project Page invites students to participate in nationwide surveys.

CATALYST is published 4 times a year in September, November, February and April

Annual subscriptions are available at the following rates:
UK: £11.50 (full), £4.50 (student)
Europe: £16.50 (full), £8.50 (student)
Outside Europe: £22.00 (full), £11.00 (student)

100th Anniversary of the Founding of MNU
The German Association for the Promotion of Mathematics and Science Teaching
by Prof. Hans-Jürgen Schmidt, Dortmund University, Germany

The Association's 82nd annual meeting, held in Göttingen 25-27 March 1991, coincided with its 100th anniversary. The MNU was founded in Braunschweig, October 1891. This jubilee is an occasion to remember the school situation in Germany in the 19th century and how science teaching came to be accepted in our state schools.

At the beginning of the 19th century there were mainly two types of schools in Germany. The majority of the school population attended the 8-grade Volkschule. Those who aimed at entering university later on enrolled in Gymnasien (grammar schools). These schools emphasised humanistic education, and Greek and Latin played an important role in the curriculum. There had already been attempts in the 18th century to teach "practical knowledge and skills" in higher education, too.

This development led to a new type of school, the Real schule. As the name indicates, these schools taught the realities (science and mathematics). The original idea was that the Realschulen were to prepare students for higher professional qualifications which did not require academic studies. Part of these schools, however, took quite a different course. They extended the number of school years to be completed and became comparable to grammar schools. Many supporters of humanistic education disapproved of this development, downgrading the Real schule as Nützlichkeitskramschule a long word with connotations of "grocer's shop" and "Jack of all trades". Other educationalists were apprehensive of this turnover of the whole system, alarmed that science education might breed revolution (Umwälzungsmenschen). Scientific ideas had indeed turned 19th century life and views of the world at large upside down. Many scientists were atheists - they no longer believed in the world being God's creation. It was the industrial revolution in Germany that gave the Realschulen the final push ahead. They began to prosper and those that were comparable to grammar schools became called Realgymnasien and Oberrealschulen. From 1870 on, students were entitled to pass their Abitur (final examination) at these schools thereby enabling them to read mathematics, sciences and modern languages at university. From 1900 on these students gained access to all departments of academic studies. Still, the Realgymnasien and Oberrealschulen remained a minority compared with the humanistic grammar schools that represented two thirds of all schools of higher education in Germany in 1905. The sciences were thus introduced into higher education from roots, whereas in Britain, the private public schools were the first to teach science.

However, at the turn of the century, the debate over arts and humanities versus realities and technology had not yet come to an end. Supporters of science education raised the question whether or not general culture can be arrived at by studying science. The Realgymnasien and Oberrealschulen did not mean to end up as Nützlichkeitskram schulen.

That was the situation in 1891 when the MNU - Association for the Promotion of Mathematics and Science Education - was founded. At the annual meetings of the new association this problem of science and general education was eagerly discussed. One of the outstanding speakers at these meetings was the German educationalist Georg Kerschensteiner. His lecture at the 1913 conference in Munich was later published in a booklet under the title Wesen und Wert des naturwissenschaftlichen Unterrichts (essential features and values of science teaching). Today Kerschensteiner is considered as the "father of the vocational schools".

100 years have passed since MNU was founded. We now take for granted that the sciences are fully integrated into the school curriculum. The question that was raised 100 years ago when MNU was founded is still relevant - what do students and society at large benefit from biology, chemistry, physics and mathematics teaching? For a century now, MNU meetings have provided the only national forum for the discussion of questions relating to science and mathematics teaching. At present, MNU has about 6000 members and organises yearly national meetings and regional conferences.

In 1970 the Gesellschaft Deutscher Chemiker (GDCh) founded the Fachgruppe Chemie-unterricht (Education Division). This body has 750 members at present. Similar divisions were formed from the Deutsche Physikalische Gesellschaft and the Verband Deutscher Biologen. In 1973 the Gesellschaft für Didaktik der Chemie und Physik came into being, and now has 300 members.

While MNU and the Education Divisions have attracted teachers mainly from the Gymnasien, the GDCCP comprises to a large extent persons who taught or were educated at one of the Pädagogischen Hochschulen (teacher training colleges).
International Council of Scientific Unions
Committee on the Teaching of Science

Report for the period
1 May 1990 to 31 March 1991
by Professor Joseph P Stoltman, Secretary, ICSU-CTS

Introduction
The Committee on the Teaching of Science (CTS) was established as an Inter-Union Commission in 1961, and was modified to a Scientific Committee in 1968. Its principal goals are (1) to develop and enhance, on an international scale, the teaching of science at all levels of education and training; (2) to cooperate with other organisations to further all aspects of the teaching of science; and (3) to facilitate cooperation between the Teaching Commissions of the International Scientific Unions.

Membership
Eighteen scientific union members of ICSU subscribe to and have representation on the Committee on the Teaching of Science. Seventeen Union members subscribed to ICSU-CTS in 1989. COSTED and ICASE are affiliate organisations.

Scientific Meetings
CTS sponsored the Harare Generator in Zimbabwe during early 1991. Additional meetings in Brazil, China, Hong Kong, and France, and organised by affiliates or Teaching Commissions of Member Unions, had CTS representation.

The Harare Generator
A major activity of CTS during the past year was the Harare Generator on the Preparation of Innovative Teaching Materials for Science Education. The Workshop was held in January 1991 and involved approximately 60 participants with responsibility for science education from 11 countries in Africa. Participants included science teachers, trainers of science teachers, and scientists. During the Generator the participants worked in teams to 'generate' classroom materials for use in African schools. In addition to print materials, the teams designed and built scientific apparatus for measuring and recording the results of experiments. The equipment used by teachers in their lesson ranged from classroom-made balance scales to microcomputers. The Workshop was co-sponsored by the African Biosciences Network, Unesco, FASE, The British Council, the Rockefeller Foundation, and the Commonwealth Foundation. The Generator was a followup to the Bangalore Conference on Science and Technology Education and Future Human Needs held in 1985. ICSU-Unesco Pilot Project in University Science Teaching
CTS continued its co-sponsorship, along with Unesco, of the Pilot Project on University Science Teaching. The Project has two major goals. First, it is a demonstration of how universities can pool resources to develop teaching materials useful for basic courses. Second, the project is demonstrating how science classroom materials and equipment may be readily produced by university teachers and technicians. The Project is progressing with science curricula in biology, chemistry, and physics at university centres in Thailand. It is planned that the newly developed courses in the disciplines will serve as prototypes for the development of science survey courses offered for non-science major students in post-secondary educational institutions in developing countries.

Science and Mathematics for Future Elementary Teachers
CTS and ICME are continuing collaboration on the Science and Mathematics Education of Future Elementary Teachers Project, sponsored by Unesco. Carried out by an Elementary Science Sub-Committee of CTS, the activities of the project have resulted in a 1990 publication entitled Science and Mathematics Education for Future Elementary School Teachers. The Project continues to meet the needs of Unesco and numerous nations through its international teacher workshops and publications.

Microprocessors and Microcomputers in Science Teaching
The introduction and use of microprocessors and microcomputers in science and technology education was initiated in 1985 in Southern Africa. Two subsequent programs, in 1987 and 1988, were successful in disseminating knowledge of and skills in using microcomputers. A followup workshop for Southern Africa is in the planning stages.

Locally Produced Scientific Equipment
The low-cost, locally produced scientific equipment produced by CTS focuses almost exclusively upon science education in the developing world. The aim of the project is to train university and college faculty to design and build the equipment necessary for student experiments. The project has developed specifications for low cost laboratory equipment, has trained science educators in the production of the equipment, and developed competencies among staff persons in the maintenance of the equipment. Collaboration between CTS, WHO, and IUB is being considered as a means to expand this project. The work on this project was initiated and continues in India, and is currently underway in Brazil, Puerto Rico, The Philippines, Jordan, francophone Africa, and most recently southern Africa as a result of the Harare Generator. These CTS activities are concerned with and address problems associated with the production of scientifically sound, low cost materials for teachers and trainers of teachers in the developing world.
Education in Global Change

The Education in Global Change Project is in its second phase of curriculum materials development. The Project has been designed to produce classroom materials for secondary science students that incorporate recent scientific data pertinent to global change research. Science educators and global change scientists participated in the writing of materials in June 1990. Four units have been distributed to science teachers, science educators and scientists for review. The materials development team met for a second writing session in May 1991 to design and draft three additional instructional units for classroom trials. It is planned to initiate teacher training workshops in various parts of the world in 1992 as a third phase of the project.

Ethics Issues in Science Education

Plans are being made for a workshop on teaching about ethical problems in science with the intention to reach a diverse, international audience. The team planning the workshop is made up of scientists and science educators who have a commitment to teaching about ethical issues in science. Pending the availability of funding, the workshop is tentatively scheduled for summer 1991.

Education in Natural Disasters Reduction

This project is underway to complement the International Decade for Natural Disaster Reduction. The rationale for initiating the project is based upon the lack of information available on natural disasters in science curriculum materials. A large proportion of the global population is at risk from natural hazards; yet little has been done to inform school students about natural disasters. The first phase of the project is being planned as a handbook for teachers, followed by the development of prototype teaching units.

Publications

Science and Mathematics Education for Future Elementary School Teachers, a joint ICSU CTS-ICME-Unesco publication, was issued in December 1990. It is the first of several monographs to be prepared as a result of the activities of the Science and Mathematics Education of Future Elementary Teachers Project. Several additional publications have been prepared or in planning stages during the last year. Science Education and the Computer Age: Applications, Resources and Standards is a handbook devoted to information processing, microprocessors and computers in science teaching, being prepared by a subcommittee of CTS. It will be made available free to science teachers and students worldwide.

The preparation of a volume of selected papers from the 1985 ICSU CTS Bangalore Conference on Science and Technology Education and Future Human Needs is being considered. The papers of the Conference were initially published as nine volumes. It is deemed important by CTS to extract the papers that meet particularly critical needs in science education and republish them in a single volume for greater access by science educators.

The initial four instructional units developed by the Education in Global Change Project have been distributed for review in draft format. The writing, formatting, and peer review of the units are the initial steps toward publication and dissemination.

New Areas of Interest

There are two areas that CTS is examining for possible future activities. The first is in conjunction with the ICSU-UNDP project proposal entitled Strengthening Science Training and Research in the Third World. The CTS component of the project would involve the development of prototype teaching units on interdisciplinary science at the tertiary level of education. The second is the concern with the public understanding of scientific concepts. These projects are concept papers presently and, if pursued, will take form over the next year. In addition, CTS is cooperating with the UNCED working party on Environmental Education and plans to participate in the future activities of the project.

Conclusion

CTS continues to serve a vital function within ICSU, both in its coordination of activities sponsored by the different scientific unions, as well as the initiatives that come from the Committee. The identification, coordination, and preparation of scientific research information for science education at all levels remains its major function.

A Report on the Annual Meeting of NVON
The Netherlands

by Jan Hendriks, ICASE European Representative

On the weekend 22-23 February 1991, the Dutch Association (NVON) organised its Annual Meeting in Utrecht, in conjunction with the National Education Exhibition. A feature of the meeting, therefore, was the focus on educational equipment, including textbooks and computer assisted instruction.

Highlights of the meeting, comprising a number of lectures and demonstrations, workshops and symposia, included (1) a session by Peter Nicolson, University of York, UK on Salters A-Level Chemistry, and (2) a lecture by Ellen Hirbel and Ole Bostrup, Espelergaarde, Denmark on "Science lessons for less clever secondary school children: a phenomenological approach based on experience with handicapped children". At the annual business meeting, Bert van Beek was elected as Chairman, NVON, to succeed Erik Jongejan who has held the position of Chairman from 1985 to 1991. Erik Jongejan organised a very successful Saturday evening and Sunday meeting for biology educators from Belgium, Denmark, France, Germany, The Netherlands and the UK.

An excellent conference buffet was organised in the National Museum.
Microcosmos: A Necessary Approach for Biotechnology Education

Adapted from Microcosmos News, Summer 1990

If we assume that effective ongoing education is central to the growth and development of the biotechnology industry, the question remains: What is the best way to achieve this? While there continues to be outstanding programs, a new and necessary frontier must be developed: a pre-biotechnology curriculum.

Whether we truly are to develop an educational appreciation and involvement in biotechnology will be determined by the answers to questions such as these: To what degree have we prepared classroom teachers and their youngsters to be comfortable with the foreign world of microbes? Are classroom teachers truly integrating hands-on, fun-oriented activities involving microbial themes into their life science curricula? To what degree are industry and educational advocacy groups pushing for more process skills development in life science classrooms? Are we teaching youngsters to observe, classify, synthesise data, cooperate, and think.

It is a mistake to think of biotechnology or applied microbiology as a discipline to be first taken up at a university, or even in an advanced high school class. Rather, it grows out of a continuum that must be started and maintained much earlier.

Any corporation or government sending a representative who has stated fear of flying, and who has received little preparation for his or her assigned country, would be considered irresponsible or careless. Yet this is precisely what we do in our approach to biotechnology education. We are not taking time to make school-age children in particular, and the public at large, comfortable with the fascinating, albeit alien, realm on which biotechnology is based - the ubiquitous universe of microbes.

Microbes are still thought of principally as disease-causers. People have fears that have been carried since the plagues of earlier centuries! They have absolutely no exposure to the fact that microbes are a major positive influence upon our survival and that of the planet.

Even something so basic as the source of oxygen we breathe is unknown to students, and seldom considered by teachers. Few are exposed to the fact that most of our oxygen comes from oceanic microbes.

Microcosmos is a curriculum development, teacher-training workshop and exhibits program, designed to make teachers more comfortable with the microbial world, and simultaneously to create for young students the necessary enthusiasm and confidence in science. It features an International Advisory Board and a coordinating Team as part of the Science Education Program at Boston University, USA.

Microcosmos has developed the Microtrek: Explorations of Microbial Space curriculum, featuring over 30 hands-on introductory activities. Teachers in more than 15 American states are currently using portions of it. In its timeline activity, Microtrek points out that all of the world’s greatest “inventors” were “born” more than 600 million years ago! Indeed, every fundamental activity we need for survival was invented by microbes or microbial consortia long before the first macroscopic creatures.

These inventions, this vast foreign landscape, must be brought to the schoolchildren of the world if biotechnology education is truly to take root and produce the future scientist seedlings upon which not only the biotechnology industry but mankind will depend.

From Microcosmos Update
March 15, 1991

A Microcosmos workshop is planned for Barcelona, Spain in November. The Director, Douglas Zook will be travelling to New Zealand to conduct on-site Microcosmos and biology explorations in April 1992.

Enhancing Elementary Students' Attitudes Toward Science

by William C. Kyle Jr, Ronald J. Bonnstetter, Maria A. Sedotti & Donna Dvarskas

In 1987, the Cheshire Public Schools initiated a science curriculum review. Teachers, parents, and students recognized that the existing textbook-based elementary science program was a dismal portrayal of such a dynamic discipline. There was community consensus that reading about science and acquiring scientific vocabulary words was not the same as doing science. A mandate was issued to identify, develop, implement, and evaluate a science curriculum that addressed the current goals in science education. Selected Delta Science Modules were identified as the focal curricular resources around which local curriculum development could be initiated. The first year evaluation supports the fact that Cheshire's ScienceQuest program is most successful. Between 50% and 88% of the students at any given grade level indicated that science was their first or second favourite subject in school. The nature of the science taught does make a difference! Administrative support and the implementation process are also keys to success.

Introduction
The 1980s were exciting and challenging times for educators. Adding to the excitement was the realization that students who entered kindergarten during the Fall of 1988 will be the first high school graduates of the 21st century. Thus, responding to the question, "Are students being provided with the scientific and technological literacy essential for life as productive citizens in the 21st century?" is a curricular imperative for the reform era of the 1990s.

In March of 1987, the Cheshire Public Schools established a K-12 science committee to address the above question. Internal audits revealed a local situation that paralleled the recent image portrayed by "The Science Report Card . . . " (NAEP, 1988). The audit revealed that: the elementary program was antiquated in nature, lacked continuity, and coordination; the process-approach was not used often; elementary teachers did not have adequate resources to teach science; and, teachers did not feel they possessed an adequate science knowledge base and were not comfortable teaching science. Teachers were not familiar with the current goals in science education (NSTA, 1982).

During the next six months the committee developed: a mission statement; a rationale for teaching science: program goals and objectives; a plan for identifying, developing, and piloting curricular materials; a rationale for staff development and program implementation; and, the evaluation component for the first year pilot. The committee decided to begin the curriculum revision process at the elementary level to allow for subsequent curriculum development and continuity at the middle school and high school.

During the 1987-88 academic year, Cheshire's ScienceQuest program was piloted in selected K-6 classrooms. A major goal for the first year was to enhance students' attitudes toward science. Thus, students' attitudes were assessed at the completion of the first year of the pilot. Concomitant goals were to enhance teachers' awareness of the current goals in science education; science background so that curriculum development efforts would be relevant and implementation efforts successful; and conceptions of teaching and science (see, for example Kyle, Abell & Shymansky, 1989; Kyle & Shymansky, 1989, Osborne & Freyberg, 1985).

The Process of Initiating Change
There are some common characteristics associated with the process of initiating change and, ultimately, improving schools. The innovation implementation model used in Cheshire was also utilised in Richardson ISD, Texas, where the implementation of different curricular materials produced similar attitudinal enhancement among students (see Kyle et al., 1988a, b; in 1989 Richardson was recognised as an Elementary Science District-wide Exemplar in NSTA's Science Education Search for Excellence).

Penick and Yager (1983) report that exemplary programs are designed to be excellent. Such programs do not rely upon routine textbook selections. A considerable amount of time is spent on developing the curriculum, organising how it will be presented, and encouraging teachers to work as teams. Thus, teachers are involved in staff development activities over several years, including summers.

The nature of staff development activities is so important that Berman and McLaughlin (1978) concluded that
the major factor affecting success of staff development efforts related to educational innovations was the administrative support of such endeavours. It is well documented that staff development is an essential component of the curriculum development, implementation, and maintenance process (Fullan & Pombrett, 1977; Hall et al., 1975; Hall & Louches, 1976; Kyle, Bonnsterter & Gadsden, 1988a; Kyle & Sedotti, 1987). Additionally, exemplary programs start with, and continue to use, an ongoing assessment of teacher, student, and program needs to guide future staff development.

Cheshire’s Science Committee recognised that exemplary science programs are the result of effective organisation, planning, and staff development initiatives. Thus, they developed a plan to ensure that ScienceQuest was well articulated and well coordinated; integrated a balance of science processes and concepts; provided students with opportunities to identify and solve problems; enhanced higher cognitive processes and skills; went beyond the mere possession of information to application of the concepts; and, included societal issues.

During the summer of 1987, the science committee identified curricular materials appropriate for pilot testing in grades K-6 during the 1987-88 academic year. Selected Delta Science Modules were identified as the focal curricular resources (see Kyle & Kane, 1988). Additional modules and activities were developed locally to integrate a focus on the application of scientific concepts, as well as science-technology-societal issues. The modules and activities were sequenced to ensure a balance between life science, earth science, and physical science across each grade. The initial piloting of the ScienceQuest program was intended to determine: the success of the modules, activities, and materials and whether they should be maintained in the program as curricular identification, project development and piloting continues; whether modules and activities need to be revised to address district, teacher and/or student needs; as well as, to identify curricular areas for further local curriculum development to address effectively the district's mission statement, rationale, goals and objectives.

Thus, Cheshire’s Science Committee sought to ensure that ScienceQuest would meet the standards for excellence cited by Project Synthesis and the National Science Teachers Association (Harms & Yager, 1981; NSTA, 1982). In addition to the curriculum identification, implementation, and evaluation efforts that have been initiated, perhaps the most important component of the entire curriculum revision process is the staff development that teachers received in conjunction with program development and implementation (see Table 1 for a description of the staff development associated with the ScienceQuest project).

ScienceQuest: First Year Results and Discussion

After only one year of the pilot project, ScienceQuest students possessed significantly enhanced attitudes toward science when compared to their counterparts in control classrooms, as measured by the Preferences and Understandings attitude questionnaire (see Table 2). The data support the fact that elementary students have a preference for inquiry-oriented, process-approach science.

Frequency analysis reveals that over 60% of ScienceQuest students selected science as their first or second favourite subject in school. Only 35% of the control students indicated similar preferences. This dichotomy is further dramatized by the fact that only 6% of ScienceQuest students selected science as their least favourite subject in

TABLE 1
SCIENCEQUEST STAFF DEVELOPMENT

Each month from September to November and January to May, there were grade level meetings for the pilot teachers. The staff development sessions provided pilot teachers the opportunity to:
- delve into the history and philosophy of science education in order to gain an appreciation of the goals associated with hands-on, process-approach science at the elementary school level.
- study the characteristics of the curriculum development initiatives of the 1960s and 1970s, as well as attributes of their success as measured by student performance.
- investigate the current goals identified for science education at the national level. Instructional strategies to address the goals in elementary science classrooms were also discussed and modelled.
- participate as active learners in the activities associated with each module that they would instruct in their classroom. During these model instructional sessions, teachers were able to make preliminary revisions or modifications to the organisation of the modules to ensure effective implementation. At the completion of these sessions, teachers ordered any additional equipment or resources that they needed to effectively instruct the module.
- receive content updating to enhance their science background in areas correlating with eventual instructional responsibilities. The content updating was provided as needed and requested by the pilot teachers.
- share information regarding the nature of curriculum implementation, the need for revision/modification of specific modules, and modes to resolve any difficulties that may have arisen. Teachers prepared and submitted written evaluations for each module. The evaluation included, but was not limited to, the pilot teacher's recommendation to keep or delete the module from the curriculum, as well as a detailed report of any adaptations made to the module to achieve the desired outcomes with their students.

During the summer of 1988, pilot teachers worked with the science committee to continue the process of identifying curricular materials, revising modules based upon pilot teacher evaluation, identifying materials and equipment necessary for instruction, and initiating the process of local curriculum development. A goal for second year pilot teachers is to develop a strand of curricular materials and activities with a focus on science, technology and societal issues and/or applications of scientific concepts that can be integrated into the curriculum.

The second year of the ScienceQuest implementation (1988-89) had approximately 40 new teachers piloting the program and participating in the sequence of activities associated with the first year staff development plan. In addition, work related to the development of a criterion referenced evaluation system to assess students' mastery of science processes and concepts began during the 1988-89 academic year. The formal evaluation of students' attitudes was continued with a longitudinal assessment of students in first and second year ScienceQuest classes compared to control classes completed in May 1989.

A formal assessment of student achievement will be a part of the second year pilot plan, as well as an assessment of teachers' concerns and levels of use of the program in compliance with the Concerns-Based Adoption Model. The implementation efforts undertaken, and planned for the future, will ensure that Cheshire's ScienceQuest curriculum will be a dynamic, rather than static, elementary science program.

school compared to 15% of the control students.

Research indicates that as students progress through school that their attitudes toward science decrease and they appear to be unenthusiastic about the value and personal relevance of their science learning (Huftile, Rakow, & Welch, 1983; NAEP, 1978, 1988). Students in the control group appear to reflect this trend when the results for their combined first or second favourite subject preferences are viewed. Forty one percent of the control students in grades 2 and 3 select science as their first or second favourite subject. This percentage drops to the 30% range by the time students reach 5th and 6th grade. Similarly, 2% of 2nd and 3rd grade control group students select science as their least favourite subject, while 20% to 28% of 4th, 5th or 6th grade control group students make such claims. However, over 50% of the ScienceQuest students at each grade level selected science as their first or second favourite subject. The percentage peaks at 3rd and 4th grade with 83% and 88% of the students making such claims. Obviously, when 50% to 88% of the students at any grade level, and 63% of the students across all grades, have such positive images of a program, it is a tremendous success!

The data also reveal that students in ScienceQuest classes wish they had more time for science (59% vs 40%); are more likely to recognise that the science they study is useful in their daily lives (74% vs 68%) and will be useful to them in the future (68% vs 59%); view their science experiences as fun (84% vs 62%), interesting (88% vs 70%), and exciting (71% vs 52%), all while fostering a feeling of success (60% vs 49%) and curiosity (71% vs 67%).

The results presented herein contrast sharply with national norms in the United States (NAEP, 1978, 1988). The positive attitudes of students in the ScienceQuest program can be attributed to the nature of the program, in conjunction with the staff development that teachers received to implement an effective science curriculum. The nature of the science taught does make a difference! In addition, when teachers are provided with appropriate staff development, they are able to portray an image of science that is fun, exciting, and interesting. Many teachers are enjoying the teaching of science as it should be for the first time in their careers, and they have the support required to do so!

Native American Elders Teach Science

by Patricia Nelson & Claudette Bradley

Helping all students succeed in science is one of the hottest topics in US education today. Many states are forecasting a trend that is now a reality - schools composed of a majority of culturally and racially diverse students.

This composition creates a unique opportunity for children to live and learn together in new and exciting ways. Science teaching methods which reflect this diversity can help teachers bring good science into the classroom, spark student interest and validate the "ways of knowing" of all cultures.

At Denali School in Fairbanks, Alaska, an innovative project has been implemented to help students blend Native American culture with science and mathematics by using the knowledge and wisdom of Native Elders. Students study the forces involved in flying a plane (gravity, lift, thrust and drag) by exploring the rich oral tradition of their ancestors and by the direct observation of nature.

Lessons may start with a "Bird Walk" and listening to stories of birds told by Native Elders in the community. Students learn from such stories that ideas from their own cultures can be "very good" and "thoroughly reliable". Native cultures have a vital oral tradition drawn from the direct observation of natural phenomena.

Scientific knowledge and wisdom of the world is embedded in stories told by the elders. When students feel their culture is validated, learning science can become a richly rewarding by-product.

At Denali School, lessons on flight begin with the study of birds, like the Eagle, Crow, Raven, Duck, Goose, and Swan. Students are assigned to a small group to gather folklore, native stories and scientific data from books, technical reports, native elders and other wildlife specialists to find out such topics as how high a bird flies, how much it weighs, how wide is its wing span and what are its habits.

Stories and information are presented in song, written reports, dramatic skits, or charts. Students then create a book on Flight by writing their observations of birds during their Bird Walks, drawing pictures and summarising stories told by the visiting elders.

When all the facts are gathered, students create a bulletin board with a graph of the altitude on the vertical axis and the name of each bird on the horizontal axis. The class plots ratios of body weight to wing span, as well as body dimensions to wing span.

From this information, students draw conclusions about how the ratio of wing span to body dimensions impacts flight. The ratios of wing span and the body shape of various airplanes can also be placed on the bulletin board next to the bird graph, with the altitude on the vertical axis and the names of planes on the horizontal axis. Students draw conclusions about the dimensions of the plane and the height it is able to reach by comparing this data gathered on birds.

A variety of follow-up activities can extend lessons and spark student interest. Students can design and make their own airplanes of various materials, hold a contest on how high and how far each plane can fly, or draw the flight curves with the height and distance travelled. A field trip to the airport, interview with a native pilot, or using a flight simulator on the computer will also enable them to enjoy learning science with their friends. Students can enjoy plotting a course from their hometown to some distant place. They can learn to read latitude and longitude, as they plan to avoid mountains and turbulent areas and gain facility in using a map.

Even Bernoulli's principle becomes simple to grasp when students gather their own data. This principle also operates in bird flight.

All cultures offer explanations of such natural phenomena. The Indian people of North America refer to the eagle as the Thunderbird. As the Thunderbird descends in the air he is also bringing the Great Spirit to the earth. When the eagle descends in the air, he bends his wings and makes a thundering noise in much the same way a jet does on landing (when the airplane descends in the air, the flaps are lowered, so that the airplane will descend).

A simple paper demonstration can illustrate the Native American's knowledge of Bernoulli's principle. By holding a light piece of paper about 3/4 inch by 3 inches against the chin under the lower lip and parallel to the floor, the paper will rise when the students blow over the top surface of the paper. The air blowing across the top of the paper moves faster.

It is through imitating models in simple hands-on experiments that students learn to reason about the principles of gravity, lift, thrust, and drag. Students become excited when they use this knowledge of everyday
life to engage in the process of scientific thinking.

Often students learn that the science is disembodied knowledge that cannot be questioned, knowledge from a scientific authority whose author is inaccessible. Through helping students think out loud about drawing conclusions from their own collected data, knowledge becomes more than the private property of teachers or textbooks.

Any teacher with time and desire can incorporate the rich traditional stories and knowledge that has existed in any culture into a science unit. By teaching science through the use of elders, oral stories and natural observation, students are encouraged to make the knowledge personal and individual. Science which stems from the authority of textbooks is revealed to be human.

A different sort of scientific authority emerges, based on personal experiences and acknowledging and nurturing the viewpoints of students' own cultures. Including cultural perspectives helps students engage in their own process of thinking, evolve their own patterns of scientific process, and experience positive feelings about themselves and their cultures. The possibilities are endless!

The Questioning Technique in Science Teaching

by Sonia Williams
Science Department
Shortwood Teachers College, Jamaica

The typical environment of a primary school student is complex as it is composed of a number of factors which interact with each other to varying degrees. The factors include limited equipment and resources, large numbers of students in each class, classroom buildings with blackboard separations so that it can accommodate more than one class, inadequate library facilities, examinations such as Common Entrance Examinations and the National Assessment Program, neglected physical plants, the teacher, students and their peers.

The most important factor in nurturing students in the primary school environment is the solitary teacher. One challenge that faces us as teachers, comes from allowing students to be active, enquiring learners. This goal can be achieved if we perform appropriate teaching techniques. This paper focuses on questioning technique.

Situation 1
Questions introduced with the pairing of some scientific phenomena can instill a sense of wonder or a spirit of inquiry when they are presented at the beginning of a lesson. Pam was a teacher of a fifth grade science class. She placed a glass filled with water on a table in full view of all her students. She then placed a pile of coins next to the filled glass and asked her students, "How many coins will this glass of water hold without spilling any water?" At first, the students were quiet. Then there was noise as many students started guessing. One eager boy came forward and the teacher allowed him to add the coins. The boy kept adding coins; as many as fifteen, before the water spilled. He was astonished as well as the rest of the class. Their guessing seemed wild in comparison to the revelation that the filled glass could hold so many coins. The students held discussions on various aspects. They wanted to know about the volume of water, the size of the coins, the size of the container, the volume of the container. One student mentioned that he observed bubbles rise to the surface each time a coin was dropped in the glass.

Situation 2
The Grade 4 Curriculum (1980) produced by the Ministry of Education, Jamaica, focuses on green plant parts and their functions as well as a food test using iodine to detect starch. One way to introduce the concept that plants need materials to make foods would be to ask, "What things do green plants need to make their food?" A discussion with primary school teachers revealed that students are most likely to respond with 'water' and 'soil', though this latter response is not entirely correct, and that they are hardly likely to respond with 'light'. Explanations suggested by these teachers revealed that students do not associate sunlight with a form of energy. The follow-up activities that teachers must engage in should serve to assist students in understanding that light is a form of energy which plants require in order to make food.

Situation 3
When students are asked "How do plants get water?", some responded, "through their leaves". An examination of the cultural context enabled us to understand that response. In common Jamaican language we say, "water the plants". No one says, "water the roots". Furthermore, these students observe that when people water plants, the focus appears to be on wetting the leaves. This they also experience when it rains. Students can become baffled and confused and may even perceive science as contradictory and difficult. It is our task as science teachers of Primary School children to help them to accept the fact that their theories, the evidence they obtain from their senses, and even everyday language, may be wrong or incomplete.

Situation 4
In showing students how to classify a group of non-living things, Mary, the teacher of a fifth grade class asked, "What is the shape of the ball?"
Alex: "Circle, Miss."
Teacher: "No."
John: "Square, Miss."
Teacher: "Anyone else? Come on, someone must know the answer."
Marsh: "Round, Miss."
Teacher: "Yes, but that is not the answer that I am looking for."
Several students: "Me Miss, me Miss." (students shouting and raising their hands)
Simon: "A sphere, Miss."
Teacher: "Yes, Simon, you are correct. Did everybody hear what Simon said?"
Chorus: "Yes, Miss."
Teacher: "What is the shape of the ball?"
Chorus: "A sphere, Miss."
Contrast this follow-up by the teacher with an episode from another teacher who asked the same question.
Teacher Harrison began her lesson by asking, "What is the shape of the ball?" Students gave various responses. Then she invited students to do an activity in order to find out. Students were placed in groups and received instructions which indicated that they should trace a particular ball on paper, observing the edge, and that they should measure several distances around the ball. These are some of the
responses the groups arrived at.
"It is round and it is hard. When I put a piece of string around it and remove the ball, the shape is a circle."
"The edge is curved all the time. It is a circle."
"When I traced the shape of the ball, I got a circle."
Teacher: "You have all agreed that the edge of the ball is a circle. Where is the middle of the ball?"
Marcia: "Out here, Miss" (pointing to a specific spot on the outside).
Joe: "Inside, Miss."
The teacher then cut several styrofoam balls in halves instructing students to make horizontal and vertical measurements from the edge to the middle. At the end of this activity, students learned that the edge and the middle are used to describe spheres and that the vertical and horizontal distances between the edge and the middle were similar.

Convergent questioning focuses on eliciting a single right answer. When convergent thinking is followed up by guessing (what the teacher is thinking as observed in Mary's class), it sometimes places the student in an uncomfortable position. This situation may result in breeding fear of answering, at the risk of being wrong. In addition, convergent questioning can inhibit productive thinking as shown in Mary's class.

How can a teacher introduce divergent questioning in a science lesson? After having worked with batteries and bulbs you might ask, "How many different ways can we change the brightness of a bulb?" The students will offer their suggestions. The teacher should avoid making judgements and instead should accept and record the students' responses. Some students might limit their thinking and therefore, may not answer right away. In this case, the teacher should provide time in which the students can give their suggestions. Children tend to focus on one answer so rephrase the question, for example, "Is there only one way to make the bulb brighter?" Next, children's activities must be closely supervised. They must be fair, and variables must be controlled. Try to allow different groups of students to work on different activities.

An open ended lesson is advantageous because it encourages a variety of responses. However, students have to become accustomed to this mode of questioning, thinking and answering, otherwise, they will not understand that some questions have a variety of answers. All the varied responses need not to be investigated. The emphasis should be on the generation of possibilities as a means of expanding the students' awareness of their environment, as well as their ability to approach the question in different ways.

A Balancing Act
Presented at CESI Make, Take, Meet and Greet
by Cris Leibner, Kettle Moraine Public Schools, Wales, WI 53183, USA

Students encounter the action of the force of gravity without really thinking much about it. Besides holding things on earth, gravity allows coasting downhill on skis, bicycles, and skateboards. Playground slides, bouncing balls, amusement park rides, paper airplanes, swings and many other things are affected by gravity. Sometimes the force of gravity is used to balance things. Students of all ages can make and use a simple toy that can help them explore and learn about the force of gravity. "Corkies" can be made by using readily available materials. By making various adjustments to the position of the wires, "Corkies" can be made to perform gravity defying tricks.
Science and Technology in Action in Ghana

by Peter Towse & Jophus Anamuah-Mensah

Background

In spite of changes over the past quarter of a century or so, much of the science taught in Africa (and elsewhere for that matter) remains closely linked to narrow, out-dated examination syllabuses which continue to emphasise facts and the rote learning of concepts. Indeed, in schools throughout the continent one could be forgiven for feeling that any changes are largely illusory as one continues to see science taught by traditional 'chalk and talk' methods. Moreover, the countries of Africa have jumped onto the science and technology bandwagon without realising the part indigenous culture could play in ensuring the success of science education which, in effect, has always been installed in a cultural and historical vacuum.

Most secondary students thus view science as relevant only within the confines of the school laboratory (if there is one) and bearing no relationship to everyday life. Since few will study science further, such a narrow academic interpretation is wholly inappropriate. To hold well-informed and socially responsible views, one needs to have not only a knowledge of science and technology, but also an awareness of at least some of the issues involved in applying that knowledge to contemporary society. Thus, we should provide students with the opportunity to think about some of the issues and ask at least some of the right questions (Steward & Towse, 1987).

Writing in Ghana nearly twenty years ago, French (1973) emphasised the importance of studying science at secondary school, not only for the advancement of the community as a whole, but also for the future prospects of the individual. This is even truer today, and applies to all individuals. In other words, science is not solely the preserve of the future scientists. It follows that our courses in schools should not be geared solely to the pyramidal structures of old, where each stage of the educational system was seen largely as a preparation for the next.

The reform of science curricula in Africa has been discussed almost exclusively within the educational community, with little contribution from those in the wider 'world of work' which will absorb the school leavers. Perhaps science education is too important to be left only to those who practise it, and what we need now is a much wider involvement in deciding what science we should teach in our schools.

Science in Ghanaian Society (SGS)

In the early 80s efforts were made in different parts of the continent to bridge the gap between the science learned in school and that encountered in the 'real' world outside. One of these responses was the Science in Ghanaian Society Project, which attempted to see science and technology through Ghanaian culture. For, although science and technology principles, theories and laws are universal, the media in which they are found and the manner in which they are practised varies from culture to culture (Yakubu, 1984). In other words, there was a call for a view of science as practised within the local culture, or ethnoscience. Thus, modern technological methods may be used in the developed countries, but in the developing countries there is often a mixture of both traditional and modern methods.

Technology is not just about machines or processes. It is essentially about the application of ideas to solve human problems. Take, for example, the smelting of iron. Traditional methods of producing iron were used throughout Africa long before the advent of the blast furnace, yet only very rarely are such methods referred to in science lessons, even when they are currently practised. Haden (1973) drew attention to traditional iron smelting in Uganda, and his students worked with village elders to build a furnace. One of us tried to do the same in Zimbabwe, but was accused by some of trying to romanticise, even trivialise, these traditional practices. There is, of course, a danger of adopting an anthropological approach, but surely such practices are not so remote that this is inevitable. Indeed, such practices must surely be more relevant to large numbers of African students than the modern technological methods described in standard textbooks. That is not to say that we should not teach the modern methods, merely that the traditional methods are a more logical starting point. Indeed the two ought to co-exist, with different emphases on each at different levels.

SGS was not a course but a 'quarry of resource materials', a series of booklets produced by practising teachers for use in schools, training colleges, polytechnics, and adult education programs, in short to serve the needs of all those interested in endogenous development of Ghana. They were to do this by encouraging students to become aware of the rich scientific and learning potential of their environment. Relevant activity must start with the students and their experiences, and 'to humanise science is to make it relevant'. What a pity we cannot, at least occasionally, treat science as we would the arts. Then
students might see science not merely as a set of facts but also a collection of social, economic and political points of view. In that way we could truly expect to produce more informed citizens.

The SGS booklets covered traditional or cottage industries as shown in Table 1. The aims of this project were admirable, but the teachers' resource materials which were developed failed to reach many of the country's science classrooms. The emphasis in duplication was on minimum cost, and the materials lacked the photographs and other illustrations which would have made them visually more appealing. Also, they concentrated on the science involved and ignored many of the underlying issues, and there was no reference to the intermediate technology industries which offer employment to many school leavers. The SGS project has recently been revived but we are looking, with the support of the SGS team, to extend its philosophy by launching a new project called Science and Technology in Action in Ghana, which will produce materials for students as well as for teachers.

Science and Technology in Action in Ghana (STAG)

For far too long, the science taught in schools and the science practised in industry have been perceived as quite different. Moreover, through a lack of awareness of what goes on in industry, teachers have tended to oversimplify the application of scientific knowledge and concepts. We think the time is right to bridge the gap between school and industry, and bring industrial applications of science and technology more into the mainstream of science teaching, particularly at the secondary level. To facilitate this, we believe that those in universities, research institutions, and industry should pool their resources and help practising teachers by producing those materials to help in the day-to-day interpretation of science syllabuses.

Goldstein (1978) points out that in the USA secondary students use textbooks for up to 75% of the time they spend in class and up to 90% of the time they work at home. In Africa, where teaching methods are often very formal, the figures could be just as high - providing that there are textbooks available, of course. He finds it surprising that studies of the sociology of education in Africa pay no attention to the role of textbooks, which 'transmit socio-political values not just openly but also by omission, biased presentation of "facts" or indirectly when the values are hidden in an exercise or task to be done'. Aware, then, that it is not enough simply to produce support materials, but that such materials must represent a balanced view of the industrial activity of the country, we propose, as a first step, to produce a book which will reflect fairly and comprehensively what goes on in the following industries (see Table 2):

<table>
<thead>
<tr>
<th>Traditional or Cottage Industries covered by Science in Ghanaian Society booklets</th>
</tr>
</thead>
<tbody>
<tr>
<td>palm wine</td>
</tr>
<tr>
<td>groundnut oil</td>
</tr>
<tr>
<td>palm kernel oil</td>
</tr>
<tr>
<td>shea butter</td>
</tr>
<tr>
<td>dragnet fishing</td>
</tr>
<tr>
<td>fresh water fishing</td>
</tr>
<tr>
<td>fish preservation</td>
</tr>
<tr>
<td>sweet kenkey preparation *</td>
</tr>
<tr>
<td>Fanti kenkey preparation *</td>
</tr>
<tr>
<td>Ga kenkey preparation *</td>
</tr>
</tbody>
</table>

* Sweet kenkey or Ashanti kenkey is a sweet meal porridge. Fanti kenkey is fermented maize dough wrapped in plantain leaves and boiled. Ga kenkey is boiled corn dough balls wrapped in leaves.

</tbody>
</table>

Table 1 Traditional or cottage industries covered by SGS booklets

Table 2 Ghanian Industries included in STAG Project
This will give a good cross section of the industrial activity of Ghana, for not only are these the industries which form the economic backbone of the country, they also provide employment opportunities for a large percentage of the country’s school leavers.

These accounts will be written initially by those working in the various industries. Our task will be to work with the teachers to eliminate bias, help with editorial changes, and assist in writing the final versions of the different accounts. Those in the field obviously have the technical knowledge; the teachers are familiar with the scientific and technological abilities and interests of children. Working together we are confident we can make that technical knowledge come alive for the students.

We are looking for fairly simple, straightforward accounts, written in a language and style that will appeal to secondary teachers and students alike. We hope that the accounts will be well illustrated with photographs, clear line drawings and, where appropriate, flow diagrams. A table will relate the various parts of the book to the syllabus, so that the full relevance of the material will be clear at all times.

Later, we will develop other materials for students, deriving in part from some of those materials produced above. Sometimes they will contain practical activities (for example, simulations of industrial processes), and sometimes they will provide the opportunity for examining certain issues in depth. In other words, they will have much in common with the Science and Technology in Society (SATIS) materials. We are also keen to produce cuttings booklets, case studies, games and simulations. Material will also be produced which describes examples of intermediate, even low, technology in the country, particularly those developed under the aegis of the Technology Consultancy Centre (TCC) at Kumasi.

Students in developed countries generally are aware of the laws and principles at the heart of scientific and technological activity in their own culture, but not of such activity in the Third World. This was the motivation behind the development of the Third World Science materials (Williams, 1983), intended to show students in the UK the science inherent in various activities in developing countries, for example:

- carrying loads on heads
- charcoal
- clay pots
- dental care
- distillation
- energy converters
- fermentation
- housing
- iron smelting
- methane digesters
- natural dyes
- plants and medicines
- salt
- soap

Why not, then, develop similar materials for use in the Third World itself, where students would be able to identify with the activities from personal experience? For some years, the Advanced Diploma course for overseas students at the University of Leeds has included the development of teaching materials based on various aspects of housing, sanitation, heating and cooking, blacksmithing and foundry work, and alternative energy sources (especially solar energy). This involves a lot of good, solid science which can be tackled through simple, everyday activities.

To appreciate the significance of the TCC as a source of relevant materials, one has to understand a little of its role in Ghana. Following the overthrow of Nkrumah and the collapse of his industrialisation program, the University of Science and Technology, Kumasi, founded to train the high-level manpower for that program, was forced to re-examine its role and adapt to the new situation (Powell, 1987).

It associated itself with Suame Magazine, the largest informal industrial area in Ghana comprising 27000 craftsmen, wayside auto-fitters and apprentices in 2000 shanty-style workshops. To many, the Magazine was a scene of squalor and disarray, but to the more astute it represented a considerable potential of human skill, ingenuity, enterprise and the will to succeed in a difficult and hostile environment. The University formalised its interest in grass roots development by creating the TCC, dedicated to solving technical problems brought to it by all Ghanaians, regardless of ability to pay. Some years up to 20% of its effort has been on behalf of Government or large businesses, which pay conventional consultancy fees, but its major effort has always been reserved for small-scale, informal, craft industry and agricultural projects funded either from inside or outside the country.

A number of enterprises were established, producing a wide range of products including steel bolts and nuts, gear wheels, agricultural tools, carpenters' saw benches and wood turning lathes, soap making plant, palm oil mill plant, food processing machines and charcoal kilns. Beekeeping and minimum tillage farming have been introduced and a pilot tilapia fish farm developed. Some 30 small-scale soap plants have been established, together with a similar number of rural palm oil mills.

The success of the pilot soap plant prompted the use of castor oil as a cheap alternative to palm oil, and led to the export of the technology to neighbouring countries. In Mali, where no palm oil is produced anyway, shea butter blended with fish oil or groundnut oil proved a surprising alternative!

The University has thus shaken off the traditional 'ivory tower image' and adapted to the needs of its environment. The success in Suame led to the establishment of two more units, one at Tamale and the other at Tema, and so the TCC has demonstrated its capacity to play a very important role in the economic development of Ghana. We consider this activity worthy of coverage in materials which reflect the full relevance of science and technology in Ghana.

The development of all these materials will actively involve teachers, several of whom will spend some time in the relevant industries or other activities to assess what would be most appropriate in the classroom and how best it might be achieved. The emphasis will be on an 'applications first' approach, as in the Salters schemes.
We will seek financial backing for the project from industry, educational trusts, aid agencies, etc., both inside and outside Ghana. Thus, although the materials will be produced to professionally high standards, the emphasis will be on keeping the cost to a minimum and putting the materials within the reach of every school in the country.

Initially, this will be a joint project involving the Universities of Leeds and Cape Coast but gradually, over a period of about two years, the University of Cape Coast will become solely responsible for the project.

Pasteur and Microbes
A Teacher Resource Book
Commemorating the 100th Year of the Pasteur Institute 1888-1988

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute.

It also contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few. These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation.

Order by sending US$8.00 or £5.00 (add 25% postage and packing) to:

NEW ICASE PUBLICATION

Empirical Research in Mathematics and Science Education
Proceedings of the International Seminar
6-8 June 1990
University of Dortmund, Germany

The proceedings (221 pages) includes the following papers: Using an expert system to analyse students' ability to process information in the area of basic electricity, Christoph von Rhoneck; Commonsense understandings of causes of motion, Denise Whitelock; Assessment of performance unit: a longitudinal study of science performance at ages 12 and 14 in the UK, Martin Braund; A label as hidden persuader: chemists' neutralisation concept, Hans-Juergen Schmidt; Student's understanding of the particle nature of matter and its relation to problem solving, Dorothy L. Gabel; Towards a more effective methodology of research on teaching and learning of mathematics: a critique, Elisabeth Sander; Introduction to the study of interdependence between selected traits and the use of the question-answer technique in problem solving, Matthias Ehrsam; On the methodology of the investigation of the pupils' structures of knowledge, acquired in the lessons of chemistry, Rolf Lammel; Concept learning in biology teaching, Diitmar Graf; Two decades of research in science education: an American perspective, Anne C. Howe; and other articles.

Copies, at a cost of US$8.75 including postage, can be ordered from:

Science Teacher Education

A new ASE publication
The Association for Science Education (ASE) has recently launched a new publication called Science Teacher Education.

This is for all concerned with the pre-service education, induction and professional development of science teachers.

It is not a research journal but a forum for discussion. Issues will be sent out in January, April and September.

Sample copies are available from:
The Association for Science Education
College Lane
Hafter
Herts AL10 9AA
UK

The National Society for Clean Air: Teaching Pack
The National Society for Clean Air (NSCA) has published a teaching pack on the issue of global warming, or the greenhouse effect. The pack contains information, evidence and enquiry sheets which form the basis for a class exercise for fourteen to sixteen year olds.

Students are encouraged to sift through a range of material and to come to their own conclusions about what should be done about the problem. The pack also contains role play activity and teachers' notes. Copies are available at a cost of £3.00 from:
NSCA
136 North Street
Brighton BN1 1RG, UK
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1991

July 7-12
CONASTA 40
Location: The University of Adelaide, Adelaide, Australia
Contact: Tony Diercks, Convener, CONASTA 40, PO Box 346, Parkholme, SA 5043, Australia
The Australian Science Teachers Association invites you to participate in the fortieth annual conference of the Association. Prominent national and international educators, scientists and classroom practitioners will present keynote addresses and workshops on the theme "Merging the Boundaries". On the Tuesday of the Conference, the keynote lecture and workshops will be combined with the Australian Reading Teachers Association Conference at the Convention Centre. A variety of excursions are included in the program.

July 12-14
Annual Conference of ASERA
Location: Iluka Inn, Surfers Paradise, Gold Coast, Australia
Contact: Dr Cam McRobbie, Queensland University of Technology - Kelvin Grove Campus, Locked Bag No 2, Red Hill, Qld 4059, Australia
All those interested in science education research are invited to attend the 22nd Annual Conference of the Australasian Science Education Research Association.

July 14-19
GASAT 6 International Conference
Location: University of Melbourne, Victoria, Australia
Contact: Ms Gaell Hildebrand, School of Education, University of Melbourne, Parkville, Victoria 3052, Australia
The conference theme is Action for Equity: The Second Decade. During the past decade, the GASAT Community has explored the nature of the interaction between gender and science and technology, and debated a variety of explanations and solutions. GASAT 6 will focus on reflections upon past GASAT work, current initiatives relating to intervention and research, and perspectives on the challenges of the future.

July 24 - August 7
33rd International Youth Science Fortnight
Location: London, UK
Contact: London International Youth Science Fortnight, PO Box 159, London SW10 9QX, UK
The Science Fortnight is the principal international youth meeting annually organised in Britain, and is the major international meeting of young scientists in the world.

Details of the 1991 program, open to students of the sciences born between 24 July 1969 and 24 July 1974, are available from the address above.

August 4-9
ChemEd 91 Conference
Location: Oshkosh, Wisconsin, USA
Contact: Bruce G Smith, Co-Director, Appleton High School-West, Appleton, Wisconsin 54914, USA or Paul Kelter, University of Wisconsin, Oshkosh, Wisconsin 54901, USA
ChemEd 91 is a major chemical education conference of interest to university, college, secondary and elementary educators from North America and beyond. Throughout the weeklong conference, activities are planned for all members of the family including excursions, field trips, sports activities and social events - a feature of ChemEd conferences.

August 19-24
32nd Annual Conference of STAN
Location: General Murtala Mohammed College, Jimeta, Yola, Gongola State, Nigeria
Contact: Mr Ben B Akpan, Administrative Secretary, STAN, Government College Campus, PMB 5075, Ibadan, Nigeria
The Science Teachers Association of Nigeria invites you to participate in their 32nd Annual Conference. The theme of Teaching Science Technology and Mathematics in the Mother Tongue will include subthemes on philosophical implications, curriculum implications, implications for the learner, and implications for the teacher. The Conference will feature workshops, exhibitions, poster sessions, lead and contributed paper presentations, panel discussions, symposium, public lecture, subject panel meetings quiz, and launching of new STAN publications.

August 25-30
11th International Conference on Chemical Education
Location: University of York, York, UK
Contact: Dr John F Gibson, ICCE 11, Royal Society of Chemistry, Burlington House, Piccadilly, London WIV 0BN, UK
This biennial conference on the theme Bringing Chemistry to Life is being organised by the IUPAC Committee on Teaching of Chemistry in conjunction with UNESCO and
the Association for Science Education. The conference will focus on (1) making chemistry accessible to all students (2) new curricula at primary, secondary and post-secondary levels (3) new teaching strategies at all levels (4) teaching and learning at a distance (5) new frontiers of chemistry and their impact on teaching, and (6) research in chemical education. The program will include plenary lectures, poster papers, symposia, workshops, exhibitions, times for participants to discuss aspects of chemical education of special interest, social events and local visits. Responses to the first circular have been received from over 70 countries. The second circular and registration form is now available from the above address.

August 27 - September 1
5th International Environmental Education Conference
Location: Cusco, Peru
Contact: MSc Eduardo Gil Mora, National University of Cusco, Zaguán del Cielo L-9, Cusco, Peru
The conference will focus on the relationship between the environment and development, and on the changes needed in today's behaviour for tomorrow's world. The program will enable participants to learn of developments, approaches and strategies in environmental education in different countries, and will cater for primary, secondary and tertiary educators; and for teacher trainers, curriculum developers, and policymakers.

September 14-16
Conference on Teaching About the Protection of the Environment
Location: Krakow, Poland
Contact: Alicja Wojtyna-Jodko, Chairperson, Organising Committee, Stowarzyszenie Nauczycieli Przyrodniczych i Technicznych (SNPiPT), Skrytka Poczciowa 62, 85791 Bydgoszcz 32, Poland
This general interdisciplinary conference of teachers will be the first annual meeting of natural science and technology teachers active in institutions of education at the elementary and secondary levels, together with people from academic institutions with a vested interest in scientific and technical education. During morning plenary lectures, researchers will present the directions of research in ecology, chemistry and physics relevant to the theme. In afternoon sessions, teachers will join small group discussions focusing on sharing examples and experiences. Participants are requested to submit a brief summary of their intended contribution to these discussions. The working languages for discussion will be English and Polish. The first general assembly of SNPiPT (Association of Science and Technology Teachers) will discuss the future of this new association and elect officers. A meeting with a delegate of the Ministry will provide an opportunity for discussing the need for improving the level of scientific and technical education in Poland in light of the experience of other countries.

The Congress will focus on the important role of chemistry in raising the health conditions and living standards for all people. The program of plenary lectures, invited papers and contributed papers will be conducted in English and will concern various topics including organic chemistry of natural products, analytical chemistry and instrumentation, environmental chemistry, agrochemistry, coordination chemistry and its applications in medicine and agriculture, polymer science, photochemistry, computers in chemistry, catalysis, and chemical education.

August 12-22
Sixth International Symposium of IOSTE
Location: Wyndham Palm Springs Hotel and Resort, Palm Springs, California, USA
Contact: Dr. Herbert K. Brunckhorst, Institute for Science Education, California State University, 5500 University Parkway, San Bernardino, California 92407-2397, USA
The theme of the 6th International Symposium on World Trends in Science and Technology Education is Science and Technology Education: Responsible Change for the 21st Century. Science and technology education will be related to responsible change with respect to the role of science educators, scientists, engineers, business/industry and government agencies in the global community. The symposium will provide a forum for dialogue to increase awareness of regional perspectives worldwide and develop closer cooperation in addressing mutual concerns. This dialogue will be held in the context of science education issues, environmental issues, technology issues and socio-cultural issues. The symposium will be presented in English.

August 26-29
Conference on the Role of Experiment in Physics Education
Location: Skofja Loka, Slovenia, Yugoslavia
Contact: Seta Oblak, Zavod Republike Slovenije za solstvo Poljanska cesta 28, YU - 61 000 Ljubljana, Slovenia, Yugoslavia
The Board of Education in the Republic of Slovenia and the Department of Physics in the University of Ljubljana are organising a Europhysics study conference in cooperation with the European Physical Society. The theme will be "The role of experiment in physics education", with an emphasis on the changes taking place in classrooms due to rapid technological development. The program consists of lectures, workshops and group discussions as well as presentations of experiments suitable for students from elementary school to university level.

August 26-30
Fourth Asian Chemical Congress
Location: Beijing, China
Contact: Prof. Dehe Zhang, Secretary General of 4ACC, Chinese Chemical Society, PO Box 2709, Beijing 100080
The 4th Asian Chemical Congress will be held under the sponsorship of the Federation of Asian Chemical Societies.

November 6-10
NABT Annual Convention
Location: Souther Hotel, Nashville, Tennessee, USA
Contact: Patricia J. McWethy, Executive Director, National Association of Biology Teachers, 11250 Roger Bacon Drive, #19, Reston, Virginia 22090, USA

37
The next annual convention of the National Association of Biology Teachers will focus on the theme Form and Function: How Should They Be Taught. Applications for program space are due on 15 March 1991.

1992

January 3-6
ASE Annual Meeting
Location: University of Sheffield, Sheffield, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated in *Education in Science*, a journal of the Association for Science Education.

March 26-29
NSTA National Convention
Location: Boston, MA, USA
International delegates are invited to participate in the International Round Table - one of the many features of this large convention. Each country is provided one or more tables in a large room where delegates can display and present information on science education in their country. Visitors move from table to table, talking with the various representatives. If you require an invitation to participate, write to John E Penick, Professor and Coordinator, Science Education Center, The University of Iowa, Iowa City, Iowa 52242, USA.

March 29 - April 10
Science Teacher Education
Location: London, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This British Council International Seminar will be directed by John Head and John May of King’s College Centre for Educational Studies, University of London, and will focus on secondary level teacher education, although some aspects will be of interest to those involved in primary science teaching. There are vacancies for 30 international participants - practising teacher trainers, advisers, inspectors, organisers of professional development programs and policy maker.

April 22-29
Symposium on Technology Education
Location: University College of Education, Erfurt, Germany
Contact: Prof D Blandow, University College of Education, Nordhäuserstraße 63, 5064 Erfurt, Germany
This symposium will be the first pan-European meeting on technology education to be held in a unified Germany - at an institution in Erfurt renowned for initiatives and developments in technology education. The principal aim of the symposium, which is being organised in collaboration with a number of organisations including ICASE and INISTE, will be to discuss technological literacy and competence in technology education within a European dimension. The majority of participants will be from European countries, with a few key people from other regions of the world. The principal language of the symposium will be English.

May 11-15
Second International History Philosophy and Science Teaching Conference
Location: Queen's University, Kingston, Ontario, Canada
Contact: Prof Skip Hills, Faculty of Education, Queen’s University, Kingston, Ontario, Canada K7L 3N6
This conference follows the very successful First International Conference on History, Philosophy and Science Teaching held at Florida State University in November 1989. All conference papers will be published in advance of the conference. Accounts of the application of history and philosophy of science in the science classroom are welcome, as are research papers on the issue.

June 10-12
ICASE Research Seminar on Chemistry and Physics Education
Location: University of Dortmund, Germany
Contact: Prof Dr Hans-Jürgen Schmidt, University of Dortmund, Department of Chemistry, Otto-Hahn-Straße, 4600 Dortmund 50, Germany
This symposium on empirical research in chemistry and physics education will focus on the methodology of empirical research in this field. There will be approximately 12 presentations each followed by a discussion period. The language of the symposium will be English. Presenters will be asked to send their paper beforehand, ready for printing as Proceedings through ICASE. Proposals of about 3 pages should include title, background, method, results, discussion, implications for research and teaching, and references, and should be sent to the contact above no later than August 31, 1991. General papers will not be accepted. Although there will be no seminar fee, participants will need to cover their own expenses.

July 6-10
CONASTA 41
Location: Perth, Western Australia
Contact: Convener, CONASTA 41, Science Teachers Association of WA, PO Box 991, West Perth, WA 6005
Australia
The Australian Science Teachers Association invites you to participate in the forty-fifth annual conference of the Association.

July 13-16
ISY International Conference for Invited Educators in Space Science and Technology
Location: National Convention Centre, Canberra, Australia
Contact: Dr John R Nicholas, Convenor, ISY Conference, University of Canberra, PO Box 1, Belconnen, ACT 2616, Australia
Museum and science centre educators with an interest in aerospace will meet with practising teachers who have shown talent in teaching young people about the nature of science through space science and technology themes. The theme “Space Enough to Learn” will focus on (Day 1) exemplary programs in museums and schools; (Day 2) critical review of
exhibits as a form of knowledge and entertainment, and the
role of technology in portraying knowledge of space
exploration; (Day 3) moving displays, teachers and learning
into the community and the marketplace; and (Day 4) dreams
of futures in space science and education.

August 2-10
Eighth ICASE Asian Symposium
Location: Colombo, Sri Lanka
Contact: Mr Asoka Weerasinghe
Hon. Joint Secretary, SLASME, Institute of Computer
Technology, PO Box 1490, Colombo, Sri Lanka
Science educators are invited to attend the eighth ICASE
Asian Symposium and enjoy the natural beauty of the
country and the hospitality of the Sri Lankans. The
Symposium, organised jointly by ICASE and the Sri Lanka
Association for Science and Mathematics Education
(SLASME), will feature outstanding speakers from many
countries who will address the theme "Science Education for a
Changing World". The Symposium aims to identify some of
the changes affecting our daily lives and to discuss ways by
which science education can respond to these changes.
Subthemes include (1) technology, (2) appropriate
technology, (3) environment, and (4) scientific literacy.
Participants will be able to experience the world famous

January 3-7
International Conference on Science Education in
Developing Countries
Location: The Amos De-Shalit Israeli Science Teaching
Center, Israel
Contact: Mr A Shoval, Ministry of Education and Culture,
Lev-Ram Building, 2 Dvora Hanavia St, Jerusalem 91911,
Israel (conference arrangements) or Dr Avi Hofstein,
Department of Science Teaching, The Weizmann Institute of
Science, Rehovot 76100, Israel (academic correspondence)
This international conference on the theme "Science
Education in Developing Countries: From Theory to
Practice" will review past experiences and achievements in
science education and plan for the 21st century with a special
focus on developing countries. The conference will feature
plenary lectures, symposia, poster sessions, workshops,
exhibitions, informal discussions, social events and local
visits. Topics for symposia and plenary lectures will focus
on current research on learning and teaching and its
implications for (1) the learner, (2) the teacher, (3) the
classroom, and (4) the curriculum.

APOLLO 11
A Teacher Resource Book
An ICASE Publication

This new publication, the latest of
a series of Commemorative Issues
produced by ICASE, has been
compiled to commemorate
the 20th anniversary of
the Apollo 11 Moon Landing
1969-1989. The book,
compiled and edited by
Linda Crow and Donna
Hare, provides information
and activities for both
elementary and secondary
science students.

ICASE - supporting science teachers around the world
Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

NSTA National Convention
Houston, Texas, USA
March 27-30, 1991

This report was compiled by Dr. Kenneth Russell Roy, ICASE North American Representative

The National Science Teachers Association (NSTA) National Convention was held in Houston, Texas on March 27-30, 1991. The Convention's theme was "The Teacher is the Key: Science Teacher Professionalism". Emphasis on multicultural access was also central to the Convention. The thrust of this confab was most timely, given the goals of ICASE focusing on multiculturalism and global education.

Several ICASE activities highlighted the Conference. The NSTA International Committee met and was chaired by ICASE Special Projects Officer, Professor John Penick. ICASE President, Bob Lepischak, and North American Representative, Dr Ken Roy, provided information and items of interest relative to the activities and plans of ICASE. Specifically noted were ICASE Service Awards, ICASE publications including *Who's Who in Science Education Around the World*, the ICASE Stepping into Science Project, Conference '93 to be held in Paris, ICASE initiatives being developed for International Space Year 1992 including the World Activity Day, and the ICASE Five Year Plan under development.

At the International/ICASE Luncheon, Sergey Krotov, physicist from Moscow in the USSR, addressed the luncheon guests on "Science Education in the Soviet Union". The luncheon was hosted by ICASE President, Bob Lepischak, with comments on ICASE activities by John Penick and Ken Roy.

The ICASE/CASE Breakfast guests heard presenter Peter J Spratt, Editor, BRIDGES from Toronto, Ontario, Canada, address the topic of Business, Industry and Government Liaison with Education.

Promotion and innovation of science education in Nepal. NESES aims to promote and propagate the teaching and learning of science from primary to higher education; to disseminate the importance of science education; to promote the exchange of innovative ideas among member institutions; to develop cooperation among those involved in science education; and to contribute to science education policies, planning, implementation and evaluation.

For further information, contact: Dr K M Shrestha, President NESES, Reader, Central Department of Science and Mathematics Education, T.U. Kirtipur, Nepal.

Institute for Education and Research, Lahore, Pakistan

The Department of Science Education of the Institute for Education and Research, University of Punjab has joined ICASE as an Institutional Member.

For further information, contact: Dr Hafiz Muhammed Iqbal, Department of Science Education, Institute for Education and Research, University of Punjab, Lahore 54590, Pakistan.

ICASE welcomes new members

As the programs of ICASE are becoming more and more well known, associations, institutions and companies are joining ICASE as members. In welcoming these new members, we acknowledge the fine contributions that these organisations are making to science education.

Nepal Science Educational Society

The Nepal Science Educational Society (NESES) became established in 1991 as a nonprofit organisation of science teacher educators, science teachers and those interested in the dissemination, promotion and innovation of science education in Nepal. NESES aims to promote and propagate the teaching and learning of science from primary to higher education; to disseminate the importance of science education; to promote the exchange of innovative ideas among member institutions; to develop cooperation among those involved in science education; and to contribute to science education policies, planning, implementation and evaluation.

For further information, contact: Dr K M Shrestha, President NESES, Reader, Central Department of Science and Mathematics Education, T.U. Kirtipur, Nepal.

Institute for Education and Research, Lahore, Pakistan

The Department of Science Education of the Institute for Education and Research, University of Punjab has joined ICASE as an Institutional Member.

For further information, contact: Dr Hafiz Muhammed Iqbal, Department of Science Education, Institute for Education and Research, University of Punjab, Lahore 54590, Pakistan.

Eighth ICASE Asian Symposium
Colombo, Sri Lanka
2-10 August 1992

Science Education for a changing world

Stepping into Science
CESI Make and Take

by Sue Dale Tunnicliffe
ICASE Project Officer
18 Octavia, Bracknell
Berkshire RG12 7YZ
England, UK

This exciting venture will happen at the ASE Association for Science Education Annual Meeting at Sheffield, 3-6 January 1992. The Stepping into Science Team is putting on the first international workshop. Based on the successful CESI Make and Takes run at science conferences in the USA, there will be a number of low cost activities from around the world for people to look at and try out. Philip Harris First Sense computer based activities will also be there for you to try out.

Please contact Sue Dale Tunnicliffe at the address above if you would like to contribute to this event.

The Organisation of Research and Educational Planning, Iran

The Organisation of Research and Educational Planning, Ministry of Education, Tehran, Iran has joined ICASE as an Institutional Member. For further information, contact Mr Daneshfar, The Organisation of Research and Educational Planning, Imam Khomeini Ave, Tehran, Iran.

Section Académique de l'Union des Physiciens Académie de Reims

This new Associate Member of ICASE is the Reims branch of the French national body - Association des Professeurs de Physique et de Chimie. For further information, contact Mme Nicole Herman, Section Académique de l'Union des Physiciens Académie de Reims, Lycée Roosevelt, Rue Roosevelt, 51100 Reims, France.

Philipp Harris International

Philip Harris International joins ICASE as a Company Member, and has already provided support for the ICASE primary science initiative - the Stepping into Science Project - by assisting with the production of the project's new Newsletter.

For further information, contact:
William Eadon, Philip Harris International, Lynn Lane, Shenstone, Lichfield, Staffs. WS14 0EE, UK.

South China Normal University

South China Normal University in Guangzhou has joined ICASE as an Institutional Member. For further information, contact Gao Lingbiao, South China Normal University, Guangzhou 510631, P. R. China.

Vietnam Union of Science and Technology Associations

The Vietnam Union of Science and Technology Associations (VUSTA) is a new member of ICASE. VUSTA is a voluntary organisation of scientific and technological associations working in Vietnam and abroad. Its aims at to promote national scientific and technological potential by uniting scientists, engineers and academics in common non-governmental programs; to communicate scientific and technological knowledge to the general public; to promote the application of science and technology to production and life; to monitor and provide advice on scientific and technological developments; to encourage scientists to be active in peace and environmental protection issues; and to advance the living standards and working conditions of scientists and technologists. VUSTA has 28 branch associations of specialised sciences, 7 territorial associations, 8 centres and companies involved in applying S&T into production and life, and 1 training and seminar centre.

For further information, contact Prof Dr Ha Hoc Trac, President VUSTA, 53 Nguyen Du Str., Hanoi, Vietnam.

Association of Science and Technology Teachers, Poland

The Stowarzyszenie Nauczycieli Przedszkolnych i Technicznych (SNPPI), formed in September 1990, has joined ICASE as a Member. The Association brings together teachers and teacher educators at primary and secondary levels in all scientific and technical fields. Plans are underway to conduct symposia, refresher courses, and an annual general congress.

For further information, contact Alicja Wojtyna-Jodko, Chairperson SNPPI, Skrytka Poczta 62, 85791 Bydgoszcz 32, Poland.
Project 2000+
by Dr Jack Holbrook
ICASE Executive Secretary

In the March 1991 Issue of this Journal, it was reported that ICASE had commenced planning, in conjunction with Unesco, a major world conference to be held in Paris in 1993. At a planning meeting in June, it was decided that this Conference become part of a new initiative, entitled Project 2000+.

Project 2000+ calls for a rethink of science and technology education in the formal (school), non-formal (out-of-school), and informal (adult) education setting for the year 2000 and beyond.

This is based on the premise that science and technology education is needed by all, but that current science programs are too difficult, too factual and largely irrelevant, except for the few who wish to take up a scientific career. It is also based on the premise that science and technology education is important, but poorly understood, often unavailable and confused with technical or vocational training.

It is felt that there are sufficient small scale science/technology projects around the world to illustrate that there are alternative approaches which promise to provide more literate programs for students as a whole. Just as Education for All was a theme of a worldwide commitment in 1990 (Jomtien, Thailand conference outcome, 1990), so Scientific and Technological Literacy for All is the theme of this follow-up project. As such it is seen as both a developed and developing world concern.

ICASE contends that new developments will only be successful if a partnership is established between governments and science/technology teachers. STAs (Science Teacher Associations) or Centres/Institutions thus have an essential role for the successful implementation of any new direction, particularly if this involves teachers adopting a change of outlook. ICASE thus recognises that its member organisations are important to Project 2000+. Their willingness to be involved, especially in Phase 3, is crucial.

Project 2000+ is a large undertaking and will need substantial funding. Other partners are being sought, especially those co-sponsoring the Education for All Project, to help with financing much of Phase 1 and 2, and for continuing support of Phase 3.

At this stage, the project is given in outline - a fuller account will be made available to those member organisations expressing an interest in becoming involved in Project 2000+.

Project 2000+ has been divided into three phases:

Phase 1 is a data gathering stage (1991-3), to collect research papers, journal articles and especially exemplary program materials related to the theme. A database will be reated, and links made with other conferences to feed outcomes and ideas for consideration in this project.

Phase 2 will be a worldwide conference, held in July 1993, to discuss the issues and dilemmas and to provide outcomes that give clear directions for the future. This may be in the form of resolutions or working models for implementation.

Phase 3 is the developmental stage and represents a longitudinal, within country program to modify existing practices where these are found wanting. Developments could be under the guidance of Unesco/ICASE although local participation would be the major thrust. The project would be extensive and provide training and evaluative studies as well as support for the local organisation to enhance teacher morale, teacher support and teaching conditions.

Note: Member organisations of ICASE have been sent a Reply Slip in order to indicate their willingness to be involved in Project 2000+.

For further information about Project 2000+, contact:

Stereotypes of Science and Scientists

by C R Boylan and D M Hill
Charles Sturt University - Riverina
Wagga Wagga, Australia

Considerable interest in the way in which science is portrayed in the media, school texts and student artifacts has occurred in the last decade. The process occurring in science classrooms, the proportions of males and females enrolled in science related educational programs and the proportions engaged in different forms of science-related employment have received much attention. The prime purpose of such research was to establish the social context in which girls grow up and make decisions relating to science studies and future employment. According to Kelly (1987) and other authors whose papers she collected in Science for Girls, girls tend to see science in the following terms: competitive, impersonal, convergent, abstract, restrictive, male, unimaginative, mechanistic, certain and rule-bound. Whyte (1986) has made similar claims: girls are seen as warm, literate and interested in people whilst scientists are portrayed as competitive, rational beings interested in things.

Mason, Kahle and Gardner (1991) claimed that female students participated in fewer science activities than males and that they were less likely to engage in activities, at home, which develop the kind of competencies needed in science classes. Male students are more likely to have experience with mechanical toys, construction kits, chemistry sets, and field trips than females (Jones and Wheatley, 1988). Teachers of science have been found to treat male and female students differently in class (Mason and Kahle, 1989).

The outcomes from these research studies have promoted attempts to change school science programs to achieve greater gender equity. Such changes include the establishment of single sex classes, an examination of the topic of stereotypes and creating classroom environments which are gender neutral. The developers of these programs have assumed that the information we have about the image of science and scientists held by students is valid. The purpose of this article is to examine this assumption.

Information about students' ideas about science and scientists has been gained by researchers who have usually adopted a sociological or psychological framework. Sociologists have emphasised the importance of social context in the development of such images. Their primary interest is in social and material conditions rather than in the role of individuals in social processes. Hurrelmann (1989) has claimed that sociologists have either ignored the latter or assumed the role to be a relatively passive one. Many cognitive psychologists, however have taken a contrary view: individuals are seen as active agents concerned with constructing and managing their own inner and outer reality. In this paper it is argued that such realities can be best understood in terms of a broad ecological framework (Bronfenbrenner, 1979) which embraces both psychological and sociological perspectives.

One of the main ways in which researchers concerned with social context have investigated students' views of science and scientists has been through a study of students' drawings using the Draw-A-Scientist Test (DAST) developed by Chambers (1983). The test procedure involves inviting students to draw-a-scientist and subsequently analysing their drawings for the presence of various indicators described by Chambers (1983). Hassard (1990) has summarized the stereotypes which have been identified in studies employing this technique as follows:

- The scientist is usually a male Caucasian.
- The scientist is either bald or has frizzy, wild hair. On the rare occasions when the scientist is a woman, her hair is in a bun.
- The scientist wears glasses and is dressed in a white lab coat.
- The scientist is shown working alone in a laboratory rather than in nature or in the field.
- The scientist is shown mixing chemicals or doing some kind of chemistry-related or physics-related experiment.
- The scientist is shown experimenting with dangerous things and is sometimes shown experimenting on people. (Hassard 1990: 10)

Kahle (1989) claimed that not only did students hold a masculine view of scientist but also of science and 'that this image probably detracts from a girl's interest and self-confidence in doing science' (Kahle, 1989: 5). She argued that DAST is both valid and reliable. O'Maoldomnaigh and Hunt (1988) have claimed that many studies have shown that different people agree in their coding of the same student drawings. Schibeci and Sorensen (1983) claimed that interviews with students can provide evidence for the validity of DAST. It appears that such interviews were often conducted after the student had completed a drawing of a scientist. This raises the possibility that the two measures are confounded.

The DAST can be described as 'epistemologically flat' (Kilbourn, 1982) in so far as there is insufficient context developed for the task for the respondent to know how to reason. Symington and Spurling (1990) have questioned
whether the prime purpose of the task is to assess an individual's knowledge of the public stereotype of the individual's private views and knowledge about science and scientists. Hill and Wheeler (1991) claimed that DAST explored the public rather than the private or inner knowledge of subjects and that a different kind of procedure was required to assess the latter.

Boylan, Wallace and Sharman (1990) and McNay (1988) have questioned the validity of the DAST procedure because these authors contend it tapped only part of a subject's understanding. These researchers found that subjects knew a lot more about science and scientists than their drawings revealed. The students recognised the limitations of their drawings as a once only portrayal and they could clearly distinguish between what is and what could be. McNay (1988) argued that if science teachers were asked to 'draw-a-scientist' they too would respond superficially and produce a stereotypical image. It has been observed that the very way in which the directions for the Draw-A-Scientist Test are given indicates that there is such a thing as a typical scientist and this is what the subject has to represent. When responding to the DAST, subjects are forced to make a series of choices concerning such things as: gender; age; race; dress of the person; the setting; and task to be portrayed. It is hardly surprising that such drawings revert to the public perception of science and scientists.

O'Maoldomhnaigh and Ni Mhaolain (1990) altered slightly the directions to the DAST to 'Draw a man or woman scientist' and obtained a very different response from students. They attributed this result to the changed expectations of the subjects created by the new directions. They found the new directions significantly increased the proportion of women scientists represented in the drawings made by young adolescents.

As students progress through school they develop images of particular occupations. These images usually involve similarities and differences on a number of dimensions including gender (masculinity/femininity), prestige, work conditions and types of work tasks performed according to Gottfredson (1981). Occupational images become more realistic by the time students reach upper secondary school. This kind of knowledge is constructed gradually as students grow in capacity to comprehend and organise information from multiple sources. Gottfredson (1981) has also argued that, as a result of this process, students develop a set of occupational preferences and perceptions of accessibility which, in turn, define their career aspirations.

It has usually been assumed that students' preferences are consistent with the stereotypes which are public knowledge in their society. The findings of a number of studies by O'Maoldomhnaigh and Hunt (1988), Fort and Varney (1989), Kahle (1989), and Mason, Kahle and Gardner (1991) appear to confirm this. However, as Boylan, Wallace and Sharman (1990) have demonstrated, this evidence must be seriously questioned. Using the Osborne and Gilbert (1979) Interview-About-Instances procedure, these authors have attempted to tap into both the sociological and psychological frameworks held by students. They used a series of pairs of illustrations which were also used by Yakop, Hill and Wheeler (1989) to focus on four aspects of the image of science and scientists held by Grade 7-10 high school students. These were:

- Appearance, eg clothing and age;
- Task, eg reading instruments and recording data;
- Work setting, eg laboratory and outdoors; and
- Employment/gender, eg male and female doctor or male and female pharmacist.

Some examples of the illustrations used by Boylan, Wallace and Sharman (1990) are reproduced here.
Each student was individually interviewed and asked such questions as: 'Is one of these two persons more likely to be a scientist than the other?' 'Could they both be scientists?' 'Could neither be a scientist?' Students were asked for reasons for their responses to these questions and their reasons were probed to elicit further detail.

Boylan, Wallace and Sharman (1990) reported that Grade 7 to 10 Australian students were able to provide stereotypical views about science and scientists. However, when an analysis of the reasons given to support the students' statements was conducted, they found a complexity and diversity of reasons that revealed insights into student perceptions that went beyond the stereotype. They reported that the students held a sophisticated view about science and scientists in which both the public stereotype and the students' private perception co-existed. The students were able to separate what is the current image of science and scientists (e.g. more males employed as scientists) from what could be possible for the student and to distinguish between gender stereotyped science careers and potential science careers for the student in which gender was not perceived to be a barrier. Similar levels of sophistication in student understandings and perceptions of science and scientists have been reported by Wheeler and Changeywo (1990) with Canadian students in Grade 7.

If the very evidence on which school science programs have been devised to 'correct' students' views of science and to encourage more girls to take up scientific careers is based on the public and superficial image, then it follows that the resources used to implement such programs represent inappropriate strategies and wasted effort. Further, if the assumptions are false and students already hold realistic and discriminating understandings about science and scientists, then the effectiveness of such programs which claim to produce change in students' perceptions of science and scientists need to be carefully re-evaluated.

Issues in the Learning of Science in Botswana Secondary Schools

by Raymond Charakupa
Department of Mathematics and Science Education
University of Botswana

Introduction
As a developing country, Botswana is striving for both improved technological and social well-being for its citizenry. A step toward achieving this goal was taken decades ago when science and mathematics curricula were introduced in Botswana schools. Clearly, the expectation was that a majority of the local students would be able to learn these subjects and, in time, this would lead to an increase in techno-scientific awareness among the population. This goal has not as yet been fully realised. The learning of science and mathematics has been, and still is fraught with many problems, some of them intractable. These problems may be categorized as follows:

- Learner background factors
- Science teacher background factors
- Science teacher preparation
- Science content delivery hurdles

Discussion of each of the above categories follows with a view to identifying problems, weaknesses and constraints.

Problem Areas

1. Learner Background Factors
The majority of Batswana pupils come from a rural, basically non-technoscientific (in the western sense) background. While they may be exposed to forms of indigenous science and mathematical concepts at an early age, such concepts are inadequate as prerequisites for the meaningful learning of the more formalised versions taught in secondary schools. A compounding factor is that a good number of these pupil's parents are functionally illiterate or semi-literate with an even larger number being scientifically illiterate. Clearly this leads to minimum after-school and in-the-home support for science and mathematics learning activities.

Germain to this latter point is the absence of an environment, both physical and cultural, which is conducive to a rich science experience and one which can augment in-school science learning. This may very well mean that for the majority of the pupils, science is only 'experienced' during the hours allocated to it on the school timetable. The import of all this then, is that the pupils may not be harnessing all their potential and other innate abilities in the process of learning science. An immediate consequence of this is a limited output of science and mathematics graduates who may in the future further the causes of localisation in the various scientific and technological fields, a goal highly cherished by the Botswana nation.

2. Science Teacher Background Factors
A typical science learning situation in the Botswana classroom context often entails teacher-pupil dialogue or interaction. At times, usually not with optimum frequency, the learning situation may assume a laboratory setting. It is easy to see that in these learning situations there is often a 'hidden' interaction between pupil background and teacher background factors. The teacher background factors that are of interest in the present discussion are the following: socio-cultural, educational, attitudinal and professional experience. The Botswana science and mathematics teaching force is made up of both Batswana and expatriate personnel. It is therefore immediately evident that there exists a diversity of socio-cultural, educational and professional backgrounds among the science and mathematics teaching force in Botswana schools. Even considering the Batswana teachers alone, the aforementioned diversity exists, albeit to a limited extent.

Let us focus initially on the background factors as they relate to the expatriate teaching force. This component of the teaching force, which presently outnumber the local component is sourced from different countries, notable examples being the United Kingdom, the United States, India and the various African countries. There is ample reason to believe teacher preparation programs are, to a real extent, unique to the learning environments existing in each of these countries. Thus, teachers are trained bearing in mind a more or less specific environment in which they will later function. It is unlikely, for example, that teachers trained in India or the United States are prepared with Batswana pupils in mind. While this latter point may be of little significance at the tertiary level of education, it is crucial in the context of secondary and lower levels. Knowledge or expertise of how to teach science to an American pupil does not readily translate into knowledge or expertise of how to teach science to a Motswana child due to the complexity of the factors that impinge on the teaching-learning process. Clearly, this has serious implications for the learning of science in Botswana schools.

First, the newly appointed expatriate teacher usually has no real feel for the background or initial state of his pupils, except perhaps for the prejudices he may have unwittingly acquired from those 'who have been there'. In terms of exposure to science and technology, the Batswana pupil from rural areas (the majority come from rural areas) may very well have a 'deficit' at the start of his secondary schooling. Confronted with a situation where the pressure is intense to 'get on with the syllabus', the expatriate teacher will limp along as best as he or she can under the circumstances. Teacher-pupil communication may thus be rendered partially ineffective, resulting in learning of dubious quality or efficiency. If the expatriate teacher has a low threshold of
frustration, he may be tempted to conclude that the scientific or mathematical concepts he is trying to impart to the pupils are beyond them. This is especially easy for the expatriate teacher to believe if he or she has been subjected to similar views from ‘experienced’ expatriates. Under these conditions not enough effort is expended in examining conflicts between teacher and pupil backgrounds. Science and mathematics learning therefore will proceed under suboptimal conditions.

Second, a Motswana pupil is, more often than not, taught by more than one expatriate teacher during his secondary education due to the turnover of contract staff. Chances are that the pupil is exposed to science teaching from teachers with different backgrounds, attitudes and professional experience. The process of adjusting to changes of teacher may lead to learning difficulties, the intractability of which increases with nearness to final examinations. Closely allied to this problem, is changing ‘types of English’, the medium of instruction. To the student, an American speaks different English from a Briton, an Indian, or a Ghanaian. Adaptation to this new change occurs in real time, during which period science and mathematics learning may be hampered, particularly for the weak or average pupils.

Last, concerning expatriate teacher background, there are indeed some expatriate teachers in the country who have overcome conflicts in pupil-teacher background and are obtaining very good pupil performance in science and mathematics examinations. The background of local teachers will be discussed under teacher preparation.

3. Preparation and Supply of Science Teachers

This category will primarily focus on the training of Botswana teachers. The accelerated expansion of secondary education has resulted in a large demand for teachers, particularly science and mathematics teachers. Until a few years ago, in-country preparation of secondary science teachers was carried out mainly at the University of Botswana. In order to compete with new demand for teachers, particularly at the junior secondary level, two new institutions have been recently established: the Molepolole and Kgalagadi Colleges of Education.

A vexing problem in the area of teacher preparation concerns the type of candidate attracted to the profession. It is common knowledge that a good science student would not consider teaching as a first career option. The reasons for this are numerous. The teaching profession is perceived to have little prestige except perhaps in the rural areas where the teacher may be an intellectual beacon on a generally unschooled flatland. Thus mostly average to slightly below average science students will go into science teaching. If educational programs are to justify their existence, a majority of these average candidates must emerge from university or college with a qualification of some sort. These teachers of average quality then go into secondary schools to teach science to students with deficits in science experiences. The situation then is one where teachers are expected to teach the same material that they found difficult in their own early schooling. The present arrangement between the Ministry of Education and the University of Botswana where one third of secondary science graduates are channelled into science and technologically-oriented careers ensures that relatively less able candidates go into the education programmes. By some deviousness there have been years when even more than one third of good science graduates have been lured away by the faculty of science. Several factors are therefore at work to ensure good science students do not easily end up in the teaching profession. Similar observations were made by the National Commission on Education (1977). Commenting on the quality of entrants to the teaching profession, the Commission observed:

"Here one is confronted with a vicious circle, because so long as the quality of the teaching profession is low, good new recruits will not be attracted to it. Yet the standing of the profession can only be raised by recruiting better candidates and providing them with better training."

Attempts have been made to turn weak candidates into good teachers. Kahn (1983) observes that the Diploma in Secondary Education (DSE) offered at the University of Botswana takes weak candidates who would not normally be considered able to do advanced level work and educates them beyond A-Level standard. Kahn further states that these DSE graduates leave the university with a broader view of science than their degree counterparts and are highly regarded in schools. Assuming Kahn’s observation to be correct, the DSE output is numerically insufficient to staff the schools with good science teachers. All these factors impact negatively on the science teaching-learning process. Consequently, pupils are not always exposed to the best of teaching during their secondary schooling, resulting in possible inefficiency in the learning process.

4. Science Content Delivery Hurdles

According to Anderson (1976), the body of scientific knowledge has grown to massive proportions and few people are certain as to the appropriate content to be included in pre-college curricula. Anderson further observes that:

"It is more clear now than ever before that we must select carefully what kinds of information will be presented and with what kinds of orientation."

In the Botswana context science content should be selected on the basis of relevance to life in Botswana. This entails an intimate knowledge of a pupil’s background and the concepts of science and mathematics he brings to a learning situation. Armed with this knowledge, the teacher can then build on such concepts, thereby facilitating the learning process. Indeed, educational researchers in the learner pre-conception or misconceptions field have highlighted the desirability of incorporating the ideas pupils bring to a learning situation into teaching strategies. In Botswana, very little research has been done in this area. However, a study by Prophet and Rowell, is the imposition of teacher viewpoints on students leading to inhibition of development of connections between students’ existing ideas and those presented in class. The impact of this on learning is obvious; the learning process becomes less efficient. The reader is encouraged to consult the Prophet and Rowell study for an excellent ‘snapshot’ of classroom interaction.

Another hurdle that limits the efficiency of the learning process is that science laboratories are inadequately equipped. The problem is particularly chronic in junior secondary
schools. Here one finds groups of up to six students sharing equipment.

Observations during teaching practice reveal that under these conditions not all group members participate equally in the practical work, resulting in different degrees of learning. The use of highly structured worksheets in integrated science tends to discourage free-formal thinking on the part of the student. On the teacher's part, there may be a tendency to focus on the completion of the worksheets to the detriment of everything else. The lack of skilled technicians in these schools means that if equipment breaks down it may remain out of commission for a long time, thereby restricting the range of activities students carry out during practical sessions. Concepts that could be better illustrated using the practical method are therefore rendered that much more difficult for the student.

Possible Solutions

The prescription of solutions to complex educational problems is a hazardous task. This is compounded by the existence of divergent perceptions of what constitutes a solution. To the bureaucrat, it may be more important for large numbers of students to be exposed to a learning situation without due regard to the quality or efficiency of the learning process. More students mean more teachers, therefore, recruit more teachers from wherever they are available. Should there be a donor country willing to supply teachers, all the better. The bureaucrat blithely assumes that the donor will supply experienced teachers. To him, it is all largely a numbers game. To the professor of education the solution lies in his area of specialisation. If he is a psychologist, the difficulties pupils encounter in learning may be partly alleviated by application of an appropriate psychological model. If she is a 'methods' person the solution may lie in the use of an appropriate teaching method. To the educational philosopher, the answer may be found in the unambiguous specification of relevant educational philosophies.

A 'content' specialist will focus on selecting relevant content and matching it to the learning group in question. The educational technologist will advocate the use of various teaching aids and media, for example, computers, overhead projectors, etc. The solution field goes on and on. It should be possible to find common ground and improve the learning of science and mathematics in our schools, despite this divergence of possibilities.

The impact of learner background on learning may be reduced if beginning junior high school science students are taught by competent and experienced Batswana teachers whose background experiences are similar to those of the students. Such teachers may be better placed to put the students' problems into context and not be quick to dismiss students' 'wrong answers' as ridiculous. In this regard, the current practice of using less qualified diploma graduates to teach junior pupils need to be re-examined. This is important given that a student's early encounter with science may shape his future attitude toward the subject. If the early experiences are negative, the nation loses potential scientists, thereby slowing the pace of localisation in scientific and technical fields.

A good teacher is partly the product of good training. While justification exists for current drives to produce large numbers of science teachers, teacher trainers and others concerned should ensure that the teaching profession does not become the depository for the less able. Care should be taken to ensure that those successfully going through teacher preparation programs do so based on their ability and not because they are needed to boost the numbers in the profession. Once in the profession the teacher should be kept abreast of developments in his field through meaningful in-service sessions. Such sessions are more than get-together

New inert element: Administratium discovered

April 1: The heaviest element known to science was recently discovered by physicists at Turgid University. The element, appropriately named Administratium (Ad), has no protons or electrons, which means that its atomic number is 0. However, it does have 1 neutron, 125 assistants to the neutron, 75 vice-neutrons, and 111 assistants to the vice-neutrons. This gives it an atomic mass number of 312. The 312 particles are held together in the nucleus by a force that involves the continuous exchange of meson-like particles called memo-ons.

Since it has no electrons, Administratium is inert. However, it can be detected chemically because it seems to impede every reaction in which it is present.

According to Dr M Languor, one of the discoverers of the element, a very small amount of Administratium made one reaction that normally takes less than a second take over four days. Administratium has a half-life of approximately 3 years, at which time it does not actually decay. Instead, it undergoes a reorganisation in which assistants to the neutron, vice neutrons, and assistants to the vice-neutrons exchange places. Some studies have indicated that the atomic mass number actually increases after each reorganisation. Administratium was discovered by accident when Dr Languor angrily resigned from the chairmanship of the physics department and dumped all of his papers into the intake hatch of the university's particle accelerator. "Apparently, the interaction of all those reports and minutes with the particles in the accelerator created the new element" Dr Languor explained.

Research at other laboratories seems to indicate that Administratium might occur naturally in the atmosphere. According to one scientist, on college and university campuses, Administratium is most likely to be found near the best appointed and best maintained buildings and is closely associated with carpeted floors.
sessions. Proper assessment procedures should be devised to determine the usefulness of such workshops in relation to changes in the teacher’s classroom practices. This would be more useful than simply asking teachers whether they considered a given workshop useful. Workshops could also be used to help expatriate teachers acquire a correct perspective of the Botswana pupil’s background and culture in order to minimise expatriate teacher - local pupil background conflicts.

Within the constraints of donor strings, educational officials should press for an active role in selecting the kind of expatriate science teacher that is recruited. In this regard, and financial resources permitting, teacher recruiting expeditions should include representatives from institutions concerned with secondary science as well as ministry officials. Together these representatives will be better placed to advise the government and the donor on the suitability of prospective candidates.

Conclusion

This paper has discussed a few important factors that affect the teaching and learning of science in Botswana’s secondary schools. These are learner and teacher backgrounds, quality of teacher preparation programs, the equipping of junior secondary schools and the kind of candidate that enters the teaching profession. A desirable situation is where academically able students enter into well thought-out and good quality teacher preparation programs that enable them to teach competently, taking into account the belief system that students bring to their learning situation. Institutions concerned with teacher preparation should not hasten to yield to political pressure to focus on quantitative rather than qualitative production of science teachers. To maintain continuing teacher competency in their fields, meaningful workshops should be organised. Proper assessment of such workshops is desirable to ensure changes in classroom practice. Broadly-based recruiting teams are needed to assist in the selection of expatriate science teachers. The combined efforts of government officials, academics and the community are needed to ensure that a good atmosphere exists in the science classrooms of our schools. This will enhance the production of good science students and facilitate broader participation of our citizens in scientific and technical fields.

NATIONAL SCIENCE SUPERVISORS ASSOCIATION
announces
THE ELEVENTH ANNUAL THOMAS EDISON/MAx McGRAW 1991-1992 SCHOLARSHIPS
Open to Students in Grades 7-12 with $22,000 in Scholarships & Travel

This program gives recognition by awarding 10 scholarships to students who most nearly demonstrate the inventive genius of both Thomas Edison and Max McGraw. Students in grades 7-12 in public, private and parochial schools in the USA, Canada or other participating nation are eligible. The entry consists of 2 copies of a proposal which may be an abstract of an already completed experiment or a project idea which deals with a practical application in the fields of science and/or engineering; and a single letter of recommendation from the student’s teacher/sponsor which indicates how the student best exemplifies the creativity and ingenuity demonstrated by the life and work of inventors Thomas Edison and Max McGraw. Entries are due by 1 December 91 to Dr Kenneth R Roy, NSSA, PO Box 380057, East Hartford, CT 06118, USA.

An Invitation to Boston
March 26-29, 1992

Each year, the International Committee of the National Science Teachers Association, USA hosts an “International Round Table”.

At this 90 minute session, presenters from different parts of the world discuss their nation’s educational programs. Each presenter has a table for materials, and participants select those countries they wish to learn about.

If you would like an official invitation to participate as a representative of your country, write to:

John E Penick
Science Education Center
Room 789 VAN
University of Iowa
Iowa City 1A 52242
USA

Unfortunately, you will have to arrange your own funding; but a letter of invitation and your name in the program may help you in that quest.
Astronomy Education International

by John R Percy
Erindale Campus
University of Toronto

Astronomy is deeply rooted in the culture of almost every society, by virtue of its practical importance in time keeping and navigation, and its philosophical and religious implications. Today, the practical applications of astronomy are mostly forgotten, and it has become the ultimate 'pure' science. As the mathematician Henri Poincaré said:

"Astronomy is useful because it shows how small our bodies, how large our minds."

Astronomy plays a fundamental role in basic science; the universe is a laboratory in which we can observe processes which cannot be duplicated on earth. Astronomy captures the imagination of the public, and contributes to a sense of shared exploration and intellectual excitement. It therefore has the potential to raise the level of scientific literacy in a society, and to attract young people to a study of the sciences. It provides an enjoyable leisure time activity for millions of people. Astronomy is unique among the sciences in the extent to which 'amateurs' can contribute to education and research.

Astronomy has no set place in the school curriculum. This is partly because science curriculum is determined nationally or locally, and partly because astronomy is not considered a 'core' science, and is discarded by some educational jurisdictions as being irrelevant or unteachable. Basic astronomical facts and concepts are usually taught in elementary school. In the 'classical' European curriculum, it is often taught also in secondary school, as a rigorous science. In the 'populist' North American curriculum, it is often taught in university, as a descriptive survey course, to non-science students, to satisfy a requirement for a science course in their program. As a result, dozens of different astronomy textbooks are available for non-science students, but relatively few for science students.

Because of the varied role of astronomy in the curriculum, the possibilities for international co-operation in astronomy education are limited - but certainly not negligible.

The International Astronomical Union

The IAU is a non-governmental union whose goal is 'to promote astronomy . . . and develop it through international co-operation'. Over 50 countries adhere to and support the IAU, and most of the world's active professional astronomers (6711 at present) are members. Members are nominated by their country; there is no membership fee. The IAU holds a triennial General Assembly, Regional Meetings, Symposia and Colloquia (over 200 in total), all in different parts of the world. It has over 40 'interest groups' called commissions, one of them dealing with education.

IAU Commission 46 (The Teaching of Astronomy)

This commission consists of an 'organising committee' or executive, representatives from each of the countries adhering to the union, and members-at-large (including some from less-developed countries which are not yet part of the union). The commission is particularly concerned about the needs of the developing countries, and most of its programs and projects reflect this. In many developing countries, there are only one or two astronomers, who are responsible for all aspects of astronomy education - teaching university courses, training school teachers, writing books and articles for amateurs and the public, and acting as resource people for government, schools, media and the public.

International Schools for Young Astronomers

Every year or two, the IAU and UNESCO hold an intensive two week school for young astronomers (scientists, graduate students, teachers) in a developing area of the world. The most recent have been in Cuba, Malaysia, and Morocco. A core of experienced instructors works with 20 to 30 participants, giving lectures, organising seminars and discussion, and suggesting projects for future research. Communication between instructors and participants often continues for many years after!

The Vatican Observatory also holds international summer schools every two years, at the Pope's summer residence at Gandolfo. The school lasts for five weeks, bringing together about two dozen graduate students, mostly from the Third World. The Vatican provides free room and board, and up to 75% of travel expenses.

Visiting Lecturers Program

This is a more leisurely program in which a series of lecturers visit a targeted country for weeks to months, giving courses, supervising student projects, consulting with local astronomers, and generally working to give astronomy a foothold in that country. VLP's are currently underway in Paraguay and Peru.

Astronomer-Schoolteacher Meetings

As part of each IAU General Assembly, there is a one day meeting between local schoolteachers and visiting astronomers with an interest and experience in education. Typically, this includes lectures and discussion on course material and teaching resources, and attracts a hundred or more participants. Since the General Assemblies are held in many different countries (most recently Greece, India, USA and Argentina), they leave behind a legacy of enrichment for the local educational system.
IAU Colloquium #105: The Teaching of Astronomy

In July 1988, the IAU sponsored the first international conference devoted entirely to astronomy education. It was held in Williamstown, USA, and attracted 160 astronomers from 31 different countries. The presentations and discussions were broad and exciting; they ranged from consideration of curriculum content at all levels from elementary to graduate school, to practical examples and content of specific courses, demonstrations, laboratories, the role of planetaria and computers, cross-cultural issues, and the needs of developing countries. The content and spirit of the meeting have been faithfully recorded in the proceedings (The Teaching of Astronomy edited by Jay M Pasachoff and John R Percy, Cambridge University Press, 1990). It should be in every science education library, and 'required reading' for every astronomy instructor.

National Reports and Astronomy Educational Material

IAU Commission 46 publishes a semi-annual Newsletter, with special issues devoted to triennial reports on astronomy education from the 51 IAU member countries. These make fascinating reading, as they illustrate both the diversity and the common aspirations and problems of astronomy education worldwide. Other special issues include a summary of the most significant and useful books, slides, computer software and other resource material of interest to teachers of astronomy, in the major languages of the world. While such material is rather sparse in some languages and areas of the world, there is an 'information explosion' in other areas (such as North America), so some selectivity is necessary. Commission 46 is particularly interested in the problem of information resources (textbooks, journals, databases, etc) for developing countries. Several organisations in the more affluent countries have organised programmes to send unused books and journals to institutions in special need.

The Travelling Telescope

This is the most recent project of IAU Commission 46: a small telescope, with simple teaching/research instrumentation, designed to travel to different areas of the developing world for periods of weeks to months. It can be used in support of ISYA's and VLP's, and as a 'bridge' to give local astronomers and students experience with telescopes, so that they can credibly approach their own government to provide them with basic astronomical facilities. The telescope was funded by the Canadian International Development Agency (Cida). Its first assignment was the 1990 ISYA in Malaysia.

Co-ordination in General

The most important (though least well-defined) function of the IAU Commission 46 is as a meeting place for those of us who are interested in and concerned about astronomy education. Most of us are involved in many different activities in our local countries: classroom teaching, liaison with teachers and schoolchildren, popularisation, textbook authorship and review, curriculum development at all levels, etc. Thus, the insight and experience which we share with each other gradually spreads out, in a vast network, into all parts of the education system - whether by mail or by occasional personal meetings.

Current Developments in Astronomical Education

Given the diversity of cultures and curricula, it seems rather rash to single out a few developments, knowing that many others will be omitted. Consult the conference proceedings The Teaching of Astronomy mentioned above, for a more comprehensive picture.

In most countries, amateur astronomers make important contributions to public education, by organizing lectures, displays and especially 'star nights', at which people, both young and old, can experience the thrill of viewing the moon, planets and stars through a telescope - often for the first time.

These events are often held in connection with International Astronomy Day, which is held each spring around the world. Amateurs bring a sense of enthusiasm which conveys, very effectively, the excitement of modern science.

In the US, the National Science Foundation's Education Directorate (which has a budget of the order of $300 million) is funding several interesting astronomy education projects, the first and foremost being Project STAR (Science Teaching through its Astronomical Roots). This project has developed materials (including inexpensive apparatus and hands-on activities) designed to overcome basic student

Contact your local association or the ICASE Executive Secretary

13
misconceptions about the universe around them - how the solar system is arranged, how it moves, and how this produces phenomena such as day and night, and seasons. Project STAR conducts workshops for teachers, and publishes a newsletter. For more information, contact Project STAR, Center for Astrophysics, 60 Garden Street, Cambridge MA 02138, USA.

The Astronomical Society of the Pacific (390 Ashton Ave, San Francisco CA 94112, USA) is an international non-profit scientific and educational organisation which plays a major role in astronomy education through its non-technical journal Mercury, its free teachers newsletter The Universe in the Classroom, and its high quality slides, videos and other teaching resources. This material is well-suited for school courses, and for the descriptive astronomy courses offered in North American universities. The ASP also publishes informative brochures on controversial topics such as UFO's and astrology, and practical topics such as computer software.

In Mexico, astronomy educators have worked hard to overcome the problem of the cost of books by producing simple, inexpensive but factually accurate 'comic books' on astronomy. These are distributed, in large numbers, to schoolchildren. This is an effective and promising solution to the problem of obtaining accurate, up-to-date resource material at a reasonable cost.

In Europe in general, there are hundreds of 'public observatories' which support both public and school education, as well as research by both professional and amateur astronomers. These institutions have no real counterparts in North America. Planetariums were developed in Europe, and adopted widely in North America, where they are found in many schools (but not always with teachers who know how to operate them, and make them part of the science curriculum). North America was, however, the birthplace of the portable 'Starlab' planetarium, which can be transported easily from one school to another.

In France, astronomers and teachers have cooperated effectively for two decades, through CLEA: Comité de Liaison Enseignants Astronomes. CLEA supports teachers by providing practical knowledge through summer schools, and a journal Les Cahiers Clairaut, by developing practical activities, and encouraging teachers to share their experience in teaching astronomical concepts. Contact Professor L. Gouguenheim, Observatoire de Paris, Section de Meudon, 92195 Cedex, France.

Further Information
I would be pleased to provide more information about astronomy education to any interested reader. You can also contact IAU Commission 46 through the IAU Secretariat, 61, avenue de l'Observatoire, F-75014 Paris, France.

About the Author
John R Percy is Professor (Astronomy) and Associate Dean (Sciences) at the University of Toronto's Erindale Campus, Mississauga Road, Mississauga, Ontario, Canada L5L 1C6. He is active in astronomy education at all levels, from the local to the international.
An Introductory Look at Curricula and Examinations Worldwide

by Dr Jack B Holbrook
Executive Secretary, ICASE

This article is an extract from a report by the same title, prepared by ICASE in fulfillment of a contract with the Science and Technology Section, Division of Educational Development, Unesco.

Introduction
The report examines curricula and examinations around the world and indicates similarities and trends. It is based on data submitted by science teacher associations worldwide and from a review of selected curricula and examination papers in the documentation centre of Unesco, Paris.

Many factors influence the acceptance and implementation of a curriculum or syllabus, including staff development, institutional development, resources, research and planning. With so many crucial parameters, it is easy to appreciate that curriculum development is not an easy task. Systems and approaches adopted in developing curricula in the past may have a strong influence on new developments with a result that little discernable difference is seen between new and old syllabuses.

The terms 'curriculum' and 'syllabus' are used interchangeably in many countries. This report does not set out to distinguish the terms. As a guideline, however, the term syllabus is used where a teaching program or scheme of work is outlined (very often a document referring to examinations would be considered a syllabus, in this case an examination syllabus). The term curriculum is used where more comprehensive information is made available on goals, teaching approaches, available support for the teacher, etc.

Education in many countries is very competitive, especially at the senior secondary level. This has meant that science curricula at primary/junior secondary levels have tended to prepare students for curricula at the senior secondary level, which in turn have prepared students for science programs in the tertiary sector. Thus many primary science curricula have tended to be geared towards developing a basis for students to be future scientists. This has continued in the junior secondary school where factual learning is encouraged by the setting of selection examinations using pencil and paper techniques.

There seems to be two main emphases in science education - one is 'science for all' and the other is 'science for continuation'. As suggested in Education for Capability: the Role of Science and Technology Education (British Council, 1989):

"The former is concerned with the level of scientific or technological literacy expected of all primary school or junior secondary school leavers, the latter with ensuring that a proportion of the most talented young people continue with science or technology through polytechnics or universities, and use their discipline in the whole range of science and technology based careers, including teaching."

It would be useful to determine how far curricula in various countries are moving towards a 'science for all' approach (as encouraged in the world declaration made in Jomtien at the Education for All Conference, 1990). Further, it would be useful to consider how far syllabuses from various countries go beyond a mere list of topics and consider support for the teacher, the role of the school, resources, and evaluation. The full report:

- lists main syllabus topics for selected countries from Asia, Africa, Europe, America, Australasia;
- comments on these syllabuses in terms of their movement towards a 'science for all' approach;
- comments on the support given beyond the curriculum topics;
- comments on the examination system and its appropriateness.

Overall Trends
This summary relates to a small section of curricula in existence around the world. It would be useful to examine the following conclusions in the light of wider information.

1. Academic science
Little evidence of newer trends existed in most of the countries examined. Curricula continue to promote 'science for the scientist' irrespective of the aspirations of the student, and continue to be developed from an academic base rather than consider societal values and links with other subjects.

2. External examinations
Teaching tends to be governed by external examinations which tend to emphasise the recall of facts, especially in Africa. Questionnaire comments overwhelmingly suggest that assessment is neither valid nor reliable as examinations concentrate on factual recall or academic conceptual learning with little relation to societal aspects.

3. Teacher assessment
The questionnaires provided evidence that teacher assessment of theoretical and practical aspects of science were taking place, although its validity was questioned. Teachers seem more at ease with the reliability of an external system than those in teacher training.

15
or curriculum development - the views presented in the questionnaires depended on who gave them. Where Science Teacher Association views were apparent, they seemed to favour assessment by a range of methods as well as assessment of practical work.

4. Teacher guidance

There is little indication that the term 'curriculum' is taken to mean any more than 'syllabus'. Little guidance appears to be given to the school, the teacher or the student on the teaching and learning of science. In some cases the textbook is the reference, and the syllabus refers to specific chapters.

5. Evidence of change

Some change is discernable at the junior secondary level with some recognition that science is a subject that is important for all students and that it should be playing its part in preparing students for society. Such change is often accompanied by a greater degree of support for the teacher in terms of resource materials, suggested teaching strategies and, in at least one case, a recognition that teachers should be treated as professionals and be expected to play their role in the curriculum process.

This need for change seems to have been recognised in some countries that continue to adopt an academic approach, as suggested by the move towards themes and topics as unit headings rather than science concepts. However, whether intended or not, the syllabus content itself remains academic and geared towards 'science for continuation'.

6. Upper secondary level

At the upper secondary level, curricula indicate that science is taught as a preparation for continuation where a sound conceptual base is important. Practical work seems to receive greater emphasis at this level.

7. Technology education as part of science education

There is little evidence of technology education being incorporated as part of science education. Any reference to technology is usually in the context of applied science and related to applications of science principles.

8. Societal emphasis

Societal concerns associated with values education tend to occur, if included, in junior secondary courses. Values education is extremely rare in senior secondary courses. Where societal ideas do occur they are usually included in units at the end of a course rather than in the context of focusing on issues and teaching science on a need to know basis.

9. Teaching approaches

The dominant teaching approach is usually not specified but, with the syllabus being academic in design and the examination papers stressing understanding, it can be speculated that the dominant teaching approach is didactic. Very few syllabuses seem to have been made shorter in response to any concern that teachers should not be forced to use a didactic approach, faced with a formidable content syllabus.

10. Deterrents to change

There is no evidence that introducing equipment lists and sets of science equipment into schools would dramatically change the current situation. It would appear that a dramatic change in the implementation of curricula is needed before teachers would have the confidence to move away from a knowledge-based, didactic emphasis. An important requirement would probably be a change in the assessment system, enabling assessment to assume greater construct validity with respect to teaching objectives.

To be continued . . .

The next issue of Science Education International will feature comments on specific countries in Africa, Asia, Australasia, Caribbean, Europe and North America.

Science Education in Iceland

by Allyson Macdonald

This article is an extract from a project proposal submitted to the Science Foundation of Iceland.

Science education has gone through many changes in the last decade. The causes of these changes are many - for example, new practices in schools, issues in society, and results arising from research.

The changes in school practices could be considered to be a reaction to trends in curriculum development work in the 1960s and 1970s. At this time, materials were usually developed and disseminated by small groups of experts working together at a project centre. In some countries these experts were scientists; in others they were experienced teachers. Now teachers and schools take an increasingly active role in producing their own materials and curricula. Thus teacher centres and teacher advisors have increased in importance in the implementation of curricula.

The distribution of and attitudes to information have changed markedly in recent years. Personal computers, interactive videodiscs and satellite transmissions have given the general public untold access to data banks and events. Using this information demands imagination, knowledge and healthy common sense. Computer-operated devices are common in our daily environment - in the home, in the classroom and in the workplace. At the same time, environmental matters have received increasing attention within and among many nations. Excellence in science education can influence the way in which individuals and nations use the newest technology and participate in the debate on the environment.

Research on the way in which students learn has increased greatly since the mid-1970s and is already affecting the organisation of courses in science. Despite this, there is still a large gap between research on teaching and research on learning. Research in both areas indicates that effective teaching practices and thus the way in which students learn is culture-dependent. The organisation of courses within a subject area should consider the classroom, the individual, the discipline and the medium to be used.

In the last twenty years new science materials have come into use in Icelandic schools, sometimes as a precursor of a new curriculum and sometimes as a consequence. Teacher
centres have sprung up nationwide, and teacher advisors offer support, especially in the areas of special education and Icelandic. Even so, support for science teaching in the educational districts hardly exists, despite the indications that such support can be more beneficial than summer inservice courses, which are nevertheless well attended. Preservice teacher education is to become a four year course, and work is in progress on flexible teacher education programs for rural areas.

With regard to the changes which are taking place in the education system in Iceland and the fact that Icelanders should keep pace with other nations with respect to technological change and environmental matters, it seems desirable to appraise the status and role of science education in Iceland. The advantages of such an appraisal are three-fold.

One would be the chance to analyse the connections between the main parties concerned with science education. Another would be to view Icelandic science education in an international context and so facilitate international contact. The third advantage would be that such an appraisal would provide the basis for purposeful research in science education in Iceland.

Dr Allyson Macdonald has been a science and mathematics primary teacher adviser at the District Education Office in Northwest Iceland, a teacher and teacher adviser at Holar Agricultural College, and a member of the governmental working group appointed to carry out a survey of science achievement in primary schools.

---

US Soviet Conference of Science Teachers  
by Dr Kenneth R Roy  
ICAPE North American Representative

From 31 July to 2 August 1991, 800 teachers from the USSR and the USA attended the first US-Soviet Conference of Science Teachers at Moscow State University. The purpose of the Conference was to provide an opportunity to explore the different science education systems, their methodologies, issues and innovations. More importantly, it provided a forum for professionals from two distant cultures to interact and share.

Each day opened with a plenary session featuring a prominent US or USSR scientist addressing topics in science and science education. After the plenary sessions, five 50 minute sessions by educators from the US or USSR focused on a variety of issues relevant to science education. Participants were able to select from approximately 20 different presentations each hour, all delivered simultaneously in English and Russian.

ICASE Special Projects Officer Professor John Penick (USA) helped to oversee the conference planning and implementation. ICASE North American Representative Dr Ken Roy (USA) presented a session titled "Preparing For and Effecting Change in Schools: Initiatives for Science Leaders and Advocates".

American participants were able to tour Moscow and Leningrad to view the culture and history of the USSR in these areas.

Russian science programs exist at the elementary and secondary levels. At the elementary level, emphasis is placed on the discussion and reading about science. Little or no attention is given to hands-on science approaches. Russian elementary teachers were most receptive to learning about activity oriented programs in the USA.

At the secondary level, science is taught throughout the grades in a spiraling curriculum. Approximately ten experiments a year are conducted by students in science classes. Teachers instruct six teaching periods per day for 45-50 minutes each. Although textbooks are primarily in a narrative format with few pictures or other illustrations, exceptional displays have been developed depicting various aspects of science. These are available for viewing and study at universities and museums.

Special schools for gifted and talented students have been created during the past two years. In addition, computers have been introduced into schools.

Many new contacts have been made between Russian and American educators with the hope of continuing dialogues and exchanging work through letters, electronic mail and possibly other visitations.

It is the hope of all conference participants that future conferences can be arranged.

---

CASTME Awards

Teachers, advisers, etc working in primary, secondary and tertiary education in Commonwealth countries are eligible to enter this award program, either as individuals or syndicates.

Entries can be based on reports of original work carried out by the teacher/official, which include a substantial account of teaching and/or other educational work such as curriculum development or programs of teacher training.

In addition to a small money prize donated by CASTME, a few travelling fellowships may be awarded, courtesy of the Commonwealth Foundation, to enable prizewinners to follow a short program of professional visits in a Commonwealth country.

Judging is based on the following criteria: (1) evidence of originality and creativity; (2) evidence of use in practice and cost effectiveness; (3) evidence of evaluation of the idea and material in use; (4) evidence of the social relevance of the project; and (5) standards of presentation, organisation and structure of the report.

Registration must be made before 30 November 1991 to your local British Council office. Entries from registered candidates must arrive no later than 1 March 1992 at the Education and Science Division, The British Council, 10 Spring Gardens, London SW1A 2BN, UK.

Write to the address above to request a Registration Form.
Global Systems Curriculum Being Developed in USA

by Dr Kenneth R Roy
ICASE North American Representative

A major area of concern over the past five to ten years has been the issue of global warming. This issue not only concerns the United States, but the global community in general. Science educators in the US are concerned about the potential changes which may follow well within the lifetime of their students.

In this way, efforts are underway to introduce the issue as a curriculum topic. Given the potential implications of such a long term event, this topic goes well beyond the borders of the science curriculum. It is truly a 21st Century issue which needs to be addressed as an interdisciplinary program.

Given this scenario and having a profound commitment to helping students understand and possibly better prepare themselves for potential changes in climate, Dr Richard Golden founded the Climate Protection Institute. The Institute has broadened its resources and services over the past three years with several major initiatives which have the potential to help shape future curriculum development in this area over the next decade.

A most important project is presently underway, resulting in part from the efforts of the Climate Protection Institute. In concert with Dr Golden's efforts, the University of California at Davis received a grant from the US Department of Energy to coordinate scientific research on global warming. Included was an educational component which will be a Global Systems Science Course. The course will address development of text material and experimental research activities. The target audience will be high school students, including those students who are reluctant to take chemistry or physics. As can be expected, the course will have an interdisciplinary nature. At present, the course Global Systems Science will have five major thrusts including:

- The problem of global warming
- The climate system and life
- Energy use and conservation
- Ecological systems
- The ozone problem

These units can be taught as one course or be infused into existing biology, chemistry, physics, earth science, or social studies classes. A pilot version of materials will be printed in the fall of 1991.

As noted, the course will include the causes and consequences of both global climate change and the ozone layer depletion. It is planned that each student will construct a personal world view of the Earth and human life as an interactive system, and recognize its consequences for individual decision-making. The text will include descriptions of the most recent research and problems in trying to analyse the complex phenomena. Given the global warming and ozone depletion concerns, the political issues involved will also be addressed.

The Climate Protection Institute also provides a newsletter - the Greenhouse Gas-ette. Among other items of interest are classroom activities offered for teachers to begin their work with students in this area. The Institute has also developed other means of helping to educate students about the potential for major climate change and its implications.

Given the international significance of this issue, science teachers and science education leaders need to take an active role. ICASE could serve as a means of providing networking efforts in this area.

Anyone interested in additional information relative to activities in the US on Global Studies can contact Dr Richard Golden, Global Systems Science, Lawrence Hall of Science, University of California, Berkeley, CA 94720, USA.

Regional Meeting in Africa

The Nigerian Federal Ministry of Education hosted an African Regional Meeting in Lagos, Nigeria on 24th July on the theme Resuscitation and Strengthening of Interaction and Cooperation among Science Educators in Africa. This meeting was held as part of the larger International Council of Education for Teaching (ICET) Assembly which was held from 21-27 July 1991. Five countries - Ghana, Zimbabwe, Cameroon, Egypt and Nigeria - participated in the meeting.

Training and education in marine sciences

Excerpts from Supplement to ims Newsletter No 53/54

Unesco's varied training and education activities executed by the Division of Marine Sciences, have been pulled together into a cohesive program referred to as TREDMAR - an outcome of the report Year 2000 challenges for marine science training and education worldwide. Over 5000 copies of this Unesco publication have been distributed in six languages.

Outputs of this program include a computer based learning module Some marine applications of satellite and airborne remote sensing and a video based learning module on the identification and biology of Reef corals and sponges of Indonesia.

Serious concern about the lack of attention to marine and coastal aspects in many secondary school curricula around the world was expressed during the workshop in Paris, July 1988 at which the preparation of the Year 2000 report culminated. Consequently, recommendations were adopted in this regard by the workshop participants. A marine science field study workshop for Pacific secondary school teachers was held in Fiji in 1989. A 90 page text Field work in marine ecology for secondary schools in tropical schools has been published as MARINF/80. Contact Unesco for further details.
OPINION FORUM
The World Population Explosion
and Related Issues
A PROJECT OF THE INTERNATIONAL ASSOCIATION OF SCIENCE CLUBS
The Firs, Southdown Road, Freshwater Bay, Isle of Wight PO40 9UA, UK

Young people throughout the world are invited to complete
this opinion survey and to return it to the address of IASC above

1. There are now more people alive in the world today than have ever lived in
total before: (a) Is this idea new to you? (b) Do you believe it?

2. There are more than 5,000,000,000 people alive today, and the population
explosion curve shown on this page shows no sign of levelling off:
(a) Do you see this as a serious matter?
(b) Should nature be allowed to take its course, or should measures be taken to
help the curve towards a steady level? (Underline the option you support)
(c) List the main consequences you think go with overcrowding.
(d) What population control measures do you think are acceptable?
(e) What population control measures you think are not acceptable?

3. (a) Do you agree that the greater the number of people, the less the room for
wildlife? (b) Does this concern you?

4. (a) Would you like to have children of your own in time?
Or (b) how many children do you already have?

5. How many children would you like to have?

6. In view of world overcrowding, how many children do you think you should
have?

7. Assuming that it is desirable for all people to have a fair quality of life, and
that this does not go with overpollution and exhaustion of resources, what do
you consider to be the optimum level for the world's human population?

8. Please state your:
(a) age
(b) sex
(c) locality (town, county or state, country)
(d) country of birth

Are you interested in attending an International Young People's Forum planned
for Paris in July 1993 at your own expense? If so, please provide your name and
address to IASC at the above address.
Middle Schools and STS: An Ideal Match
by Barbara S Spector
University of South Florida, USA

This paper compares hallmarks of middle school philosophy to characteristics of STS curricula with which I am familiar. Examples are given of ways to use different STS formats to link the sciences (natural, mathematical, and social) to technology, to the humanities, and to the arts creating a transdisciplinary curriculum that is meaningful to middle level students. The examples given come from projects with which I have been working in Florida.

Characteristics of Middle School

Appropriate middle schools build on a holistic view which focuses on helping transescents learn to make connections among separate pieces of information and events. Therefore, middle school science not only integrates earth, physical, and life science, but connects to subject matter in all disciplines. Teachers working in transdisciplinary teams create opportunities for students to experience continuity from one class period to another.

Instruction focuses on the individual recognising that each child has a personal learning style and is interested in his/her own real world issues and problems. Students are helped to clarify their values and deal productively with the emotional and social aspects of life. The curriculum is exploratory and focuses on learning for today. Emphasis is on decision-making, thinking creatively and critically, and generating multiple ways to solve a problem.

Teachers share in the advising of students and instruction is deliberately designed to give students opportunities to experience success. Grades reflect the student's personal growth ascertained by a variety of procedures. Intended outcomes for students include learning how to learn (not just take tests), becoming self propelled learners, developing physically and mentally healthful life styles, having career awareness, and becoming active citizens.

Characteristics of STS Curricula
The characteristics of STS curricula with which I am familiar are consistent with the preceding characteristics of middle schools that are tailored to the needs of transescents. STS curricula build on a holistic world view. Knowledge and skills from many disciplines are integrated to construct concepts which reveal the whole. All the natural, mathematical, social, and information sciences are connected to technology forming a coherent curriculum in which the disciplines articulate with each other via a transdisciplinary approach.

Transdisciplinary refers to the disciplines being woven together into a whole in such a way that they lose their discrete identities. It is only upon deliberate analysis that one can identify the items found in the lists of mandated skills and knowledge or scope and sequences that drive courses in conventional disciplines in traditional schools.

Transdisciplinary approaches contrast to interdisciplinary approaches in that the latter often relate disciplines to each other in formats which maintain clearly defined discipline boundaries (see Figure 1). Commonly, everyone teaches what they have always taught, but they bridge to other disciplines by acknowledging when something is covered that also appears in another discipline (eg metrics, graphing, spelling). Another interdisciplinary strategy is for teachers in different disciplines to agree to follow a particular pattern (eg everyone starts from the smallest part and builds to the larger whole, or vice versa). This results in parallel tracks among conventional discrete disciplines.

Understanding relationships among people, things, and ideas is vital to students if they are to be effective in today's fast changing world. The nature of this knowledge, its connections and complexities, require a transdisciplinary approach to teaching and learning.

In STS curricula, topics are selected from real world issues and events of interest to students. They, therefore, readily perceive the relevance of what they are studying. Instruction
emphasises inductive reasoning and is experiential. Activities are open ended, have more than one right answer, and have more than one way to determine a viable answer. Students' guide the paths of lessons.

STS activities require risk assessment, cost/benefit analysis, environmental impact analysis, trade-offs, and decision-making. The needs of individuals and diverse groups with vested interests are considered when decisions are made. The interaction of values people hold derived from ways of knowing other than science, such as religion, philosophy, or aesthetics become part of the data explicitly considered in the decision making process. The scientific enterprise is portrayed as a dynamic human endeavour: a part of the global society in which changes in science and technology affect decisions people make, and the decisions people make affect further scientific and technological developments and the future of our planet.

Format for STS Curricula
A transdisciplinary approach to STS can use a variety of organizers for curriculum, all of which provide natural linkages with other disciplines (see Figure 2). Some examples of possible formats include organising a curriculum around (a) topical themes, (b) site exploration experiences, (c) themes unifying the sciences, (d) current events in the news, and (e) the history and philosophy of science and technology. What follows are samples of STS formats linking to other disciplines from successful projects with which I have been working.

Topical Themes
Topical themes, such as water, communication, or the circus work well as STS organisers. Water was selected as the unifying theme in the World of Water, a residential middle

**ICASE AWARD SCHEME**

for outstanding contributions to international science education

_Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below._

**ICASE Distinguished Service Award**

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations

**ICASE Regional Service Award**

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

**ICASE Association Award**

This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Contact Dr Jack Holbrook, Executive Secretary ICASE
Department of Curriculum Studies, University of Hong Kong, Hong Kong
school program, because the uniqueness of fresh water on planet earth is what makes life as we know it possible (Spector, 1991). Water is an ideal theme around which to build a program for students to acquire the knowledge and skills necessary for solving real world problems.

One way the natural, mathematical, and social sciences and technology were woven together was through laboratory and field experiences addressing the problem of the economic impact of developing ways to supplement nature's filtration system to maintain adequate supplies of potable water in Florida, given the state's population explosion (900 new residents/day).

Dance, music, and the visual arts were all used as vehicles to teach key concepts and principles in the sciences. Free flow writing was used in personal logs as a vehicle to help students construct knowledge through reflection. More formal expository writing formats were practiced as they recorded data from the field investigations and the laboratory, used technical writing for research proposals, and used persuasive writing for an essay contest.

Haiku poetry, creative drama, and role play were used to identify incomplete conceptions and assess students' abilities to synthesise what they had learned from their opportunities to gather data on the properties of water and the role of water in both natural and human settings. Using other disciplines as vehicles to learn science helped students develop a holistic world view consistent with an understanding of the strengths and limitations of the scientific enterprise.

If we select topics students associate with leisure time activities, such as fishing, sailing, photography, etc., when using topical themes as organisers, and study the science and technology inherent in the activity students perceive learning to be relevant. It also makes success experiences readily available to youngsters because they can build on the knowledge they have gleaned informally through their recreation. For example, in the World of Water, we use sailing to study Bernoulli's Principle and wave motion in physics and hull and sail design to study materials chemistry and mathematics. Fishing is the vehicle for learning the physics of a rod, reel, and monofilament line. Finding good places and times to fish involve the study of food chains, habitats, and meteorology. Literature of the sea, fish stories from the comics to the classics, provide insight into ways people around the world have learned the science and technology that students are learning from their own experiences.

Site exploration experiences

Site exploration experiences (SEE) are excursions to locations in the community for in-depth studies of real life situations. Activities at a site are developed to meet the perceived needs of a specific group of students. Any place has potential to be a SEE from an open field, to a manufacturing plant, to a theme park. SEEs provide a common base of experience for students who may have very different life experiences and few things in common around which to interact and build concepts. The common experience serves as the cameo around which teachers from all disciplines develop classroom activities, thus establishing continuity from one class period to the next during a day. The social interaction and cooperative learning outside the confining structure of a classroom help students develop their personal skills while learning science. In addition, SEE's make it easy for teachers to abandon the 3Ts (Teacher, Talk, and Textbook) and use a mosaic of instructional designs including role playing, simulations, debate, varieties of computer programs, mapping (V, concept, and theory), individual projects, small group activities, and group presentations.

Here are edited excerpts from reflective logs kept by teachers in a middle school during the first year in which they began converting from a junior high school to a middle school (Spector, 1990). The team leader and initiator of the school's holistic approach to curriculum was a science teacher steeped in STS

A nine week theme title, WDIIDWWDW - What do I do with what I don't want? - connected to the SEE at a sewage treatment plant.

Students were told things to look for at the sewage plant by teachers from each discipline. Ratio and proportion were the key ideas for mathematics. Geography focused on sewage treatment and disposal as a community-wide and world-wide issue. Science dealt with the environmental impact of sewage disposal and with the study of zooplankton and methane gas. A teacher played the keyboard and taught the students to sing a song which describes the relationships between pollution and the lowest part of the food chain. For English, students were asked to act as reporters. They recorded their observations and later wrote about their experiences at the sewage plant. Students generated concept maps of the SEE as an evaluation.

Figure 2

SAMPLE STS CURRICULA FORMATS

STS Curriculum may be organised around

1. Topical themes
2. Site exploration experiences
3. Themes that unify the sciences
4. Current events in the news
5. History and philosophy of science

22
A nine week theme on communication revolved around the SEE at the local newspaper. Students had made recycled paper earlier in the year before the site exploration. The technology of the printing presses and the multiple uses of computers at the newspaper plant impressed them. They were coached on questioning techniques before they visited the newspaper plant.

In English, they had discussed various methods of asking questions and discovered that more information could be obtained by avoiding questions that required a single word answer, such as yes or no. Students enhanced their speaking skills while they practiced interviewing each other. The students also practiced questioning and listening skills in mathematics, science and geography. Developing a line of questioning with which to investigate a topic is critical to systematic inquiry in all disciplines. The geography teachers helped students explore the various sections of the newspaper.

The day following the SEE, students were asked to write in their journals in English. They were free to write whatever they wished about their experience. Some leading questions were offered as possibilities to stimulate thinking, such as "How was the experience different from what you expected?" "What did you find most interesting?" and/or "What was something new you learned?" Prior to the trip, this is what a student had written about the newspaper: "It's black and white and comes in a plastic bag". His journal entry after the trip covered half a page.

In English class, they also cooperatively wrote a thank you note to someone at the newspaper. In each group individuals took the role of editor, proofreader, reporter, and scribe. Students understood a group grade would be given, and each student had to contribute to the total grade. Groups were randomly selected. Within the group, it was decided who would handle each job and to whom they would write. Students in every group contributed ideas on what to write and the reporter recorded the ideas. The editor had the final say as to what should be in the letter, and the scribe wrote it. The proof reader checked the letter and made any necessary changes. It was then rewritten and checked by the editor who gave it to the teacher to mail. The students were very vocal about anyone who did not take part in this activity. At the same time, there was always someone in the group who took up the responsibilities of a 'slacker'. Peer pressure effectively encouraged nonparticipants to join in a learning experience.

Themes unifying the sciences

The relationships about which students need to know, their interactions and intricate connections, suggest organising information around themes which describe the relationships of the extant body of knowledge. A variety of such themes pervade the sciences, the humanities, and the arts and work well as organisers for STS curricula. For example, in the BSCS middle school project (1989), Science and Technology: Investigating Human Dimensions themes such as patterns of change, limits and diversity, equilibrium, evolution, energy and interdependence are used. Science for All Americans: Project 2061 (AAS, 1989) suggests organizing themes this way: Systems; Models - physical, conceptual and mathematical; Constancy - stability and equilibrium, conservation, symmetry; Patterns of change - trends, cycles, chaos; Evolution - possibilities, rates and interactions; and Scale.

While these themes are being publicised because they run through the natural sciences, they are also evident in other disciplines traditionally taught to middle level students in schools.

For example, in English classes patterns of change are noted as one traces the development of language and
culture from Shakespearian English to current slang.

In literature, patterns of change are studied in the characters from the beginning of a story to the end. Social studies classes explore patterns of change in culture of civilisations around the world. Patterns of change are studied within a musical composition, and in the passage from one era of music to another, eg classical to new age music.

In English, there are limits and diversity in writing forms from styles of poetry, to essays, to technical reports. In social studies, acceptable social behaviours differ and are limited by the variety in cultures. In mathematics, limits and diversity can be seen in the difference between the arabic numbers and Roman numerals, Euclidian geometry and non-Euclidian geometry, Newtonian calculus and non-Newtonian calculus, and the existence of multiple ways to solve a mathematical problem.

Career awareness initiatives, such as having students solve anthropometric problems in architecture, illustrate the holism of using the theme of scale in STS curricula. One has to combine mathematics, art, and human science to create functional architectural designs. For example, we have to know how human elbow joints work in order to design drawers that can be pulled out or how human body parts articulate when one designs a comfortable chair, or establishes the height of steps. Scale is a theme that also ties the study of ratio and proportion in mathematics classes to mapping in geography classes.

Other forms

Current events in the news lend themselves equally well as transdisciplinary STS organisers, especially events reported for their local impact while they are part of global issues. For example, newspaper reports of local families being separated as troops left for the Gulf War, or reports of a foreign owned corporation applying to a governing body in rural America for permission to burn hazardous waste in a cement kiln, illustrate how real world problems require an understanding of the interaction of science, technology and society and the weaving together of knowledge from numerous other conventional disciplines to reach resolutions with world-wide implications.

The history and philosophy of science and technology is another format that works well as an STS organiser. A historical approach to which students are very receptive is the televised version of Burke's (1978 and 1985) Connections and The Day the Universe Changed.

Summary

After studying the needs of transcents (11-14 year olds) and the subsequent nature of schooling that would meet their needs, I concluded that STS is an ideal core upon which to build schooling for middle level youngsters. The characteristics of the STS initiatives I've experienced match the philosophy of the middle school visionaries. Further, STS provides natural linkages to all other disciplines taught in a school. Science teachers who use STS approaches readily take the lead in restructuring the many separate disciplines in their schools into an articulated, coherent, transdisciplinary whole which is considered to be the desired state for schooling of middle level youngsters (Spector, 1991).

Multicultural Science Education by Practicing Teachers
A Model with International Implications
by Anjana Arora & Elizabeth Kean

Access and Appropriateness

According to the Indian National Policy on Education (1986): "In our culturally plural society, education should foster universal and eternal values, oriented towards the unity and integration of our people. Such value education should help eliminate obscursism, religious fanaticism, violence, superstition, and fatalism." This Policy further stated: "The new Policy will lay emphasis on the removal of disparities and will equalise educational opportunity by attending to the specific needs of those who have been denied equality so far." These groups of people with specific needs have been identified as women, schedule castes, schedule tribes, people in backward areas, religious minorities, linguistic minorities, handicapped, adult learners, etc. This Policy also stressed decreasing dropout rates.

One cannot help but be struck by the parallels between the stated problems and goals in the Indian educational system and many other worldwide locations. In the United States of America the number of students from various ethnic backgrounds (primarily African American, Latino, Native American, and some recent Asian immigrants) who are interested and successful in schools is intolerably low. High school dropout profiles also correlate with ethnicity and poverty. In 1982, high school dropout rates were reported as 14% for whites, 24% for African Americans, and 40% for Latinos. These children, many of whom are poor, are effectively cut off from careers in science and technology - just the types of jobs most likely to offer them financial security.

Moreover, as a society, the percentage of US youth who are members of a minority group is rising dramatically. By the year 2000, 1 in 3 Americans will be minority and the proportion of minority students of school age will approach 50% (Hodgkinson, 1985).

In both countries, the problem comes down to two issues: access and appropriateness. Are children able to get to schools and, if so, is the education they receive appropriate? It is this latter issue, the ability of children to make use of the education offered by the schools, that we would like to address in this paper.

Cultural Matches

Many factors contribute to the failure of minority youth to pursue learning in school, and especially learning in science. Given the structure and the content of traditional science classes, many of these students cannot perceive the relevance of what they are being taught to their current or future lives. The culture of many minority students does not match well the white, middle class social and instructional school paradigms, for example an emphasis on individual performance, the passive nature of school work, the valuing of knowledge possession over human relationships. As a result, minority children often fail to engage in the work of the school.

We cannot overlook the societal factors that produce uninterested science learners. Rather, teachers must learn to change the culture of their schools in order to bridge the gap between where students are when they enter and where we wish them to be when they leave. This will enable more minority students, especially poor children, to thrive in school science, preparing themselves to participate fully in the civic and economic life of our nation (Bryk and Driscoll, 1988; Comer, 1988).

Moreover, although it is important to train the up-coming generations of science teachers to teach in culturally appropriate ways (O’Brien, 1991), it is even more necessary to support the current group of science teachers to change their practice. Below are some of the issues that must be addressed in supporting practicing, experienced teachers' growth in multicultural science teaching.

Changing the School Science Teaching Culture

Over the past two years through our observations, interviews with teachers, administrators and students, we have identified the following needs for change in the school culture:

1. Teachers report that a persistently large number of their students fail to engage in science learning. Such students appear to be uninterested, angry or bored. It is not that these students cannot learn, but rather that they are choosing not to learn. These students will not suddenly transform themselves into model students. If there is to be a change in science learning, it will come about because teachers find a way to change their own behavior, setting a new context in the classroom in which students find it harder to stay unengaged, uninterested, angry or bored. Such changes involve changes in teacher attitudes as well as
how and what content is presented. 

2. Teachers cannot teach what they do not know. Many teachers rely primarily on texts for their content knowledge. Such text knowledge is often out of date with respect to current issues and knowledge in science. Further, it is often alien and unengaging to the targeted students. Teachers need to develop content knowledge that is accurate, relevant to students, and which promotes problem solving skills and scientific literacy.

3. Many science teachers have control of traditional pedagogical skills that work well with compliant, willing students who have been well socialised into the traditional school culture. These traditional teaching strategies are often not effective with unengaged students. Teachers need to develop a wider variety of teaching strategies specific to their courses.

4. Because the problem of unengagement is complex, the response must be complex. New content, new strategies, new ways of working cross culturally need to be developed concurrently. Our experience to date is that teachers have more trouble changing the content from text-focused to problem-focused, than with any of the other needed changes.

The Process of School Science Cultural Change

We believe that in order for these changes to be implemented, teachers must be co-creators with program staff of much of the new curricula and teaching methods, and that they must learn to implement them in real multicultural classroom settings. Moreover, administrators from their schools must likewise be knowledgeable about the changes and willing to support them. In the past two years, much new science content for use in multicultural settings has been developed by participating teachers during four week summer workshops. In preparing teachers for their role as curriculum developers, the 1989 and 1990 summer workshops had the following objectives:

- participants develop new understandings of the characteristics (strengths and needs) of minority students and how to respond to those characteristics.

- participants develop new understandings of the power of problem-solving and cooperative learning approaches, singly and in concert.

- teachers plan and implement new course materials for their own classes, based on these understandings.

- administrators develop procedures to support implementation of these materials by teachers.

- participants develop outreach programs to inform others of new strategies which have been effective in their classes.

The major themes of the workshop are described as follows:

- Multicultural Understandings

   Presenters from various ethnic groups lead participants to confront issues of ethnic differences and similarities. Activities help participants to understand their own cultural base as well as to understand and value cultures different from their own. Participants examine some of the cultural biases that influence interactions among minority and majority people and develop ways of responding more flexibly and creatively with minority students. Special attention is given to minority students' needs for nurturing relationships as a foundation for effective learning (Bryk and Driscoll,
1988; Comer, 1988). Participants interact with the minority communities and with minority children to provide a greater experiential base for developing multicultural sensitivities.

**Problem Solving**

Problem solving consists of 3 P’s; problem posing, problem solving, and persuasion of peers (Peterson and Jungck, 1988). Among the topics considered are: problem solving approaches to algorithmic and non-algorithmic problems, heuristics useful in varying contexts, development with students of interesting science questions with attention to science issues in their lives, strategies for teaching problem solving, etc. (Middlecamp and Kean, 1987; Reif, 1983; Rubenstein, 1986). Teachers consider problems which are part of their current science courses, as well as problems that introduce new topics for study. Teachers are taught the question: "Why would any student want (need) to know that?" as the ultimate question to be addressed when planning new content.

**Cooperative Learning**

Cooperative learning has been shown to enhance the performance and integration of minority students in the classroom. It is a learning mode that increases achievement as it develops appropriate social interaction skills among students (Johnson, Johnson, Buckman & Richards, 1985). Therefore, it is an effective method of instruction to enhance racial integration within classrooms (Johnson & Johnson, 1984). During the workshops, participants learn to use the five essential elements of cooperative learning - positive interdependence, face to face interaction, individual accountability, collaborative skills, and group processing (Johnson, Johnson & Holubec, 1988). They experience many cooperative learning situations and develop teaching plans that incorporate cooperative learning. The technique is highly interactive, integrating concepts of coaching and learning styles with methods of explicit instruction.

These three themes are highly interrelated and they were taught in the workshops in an integrated manner.

Although each instructional activity of the workshops addressed a specific theme, aspects relating to the other themes were brought in as appropriate. For example, the first days of the workshops focused on ethnicity issues. However, the learning characteristics of various ethnic groups were further discussed during segments centered on problem solving (What problems might be of interest to minority students?) and cooperative learning (How can strengths of minority students be utilised in a cooperative learning activity?).

Participants spent much of the 17 days of the workshop constructing teaching units incorporating ideas from these themes. After having been introduced to the themes through a variety of experiences and exercises, participants designed a short instructional unit (2-3 days). Participants worked in groups, focusing on topics from their science texts, but using problem solving and/or cooperative learning strategies as the instructional framework. Each group worked cooperatively to solve the problems of selecting content, assigning roles to group members, etc. Units were critiqued by the entire group (for ethnic sensitivity, alternatives to "telling" by teachers, problem solving focus, multiple level goals, etc).

Participants later designed a 2-3 week unit. Topics were generated in a brainstorming exercise and categorised into clusters. Once general areas were identified, participants self selected to work in one of the areas. The groups which formed through this process were mixed with respect to schools, subject areas, and grade levels.

Learning in these units often is assessed in ways other than by pencil and paper tests and conventional grades. All units were developed on computer so that they could be easily shared with other teachers.

The organisation described above is non-traditional. For example, issues were not presented linearly, but were treated repeatedly in ever more complex ways. Administrators, some not trained in science, involved themselves in developing science units with teachers. The response by participants to the workshops has been overwhelmingly positive, as evidenced by their journals and responses to formal and informal evaluation instruments.

In addition to the summer workshops, follow-up during the academic year is vital and has assisted teachers in maintaining connections with one another and working through implementation problems. Project staff visit each teacher's classroom at least once per semester and discuss specific problems and successes the teacher has encountered. The entire group gathers quarterly for a half day to discuss implementation patterns and plan new activities, including dissemination to teachers unable to attend summer workshops.

**What Next?**

Over the next three years, projects in the following areas are planned:

- Continue to plan new curricula, especially to provide new content information and integrate problem based modules into cohesive themes.
- Conduct on-site visits to other science curriculum improvement projects in the region (AAAS, 1989; NSTA, 1990) to share expertise in producing effective units and activities.
- Refine instructional methods of teaching the new content and teaching strategies to other teachers.
- Plan and conduct in-services for teachers unable to attend summer workshops.
- Develop links with external communities to enhance science content, career contacts, and minority resources.
- Develop computer capabilities to enhance management and networking skills of participating teachers.

The intent of this phase of the project is to consolidate the changes in the science classroom culture and to institutionalise those changes throughout the school system. Only then will systematic change take place, reaching all of those students who have in prior years been largely failed by the system.

**Applicability to the international context**

The workshop described above is an example of collaborative effort between
university researchers and school people. Workshops like this enable teachers to discuss their own needs and use their own resources to meet these needs.

As teachers analyse their problems they will be able to find many direct and indirect ways to tackle these problems. Researchers can work further on the teacher experience-generated issues, cementing the partnership between teachers and researchers. Teachers will be more willing to be involved in issues they have generated.

The success of such an effort depends upon how often these teachers exchange ideas. Where possible the teachers involved should be from the same geographical area so that they can meet often in order to exchange their successes and failures and to come up with new issues.

One of the main constraints in conducting or applying research is the availability of funds. On the other hand, whatever funds are available can be utilised in a more effective manner. Rust and Dalin (1990), based on a number of research articles and UNESCO publications related to Asia, state:

"... that conventional teacher training and upgrading programs have little or no impact on student learning, that they are generally irrelevant to teacher needs and conditions, and that they are longer and more costly than necessary."

Conventional programs, while not always ineffective, are costly. Hence teachers, teacher educators, and researchers (including researchers from fields such as Psychology, Sociology, Political Science, Natural Science) must pool their internal and external resources for improving both conventional and non-conventional approaches.

In getting together, teachers, teacher educators and researchers can understand, recreate and analyse their problems within the framework of their working conditions.

It is up to teachers to decide how they can best tackle a problem within the constraints (fixed curriculum, teaching for an exam) of their working conditions. We do not visualise a direct or immediate global change from efforts such as this. As educators and teachers, however, we can influence our immediate surroundings.

**Pasteur and Microbes**

*A Teacher Resource Book*

*Commemorating the 100th Year of the Pasteur Institute 1888-1988*

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute. It contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few. These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation.

Helping Primary School Teachers Help Children in Science

by Dr David Palacio
School of Education
Westminster College, Oxford, UK

Introduction of a Science National Curriculum in England in August 1989 had two important features as far as primary schools are concerned. First, science became a mandatory part of the curriculum for all children during their primary school years. Second, for many of those schools who were already introducing children to some form of science education, a shift towards a greater emphasis on developing children's understanding of science concepts was required. This latter point has very important consequences for the effective delivery of this curriculum since it was not known whether, or to what extent, primary school teachers themselves have the required knowledge and understanding of the relevant concepts to be able to competently and confidently introduce them to children.

The Primary School Teachers and Science (PSTS) Project, a joint venture between the University of Oxford Department of Educational Studies and Westminster College, Oxford, has been set up with the major aim of helping teachers acquire the knowledge and understanding of the concepts central to science at a level which will enable them to introduce these concepts effectively to primary school children. Two projects have been set up under the PSTS umbrella, both funded by Charitable Trusts.

The first project is investigating teachers' existing understanding of science concepts and using this information as a starting point for the production of teacher education materials aimed at further developing conceptual understanding. Concepts chosen for detailed investigation were those that were known to cause difficulty for primary teachers. Hence the work began with the concepts force, energy and change in materials; later work focused on a range of biological concepts such as respiration and photosynthesis, and concepts associated with the Earth and atmosphere and Earth in space.

The second project is investigating whether the theory of and approach to learning employed in developing and writing these materials (constructivism coupled with metacognition) can be effective in bringing about long term conceptual change in adult 'non-science' learners.

This article deals with the first of these projects and describes the process by which the teacher education materials have been developed.

Finding out teachers' existing understanding of targeted science concepts was accomplished via a three phase process. In the first stage, a small number of teachers (about 20) were interviewed using a procedure known as 'interview about instances / interview about events' to find out in some detail the nature of their existing conceptual understanding in the targeted conceptual area. The second phase used some of the ideas that emerged from the interviews as a basis for the construction of a multi-choice questionnaire that was completed by around 150 teachers per conceptual area. Taken together, both phases formed a fairly reliable basis from which to go forward to the next phase - the production of teacher education materials.

During both the interview and prevalence phases, other background information was collected from the teachers (such as their experiences of science in school and during their professional training) and was subsequently fed into the materials production phase. This whole procedure was repeated for each of the conceptual areas in the list above, with the addition that, for some conceptual areas, a technique known as concept mapping was used to supplement the information obtained during the interview phase.

Even though the materials are set within a constructivist - metacognitive approach to learning in science, background information gathered during the interview and prevalence phases led the project team to reject...
Moving on Air

From SATIS 8-14
Association for Science Education, UK

These activities will help you understand why moving on a bed of air is so easy.

The Air Track

Make an air track with a plastic drink bottle, using a compass point or thumbtack to make holes as shown.

Make a 'vehicle' by cutting a plastic ring from another larger bottle. Make sure the ring has no ragged edges.

Put the ring over the holes in the air track.
Blow into the bottle and watch the vehicle move along freely.
How much weight can you put on the vehicle?

The Balloon Hovercraft

Make a model like this.
Blow up the balloon and see how it moves.
Can you make your hovercraft bounce off things?
The 1991 Singapore Youth Science Fortnight

by Sue Stocklmayer
SMEC, Curtin University of Technology
Perth, Western Australia

The Singapore Youth Science Fortnight is an annual event sponsored by Shell Companies in Asia and Australasia. Each year, one science teacher from Australia accompanies two students to Singapore for a succession of activities with a science theme. In 1991, Emma Runciman, from St Paul's Anglican Grammar School in Warragul (Victoria) and David O'Connor, from Heathfield High School near Adelaide (South Australia) were the Australian student delegates. Emma and David were Science Talent Search winners in their respective States; Emma for her "Phoeboscope" and David for his "Bedroom Control Interface".

Centre. Dr Gore delivered the Keynote Address which was enthusiastically received by Singaporean teachers.

The main focus of the fortnight was the Science Fair, an occasion at which the international student delegates were expected to explain their projects and talk to the public. Emma's and David's projects attracted considerable attention and a constant stream of visitors, but we nevertheless found time to visit some of the local students' displays.

The Fair this year was for primary students in Singapore; next year it will be the turn of the secondary schools. It was an absolute delight to talk to these very small children about the principles underlying their projects; from the Bernoulli Effect to Global Warming, they were able to explain exactly what their experiment was all about.

The fourteenth Science Fortnight had as its theme "Values in Science Education". Its stated aims were:

- to provide young scientists with an opportunity to discuss scientific problems and the implications of science on society, both among themselves as well as with senior members of the scientific community, and;
- to allow educators of youths to exchange views and experiences in science education.

There were eight nations present - Singapore, Thailand, Brunei, Indonesia, Malaysia, Philippines, New Zealand and Australia. From first to last the organisation was superb. We attended dinners, sang Karaoke, and generally had enormous fun. It is impossible to list all that we did; suffice it to say that we really felt that we had got to know Singapore and its people in a special way.

The most important outcome of the fortnight was, for Emma, David and me, the interactions we had with the students and the teachers of the participating nations. We were together most of the time, sharing both work and recreational activities, and there was plenty of time to make friends. There is no doubt that the Youth Science Fortnight is a notable event on the calendar of science education, and we are indeed fortunate that Shell Australia so freely offers its support.

We have brought back not only memories of a wonderful experience (and the addresses of many new friends!) but a greater understanding of some of the strengths and some of the problems which other countries experience in science education, and a knowledge of many difficulties which we share.

Events such as this can only result in more interaction, more help, and more global understanding.
The Special Topics Club
Extra-Curricular STS Activities

by Dr. Michael J Demchik & Dr. Virginia C Demchik
Jefferson High School
West Virginia, USA

Science Technology Society (STS) activities are an excellent way of bringing real world learning into the classroom. In our recent and on-going revisions in chemistry and physics at Jefferson High School, West Virginia, STS is incorporated at the 20% level. While we consider that the resources used are excellent, we also feel that another element - career education - can be incorporated into this format easily.

Early in the school year, students at the junior and senior level in Chemistry I, Chemistry II, and Physics, are surveyed in order to determine their projected fields of endeavour. (Other items are examined as well with this survey but the career education portion is the only part reported in this article.) The individual data is developed into a composite, and student interests are determined. Each year the results are much the same and the numbers vary slightly. From the data the most frequently appearing fields are the engineering, medical, biological and physical sciences (infrequently physics). Others appear to a lesser degree.

At a date prior to the initial survey work three years ago, a letter was sent to governmental agencies, state agencies, college and university staff, and a few companies, requesting their help in arranging for someone who would be willing to informally present to our students, information about his or her work.

Additionally, we requested each participating individual to prepare an activity in which our students could participate. The activity had to represent something that they did in their work which was suitable for high school level. The list has grown to 55 resource people, including professors, researchers, and practitioners of science.

Individuals were selected from this list based on the student survey results. Resource people have presented topics on robotics, lasers, oscilloscopes, electromagnetic induction, aquaculture, motors, raptor centres and more. As a result of these presentations, some field trips were developed which took us to places such as the National Fisheries Laboratory, where we toured the laboratories and had a short talk by the member of staff responsible for each lab. One interesting aspect was the work being done to research a specific hybrid fish that would be suitable for the conditions in the nearby Potomac River.

Another visit involved the Chemistry Instrumental Laboratory at nearby Shepherd College. The laboratory director arranged for some of his advanced students to demonstrate the types of equipment available, and provided our students with the opportunity to operate them. We were able to borrow a Beckman Acculab 3 Grating Spectrometer, and an Aldrich-Nicolet Search Program for the Apple IIe computer to use with the aqueous section of the Chemistry course.

Another development has been to involve graduates of our program who are now majoring in specific areas, by having them visit the school to discuss their work at college/university level. For example, one student, a raptor centre volunteer for two years, brought some birds that were strongly imprinted on humans.

In the past nine years, we have placed nine students at the National Fruit Lab as research apprentices. Two others worked at the Soil Conservation Service. With the help of this program, students are gaining a better view of their chosen career and, as a result, they are proceeding to college/university with more confidence. The program, well received by our students, supports STS objectives so necessary in today's world.

About the authors
Dr. Michael J Demchik, with 32 years experience in administrative and teaching positions, has been teaching chemistry and physics for five years at Jefferson High School. Dr. Virginia C Demchik has been teaching at college and secondary level for 25 years, and has been at Jefferson High School for the past five years.

Science across Europe

Reprinted from the Newsletter June 1991
of the Science across Europe Project

Why 'Science across Europe'?

As the countries of Europe move closer together, it is important to raise the awareness of European citizens for one another's societies.

Europeans have many traditions and languages, but they hold in common a culture of scientific values and beliefs. Pupils in schools across Europe follow similar science courses.

It is a common experience in most countries that the most effective way of introducing new educational topics is to tie them closely to the curriculum. The Science across Europe Project sets out to provide opportunities through the science curriculum for 14 to 17 year old students to share their ideas.

Intended outcomes

The project is producing a series of short units (lessons) for use with the science curriculum for 14 to 17 year olds. The units are translated and adapted to make them appropriate to each of a range of European countries. Each unit is based on a science-related issue, selected according to the following criteria:

- the extent to which the issue affects students throughout Europe
- the extent to which it links mainstream science curriculum topics.

The project has already established a successful formula for student material. In its second year it will be seeking to improve the arrangements for contacts between classes and to involve more schools and languages. Its major challenge will be to arrange distribution of published material.

Phase 1

Phase 1 took place during 1990. Trial versions of two units were produced in seven languages.

The development team consisted of eight people drawn from educational establishments representing six countries in Europe. A general strategy for the project was agreed. The team drafted two short units in English, Acid rain over Europe and Using energy at home. A feature of the units is that students need to contact other schools in Europe to exchange data and ideas. Members of the team undertook the translations and adaptation into German, French, Dutch, Swedish, Spanish and Catalan.

Trials took place in early 1991 with about 50 schools participating.

An evaluation study was undertaken by Harrie Eijkelhof of the University of Utrecht. Teachers reported that their students had enjoyed receiving information from students in other countries and learning about their perspectives. They were keen to undertake similar work in the future. There seemed little difficulty fitting the units into the regular science curriculum.

Phase 2

In this phase the project will develop on a modest but more formal basis. We began work in April 1991.

In phase 2 we aim to:
- increase the number of languages in which we work
- extend the network of schools using the materials
- develop and trial three new units

The writing team, enlarged to 10 members, met for a weekend workshop in Brussels during April and made the following recommendations:
- to publish the units developed during last year as two books (for September 1991)
- to set up a database of schools wishing to participate in the network (for November 1991)
- to write and trial three new units: Renewable energy, Water quality and What did you eat ... ? (These are temporary titles). These units will be ready for publication in September 1992.

Each unit will be published as a single book containing all its language versions to provide opportunities for further language work in schools. The books will be available for purchase from organisations such as the Association for Science Education, UK and for distribution through the BP network.

Feedback from trials identified a need to harmonise the timing of contacts between schools. With the new publications we hope to refine our procedure. Schools will be able to join
the Project's network or arrange their own contacts. BP will also operate a network for schools linked to local sites around Europe. We would like to offer a choice of periods during the year for exchanges of information between schools.

Initially, we anticipate that distribution of the new books will present the greatest challenge to the growth of the Project.

In some countries, schools do not have budgets to spend on books, and formal administrative procedures are too lengthy to be overcome during the year of phase 2. We therefore propose to distribute 50 free copies of each book in such countries. The remaining copies would be offered for sale.

Even so, no country has an organisation comparable with the ASE (Association for Science Education, UK) that can handle distribution, and BP has offered help.

The Project will need to establish permanent channels of distribution for the future.

A typical unit

'Acid rain over Europe' is a survey of the acid rain problem in different countries, and a comparison of different perspectives. Students contact those in other countries to collect information on the nature of the acid rain problem, the measures being taken to counter it, and their perspectives on where the blame lies.

Students then evaluate the subjective information they have collected by comparing it with a collection of factual data for different countries on, for example, production of sulfur dioxide, prevailing winds and average pH of rainfall. They can thus get a view of differing perspectives and evaluate them based on hard fact.

Science across Europe units

Available September 1991

- Acid rain over Europe
- Using energy at home

Trial versions available November/December 1991
Publication September 1992

- Renewable energy
- Drinking water
- What did you eat . . . ?

Collaborators

The project has been initiated by the Association for Science Education (ASE) in collaboration with British Petroleum (BP). ASE has close links with science teaching associations in most European countries, and with the International Council of Associations for Science Education (ICASE).

NEW ICASE PUBLICATION

Industry - Education Liaison

ICASE YEARBOOK 1990

Based on a symposium held in Brussels
5-7 September 1990

The 1990 ICASE Yearbook, sponsored by CEFIC (Conseil European Des Federations De L'industrie Chimique), is a timely publication. The collection of papers presented at the Seminar on Industry-Education Liaison acknowledges the critical importance of partnerships between industry and education. The Seminar, held from the 5th to 7th September 1990, was organised to: (1) provide opportunities for the exchange of information and experiences in schemes for industry-education liaison; (2) develop models for industry-education liaison; (3) establish, through ICASE, a network for information exchange for future developments; (4) publish a resource book for teachers and administrators on industry-education liaison.

The Yearbook addresses a variety of topics, for example: An Overview of Demographic Trends in Industry; Chemical Industry Education Centre; Exciting Science and Engineering; Cologne Model: Chemistry-Technology-Everyday Life; Contact between School and Working Life in Sweden; Forms of Cooperation between the Chemical Industry and Secondary Schools in the Netherlands; and The Planning and Organisation of Industry Study Tours. A Summary of Seminar Discussions outlines some key principles and proposes a course of future action.

Copies, at a cost of US$7.50 or £4.50 plus 25% postage, can be ordered from:

Science and Technology Education in Africa

Focus on seven sub-saharan countries

Edited by Duro Ajeyalemi

This book has been compiled to bridge the knowledge gap about science and technology education in sub-Saharan Africa. It will be of interest to science and technology educators, student teachers, planners and policy makers in education and in science/technology, and all those in a position to contribute effectively to the improvement of science and technology education in Africa, including aid agencies.

The Editor has contributed an article Science and Technology Education in Perspective which examines the African situation in the light of worldwide trends. The following chapters, written by eminent African scholars, present a detailed analysis of past, present and future trends in science and technology education in each of the seven countries - Ghana, Lesotho, Nigeria, Swaziland, Uganda, Zambia and Zimbabwe. The final chapter Science and Technology Education in Africa: A Comparative Analysis and Future Prospects, concludes that much still needs to be done, and proposes suggestions for addressing the common problems unique to sub-Saharan Africa.

Marine Science Resources

from the Division of Marine Sciences
UNESCO, 7 place de Fontenoy
75700 Paris, France

A video-based learning module on the identification and biology of Reef corals and sponges of Indonesia has been produced. It consists of a 3.5 hour video with underwater filming of numerous species and computer simulations of reproduction, growth, etc. It is available in PAL (VHS and Betamax) and NTSC (VHS) formats, and is accompanied by a 65 page text (MARINF/75).

The Division wishes to ensure the widest possible distribution of these materials to the targeted teacher/student community.

Therefore, modules are provided, free of charge, to "primary" recipients (individuals, institutions, associations, etc) with the request that they in turn make copies of the material and make them available free of charge to interestd third parties.

Call to readers
Information is sought on any other marine science learning materials in existence or being finalised, using:
- computer based
- video based
- or similar advanced learning technology.

Some examples of this type of material are already listed in Annex 6 of the Unesco report Year 2000 challenges for marine science training and education worldwide.

Scientific and Technological Literacy: Education for Change

by Jane Bowyer

This is a special report generated in the context of the World Conference on Education for All, 5-9 March 1990 in Thailand. The author stresses that scientific and technological literacy must be given priority as an essential component of basic education by:
- examining the nature of science and technology as human activities
- analysing why basic education needs to be broadened to include science and technological literacy
- defining essential areas of scientific and technological knowledge and skills necessary for basic education.

The 39 page report is available free of charge from: ED/EDV/STE, Unesco, 7 place de Fontenoy, 75700 Paris, France.
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1991

September 14-16
Conference on Teaching About the Protection of the Environment
Location: Krakow, Poland
Contact: Alicia Wojtyna-Jodko, Chairperson, Organising Committee, Stowarzyszenie Nauczycieli Przyrodniczych i Technicznych (SNPPiT), Skrytka Pocztowa 62, 85791 Bydgoszcz 32, Poland
This general interdisciplinary conference of teachers will be the first annual meeting of natural science and technology teachers active in institutions of education at the elementary and secondary levels, together with people from academic institutions with a vested interest in scientific and technical education. During morning plenary lectures, researchers will present the directions of research in ecology, chemistry and physics relevant to the theme. In afternoon sessions, teachers will join small group discussions focusing on sharing examples and experiences. The working languages for discussion will be English and Polish. The first general assembly of SNPPiT (Association of Science and Technology Teachers) will discuss the future of this new association and elect officers. A meeting with a delegate of the Ministry will provide an opportunity for discussing the need for improving the level of scientific and technical education in Poland in light of the experience of other countries.

September 16-20
EURYSN Training Seminar
Location: Science and Nature Centre, Sivry, Rance, Belgium
Contact: John D McGrath, European Youth Science Network, c/o ECO, 11 Cope Street, Dublin 2, Ireland
Youth science workers, volunteers in EURYSN organisations, and others interested in youth science activities (under 25 years of age) are invited to the first major training event of its kind in Europe. The aim of the Training Seminar is to introduce new people and organisations to Youth Science activities and programs, "Science in Society" education programs, and different techniques in informal science education for young people.

1992

November 6-10
NABT Annual Convention
Location: Souffier Hotel, Nashville, Tennessee, USA
Contact: Patricia J McWethy, Executive Director, National Association of Biology Teachers, 11250 Roger Bacon Drive, #19, Reston, Virginia 22090, USA
The next annual convention of the National Association of Biology Teachers will focus on the theme Form and Function: How Should They Be Taught. Applications for program space are due on 15 March 1991.

November 21-23
NSTA Area Convention
Location: Vancouver, British Columbia, Canada
Contact: Director, Meetings and Conventions, 1742 Connecticut Ave, NW, Washington, DC 20009, USA
Canada is the venue for this Area Convention of the National Science Teachers Association.

January 3-6
ASE Annual Meeting
Location: University of Sheffield, Sheffield, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated in Education in Science, a journal of the Association for Science Education.

March 26-29
NSTA National Convention
Location: Boston, MA, USA
International delegates are invited to participate in the International Round Table - one of the many features of this large convention. Each country is provided one or more tables in a large room where delegates can display and present information on science education in their country. Visitors move from table to table, talking with the various representatives. If you require an invitation to participate, write to John E Penick, Professor and Coordinator, Science Education Center, The University of Iowa, Iowa City, Iowa 52242, USA.
March 29 - April 10
Seminar on Science Teacher Education
Location: Centre for Educational Studies, King's College London, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This British Council International Seminar will be directed by John Head and John May of King's College Centre for Educational Studies, University of London, and will focus on secondary level teacher education, although some aspects will be of interest to those involved in primary science teaching. Six areas will be addressed: What is the nature of science education for schools?; To what extent should teacher education reflect and shape societies' values and cultural traditions?; How can we aid their professional development so that science teachers have the skills they need in the classroom and laboratory?; What can the results of research tell us about new ways to approach children's learning and classroom practice?; How is the work of pupils, teachers and trainees to be evaluated?; How does the structure of national and regional administration affect the management of teacher education? There are vacancies for 30 international participants - practising teacher trainers, advisers, inspectors, organisers of professional development programs and policy maker.

April 26-May 1
International Conference on Technology Education - INCOTE 92
Location: Weimar, Germany
Contact: Dr D Blandow, INCOTE 92, Pädagogische Hochschule, Nordhäuserstraße 63, 0-5063 Erfurt, Germany
This symposium will be the first pan-European meeting on technology education to be held in Germany. The principal aim of the symposium, which is being organised in collaboration with a number of organisations including ICASE and INISTE, will be to discuss technological literacy and competence in technology education within a European dimension. The majority of participants will be from European countries, with a few key people from other regions of the world. The principal language of the symposium will be English.

May 11-15
Second International History Philosophy and Science Teaching Conference
Location: Queen's University, Kingston, Ontario, Canada
Contact: Prof Skip Hills, Faculty of Education, Queen's University, Kingston, Ontario, Canada K7L 3N6
This conference follows the very successful First International Conference on History, Philosophy and Science Teaching held at Florida State University in November 1989. All conference papers will be published in advance of the conference. Accounts of the application of history and philosophy of science in the science classroom are welcome, as are research papers on the issue.

May 11-22
Seminar on Developments in Primary Science Education
Location: Liverpool, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This British Council Seminar will examine major concerns and activities in primary science in the UK as well as their international context and implications. Major research and development projects in the area of science and technology relevant to the primary phase will be represented, including Learning in science, Research into children's ideas, Contexts of learning, Out of school learning, Curriculum development and evaluation, Pupil assessment, and Teacher education. There are vacancies for 35 participants, including science educators and curriculum developers concerned with the primary phase.

June 10-12
ICASE Research Seminar on Chemistry and Physics Education
Location: University of Dortmund, Germany
Contact: Prof Dr Hans-Jürgen Schmidt, University of Dortmund, Department of Chemistry, Otto-Hahn-Straße, 4600 Dortmund 50, Germany
This symposium on empirical research in chemistry and physics education will focus on the methodology of empirical research in this field. There will be approximately 12 presentations each followed by a discussion period. The language of the symposium will be English. Presenters will be asked to send their paper beforehand, ready for printing as Proceedings through ICASE. Proposals of about 3 pages should include title, background, method, results, discussion, implications for research and teaching, and references, and should be sent to the contact above no later than August 31, 1991. General papers will not be accepted. Although there will be no seminar fee, participants will need to cover their own expenses.

July 6-10
CONASTA 41
Location: Perth, Western Australia
Contact: Convenor, CONASTA 41, Science Teachers Association of WA, PO Box 991, West Perth, WA 6005 Australia
The Australian Science Teachers Association invites you to participate in the forty first annual conference of the Association.

August 2-10
Eighth ICASE Asian Symposium
Location: Colombo, Sri Lanka
Contact: Mr Asoka Weerasinge
Hon. Joint Secretary, SLASME, Institute of Computer Technology, PO Box 1490, Colombo, Sri Lanka
Science educators are invited to attend the eighth ICASE Asian Symposium and enjoy the natural beauty of the country and the hospitality of the Sri Lankans. The Symposium, organised jointly by ICASE and the Sri Lanka Association for Science and Mathematics Education
(SLASME), will feature outstanding speakers from many countries who will address the theme "Science Education for a Changing World". The Symposium aims to identify some of the changes affecting our daily lives and to discuss ways by which science education can respond to these changes. Subthemes include (1) technology, (2) appropriate technology, (3) environment, and (4) scientific literacy. Participants will be able to experience the world famous pageant "The Kandy Perahera" in Sri Lanka.

August 31 - September 3
SCICON Biennial Conference of NZSTA
Location: University of Waikato, Hamilton, New Zealand
Contact: Neal Utting, Education Advisory Service, 4 Hill Street, Hamilton, New Zealand
The theme of SCICON for 1992 will be Science - Technology ... A Partnership. Information and registration forms about the biennial national conference of the New Zealand Science Teachers Association can be obtained from the contact above.

December 17-21
Twelfth International Conference on Chemical Education
Location: Bangkok, Thailand
Contact: Dr Somjai Wichaidit, The Secretariat - 12th ICCE, c/o Research Centre, Faculty of Medicine, Ramathibodi Hospital, Rama 6 Road, Bangkok 10400, Thailand
The theme of the Twelfth International Conference on Chemical Education will be Chemistry in Transition and it is hoped that the participants will interpret this in many different ways. This biennial Conference, to be held for the first time in South East Asia, is organised by the Committee on Teaching of Chemistry of the International Union of Pure & Applied Chemistry, and The Chemical Society of Thailand in cooperation with UNESCO. It is attended by chemistry teachers at both high school and university levels who wish to improve their teaching and to learn from one another techniques and experiences. A second circular including instructions for submitting abstracts and registration will be mailed in March 1992 to those responding to the address above.

1993

January 3-8
International Conference on Science Education in Developing Countries
Location: The Amos De-Shalit Israeli Science Teaching Center, Israel
Contact: Conference Secretariat, ORTRA Ltd, 2 Kaufman St, PO Box 50432, 61500 Tel-Aviv, Israel (conference arrangements) or Dr Avi Hofstein, Department of Science Teaching, The Weizmann Institute of Science, Rehovot 76100, Israel (academic correspondence)
This international conference on the theme "Science Education in Developing Countries: From Theory to Practice" will review past experiences and achievements in science education and plan for the 21st century with a special focus on developing countries. The conference will feature plenary lectures, symposia, poster sessions, workshops, exhibitions, informal discussions, social events and local visits. Topics for symposia and plenary lectures will focus on current research on learning and teaching and its implications for (1) the learner, (2) the teacher, (3) the classroom, and (4) the curriculum.

June 27 - July 3
VII Pacific Science Inter-Congress
Location: Okinawa Convention Center, Okinawa, Japan
Contact: VII Pacific Science Inter-Congress, c/o Section of International Affairs, University of the Ryukyus, 1-Senbaru, Nishihara, Okinawa, 903-01, Japan
The Symposia will be organised around the theme The Pacific: Crossroads for Culture and Nature and subthemes (1) Cultural Interchange among Pacific Peoples; (2) Speciation, Dispersal and Conservation of Species in the Pacific; (3) Towards Appropriate Technologies and Policies for Development and for the Conservation of Natural Environments in the Pacific. Scientific sessions organised by the Scientific Committees of the Pacific Science Association focus on a range of science disciplines and issues, including Science Communication and Education.

APOLLO 11
A Teacher Resource Book

Commemorating the 20th anniversary of the Apollo 11 Moon Landing, this ICASE publication provides activities for primary and secondary science students. Send US$10 or £6 plus 25% postage to:

ICASE - supporting science teachers around the world
Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

ICASE Caribbean Regional Conference
Trinidad and Tobago
August 27-30, 1991

This report was compiled by Judith Reay, an ICASE Award Winner who attended the Conference as Co-Editor of the Conference Proceedings.

The ASETT-ICASE Conference 91 was held at the University of the West Indies, Trinidad and Tobago, from August 27 to 30, 1991. The theme of the Conference was 'Education in Science and Technology for Development: Perspectives for the 21st Century'.

Among the Conference participants were Dr Winston King from Barbados, the ICASE Past President, and Bob Lepischak from Canada, the current ICASE President. In his address, the President drew attention to Project 2000+, a major thrust of Unesco and ICASE on scientific and technological literacy - closely related to theme of this Conference in the West Indies.

It is expected that the Conference Proceedings will be available early in 1992. The South American/Caribbean Representative on the ICASE Executive Committee - Althea Maund (photo below) - is a member of the Association for Science Education of Trinidad and Tobago which organised the Conference.

This section provides news for the information of member associations, institutions, centres, foundations and companies. The Executive Committee encourages members to reproduce this section in journals and newsletters to communicate this information to as many as possible.

ICASE welcomes new members

St Kitts Science Association
The St Kitts Science Association, West Indies, joined ICASE as a member during the recent ASETT-ICASE Conference 91, which was held in Trinidad and Tobago during 27-30 August this year.

For further information, contact: Lincoln Carty, President of St Kitts Science Association, who is a Lecturer in Science Education in the Division of Teacher Education, College of Further Education, PO Box 268, St Kitts, West Indies.

American Chemical Society
ICASE welcomes the American Chemical Society - a large and active professional organisation in the USA - as a Member Association of ICASE. Sylvia A Ware, Director of the Society's Education Division, has written that all official channels in the Society have endorsed this membership move, and are looking forward to actively participating in ICASE in the coming years.

For further information, contact Sylvia A Ware, Director, Education Division, American Chemical Society, 1155 Sixteenth Street, N.W., Washington, D.C. 20036, USA.

The number of new members of ICASE during this year has been a most pleasing aspect of the organisation's growth. For further enquiries about membership, please contact the Executive Secretary - Dr Jack Holbrook (refer to address on page 40)

Who's Who in Science Education Around the World
1991 Edition

Published by ICASE with assistance from Unesco

This biographical volume is now available from:

Brenton Honeyman, Editor
Who's Who in Science Education
10 Hawken Street
Monash ACT 2904
Australia

This new ICASE publication contains brief profiles on prominent science educators, their work, their projects and their interests. The valuable reference book includes key women and men in many countries throughout the world who are contributing to science education at primary, secondary or tertiary levels. The information will help readers to contact colleagues in both developing and developed countries who may be working on projects of interest to them, who may be potential speakers at upcoming meetings or conventions, and who may be invited to work on collaborative projects. Copies are being distributed to ICASE member associations, institutions, centres, foundations and companies, and to international science education organisations including Unesco, and the ICSU Committee on Teaching of Science.

STOP PRESS

Negotiations are currently underway to hold a second ICASE Symposium on Education - Industry Liaison in 1992

This will follow the very successful symposium organised by ICASE in conjunction with the Chemical Industry in September 1990
Eighth ICASE Asian Symposium

University of Iowa
Iowa City, Iowa 52242
USA

All submissions will be acknowledged in the review.

Space Science Seminar and Workshop

by R Lepischak
President, ICASE

The 1991 Space Science Seminar and Workshop held at the Lyndon B Johnson Space Center, Houston, Texas during 8-13 July 1991 was yet another outstanding success.

This year's program was attended by 140 educators from Canada, 6 from the UK, and 15 from a space magnet school district at San Antonio, Texas. The program provided rich experiences for participants and valuable educational resources — print materials, videotapes, slides, posters, and computer diskettes.

The program has fostered international links, and has been instrumental in the setting up of task forces now at work enhancing education through space science.

Plans are underway to hold another Space Science Seminar and Workshop in July 1992 — hopefully involving more delegates from ICASE member associations worldwide.

Coming ICASE Events

Secondary School Biology in the USSR

by Vladislav I Sivoglasov
Moscow Pedagogical State University
Moscow, USSR

Soviet schools are preparing a new generation, ready for active participation in the process of restructuring and democratisation of Soviet society. We need well-developed and challenged persons who are well educated and aware of the necessity of self-education. Biology, now taught according to new curriculum and programs developed in 1986, emphasises learning the main biological concepts and leading scientific theories and ideas.

Concepts and leading ideas determine course content and structure and include: (1) organic world evolution; (2) interconnecting structure and function on wildlife; (3) interconnections of the biological systems with the environment; and (4) connection of theory and practice. The biology course is preceded by a course in natural history in primary and early secondary school.

3. Animals (VII grade - 24 hours; VIII grade - 68 hours)

4. Human health (IX grade - 68 hours)

5. General biology (X grade - 34 hours, XI grade - 51 hours)

The biology course at some Soviet schools isn’t divided into traditional parts such as botany, zoology, human anatomy, physiology and hygiene, or general biology. In these schools, we created an integrated biology curriculum where the contents have been simplified. And, much more attention is paid to interrelations between specialised biological disciplines.

Course content varies according to the grade. VI grade includes information on morphology, vital activity, reproduction and development of flowers, and interactions of plants and surroundings.

In the primary grades students study natural history, including seasons and weather, agriculture, plants and animals, and the general structure of the human body. Great attention is paid to personal and social hygiene.

Natural history in the secondary school (beginning with grade five, one hour a week) is devoted to the study of physical science, interrelations of living organisms and environment, variety of living organisms and conditions, and necessities for their vital activity.

The secondary biology course is divided into five parts:

1. Plants (VI grade - 68 hours; VII grade - 36 hours)
2. Bacteria, Mushrooms, Lichens (VII grade - 8 hours)

VII grade students study biodiversity and systematics of plants, bacteria, lichens and mushrooms and differences in their structure due to the evolutionary process.

In grades VII and VIII the 'Animals' unit gives information on the variety of animals from Protozoa to Mammals, their structure, functions, systematics, and relationships. Students of IX grade study 'Human Body and Health', which provides information on the peculiarities of the human body, its vitality, elementary first aid and also on sexual and hygiene problems.

The Unit 'General Biology', studied during X and XI grades, ends the course of biology at secondary school. This unit provides information on cell biology, genetics, evolutionary

theory, biotechnology, ecology, and environmental protection.

After IX grade students may continue their education in secondary professional schools (3 years) or secondary special technical schools (3 years). General biology at this level is studied as an obligatory educational subject (73 and 70 hours accordingly). Students also can deepen and extend their knowledge in special groups at various extra-school Pupils' Houses, Institutes, and Universities.

In addition, the USSR State Committee on Peoples' Education worked out sixteen on biological and ecological elective courses. These elective courses start from the VII grade with students of VII-IX grades able to choose courses for two hours a week and grade X and XI four hours per week.

In the USSR programs of advanced study on different subjects are being developed. In 1986 the new curriculum on biology was designed to provide an extended theoretical and practical study of the subject. The program is introduced from the VIII grade (VIII-IX grades - 4 hours a week, X-XI grades - 3 and 3/4 hours plus 2 extra hours on studying additional units, chosen by teacher).

The main goals of studying biology at school are to:

1. ensure the mastering of main ideas of biology as a field of science (structure, vitality of the organic world, structure and function of ecological systems, and their changes due to human impact);
2. form a scientific world outlook and ensure the awareness of a humankind in the world, their place and role in the biosphere;
3. understand the practical significance of biology as the basis of agriculture, food industry, biotechnology, and environmental protection;
4. use subject knowledge for professional and career orientation;
5. form ecologically-educated people with responsibility towards nature and readiness for its protection;
6. form skills and habits necessary for people to extend their knowledge, to develop logical thinking during education and future practice.

Current liberalisation of education in the USSR allows many schools and regions to work out their own school, city or national curriculums and programs on biology. Most of

They are based on the state obligatory program and/or take into consideration main guidelines of biological education in the country. We are optimistic that these new programs of study will help ensure that our students are as biologically and scientifically literate as they must be to succeed in the future.

About the Author
Vladislav I Sivozlasov is Vice President of the Russian Association of Biology Teachers, Moscow Pedagogical State University, Kibaichicha 6, Building 4, Moscow 129278 USSR.

ICASE AWARD SCHEME
for outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.

ICASE Distinguished Service Award
This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations

ICASE Regional Service Award
This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

ICASE Association Award
This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Contact Dr Jack Holbrook, Executive Secretary ICASE
Department of Curriculum Studies, University of Hong Kong, Hong Kong
Science teachers depend upon diagrams to assist them in the explanation of many important scientific ideas and relationships (Wheeler and Hill, 1990). Diagrams offer the promise of making so many of the abstract ideas in science more concrete by providing an effective organiser or mental model (Mayer, 1989 and Winn, 1981, 1988). While the advantages of using scientific diagrams seems obvious, the work on visual communication in science by Barlex and Carre (1985) clearly indicates that diagrams are far more complex than we normally assume and can be a source of difficulty for learners.

Scientific diagrams are embedded in a particular conceptual framework; they are not "epistemologically flat" (Kilbourn, 1982). For example, chemistry diagrams relating to the kinetic theory of matter require an understanding of that theory for their interpretation. These conceptual underpinnings, together with an understanding of the nature and purpose of diagrams, provide an important part of the context for the interpretation for diagrams depicting the arrangement of particles in solids, liquids and gases, an almost universal topic in secondary school science programs. However, learners frequently view such diagrams as a primary source of knowledge about the scientific ideas they represent. In these cases, diagrams can lead the learner to generate minor misunderstandings or serious misconceptions. For example, diagrams in chemistry relating to the arrangement of particles associated with a phase change may misdirect naive students and lead them to construct erroneous ideas about relative densities (Wheeler and Hill, 1990). Teachers who approach science instruction from a constructivist perspective are more likely to appreciate the educational implications of such generative activity on the part of the learner (Wheatley, 1991).

Diagram 1 presents a universally common textbook illustration designed to 'explain' phase changes in terms of increased molecular motion. The diagrams are effective in conveying this idea but at the same time they over-represent the decrease in density when depicting the liquid to gas change. The inability of many students to recognise the inherent limitations of diagrams may affect students' understanding of science relationships in everyday experiences. For example, the acceptance of the above molecular model for a liquid at face value would imply that liquids are far more compressible than is the case. On the other hand, under-representing the density decrease in changing from a liquid to a gas may tend to downplay the considerable compressibility of gases. Either way, diagrams mediate in the development of students' understanding of ideas and concepts in science. This mediation process may well vary culturally according to the importance and reliance placed upon textbook learning in different countries.

Diagram 2: A Liquid Solution

Similarly, standard textbook diagrams on solutions and the dissolving process (Diagram 2) may lead to a variety of student misunderstandings (for example, the actual number of particles involved, relative size, shape and distribution of solute and solvent particles).

As a type of visual communication in science the use of diagrams is both powerful and inherently complex. Diagrams are regularly used to both supplement and complement descriptive text in order to communicate in science more effectively. Effective communication assumes, however, that students interpret the diagrams in the manner in which it was intended by the illustrator.

Most scientific diagrams are iconic representations of mental constructions. They have both a scientific component and a pictorial one. The latter involves an understanding of the manner in which relationships can be illustrated and the associated assumptions, conventions and limitations. These aspects are seldom discussed in science classes (Lowe, 1986). If this is true, then it could be predicted that students would
not be familiar with the conventions and exaggerations which follow. One purpose of this study was to test this prediction.

**Conventions**

There are a number of underlying conventions associated with science diagrams relating to the particulate nature of matter. These include the notions that:

1. Any illustration is not to be taken at face value but represents one possible arrangement at a particular moment in time.
2. What is shown in two dimensions should be considered in three dimensions.
3. Particles are represented by circles and the relationship between them can be shown by lines.
4. Particle size remains constant irrespective of state.
5. Equal volumes are represented by equal areas.
6. Unless otherwise stated all conditions are equal.

**Exaggerations**

Many texts contain diagrams which exaggerate certain aspects in order to highlight particular relationships or features (Hill, 1988). The present study dealt with the following exaggerations:

1. The decrease in density is exaggerated when a solid melts.
2. The expansion of a solid when heated is exaggerated.
3. The spacing between liquid particles is exaggerated.
4. The relative number of solute to solvent particles in a solution is exaggerated.
5. The relative number of gas to liquid particles is exaggerated when a liquid and its vapour are in equilibrium.

In addition, there are other, more subtle aspects found in scientific diagrams which may influence the ideas which learners generate. These include regularly illustrating the arrangements of particles in solids using large circles, illustrating the behaviour of liquids using smaller circles and representing gas molecules as dots. Strongly bonded particles are usually shown close together. The particles in liquids are seldom shown in contact. Covalent bonds and the outlines of crystal lattice in ionic solids are both represented in the same way by straight lines.

**Purpose of the Study**

This study investigated student interpretations of chemistry diagrams across four distinct sample groups (Australia, Canada, Malaysia, Nigeria). It was designed to determine whether secondary chemistry students from the four culture groups differed in their acceptance of diagrams at face value or whether they appreciated their intended purpose and inherent limitations.

The study focused on students' understanding of commonly used conventions and limitations of chemistry diagrams dealing with the particulate nature of matter and the Kinetic Molecular Model. The content area was chosen because it is known to be a difficult area of chemistry for many students. This difficulty is related to the abstract nature of the concepts associated with the topics and the difficulty in providing suitable material to illustrate these concepts - the very reasons why diagrams usually abound in chapters on these topics in school chemistry texts.

**Study Sample**

A total of 766 senior secondary chemistry students in four countries (Australia, N=59; Canada, N=184; Malaysia, N=363; and Nigeria, N=160) constituted the total sample for the study. While the total sample (excluding the Australian group) contained more males (58%) than females (42%), it was deemed representative of the general student population at the secondary level. Classes involved were heterogeneous in ability and had received instruction in the general topics dealt with in the diagrams. Classroom teachers associated with the study all felt that the science diagrams involved concepts familiar to the students.

**Test Instrument**

The six two-tier questions on the test instrument asked students to:

1. Select diagrams which best represent given situations (Q1, 2, 3);
2. Draw a diagram to represent a particular instance (Q6);
3. Select diagrams to best represent specific relationships (Q4, 5).

In addition, students were also asked to give a specific reason for their response to each item. The development of the instrument and details of its reliability and validity have been reported elsewhere (Hill, 1988).

</tbody>
</table>

Examples of the three different types of questions are reproduced below.

**Question 3**

Exaggeration 5 - the relative number of gas to liquid particles is exaggerated.

Diagram A (i) (ii) (iii)
A certain petroleum wax boils at 230°C. Diagram A shows an arrangement of the wax molecules at 228°C. Which diagram could best represent the most probable arrangement, at a particular instant in time, in a sample of the wax vapour at 230°C at the same pressure? Tick one alternative (Refer to diagram on previous page).

Question 4
Convection 4 - Particle size remains constant irrespective of state.

Imagine that the molecules of a wax in the solid, liquid and gas states can be represented as spheres. Which set of diagrams would best represent the molecules of this wax under these conditions? Tick one alternative.

Question 6
Exaggeration 4 - The relative number of solute to solvent particles in a solution is exaggerated.

The series of circles below represent part of a dilute (2M) aqueous solution of ammonia.

Show the relative distribution of water and ammonia molecules in this solution by shading in circles to represent ammonia and leaving those which represent water unshaded.

Sample reasons for questions 3, 4 and 6 are given below together with a brief general comment.

Question 3 Sample Reason
"... at 230°C (20°C above the boiling point) the molecules (in the vapour) ... have just begun to separate and move apart from one another. In diagram (i) the molecules are too close and in (ii) and (iv) they are too far apart." (Here the student seems to have a picture of a typical 'liquid' and a 'gas' in mind but thinks of the transition as a 'gradual process' requiring a temperature higher than the boiling point to produce the dispersion of molecules characteristic of a gas.)

Question 4 Sample Reason
"Molecules in solids are arranged more tightly ... they are heavier and no spaces are found between them. However, in a liquid the molecules are lighter and capable of moving apart. Gas molecules are smallest ... and lightest and therefore easily released to the atmosphere." (Most diagrams which illustrate the arrangement of particles in solids show relatively few atoms, ions or molecules. This means the particles appear larger than in corresponding diagrams for liquids. For the nature of gases most illustrators use a large number of relatively small dots. From this data the student has constructed the above ideas.)

Question 6 Sample Reason
"The distribution in a 2M solution would be equal." (The student shaded in every circle. This item proved to be difficult. Most students failed to compute the solute to solvent ratio from the information provided and shaded in half or more of the circles.)

Discussion
The overall pattern of responses on each of the six items is fairly consistent. This may reflect the similarity in content for this topic, including the diagrams found in the textbooks which are used. It appears that students in all four study samples do not understand the exaggerations or appreciate the conventions associated with diagrams which appear in chemistry textbooks. Chi square analysis of the six items response patterns revealed that small, but statistically significant differences between cultures (p<.001) existed for all questions. It seems likely that students respond to diagrams in much the same way irrespective of cultural setting, and that such differences are due to the way the topic, the kinetic theory of matter, is treated in the four countries. This is consistent with the findings of other cross-cultural studies within the constructivist framework (Driver, 1989).

Of the five test items concerned with 'exaggerations' the majority of students responded as if they accepted the diagrams at face value. The high percentage of responses consistent with textbooks across all four study samples would suggest that students operate at a surface level and consider 'exaggerated forms' as accurately portraying actual situations. That is, they fail to process at a deeper level which distinguishes between pictorial and scientific dimensions of a diagram.

While convention 4 (Particle size remains constant irrespective of state) is taught in all four countries studied, a significant percentage of students (13% in Malaysia, 35% in

</tbody>
</table>

Note: The entry for the last alternative indicates the number of non responses.

Canada, 65% in Nigeria and 65% in Australia) hold contrary views. Explanations offered by these students reveal considerable confusion and misunderstandings. Students appeared to confuse particle size with the volume the molecule effectively occupies with increased kinetic energy. Those who offered an explanation for selecting alternative (1) frequently stated that molecules in solids were large, molecules in liquids somewhat smaller and gas molecules were very small. It may well be that such ‘misunderstandings’ were gained from the way molecules are represented in textbook diagrams. On the other hand some students interpreted the question in terms of what they had learned about paraffins and the effect of molecular weight on melting point and boiling point.

Question 6, which required students to actually represent a solution, was less frequently answered and proved much more difficult than earlier questions which simply asked for a choice between alternative diagrams. Some students commented on the difficulty level of this question - they were not used to creating diagrams to illustrate particular situations.

It is common for publishers in the United Kingdom to have branches in former British colonies and for them to distribute the same science materials or to develop local versions. This is one of the reasons why programs such as Nuffield Science have often provided a common reference point for teachers and students in the countries involved in this study. The curriculum content of science programs tend to be very similar and it is likely that students would have been exposed to the same kinds of diagrams in relation to the particular nature of matter. Students would thus know that when solids, such as lead, melt, the immediate volume change is several percent but when liquids, such as water, boil at atmospheric pressure, the immediate volume increases in the order of 1000-fold and that for dilute aqueous solution the molarity of water is approximately 55 mol l-1.

---

An Invitation to Boston to participate in the National Convention of NSTA

March 26-29, 1992

Each year, the International Committee of the National Science Teachers Association, USA hosts an "International Round Table".

At this 90 minute session, presenters from different parts of the world discuss their nation's educational programs. Each presenter has a table for materials, and participants select those countries they wish to learn about.

If you would like an official invitation to participate as a representative of your country, write to:

John E Penick  
Science Education Center  
Room 789 VAN  
University of Iowa  
Iowa City IA 52242  
USA

Unfortunately, you will have to arrange your own funding; but a letter of invitation and your name in the program may help you in that quest.
Conclusion
Given that diagrams are an integral part of many science lessons, the results of the study suggest that teachers should strongly discourage the blind acceptance of chemistry diagrams by their students. Teachers should be aware of the epistemological features of scientific diagrams in order to convey to students the richness inherent in such illustrations. Students should view all diagrams critically and be readily able to distinguish between the diagram as a representative 'pictorial model' and the scientific component or idea portrayed. As a first step towards a greater awareness and appreciation of the nature and role of scientific diagrams, students should be given opportunities to actively engage in drawing diagrams. The active construction of diagrams by the students themselves has the potential of becoming a powerful learning tool in science by developing the intentions of the illustrator and the inherent limitations associated with scientific diagrams (Lowe, 1989). Engaging students in constructing and then discussing their various representations of the same concept or situation would serve to highlight the problems associated with a single representation and encourage them to look beyond surface features.

INCOTE 92
International Conference on Technology Education
Weimar, Germany

This symposium will be the first pan-European meeting on technology education to be held in Germany. The principal aim of the symposium, which is being organised in collaboration with a number of organisations including ICASE and INISTE, will be to discuss technological literacy and competence in technology education within a European dimension. The majority of participants will be from European countries, with a few key people from other regions of the world. The principal language of the symposium will be English.

Nordhäuserstraße 63, 0-5063 Erfurt, Germany
The Future Direction of Sustainable Development in the Curriculum

Summary Report of the World '90 Preconference, Canada

by Dennis Chisman, Jack Holbrook & Cele de Var

Introduction

This report is a document for action! It is based on papers and discussions presented at a workshop in Winnipeg, Manitoba to examine the future directions of sustainable development in the curriculum. It was held immediately prior to the major international conference World '90 - World Environment, Energy and Economic Conference, 17-20 October 1990, also in Winnipeg.

The small meeting of 40-50 specifically invited participants from across Canada and from overseas was held at the St Benedict's Education Centre, Winnipeg, from 14-17 October 1990. It was organised by the Science Teachers' Association of Manitoba (STAM), the Canadian Association for Science Education (CASE) and the Manitoba Education and Training Department of the Government of Manitoba, with support from UNESCO and the International Council of Associations for Science Education (ICASE).

The full report with plenary papers, the opening address by Mr Len Derka, Provincial Minister for Education in Manitoba, discussion group reports and a list of participants, is available as a supplement to this Summary Report. The full report also contains some of the curriculum models presented at the workshop.

The Background

The background to the meeting can be traced to a general appreciation, especially in Canada, that the future of the human species depends on a recognition that natural resources are finite and on a recognition that the continuation of the human race will depend on the willingness and ability of humans to abstain from destroying the natural systems that regenerate the world as we know it.

Appreciation for a livable global environment being dependent on sustainable development of the entire human family, is described in more detail in the report of the World Commission on Environment and Development, 1987 Our Common Future - known as the Brundtland Report, after the Chairman, Gro. Harlem Brundtland, the then Prime Minister of Norway. Sustainable Development, in that report, is defined as:

'Development that meets the needs of the present without compromising the ability of future generations to meet their own needs'.

The overall objective of the meeting was the interpretation of this understanding of sustainable development in an educational context, leading to a model of how sustainable development concepts can be integrated into the curriculum.

The participants in the meeting endeavoured, therefore, to identify sustainable development education and illustrate how it might be incorporated into the curriculum at various levels, and to identify teaching strategies, teaching methods and resources which would be required to implement such strategies.

The Need for Change

The need for change, from an educational point of view, is based on the overall desire to develop an educational literate society in which sustainable development is understood and appreciated within the context of environmental, economic and energy strategies thus promoting the sharing of a better quality of life, now and for future generations. This need is in harmony with the declared aims of UNESCO for scientific and technological literacy for all worldwide, alongside universal literacy and numeracy.

Environmental concerns have risen, peaked, and declined in the past, with little fundamental change in human behaviour. Some environmentalists maintain that clean-up campaigns to address local pollution problems are merely cosmetic approaches to a disease which has deeper causes. If we take the scientific findings concerning global environmental changes seriously, then they indicate the need for a much higher level of public awareness and greater commitment to personal and community action. As major agencies of education and socialisation, schools can plan an important role in developing citizens who are environmentally informed and aware. But before programs can be designed or implemented effectively, we need to develop a clear understanding of the elements of environmental literacy.

In many countries, curricula changes are moving towards the integration of science and technology education with societal issues and values - the Science Technology and Society (STS) movement. The emphasis in many science courses is thus moving towards an appreciation of the quality of life and the relevance of science in society and in meeting the issues facing a society. But this trend, which should permeate formal and non-formal education systems, requires much greater support and understanding from Governments, parents, and even teachers and students for it to succeed. The need is urgent and the inclusion of sustainable development education, through environmental education, energy education, health education and an understanding of economic development, is essential.

This change requires more than a change of syllabus content and knowledge and more than a change in understanding and process skills. It requires strategies to bring about a major change of attitudes and societal expectations of the role of schools in values education.

The need for change is urgent. The problems will not go away; and education, in its widest sense, is the only hope we
have to ensure that our fragile environment is cared for.

**The Obstacles to Change**

Change is expensive. Change is disruptive of habits and values held by parents and students. Change affects the morale of teachers if handled badly. The attitude of many individuals to the need for change, which is unfortunately reflected by decision-makers, administrators and policy-makers in education, including politicians at the highest levels of Government may be summarised by one or more of the following:

- Since we do not know all there is to know, let us wait to act in case we may not have to act at all;
- Because there is no historical precedent for what is happening we refuse to believe it is happening (this is the 'there is nothing new under the sun' syndrome);
- It will be easier to adapt than try to change (this is the 'we will evolve out of the problem' syndrome);
- Lack of widespread awareness among the general public and among political leaders;
- Because the problems are so severe, their solutions will be difficult - very difficult (the 'we may fail, so why try?' syndrome).

**The Power of Education to Bring About Change**

Education is the central theme in our lives. It prepares the young generation for the life that lies ahead, and it informs adults of the world about them.

The transformation in what we teach, how we teach it and the manner in which it is assessed will be crucial to the major knowledge and attitude changes which are essential if we are to introduce aspects of sustainable development into the curriculum and prepare students to give greater consideration to values and ethics. This transformation and progression will involve consultations and agreements and needs the active involvement of those concerned at every level, right up to the senior levels in government.

The power of education can only be harnessed by involving all the key figures and organisations in the developmental and decision-making process, perhaps through the establishment of educational task forces, thus including teachers, curriculum developers and advisers, outside agencies that can provide the link between school and the community, as well as Ministry of Education officials, and employers.

**Educational Strategies for Change**

(1) The overall strategy

This is to design courses so as to prepare for a 'sustainable development' literate society. To this end three important criteria for curriculum change are:

- relevance
- practicality
- values driven

**Relevance** implies the use of community resources and the incorporation of local issues and practices into the curriculum.

**Practicality** means activity-based learning (doing and action), with the inclusion of gaining balanced points of view and training in the recognition of bias.

**Values** involve cultural issues, personal interdependence and informed judgements both from a holistic view of the world and from a local society perspective.

(2) Major issues.

These include, for example:

- population control and support
- poverty eradication and avoidance
- intercultural tolerance
- self-sufficiency and quality of life
- global economics: needs not greed
- transfer of appropriate technology
- environmental literacy

(3) Curriculum models for sustainable development

These should be based on the interrelation of knowledge, skills and values.

**Values**, the pinnacle of the triangle, places emphasis on a respect for life, the quality of personal life, aesthetics in nature, ethical issues and cultural and societal priorities. The development of such values should be seen as a priority goal for education.

**Knowledge** embraces the factual part of the curriculum and covers, on a need to know basis, the scientific, cultural, economic, social and environmental data and structure plus

**Contact your local association or the ICASE Executive Secretary**
the interconnection of systems, methods of enhancing scientific and technological processes and the management of risk.

Skills includes the variety of scientific methods and particularly decision-making, problem solving and communication skills.

The development and success of any curriculum model depends, for both formal and non-formal types of courses, on four important components, namely curriculum development; assessment strategies; resources available; and the implementation strategy.

The curriculum to be developed needs to emphasise values education, incorporating on a need to know basis, knowledge, conceptual learning and skills.

The assessment needs to measure the values and skills alongside factual knowledge and put emphasis on the societal learning.

Resources are needed to support the teaching of such a new curriculum. For example, case studies would require visual aids and experimental support materials.

The implementation is a crucial factor and in particular an emphasis is required on the need for pre- and in-service teacher support which highlight community needs and the local situation.

Areas of study can be illustrated in another model emphasising interconnections and showing that sustainable development is not confined to any one subject area.

---

**THE BRITISH COUNCIL**

**Developments in Primary Science Education**

**11-22 May 1992**

**Liverpool, UK**

This course will examine in detail the major concerns and activities in primary science in the UK as well as their international context and implications. The program will consider:

- Learning in science
- Research into children's ideas
- Contexts of learning
- Out of school learning

Germany
• An understanding that we need to survive and improve our quality of life, but at the same time, be caring of other species that make up the fauna and flora of our planet;
• An understanding of global perspectives.

Important components of an environmental education program that incorporated sustainable development goals are seen as the ability to:
• Think ahead, to predict (forecast) and to plan;
• Consider value issues from different perspectives and make informed decisions;
• Distinguish between facts, conjecture (hypotheses), proven theories (scientific laws) and values;
• Go beyond awareness and knowledge, to suggestions for action based on balanced judgement;
• Understand a set of basic concepts and facts, for example ecosystems, and acquire new concepts;
• Work cooperatively with others and be sensitive to the views of others;
• Develop and use skills in the processes of knowing, enquiring, acting, judging, opening, imagining, connecting and making value judgements;
• Distinguish between the maps and representations of nature we receive from the media (TV and newspapers), and recognise that the real world may be quite different when personally experienced. (Seeing pictures of beautiful wildlife on TV may not be the same as our reaction when standing a few metres away from a bulging bull elk!)

Topics in a program of environmental education would need to address population and food supply; environmental deprivation through greenhouse effect, ozone layer, deforestation, soil erosion, acid rain, air, water and land pollution, species depletion, the finiteness of resources (energy conservation), maintenance of health (work and leisure), measures to balance technological advancement with environmental conservation, and the interpretations of thinking globally.

Sustainability as a concept in this context was examined in the workshop. One view was that sustainability should be regarded as a tripod of ideas:
(1) The human species is part of nature. Its existence depends on its ability to draw sustenance from a FINITE natural world; its continuance depends on its ability to abstain from destroying the natural systems that regenerate the world.
(2) Economic activity must account for the environmental costs of production. The 'wealth' we create today is stolen from our descendants.
(3) The maintenance of a livable global environment depends on the sustainable development of the entire human family.

The Proposed Changes

The proposed changes would imply changes in teacher education, changes to the educational system and its organisation, and changes in course content.

Teacher education needs to include techniques whereby teachers are able to function without textbooks and be able to design teaching materials that can emphasise the affective domain, plus the decision-making and problem solving skills. It would also have to prepare teachers more adequately to teach sensitive issues, including bias and conflict.

The changes to the Educational System and its Organisation need to include greater flexibility with greater attention to education and less to bureaucratic expediency. Flexibility is needed in areas such as timetabling - to allow for fieldwork and field trips; additional preparation time for teachers for activity-oriented work and the changing society; support materials and support technology to keep pace with the learning expectations of the young, inculcated by society; and acceptance of teachers' ability and need to deal with controversy and bias based on value judgements.

The content would be less factual and more attention given to developing skills, particularly in the areas of communication, problem recognition and solving, and informed, balanced decision-making.

Such changes imply changes in assessment strategies so that values education is given more prominence and skills such as problem solving and decision-making emphasised.

The Role of Educators

The implementation of the proposals to establish curriculum models incorporating sustainable development in courses such as environmental education will require the active involvement of educators.

Educators will be required to design and organise programs and the accompanying pre- and in-service courses for teachers, to select appropriate topics for the new syllabuses on which to build the skills and values related to sustainable developmental thinking, to review resources from the community and elsewhere for such teaching, to involve the local communities in understanding and supporting such change and generally to develop implementational strategies.

The role of the teacher will inevitably have to change. They will become more involved in facilitating changes of attitudes and guiding students to gain values rather than merely teaching factual knowledge. Much is already happening in some countries - at the grassroots level. An appreciation of sustainability is already evident as shown for example by the seminar examples in the World '90 conference given by teachers on recycling in elementary schools. Teachers need to coordinate with other teachers across nations and across continents. To aid this, science teacher associations have formed links through an international umbrella - the International Council of Associations for Science Education (ICASE).

Systems in countries around the world do differ. Changes need to be considered in the national or logical context. Teachers will have to be trained to manage such change; and ensure that improvements will follow from change, and that equity prevails. They will have to be involved at the political, social and economic levels. The benefits can be for everyone, throughout the world. But teachers will need help, encouragement and recognition to undertake these new roles. Time is pressing. Sustainable development in the curriculum is an urgent need.
An Introductory Look at Curricula and Examinations Worldwide

Part 2

by Dr Jack B Holbrook
Executive Secretary, ICASE

This article is an extract from a report by the same title, prepared by ICASE in fulfillment of a contract with the Science and Technology Section, Division of Educational Development, Unesco. Part 1, published in the September 91 issue Vol 2 No 3, dealt with worldwide trends. Part 2 features comments on specific countries in Africa, Asia, Australasia, Caribbean, Europe and North America.

AFRICA

1. Botswana

The Integrated Science curriculum for grade 8 and 9 is a junior secondary examination syllabus first introduced in 1987. The syllabus is based on academic science although societal topics are included. The examination seems to be knowledge and science skills orientated and thus aimed at providing an assessment of the base from which further science can continue.

2. Ghana

The Science syllabuses for grade 7-8 and 10-12 were produced by the Ministry of Education in 1990. These teaching syllabuses seem vague but the grade 7 and 8 syllabus includes some societal points. The grade 10-12 syllabus is academic in nature.

3. Lesotho

The course for grade 9-12 is externally assessed. There is no assessment by teachers, but this is not seen as being particularly necessary. More worrying is that the lack of assessment of practical work is accepted as appropriate with the reason given that it is difficult to maintain security. No mention is made concerning the lack of interest in assessment of experimental work by the teacher, but one suspects the competitive system brings concerns on reliability of such a system.

4. Nigeria

The grade 7-9 syllabus, introduced in 1985, refers to Integrated Science, whereas the grade 10-12 syllabuses cover Biology, Astronomy, Physics and Chemistry as separate courses. All are teaching syllabuses with aims and objectives given. The approach is basically through science concepts, although the integrated science course uses thematic headings and brings in some societal factors following the conceptual introduction.

5. Sierra Leone

The 1990 grade 7-9 draft teaching syllabus was produced by the Institute of Education and called Integrated Science. It is based on themes but, as a whole, the course is driven by fundamental science concepts.

6. Swaziland

The curriculum at grade 11-12 level is externally assessed. This is seen as being both valid and reliable although there is some concern that the examination questions should have more local relevance. Practical skills are not assessed at this level, but its appropriateness is not questioned. The impression given is of an academic course, organised around the dominating external examinations.

7. Zambia

Both an Environmental Science and an Agricultural Science syllabus for the junior secondary level, produced in 1983, were mainly traditional science introduced by topics. Project work in Agricultural Science was specifically encouraged and was awarded 20% of marks. The use of project work as a means of assessment is now discontinued because of poor reliability.

8. Zimbabwe

The 1989 grade 7-9 science syllabus and the 1991 0-level syllabus in science were developed using themes but again relied upon fundamental science concepts for sequencing. Little help was given to the teacher in these examination syllabuses.

ASIA

1. Bahrain

Syllabuses at the junior secondary level are separated into Chemistry, Physics and Biology. The latest, introduced in 1987, are organised by concepts and are thus typically academic. Little support is provided for the teacher.

2. Bangladesh

The curriculum for grade 9-10 is factual and academic. There is no teacher assessment. The assessment is seen as not valid nor reliable as it encourages little more that rote learning. Practical work is assessed, but this is not seen as being particularly valid.

3. Bhutan

Syllabuses were available for grade VII to X. These 1989 syllabuses which were based solely on the prescribed textbooks, were concept oriented and very much seen as providing a science base for later studies. Little help was given to the teacher, and the examination is very much knowledge based.
4. India

A syllabus book, covering all courses at grade IX and X levels, was produced by NCERT in 1988. Although organised through science concepts, the unit headings are thematic and include areas such as ‘world of work’. As well as the science course, students undertake a course called work experience in which many societal aspects are met; unfortunately little link was apparent between the two syllabuses. A trend from the questionnaire was that examination questions were becoming more objective and geared to academic science. This seems to differ from the trend in other countries where more open ended questions are being developed. Practical work is assessed through project work and by a teacher based examination, but there seems to be little trend towards continuous assessment.

5. Jordan

Very traditional syllabuses in Physics, Chemistry and Biology, developed by the Ministry of Education for levels Secondary 1 and 2, are geared to the textbook. The English translations of the syllabuses were textbook extracts which offered little help to the teacher. Examination papers were available in Arabic.

6. Korea

An English translation of the science syllabus for grade 7-9 and separate science syllabuses for grade 10-12 in Physics, Chemistry, Biology and Earth Science, was available. These teaching syllabuses, produced by the Korean Educational Development Institute in 1984, are based on a science concept approach and depict academic science courses.

7. Pakistan

It appears that the curriculum in operation in Pakistan has an academic approach, factually and concept oriented with little societal emphasis. No assessment by the teacher takes place at the grade 9-10 secondary levels, but there is assessment of practical skills (25%) which is seen as valid to some extent.

8. Philippines

The curriculum at grade 10-11 level in the Philippines is part of tertiary level education. This frees the course from external examination pressures and teachers are able to assess students on a variety of scientific skills such as experimental work, project work and attitudes. Nevertheless, the validity and reliability of this is questioned as the system is informal and little link is undertaken between institutions.

AUSTRALASIA

1. Fiji

Senior secondary examination syllabuses in the separate sciences are academic in approach and concept driven. Examination papers stress knowledge.

2. New Zealand

A very different approach to syllabus development applies to grade 7-11 science. The 1989 science syllabus produced by the Department of Education, provides extensive guidelines for the teacher including a grid of skills against context, but not a prescribed content. Teachers are encouraged to produce their own schemes of work based on local interests and conditions. The syllabus stresses ‘science for all’ and that science should be relevant to the society in which students live. The separate science syllabuses for grade 12 and 13 produced in 1990, contrasted greatly with the grade 7-11 syllabus and followed a traditional conceptual approach; units are based on concepts. As these were examination syllabuses, it was seen that there was a need to determine how far students had gained a basis in science concepts before continuing further in the subject.

CARIBBEAN

1. Barbados

Examination syllabuses at the grade 10-11 levels in Integrated Science (single and double awards), Chemistry, Physics, Biology and Agricultural Science (double award) were produced between 1985 and 1989. They are based on themes or topics. Examination papers stress knowledge; assessment of practical work is carried out on an internal basis. The syllabuses stress fundamental science concepts.

2. Trinidad

The syllabus governing the teaching at grade 10-11 level is the examination syllabus, and is seen as too factual and too long. Teacher assessment contributes 20-30% and includes experimental work, course content and attitudes. This is seen as both valid and reliable. There is some concern as to whether moving to a 100% teacher assessment would be more appropriate as two systems, internal and external, seem a duplication of effort.

EUROPE

1. Iceland

The grade 8-10 science teaching syllabus, produced by the Ministry of Education in 1989, has a considerable emphasis on values. Teachers can select topics and can provide additional experiences for students. Environmental education is incorporated in a whole school policy. The syllabuses for grade 11-14 are in the separate sciences. These are organised by concepts but do provide for students to complete different levels of science within each discipline. These courses tend to be traditional and stress science for continuation. As such, there is little emphasis on societal aspects of science.

2. Ireland

The junior secondary teaching syllabus for age 12-15, produced by the Department of Education in 1989, was organised about topics and conceptual units, and allowed for core and extension material. Local studies contributed 40% of the examination, and a variety of assessment methods were advocated.

3. Malta

Chemistry and Physics teaching syllabuses for Form 4 and 5 are academic and based on textbooks. An integrated science syllabus for grade 9 has topic headings for each unit; it appears that the course is very prescriptive and concept driven.

4. Spain

At the grade 11-13 level, assessment by the teacher accounts for 30-40% of the marks. This is not seen as valid
Science and Technology Education Activities in Asia and the Pacific

by Lucille Gregorio, Unesco PROAP, Thailand

In accordance with UNESCO's Program in Science and Technology Education, and the 1991 Schedule of Activities of the Asia and Pacific Program of Educational Innovation for Development (APEID), UNESCO-PROAP organised two regional workshops, one in Shanghai, China and the other in Penang, Malaysia.

Regional Workshop on Nurturing and Identifying Talents in Science, Technology and Mathematics

The meeting, held from 16-27 September 1991 at Shanghai Normal University, was organised by the Shanghai Institute of Educational Research.

The objectives of the workshop, with reference to science, technology and mathematics were:

1. to promote exchange of experiences/ideas and collectively develop guidelines/strategies for nurturing and identifying talents;
2. to cooperatively develop guidelines and instruments in preparing curricular programs for nurturing, identifying talents; and
3. to identify competencies required of teachers so as to enable them to nurture, and identify talents from amongst the learners.

Participants at the meeting were invited from the following Member States of UNESCO: Australia, Bangladesh, China, India, Indonesia, Iran, Japan, Malaysia, Myanmar, New Zealand, Pakistan, Philippines, Republic of Korea, Sri Lanka, Thailand, USSR and Vietnam.

The topics discussed in the workshop were focussed on the current situation in nurturing and identifying talents in science, technology and mathematics in the participant's country; the curriculum strategies practised in the initial development of creativity, problem solving and critical thinking skills; criteria in identifying the talented amongst the learners; abilities to be further developed by the identified talents and the curriculum strategies proposed for further nurturing of the talents; competencies required by teachers so as to enable them to nurture, identify and further nurture talents; and recommendations for follow-up actions at country/school levels.

Regional Experts' Workshop on Development of Strategies and Methods for Teaching Values in the Context of Science and Technology

The workshop was organised by SEAMEO-RECSAM, Penang, Malaysia from 18-29 November 1991. The workshop, with reference to science and technology education at the primary and secondary levels, developed training materials on the teaching of ethics and values.

The participants invited were from Australia, Bhutan, China, India, Indonesia, Iran, Japan, Malaysia, Maldives, Nepal, New Zealand, Philippines, Thailand, USSR and Vietnam.

The discussion at the workshop in the context of science and technology education at primary/secondary level was focussed on: the objectives and contents of values/ethics education; strategies for learning/teaching of values/ethics; methods of evaluation of learning of values/ethics; development of sample lessons; and the description of the developmental process (planning to implementation) involved including training of teachers in learning and teaching of values and ethics.
Education in Global Change

Moving Scientific Research Into the Classroom

A study in global change - the International Geosphere-Biosphere Program - has inspired the Committee on Teaching of Science (CTS) of the International Council of Scientific Unions (ICSU) to initiate a major curriculum development project, called Education in Global Change.

The IGBP is carrying out scientific research that is of immediate interest to young people, and it was judged feasible by CTS to produce related teaching materials about global change at all levels, from elementary through postgraduate. CTS has targeted its initial curriculum project in global change at 16-19 year old science students. The project uses global change issues to introduce and illustrate scientific principles. In this endeavour, CTS has sought active help from scientists involved in global change research.

The CTS believes it is of crucial importance to attract more young people into the science professions, countering the current downturn in students entering the sciences. Young people must come to understand the role of science within society and how scientists are able to provide the information needed for the solutions of both natural and human induced problems facing societies and the concomitant political, social economic, and technological issues.

Often, the research issues that are currently facing the scientific community are ignored by science teachers in schools and colleges. There are several reasons for this: the concepts are very difficult; teachers do not have enough information; and there is not enough time in the syllabus. Young people may pick up information from the media, but it often is only a superficial coverage. Thus, many young people find out neither about the scientific issues, nor the scientists who might inspire them to choose science as a possible career.

By bringing together scientists and science educators, the CTS is providing teaching materials for schools and colleges that illustrate the essential role of the scientist in society. The materials also offer authoritative information on important scientific principles. They demonstrate that the science being used to study global change has no national boundaries.

The materials are designed to be easy for teachers to use. They are interactive and encourage the participation of students, requiring practical work, discussion, data collection, and data interpretation. Suggestions to the teacher include advice on easy ways to adapt and extend the materials to meet local conditions.

It is planned that the final, printed materials will be in the form of inexpensive booklets. Teachers using the materials with students can readily copy (copyright waived) the sets they require. To implement the materials, a school or college need only obtain one copy of each booklet.

The CTS held writing workshops in June 1990 at the University of California, Berkeley and in May 1991 at York University, UK. Drafts of seven units have been produced: The Global Carbon Cycle; Remote Sensing: Window on Global Change; The Changing Atmosphere; Clues from the Past: Glimpses of Our Future; Land and Sea Effects on Global Change; Energy Cycles; and the Stratosphere. The units are edited by teams of scientists and science educators based in the United Kingdom, United States, France and India. During its various stages, the project has been co-directed by D J Waddington, M H Gardner, and J P Stoltman.

There are several important ways in which the scientific community can contribute to the ICSU CTS initiative: by reviewing units, helping to plan implementation of units, and suggesting topics. As part of the development process the units are being tried out in schools and contacts with teachers are important. The Committee would like further opportunities to visit scientists working directly in the fields in which it is producing teaching materials.

Report on the Meeting of the ICSU Committee on the Teaching of Science May 1-2 in Paris

by Joseph P Stolman, Secretary ICSU-CTS

The International Council of Scientific Unions (ICSU) Committee on the Teaching of Science (CTS) held its meeting in Paris at ICSU headquarters on May 1 and 2, 1991. Officers of CTS, representatives from the Scientific Union members of CTS, affiliate representatives from COSTED and ICASE, and observers from UNESCO, ICSU, IUIS, and URSI attended the meeting. CTS meets every two years in order to review policies, programs, and projects in science education internationally, and to develop and discuss plans for future initiatives.

Professor D Waddington welcomed the large number of colleagues attending, and made introductions of CTS representatives and observers. The death of Professor M Gardner, USA, was announced, and a moment of silence was held in her memory. Two members of CTS, Professors Chandrasek, India, and L Tan, Singapore, are ending their terms as officers and were thanked by the Chairman for their years of service to the Committee.

Reports on the various activities of CTS that have been underway the past two years were presented. These included the Education in Global Change Project, the Harare Generator, the Informatics and Microcomputer Publication, the Inexpensive Equipment Project, the University Science Teaching Project, the Subcommittee for Elementary Science, and the Ethical Issues in Teaching Science Workshop. The reports on the Education in Global Change Project and the Harare Generator represented the major commitments of resources by CTS during the past two years.

D Waddington reported on the Education in Global Change Project (see report in this section).

J Stolman reported on the Harare Generator held at the University of Zimbabwe in January 1991. The Generator was designed to bring African teachers together with experts in curriculum design and materials production in order to write curriculum materials that were appropriate for teaching science in African schools. There were 106 participants, with 55 of them coming from Zimbabwe. The others were scientists, teachers, and science educators from other African countries and guests from outside of Africa.

Of the other projects, a draft of an informatics and microcomputer manuscript has been distributed for review by science educators and scientists. There is interest in continuing the work on inexpensive equipment development, especially for laboratory instruction in the developing countries. CTS will complete a sample survey to assess the availability of information regarding inexpensive equipment from different scientific unions and organisations. The University Science Teaching Project has completed its first phase and newly designed curriculum materials are being produced for use in Thailand in chemistry, biology, and physics. The next phase of the project is being discussed by the principal investigators and the funding agencies, and there is interest in carrying the project to a regional level through workshops and dissemination of products. The Subcommittee on Elementary Science will have a two volume series reporting their recommendations on the preparation of future elementary science and mathematics teachers published by UNESCO in 1991.

During 1991 an ICSU appointed Ad Hoc Committee on ICSU Science/Teaching Education Activity met and prepared a report, with input from the ICSU-CTS Chairman and Secretary, which has been forwarded to the ICSU Executive for consideration. The Ad Hoc Committee Report calls for a restructuring of CTS membership, providing a stronger financial support base, and for aligning initiatives by CTS to broad scientific education policy goals internationally.

During the CTS meeting, copies of the report were distributed to representatives for their review and discussion. In general, the report was accepted by the CTS representatives as positive. However, the discussion did result in several recommendations to the report that have been submitted to the ICSU Executive.

Reports of the activities of the Education Commissions of the Scientific Unions were both submitted in writing and distributed as well as commented upon by representatives. The reports revealed a number of significant educational activities that are being carried out by the Unions. They also reinforced the important role of CTS in coordinating and facilitating interdisciplinary initiatives in science education.

New initiatives by CTS were discussed at length. They include:
- Leadership workshops for implementing the Education in Global Change classroom materials in South Asia, Francophone Africa, and Latin America.
- The education in Natural Disasters Reduction Project being undertaken to produce an international handbook for teachers on natural disasters reduction through science education.
- Co-sponsorship with ICASE and several other organisations of the Space Science Project for Teachers of Science in conjunction with the International Space Year.
- Co-sponsorship with ICASE of the UNESCO Conference on Science Education for All in 1993.

The next meeting of the full body of ICSU-CTS is scheduled for 1993. For information about ICSU-CTS, please write to:

teaching; Dr Zöchling, Berndorf, Austria, on Environmental measurements at cross roads; J Holman, Watford, UK, on the British approach to environmental education and the SATIS Project; J P Simon, Brussels, Belgium, on Retraining science teachers for teaching ecology; and Prof Ciesielska, Krakow, on Teacher education in the field of ecology.

There were also eight workshops on the theme of environmental education. The European Representative of ICASE addressed the general assembly on possible activities by science teacher associations; and contributed to a workshop on chemistry education and the environment.

Sixty five participants attended the Conference including three from Belgium, two from The Netherlands, one from Austria, and one from the UK.

The Conference has provided an excellent start to the programs of SNPPiT - the first science teachers association in Eastern Europe to become a member of ICASE.

AISTA - All India Science Teachers Association

The proposal to form an Association of science teachers from all over India originated at the All India Seminar on the Teaching of Science in Secondary Schools held in June 1956. Contacts made at this event and the work accomplished there proved so stimulating that participants decided to set up a permanent organisation - thus the All India Science Teachers Association was born. The Association's activities are wholly devoted towards the promotion of science education and are recognised by the National Council of Educational Research and Training and other organisations.

The Association holds a three-day conference each year, usually towards the end of December, in different cities of the country. The program includes lectures, demonstrations, discussions, excursions to places of scientific interest, and exhibitions. The Krishnan Memorial Lecture and the Joshi Memorial Lecture are delivered by distinguished scientists and educationists each year. Teaching and science films are also screened.

Regional activities are organised by branches - some state branches organise state level conferences, lecture demonstration series, science quiz contests, science fairs, science aptitude and talent tests. Some local branches have been preparing science films and other aids related to scientific topics.

The Association is participating in an International Study on Science Education. The Association is a founder member of ICASE and participates in its activities. The Association's President, Shri B G Pitre, was the Chairman of ICASE for the term 1976-79.

The Association operates through an Executive Council on which each state and branch association with a membership of more than 50 is represented.

The Vigyan Shikshak, first published in March 1957, is the official journal of the Association. It is a quarterly journal with a nationwide circulation, and contains articles, teaching units and information on a wide spectrum of scientific and educational topics relevant to primary and secondary teaching. There are also film and book reviews, diagrams and notes on improvised apparatus, and original experiments on all branches of science teaching.

The Association has recently undertaken the publication of a series of background readers for pupils on a variety of subjects, and a guide book on science club activities and topics.

For further information about AISTA, contact:

Mr R K Mohra, HQ Secretary,
AISTA, Sardar Patel Vidyalaya, Lodhi Estate, New Delhi 110003, India.
Update: Project 2061
by Dr Kenneth Russell Roy
ICASE North American Representative

Project 2061 is a three phase initiative to provide direction for the restructuring of science education in the United States. In actuality, the American Association for the Advancement of Science under the leadership of Dr F James Rutherford, Director, has focussed on an interdisciplinary approach with touchstones to mathematics, technology education, social sciences and others. The project's main mission is to provide science for all Americans.

At present, Phase II is in operation and addresses the task of developing alternative curriculum models and Blueprints for Action. Phase I involved the development of exit outcomes resulting from twelve years of education. The models to effect these outcomes are being prepared by teams of educators in six school districts around the country. Blueprints for Action will address other aspects of the education matrix needed to restructure the present framework to allow the new models to work.

Issues to be addressed in the Blueprints for Action will include the following major areas:

1. **Teacher Education**
   Needs in preservice and inservice training to produce teachers who will understand Project 2061 ideas and become effective change agents.

2. **Materials and Technology**
   Development and evaluation of instructional materials and technology which are not available presently in many areas.

3. **Assessment**
   All facets on assessment will be addressed from in-class assessment during instruction, school program evaluation, to general monitoring of educational progress at state and national levels.

4. **Research**
   In order for models to be developed and to evolve, more research on learning to learn through thinking skills will be addressed. Also, the myriad of present research needs to be considered for practitioners.

5. **Curriculum Connections**
   Given that the project touches on many disciplines, attention must be given to scheduling models, achievement ability grouping issues and other levelling phenomena.

6. **School Organisation**
   Alternatives for the general philosophy and organisation of school structures may also be addressed.

7. **Parents and Community**
   Key to restructuring is the support and involvement of parents and the business community. The Blueprint for Action will address how these groups can be effective.

8. **Equity**
   Given that the mission statement of 2061 is "Science for all Americans", new areas need to be explored to address equity issues relative to minorities, females, the poor and other at-risk populations.

9. **Higher Education**
   Key to the restructuring is the articulation with higher education. Specifically issues dealing with the credit for course work, admission requirements and more.

According to Dr Rutherford, the curriculum teams have been working during the past two years on what they believe students should have achieved by grades 2, 5, 8 and 12. A 1992 timeline is in place to publish the final consensus for national norms and indication of progress.

The Project will take over 20 years to effect change. It is one of several major reform movements in the USA at present.

Many additional programs have been initiated at the state levels such as the California Science Framework and the Kentucky Ky Aces program. Another major national program of significance is the National Science Teachers Association's Scope, Sequence, and Coordination Project. All of these programs are being developed to prepare US students in science for the 21st Century.

For additional information, contact Project 2061, AAAS, 1333 H Street, NW, Washington, DC 20005, USA.
Creating a Cooperative Classroom
by Alan Colburn & John Penick
Science Education Center
University of Iowa, USA

Cooperative learning, a powerful classroom strategy, particularly valuable for helping students learn new content and how to work together, was discussed in the March 1991 issue of this journal (Colburn & Penick, 1991). Teachers interested in cooperative learning ask: How do I do it? Where do I begin? How can I implement cooperative learning techniques in my classroom? Each of the questions is valuable, useful, and necessary.

Effective cooperative learning depends on the teacher structuring the class so that several things happen. First, small groups of students have to work together to learn something successfully or complete an assignment. Students must depend on one another in a positive way. Students are nevertheless still held accountable for their own learning; there is no freelinking. Every student, for example, will take his or her own test even if students were working together all the time leading up to the test. Finally, unlike more traditionally structured classrooms, social skills are explicitly taught to students in the cooperative classroom. For students to work together in this fashion, the teacher must provide appropriate skill development, classroom structure, strategy and encouragement.

Before outlining specific cooperative learning techniques, a few general strategies will help the teacher new to cooperative learning. The chances of success and satisfaction - on your part as well as students - are higher if the first cooperative activities are not full class period activities. Start small. Rather than groups of four, students can work in pairs. With only two students working together, the chances of students being incompatible or not doing their share of the tasks are lessened. And, a slow start will provide more opportunities to teach students how to learn cooperatively.

The first cooperative activities should also be fast, simple activities. They might, for example, last only ten minutes. With these short activities, students learn the most basic of cooperative skills, like moving their chairs from a whole group arrangement, the way chairs are set up when all students are listening to the teacher, to an arrangement more helpful for cooperative learning. Another example of a basic skill that students often have to learn is speaking in a voice quiet enough that other group members can hear, while not being so loud as to disturb members of other groups. The first attempts at cooperative learning allow the teacher to begin to find effective ways to teach his or her class these kinds of skills. This pedagogical knowledge is useful later, when the teacher is teaching more complex social skills. For the same reasons, initial group attempts do not necessarily have to involve new content. Students may use cooperative techniques in reviewing previously learned content, brainstorming, rehearsing answers to the teacher's questions, or activities addressing other non-content classroom goals.

Once teacher and students begin to feel comfortable with elements of cooperative learning, the class can then move on to fully structured cooperative strategies. Student Teams Achievement Divisions (STAD), a common cooperative strategy, is one place to start. STAD is straightforward and fits with most traditional science curricula, while still having the advantages of cooperative learning. STAD is made up of five basic components.

1. The class is presented with background content. Presentations can come from the teacher, students, or any other source of information.
2. Students then work in teams, usually of four, to prepare members to do well on a quiz (or other graded instrument that, ultimately, all will complete individually). Team members teach and help others in their small group.
3. Students then go on to take individual quizzes after team practice.
4. Team recognition for individual improvement is an important part of STAD lessons. Each student is given a base score, the minimum score that individual should achieve on a given quiz. The base score is usually based on past performance in the class. Students earn bonus points for their team based on how much their quiz scores exceed their base scores. Recognition and reward is given to any team that earns some minimum number of these bonus points. Since bonus points are awarded for improvement, all students in a group have the opportunity to contribute toward the reward. As a matter of fact, students with the lowest base scores (sometimes scorned by their peers) have the opportunity to provide the group with the largest number of
bonus points since they have the greatest opportunity to show improvement.

Teams should be selected by the teacher. High scoring and low scoring students should be together, as should students of different race and gender. The more heterogeneous the group is, the greater the opportunities for students to learn to work with and from different kinds of students.

The way one teacher uses STAD to teach students about water serves as an example of the technique in action. "I developed five labs and activities centred around the study of water," she says. "Rather than having the whole class do the same lab, each cooperative team does a different lab each day of the unit. This saves on material needs and the teams must depend only on themselves. The initial organisation takes time, but the next few days run very smoothly, and the students like this independence."

For each of five days, a team is assigned a lab activity, reading material, and a study guide on a particular water related topic. After completing a lab, students work together on a reading assignment and review for the coming quiz. Each student individually takes a quiz following the day of the lab activity.

Students are assigned a base score, the minimum score the student should (theoretically) achieve on the quiz. The students receive an individual grade earned on the quizzes and bonus points for their team based on how much their quiz score exceed their base score.

Some of her five activities include using expensive equipment the school lacks enough of for the entire class. One activity uses a stream table and another uses a computer program. By structuring the activity, students are able to explore with the stream table and the computer program for the entire class period without the teacher worrying about what to do with the rest of the class.

Discussing the five activities, this teacher says, "A cooperative unit like this takes a lot of pre-planning, and this organisation is very important if you want success. Once the labs and quizzes are set up, it is really fun to stand back, be the facilitator and observe learning taking place. The students also enjoy the independence they have in the learning process and the STAD method offers just enough competition to stimulate motivation."

On the sixth day students review everything studied during the previous five days, preparing each other for a cumulative test. Note again that each student still takes the unit test individually and receives their individual grades. However, teams receive special recognition (like extra credit) for earning the highest number of bonus points. This encourages students to help each other. The award can be agreed on by the class and teacher before the unit begins. Jigsaw technique is another common cooperative learning strategy. Students work in heterogeneous groups and each team member takes a different topic to study. They become experts on their topic by meeting with members from different teams and take turns teaching their teammates about their topics. Students are given quizzes and scoring is done the same as in STAD. Group interdependence comes when students must depend on their teammates to provide information needed to do well on the quizzes. This method is particularly successful for review of material that covers a broad spectrum. Jigsaw is a flexible cooperative learning method with an endless number of ways the teacher can modify the strategy. Presentations can replace
SURFACE OF SILICON CRYSTAL
Magnified approximately 100,000,000 times

It is only since the recent invention of the Scanning Tunnelling Microscope linked to modern computer development, that objective views of the mysterious lattice networks of energy known as electron fields have become before human vision.

Detailed geometric study of these extraordinary discoveries was undertaken in order to produce the poster's accurate hand drawn artwork. Small circles represent electron fields which are arranged tetrahedrally around their nuclei and which bond together basic units of the crystal.

quizzes, for example, or expert groups can work with sub-topics that are part of a broad class topic.

In all cooperative learning strategies, the teacher must work with groups and not do all the work personally. This means letting students make decisions within their groups, about learning and closure. If you do their thinking, they don't have to cooperate except to compete with you. Give them some room to be creative, to structure, cooperatively, their own learning.

As we pointed out last March, cooperative learning is more than merely working together. To be successful, the teacher must plan ahead, setting group goals and designing a strategy where a group can work together. This does take more time initially, but teachers report that it is quite worthwhile. They say that once students learn to work together teachers can be more relaxed and spend more time having real conversations with students. Students are seen to take more responsibility for their own (and other's) learning.

To do this, you, the teacher, may have to change your behaviour. If you take responsibility, students cannot. If you do all the evaluation and decision making, they remain passive. Structure your tasks and groups and wait; give them time. Together you can learn to make it work. Sometimes progress will be slow. Don't be impatient, it will happen. Trust us and trust them.

Portfolios
A national trend with worldwide potential

by Ronald J Bonnstetter
University of Nebraska, USA

Imagine an assessment tool that revealed a range of skills and student understandings and truly coincided with our instructional goals. Imagine an assessment that yielded more than a simple grade or a score, and allowed for input and reflection both by teachers and students. Also imagine an assessment tool that will show changes in student understanding over a period of time. And finally, imagine that this same assessment tool provided insights into what should be taught next for each and every student.

Starting with language arts, the performance-based portfolio assessment concept is gaining momentum in all subject areas throughout North America and is being discussed in Europe and Asia.

As you read this article please consider the commonality between these suggestions and processes already in place within your own programs.

As an example, how could some of the portfolio concepts and procedures be used to expand the documentation of European apprenticeship experiences? How could the Asian after-school skill development programs better document outcomes and pass this information back to the schools?

The following questions are a result of working with both in-service and preservice teachers who wanted to know more about authentic assessment and the role of performance portfolios.

The answers represent a synthesis of educational research; much of which is cited in the reference list.

This section focuses on the pre-service and in-service education of science teachers, and aims to communicate ideas and strategies which will assist science teacher educators to enhance and enrich their pre-service and in-service programs.

What does educational research say about the purpose of assessment?
The purpose of assessment should be to improve learning. However, far too many teachers view assessment as merely a tool to document what children do NOT know and make no effort to provide remediation. This missing step can only be provided when we systematically reveal how students think.

What is authentic assessment?
Authentic assessment is not a single method. It is a set of evidence that best shows progress toward goals. The extent and kinds of evidence should reflect desired outcomes and communicate not only what students know but how they think.

Therefore, authentic assessment is a set of artifacts of learning. Together, this collection provides far more than an image of a students' content knowledge. One tool that will help create this holistic view of student learning is the portfolio.

What is a portfolio?
A portfolio is a systematic, well organised, collection of evidence, used to monitor the growth of a student's knowledge, process skills, and attitudes. This assessment tool more closely matches our curricular goals by exposing what students are doing, the processes they have employed, the range of activities, the effort exhibited, as well as documenting student improvement and ability range.

How do you decide what goes into this portfolio?
There are a series of portfolio planning steps developed at the University of Nebraska which provide an excellent planning guide for any school system. By responding to each of the following questions posed in this guide, science instructional teams can collaboratively work through both the portfolio conceptual framework and formulate the documentation plan.

Developing a portfolio plan for student assessment

Creating the Portfolio Conceptual Framework

1. What kinds of assessment are currently used to assess student growth and performance in science? What do these assessments tell about student learning?
2. What are important aspects of student learning and performance that are not satisfactorily assessed with current practices?
3. What are the building-wide or school system goals that teachers expect students to know and be able to do when they leave?
4. What are the grade level curricular goals in relation to school system goals? (Each grade level should focus on different elements of the building goals.)
5. Finally, teachers should prepare goal statements for what students
should learn or be able to do and identify how each of these goals are currently being assessed.

Developing a portfolio documentation plan

1. What will be the purpose of the portfolio?

2. What documents (work samples, formal and informal tests, observation records, interviews, surveys, laboratory reports) might be included relative to each goal?

3. What are the expectations for students to demonstrate successful growth and/or learning related to each goal?

4. What initial assessment information is presently available for a student's portfolio and how will this information be incorporated into instruction?

5. Lastly, what kind of student growth documentation for each goal can be generated as part of on-going instructional activities during the year and how often will these documents be selected/obtained for the portfolio? Who will make the selections, the teacher or student, and prepare reflective captions about what a particular document shows related to each goal?

How will we grade students?

First, we must recognise that education for many years has viewed assessment as something to be scored and sterilised into a letter grade. What does that letter or number really tell us about student learning? To a certain extent all evaluation, and certainly a letter grade, is a subjective and limited assessment by a biased judge that, once stated, becomes a shadowy truth.

The first step to scoring any tool, including portfolios, is to establish criteria which reflect desired student outcomes before the actual data are collected. Many of these artifacts of learning can be broken down into levels of performance attainment, by identifying examples of the kind of work that are representative of each level.

We must remember, the reason for going to all this added work is not to throw away this rich and insightful collection of learning and record a letter grade, but to start to build a vision of student learning by documenting progress and development. The important and underlying goal is to trace learning growth and to identify skill and concept development over time. We all know that many of these desired outcomes are occurring, but past assessment procedures have not captured them.

What becomes of the portfolio at the end of the year?

The teacher's written summary assessment of student progress in both process and content acquisition closes each year's portfolio. Maintaining and passing these collections on is the real strength of portfolios. This practice allows teachers the opportunity to build from previous student knowledge and skills in ways never before possible.

Obviously, if portfolios are to be a progressive process, teachers from different grades and courses must decide the kinds of information that would be most helpful and in what format this information should be transferred.

How will teachers find the time?

This process does take time and, therefore, a commitment by all involved must be made. Time must be set aside in the form of assessment

**Pasteur and Microbes**

*A Teacher Resource Book*

*Commemorating the 100th Year of the Pasteur Institute 1888-1988*

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute. It contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few. These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation.

days for teachers to organise information. Conferencing sessions must be scheduled with students to review portfolio progress and teachers must be given time to meet and share individual student progress during the academic year as well as time for sharing the data in preparation for the next grade level.

What other questions concerning portfolios should be considered?

Several other questions come to mind, for example:

1. How will YOU, the teacher, use the student portfolios?
2. How will the student be involved in portfolio development or use of the portfolio?
3. Who else might find these portfolios useful?
4. What role will the administration play in helping teachers with the portfolio development process?
5. What are specific problems your school must overcome to successfully implement portfolios and what possible solutions can be generated?

Where else might this portfolio concept be used?

The portfolio concept is making its way into teacher assessment at all levels.

Evaluating college and university teaching has been an ongoing concern. Many schools are giving more weight to the role of teaching and expanding documentation through the use of teaching dossiers.

The following bibliography provides examples of publications which explain the use of portfolios to record teaching accomplishments.

Bolton, MA: Anker Publishing Company, Inc

Seldin, P & Annis, L (1990) The Teaching Portfolio The Journal of Staff, Program & Organisation Development Vol 8 No 4, Winter

Where do teachers go for more information on student portfolios?

As previously stated, a great deal of work has been done by the language arts educators in the United States and many of their ideas can be directly transferred into science programs. However, in the last couple of years a number of excellent sources of information directly related to science have emerged. The following articles are a must for further understanding of portfolios.

Effects of inservice programs on elementary teachers' attitudes towards science and the teaching of science

by William Spooner & Sue Dale Tunicliffe

This article is the report of a NSTA/ASE Joint Research Project. The project, conducted from 1987 to 1988, was a comparative study of the effects of two types of inservice programs on elementary teachers' attitudes towards science and science teaching.

Purpose
The purpose of the project was to examine the effects of two types of elementary science inservice programs on elementary school teachers' attitudes toward the subject of science and toward the teaching of elementary science. These programs were designed to improve science teaching methodologies related to problem solving and thinking skills.

Design
The design of the study included a pre/post test of attitude measures to assess the effects of treatments. A comparison of the two teacher groups was made with respect to their entry attitudes towards science and teaching elementary school science. Comparison was also made on several demographic variables.

Inservice programs
The North Carolina (USA) program was of 5 days duration with 32 contact hours. Maximum opportunity was given for hands-on activities. The Richmond (England, UK) group were sent by their principals on a two day course at the Teachers Centre. The total of 10 hours contact time was divided evenly between discussion and practical, hands-on activities.

Instruments
Likert-type scales were used to measure the attitudes toward the two concepts. These scales were the Survey of Opinions Toward Teaching Elementary School Science (SOTESS) developed by Spooner and Simpson (1979) and the Science Attitude Scale (SAS) which was modified from the Revised Math Attitude Scale (REMAS) developed by Louis Aiken (1963). This scale was modified with permission from the author to reflect science.

Both scales consisted of 20 items with five possible responses - strongly agree, undecided, disagree, and strongly disagree. The most favourable response (strongly agree or strongly disagree) scored 5, and the least favourable scored 1. Items were constructed and randomly arranged so as to elicit both positive and negative responses from the respondents. The maximum score on the 20 item instrument was 100 with the minimum score 20. A score of 60 would indicate a neutral attitude toward science or science teaching. Likewise, an individual score below 40 would indicate a strong dislike for science or science teaching; a score above 80 would indicate a strong positive attitude.

Results
For teaching elementary science the North Carolina teachers' mean score was 76.39; the Richmond teachers' mean score was 77.00. Both scores were well above the neutral score of 60. The post test score shows a higher gain for the North Carolina group (4.39) than for the Richmond group (1.99).

The SAS scale for science attitude differences between the Richmond group and the North Carolina group were 1.30 points. Mean scores of 74.45 and 73.15 respectively were lower for the concept science than for the concept science teaching.

Discussion and summary
There were limitations to this study. The teachers were not randomly selected; the two workshops were not of the same duration nor at the same time; the Richmond study was conducted over a much longer time frame than the one week North Carolina study.

Nevertheless, this study has shown that these two sets of teachers hold virtually identical attitudes towards the subjects science and elementary science teaching as measured with the SAS and SOTESS instruments. Teachers in the North Carolina sample

had statistically significant changes in a positive direction on how they felt about science and science teaching. Teachers in the Richmond sample made positive gains in attitudes as a result of the treatment but these gains were not significant at the 0.05 level. We believe a major variable is the duration of the inservice courses and the amount of actual time the teachers spend on hands-on activities (4 days in the North Carolina sample, 1 day in the Richmond sample).

The program as well as the nature of the inservice activities are variables which must be considered if we are to enhance elementary teachers' attitudes to science and to science teaching. We believe that elementary science teachers need to experience science inservice workshops in a way that will allow them to gain hands-on learning experiences that are directly replicable in the classroom.

Stepping into Science
An ICASE Primary/Elementary Science Project

AIMS
Stepping into Science is an ICASE project which aims to:

• Establish an international network for teachers to share ideas on the teaching of primary/elementary science and technology.
• Provide activities and support for teachers, thereby encouraging them to include more science in the primary/elementary curriculum.
• Promote the value of science experiences for young children throughout the world.
• Facilitate professional development opportunities for teachers by including sessions on primary science and technology in regional and international conferences.

ACTIVITIES
The Stepping into Science Team is actively involved in a number of projects and activities including:

• Publishing STEPS, the Stepping into Science Project Newsletter. This newsletter contains ideas for class activities at various levels in primary/elementary schools, activities for children to do at home, comments by network members on issues, examples of children's work, lists of helpful resources and contacts. ICASE acknowledges the contribution of Philip Harris in sponsoring STEPS.
• Contributing articles and ideas for the Primary Science Section in Science Education International, the ICASE quarterly journal.
• Compiling ideas and activities for inclusion in a series of sourcebooks on the teaching of primary/elementary science and technology.
• Coordinating a scheme to encourage children to participate in science and technology activities. Certificates of Participation have been produced, and are available for schools to use in rewarding students as they complete a number of activities. Certificates are colour coded in seven different colours, so that they can be used to acknowledge progress in science from early to advanced levels within primary/elementary schools. ICASE is grateful to BP (Oman) for sponsoring this scheme.
• Organising Stepping into Science workshops and displays of children's work at national, regional and international conferences.

Science as Part of Our Culture

by Michael Gore
Director, The National Science and Technology Centre
Canberra, Australia

While teaching Physics at the Australian National University in Canberra about ten years ago Michael Gore set up an interactive science centre called Questacon. This has been developed into the National Science and Technology Centre with Dr Gore as its Director.

In this article, the text of a speech delivered at the AGM of the South Australian Science Teachers Association in May 1991, Dr Gore outlines his belief that science is the most vital part of our culture and that there is no problem in educating and entertaining at one and the same time.

I find it interesting and instructive on occasions to ask people to list the various facets of our culture. Try the experiment some time and see how far down the list science appears. In some cases it does not make the list at all!

Very quickly you will get responses that include art, literature, music, theatre, sport, ballet, but it is instructive to observe the ranking given to science. If, as I suspect, many people do not perceive science as a part of our culture, then what do they rank as the most important part of culture as far as they are personally concerned?

The average family does not usually have an extensive library in the house. They will rarely if ever go to the theatre or attend a live symphony concert. The walls of their homes will not be adorned with too many oil paintings or numbered prints. However, if one were to carry out an inventory of devices having their origins in science and technology, I predict that the list would be quite extensive. It would be bound to range from such items as electric lights to microwave ovens, radios, telephones, compact disc players, freezers, dishwashers, television sets, video players, computers, washing machines, amplifiers, tape recorders and a host of other items which are all products of that part of our culture which is called science.

We who study and teach science are indeed fortunate. It is a discipline that never palls, that never becomes tedious. There are always new horizons to be reached. In a whole lifetime it is not possible to 'know' everything about a particular branch of science.

Konrad Bloch, a German biochemist, made the following observation when accepting his Nobel Prize in 1964:

Science is, in the best and strictest sense, glorious entertainment.

Science is a firm, reliable, orderly, logical discipline. The ground that is science does not shift under your feet; not like some other disciplines! There is a story about the man who returned to his university 30 years on and visited his old economics lecturer who had risen to become a revered professor. They reminisced about the old days and the visitor noticed an examination paper lying on the coffee table. He picked it up and scanned it with avid curiosity. He was amazed at what he read! 'These questions,' he exclaimed 'are exactly the same as those that appeared on a paper I sat 30 years ago.' 'Ah yes,' said the Professor, 'but today the answers are different'.

I quoted Konrad Bloch as saying that science is 'glorious entertainment'. This sums up part of my own personal philosophy of teaching. I believe that there is absolutely no problem in educating and entertaining at one and
the same time. There are those however who believe that it is an anathema to be entertained by science. Many hold the view that science is a very serious part of our culture - and that to utter the words science and entertainment in the same breath is tantamount to sacrilege. But is this really so? If it is - then I assert that it is this sort of thinking that has made a major contribution to the layperson's perception of science. We do not adopt the same attitude to other parts of our culture. No one would consider that there is anything amiss about being entertained by a performance of Beethoven's Violin Concerto, or for that matter enjoying a production of Shakespeare's tragedy Macbeth.

People expect to be entertained by Handel's Messiah or by a performance of Swan Lake. Until now, we have not been entertained by science.

Because of this attitude, the general public have come to view science as something that belongs to scientists alone, something the average layperson can neither share nor understand.

The way science has been taught in some cases has directly contributed to this situation. All too often it has been presented in a mind-dulling way, with no compassion or humour, a subject to be learned and memorised. My first physics teacher in Lancashire did it this way. He had neither interest in nor knowledge of the subject and his lack of enthusiasm was infectious. I came to believe, in common with many students today, that physics is about memorising formulae and then solving some curious meaningless problems by plugging in numbers.

At the Australian National University (ANU), where I taught physics for twenty five years, I found that most first year students came to us with the firm conviction that physics was about learning formulae. They apparently got this impression from their school days. This I found particularly worrying as, in common with all other universities, we were admitting top class secondary students.

It must have been back in the early seventies that the staff of the ANU Physics Department adopted a new tactic with first year students. In order to demonstrate that we wanted them to understand concepts and not memorise formulae, we introduced the practice into our first year classes of giving all the students a printed list of every formula that was derived in the first year course.

We distributed this list in the first lecture of the year and told the students that they would be allowed - nay, encouraged - to take it into all tests and examinations throughout the academic year. We went even further by telling them that anyone who forgot their crib sheet would be provided with a new copy as they entered the examination hall. You can imagine the consternation this caused.

Although one of my teachers nearly turned me away from physics for life, Alfred Whitaker did the exact opposite with regard to mechanics. He taught the subject with flair and humour. He made us laugh a couple of times in each class and as a result we loved him and we came to share his love for the subject he taught. He was an inspired teacher - and he inspired us.

It was that man back in 1947 who demonstrated to me that teaching was a very worthwhile thing to do with one's life. I have always had nothing but contempt for George Bernard Shaw when he said that 'Those who can, do; those who can't, teach.' In the immortal words of Henry Ford, and unashamedly mixing my quotations, that statement is 'bunk'.

The philosophy that I have evolved for myself over the years with regard to science teaching is that, to be successful and effective, the teacher must be an actor. The theatre of course is a revered facet of our culture. I believe that if I am to inspire the people to whom I speak, if I am to inspire them to find out more - to learn - then I must by my actions enthuse and excite them. I must present the subject matter with enthusiasm, humour, imagination; and I must - this is very important for science - make it relevant to the everyday world - the world with which my listeners are very familiar.

Robyn William's portrayal of a school teacher in the movie Dead Poets Society may be a little 'over the top' but it demonstrates what I mean by an imaginative presentation. I believe that science teachers at both secondary and tertiary levels have a great responsibility to exercise their skills to change the public's perception of science.

There is also a more worrying aspect about secondary teaching and that is that I believe that the teaching profession is not valued by the community as highly as it deserves. I know many teachers who feel that they are considered to be second rate citizens in relation to what they do. I believe that there are many people in the community who see teachers as little more than glorified childminders between the hours of 9.00 am and 3.30 pm. The problem of course is not simply concerned with science teachers - I believe the problem is spread right across all the teaching disciplines. If this regression is not halted, the implications for Australia will be horrendous by the time we reach the year 2000.

I believe that some incentive must be offered in the tertiary arena to ensure that excellence in teaching is rewarded. At present there is absolutely no incentive to try to teach well in universities. It is easy to judge an academic's research output, but rather more difficult to judge the quality of a person's teaching - but not impossible, and it must be done if we really believe that it is worth doing.

Since I left my teaching post at the Australian National University, I have been working on the task of trying to alter the general public's perception of science and its role in our society. The interactive science centre was introduced into Australia in the early 80s and since then little centres have spread across the country like wildfire.

The Questacon was established in Canberra in 1980 and since then, interactive science centres have been established in Brisbane, Newcastle, Wollongong, Perth and later this year The Investigator will open its doors to the public in Adelaide.

For those of you who might be wondering what an interactive science centre is, it is a place specifically designed to encourage the public to
'mess about' with science. There are a host of activities laid on that visitors can be actively engaged in doing.

David Attenborough wrote an article a few years ago in which he described how many conventional museums were beginning to include new style interactive exhibits in their collections. He described how he had taken his eight year old son to visit the Victoria and Albert Museum in London and how they spent the day looking at its many priceless treasures. Attenborough described how, when they got home, he asked his son what, out of all the marvellous things he had seen that day, he had enjoyed the most. Without hesitation the young boy answered - the revolving doors.

The attraction and fascination of interactive science centres can best be summed up in the old oriental proverb:

*When I hear I forget, When I see I remember, But when I do, I understand.*

Our culture has introduced concert halls where the public can involve themselves in an appreciation of music even though they may not be able to read a note of music, let alone compose a symphony. We have had theatre from the earliest times and can enjoy plays without being playwrights. And we all from time to time, browse - mess about - in libraries even though we'll never write a novel.

Interactive science centres began their spread across the globe from about 1968, and all are places where you can 'mess about' with science, without any qualifications except the desire to explore. It is my belief that such centres along with many other different endeavours will help in time to change the public's attitude to science. These centres are designed to enable people to discover for themselves that science is a thoroughly entrancing and entertaining part of our culture.

Questacon - The National Science and Technology Centre in Canberra is dedicated to raising the public's awareness of science and technology. It attempts to let the public see how science is part of our everyday life, how science is part of our culture.

The Centre is in the Commonwealth Department of the Arts, Sport, the Environment, Tourism and Territories. Although the word culture does not rate a mention in the title of the portfolio, Questacon is in fact within its Cultural Branch.

One of several initiatives to come out of the establishment and expansion of Questacon - The National Science and Technology Centre has been the Australian National University's Graduate Diploma Course in Science Communication. This is a post graduate program - we believe the first of its kind in the world - that is run jointly by Questacon and the ANU. It is open to science and engineering graduates who, in addition to having a science or engineering degree, must also demonstrate at audition that they have an engaging personality and can communicate in a lively and confident way.

The National Science and Technology Centre with all its programs is based on the foundation of education. What you as teachers do, what the National Science and Technology Centre does, is to show, each in their own way, that science is at the root of everything - and that it is the most vital part of our culture. Anatole France wrote in 1983:

*Do not try to satisfy your vanity by teaching a great many things. Awaken people's curiosity. It is enough to open minds; do not overload them. Put there just a spark. If there is some good flammable stuff, it will catch fire.*

The Second IEA Science Study

The three volumes of the Second IEA Science Study, available from Pergamon Press, present a comprehensive view of science education around the world.

The IEA Study of Science I: Science Education and Curricula in Twenty Three Countries Edited by Malcolm J Rosier and John P Keeves

This 318 page volume makes comparisons between countries in terms of the conditions under which science is taught, the organisation of science teaching, the emphasis on different science content areas and on the process of science, the focus of decision-making with respect to the science curriculum, and the penetration of new ideas in science teaching. Consideration is also given to the fair and valid assessment of science education across countries. Reports on the provision of science education in each country studied are included. Cost £26.50.

The IEA Study of Science II: Science Achievement in Twenty Three Countries Edited by T Neville Postlethwaite and David E Wiley

This 248 page volume presents the data on students, teachers and schools for each country and analyses the science performance of the students and their attitudes towards school and science. Further themes include the opportunities available for learning science, the qualifications and teaching load of staff, the structure of the science curriculum, and the influence of home and school circumstances on science achievement. Cost £25.00.

The IEA Study of Science III: Changes in Science Education and Achievement: 1970 to 1984 Edited by John P Keeves

This 320 page volume considers the shifts in science education and achievement from 1970 to 1984 in Australia, England, Finland, Hungary, Italy, Japan, The Netherlands, Sweden, Thailand and the United States (the countries that took part in both the first and second IEA Science Studies). Specific chapters address such issues as the influence of attitude on science achievement, gender differences, beginning science in the elementary school, the influence of home circumstances on achievement and on educational and occupational expectations, and the teaching practices which enhance the learning of science. Of particular interest are the examinations of the changes in achievement in the 10 and 14 year old age groups, in the conditions under which science is taught, and in the science curriculum. Cost £52.00.

NEW ICASE PUBLICATION

Industry - Education Liaison

ICASE YEARBOOK 1990

Based on a symposium held in Brussels 5-7 September 1990

The 1990 ICASE Yearbook, sponsored by CEFIC (Conseil Europeen Des Federations De L’industrie Chimique), is a timely publication. The collection of papers presented at the Seminar on Industry-Education Liaison acknowledges the critical importance of partnerships between industry and education. The Seminar, held from the 5th to 7th September 1990, was organised to: (1) provide opportunities for the exchange of information and experiences in schemes for industry-education liaison; (2) develop models for industry-education liaison; (3) establish, through ICASE, a network for information exchange for future developments; (4) publish a resource book for teachers and administrators on industry-education liaison.

The Yearbook addresses a variety of topics, for example: An Overview of Demographic Trends in Industry; Chemical Industry Education Centre: Exciting Science and Engineering; Cologne Model: Chemistry-Technology-Everyday Life; Contact between School and Working Life in Sweden; Forms of Cooperation between the Chemical Industry and Secondary Schools in the Netherlands; and The Planning and Organisation of Industry Study Tours. A Summary of Seminar Discussions outlines some key principles and proposes a course of future action.

Copies, at a cost of US$7.50 or £4.50 plus 25% postage, can be ordered from:

Dennis Chisman, Honorary Treasurer, ICASE
Knapp Hill, South Harting, Petersfield GU31 5LR, UK
Cheques payable to "ICASE"

Another new release from Pergamon Press is the following publication.

Issues in Science Education: Science Competence in a Social and Ecological Context Edited by Torsten Husen and John P Keeves

This 262 page publication presents a collection of papers from the international symposium Science and Education in the 21st Century held at the Royal Swedish Academy of Sciences as part of a celebration of their 250th anniversary. The papers present state-of-the-art of science teaching and discuss the main questions facing teachers. Cost £24.95.
Education and Training in Chemistry in Europe

A new publication available from ICASE
A Royal Society of Chemistry Publication

The Royal Society of Chemistry - an ICASE member association - has published a new edition of Education and Training in Chemistry in Europe. This 180 page book contains descriptions of the education systems of 25 European countries and a series of comparison tables covering chemical education from primary level through to university and higher education levels.

It has been produced for the Federation of European Chemical Societies (FECS) with support from Unesco and the Royal Society of Chemistry.

Copies can be purchased at a cost of £10.00 each plus 25% postage and packing from the following:

Honorary Treasurer, ICASE
Knapp Hill, South Harting
Petersfield GU31 5LR
UK
Cheque payable to
‘ICASE’

Who’s Who in Science Education Around the World
1991 Edition

Published by ICASE with assistance from Unesco

This biographical volume is now available from:

Brenton Honeyman
Editor
Who’s Who in Science Education
10 Hawken Street
Monash ACT 2904
Australia

This new ICASE publication contains brief profiles on prominent science educators, their work, their projects and their interests. The valuable reference book includes key women and men in many countries throughout the world who are contributing to science education at primary, secondary or tertiary levels.

The information will help readers to contact colleagues in both developing and developed countries who may be working on projects of interest to them, who may be potential speakers at upcoming meetings or conventions, and who may be invited to work on collaborative projects.

Copies are being distributed to ICASE member associations, institutions, centres, foundations and companies, and to international science education organisations including UNESCO, ICSU Committee on Teaching of Science, etc. Copies are also being distributed to those who have sent pre-paid orders.

Further copies at the price below are available from:

Brenton Honeyman
ICASE Publications
10 Hawken Street
Monash ACT 2904
Australia

Please enclose a cheque payable to ‘ICASE’ for:

• US$15.00 (includes postage)
• UK£9.00 (includes postage)
• A$20.00 (includes postage)

Journal of Elementary Science Education
Call for Manuscripts

The Journal of Elementary Science Education invites submissions of manuscripts written in accord with its purposes that have not been previously published and are not under review by any other publication.

The JESE, published biannually, is a national, refereed journal devoted exclusively to the issues of elementary science education. The purpose of the journal is to communicate ideas, theoretical formulations, research findings, and practical field-oriented information related to supervision, curriculum and instruction. Lesson activities alone are generally not accepted. The audience of the JESE includes colleges and universities with teacher education programs, State Departments of Education, local education agencies, science educators, and science teachers.

Manuscripts, which should generally be limited to 15 pages, should focus on issues related to elementary science education theory, research or practice including, but not limited to the following interest areas:

• Needs assessment, research and evaluation
• Preservice teacher preparation
• Inservice teacher enhancement
• Recruitment and retention
• School board policies and practices
• Teaching and learning
• Gifted/special education
• National/international issues
• Public/private school administration

Please send manuscripts to: J. Preston Prather, Editor, Journal of Elementary Science Education, Curry School of Education, CISE - 250 Ruffner Hall, University of Virginia, Charlottesville VA 22903-2495, USA

36
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1991

December 27-29
33rd Annual Conference of AISTA
Location: Campus of Bharatiya Vidyavashram, Jaipur, India
Contact: Mr R K Mohta, HQ Secretary, AISTA, 31 Jangpura Road (Rear), Bhogal, New Delhi 110014, India
The next Conference of the All India Science Teachers Association (AISTA) will be held in the campus of Bharatiya Vidyavashram during December. The theme is Science and Values. Subthemes are (1) Science curriculum for the future citizen; (2) Attitudes in science teaching; (3) Science and the value of experiments. Papers will be published in the journal Vigyan Shikshak. An exhibition of teaching aids prepared by delegates will be a special feature of this conference.

1992

January 3-6
ASE Annual Meeting
Location: University of Sheffield, Sheffield, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event have been circulated in Education in Science, a journal of the Association for Science Education.

March 26-29
NSTA National Convention
Location: Boston, MA, USA
International delegates are invited to participate in the International Round Table - one of the many features of this large convention. Each country is provided one or more tables in a large room where delegates can display and present information on science education in their country. Visitors move from table to table, talking with the various representatives. If you require an invitation to participate, write to John E Penick, Professor and Coordinator, Science Education Center, The University of Iowa, Iowa City, Iowa 52242, USA.

March 29 - April 10
Seminar on Science Teacher Education
Location: Centre for Educational Studies, King's College London, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This British Council International Seminar will be directed by John Head and John May of King's College Centre for Educational Studies, University of London, and will focus on secondary level teacher education, although some aspects will be of interest to those involved in primary science teaching. Six areas will be addressed: What is the nature of science education for schools?; To what extent should teacher education reflect and shape societies' values and cultural traditions?; How can we aid their professional development so that science teachers have the skills they need in the classroom and laboratory?; What can the results of research tell us about new ways to approach children's learning and classroom practice?; How is the work of pupils, teachers and trainees to be evaluated?; How does the structure of national and regional administration affect the management of teacher education? There are vacancies for 30 international participants: practising teacher trainers, advisers, inspectors, organisers of professional development programs and policy maker.

April 26-May 1
International Conference on Technology Education - INCOTE 92
Location: Weimar, Germany
Contact: Dr D Blandow, INCOTE 92, Pädagogische Hochschule, Nordhäuserstraße 63, 0-5063 Erfurt, Germany
This symposium will be the first pan-European meeting on technology education to be held in Germany. The principal aim of the symposium, which is being organised in collaboration with a number of organisations including ICASE and INISTE, will be to discuss technological literacy and competence in technology education within a European dimension. The majority of participants will be from European countries, with a few key people from other regions of the world. The principal language of the symposium will be English.

May 11-15
Second International History Philosophy and Science Teaching Conference
Location: Queen's University, Kingston, Ontario, Canada
Contact: Prof Skip Hills, Faculty of Education, Queen's University, Kingston, Ontario, Canada K7L 3N6
This conference follows the very successful First International Conference on History, Philosophy and Science Teaching held at Florida State University in November 1989. All conference papers will be published in advance of the conference. Accounts of the application of history and philosophy of science in the science classroom are welcome, as are research papers on the issue.

May 11-22
Seminar on Developments in Primary Science Education
Location: Liverpool, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This British Council Seminar will examine major concerns and activities in primary science in the UK as well as their international context and implications. Major research and development projects in the area of science and technology relevant to the primary phase will be represented, including Learning in science, Research into children's ideas, Contexts of learning, Out of school learning, Curriculum development and evaluation, Pupil assessment, and Teacher education. There are vacancies for 35 participants, including science educators and curriculum developers concerned with the primary phase.

June 10-12
ICASE Research Seminar on Chemistry and Physics Education
Location: University of Dortmund, Germany
Contact: Prof Dr Hans-Jürgen Schmidt, University of Dortmund, Department of Chemistry, Otto-Hahn-Straße, 4600 Dortmund 50, Germany
This symposium on empirical research in chemistry and physics education will focus on the methodology of empirical research in this field. There will be approximately 12 presentations each followed by a discussion period. The language of the symposium will be English. Presenters will be asked to send their paper beforehand, ready for printing as Proceedings through ICASE. Proposals of about 3 pages should include title, background, method, results, discussion, implications for research and teaching, and references, and should be sent to the contact above no later than August 31, 1991. General papers will not be accepted. Although there will be no seminar fee, participants will need to cover their own expenses.

July 6-10
CONASTA 41
Location: Perth, Western Australia
Contact: Convenor, CONASTA 41, Science Teachers Association of WA, PO Box 991, West Perth, WA 6005 Australia
The Australian Science Teachers Association invites you to participate in the forty first annual conference of the Association.

August 2-10
Eighth ICASE Asian Symposium
Location: Colombo, Sri Lanka
Contact: Mr Asoka Veerasinghe
Hon, Joint Secretary, SLASME, Institute of Computer Technology, PO Box 1490, Colombo, Sri Lanka
Science educators are invited to attend the eighth ICASE Asian Symposium and enjoy the natural beauty of the country and the hospitality of the Sri Lankans. The Symposium, organised jointly by ICASE and the Sri Lanka Association for Science and Mathematics Education (SLASME), will feature outstanding speakers from many countries who will address the theme "Science Education for a Changing World". The Symposium aims to identify some of the changes affecting our daily lives and to discuss ways by which science education can respond to those changes. Subthemes include (1) technology, (2) appropriate technology, (3) environment, and (4) scientific literacy. Participants will be able to experience the world famous pageant "The Kandy Perahera" in Sri Lanka. 100-150 science and mathematics educators from all parts of the world, and 200-250 local delegates are expected to participate in this event.

August 31 - September 3
SCICON Biennial Conference of NZSTA
Location: University of Waikato, Hamilton, New Zealand
Contact: Neal Uting, Education Advisory Service, 4 Hill Street, Hamilton, New Zealand
The theme of SCICON for 1992 will be Science - Technology . . . A Partnership. Information and registration forms about the biennial national conference of the New Zealand Science Teachers Association can be obtained from the contact above.

December 17-21
Twelfth International Conference on Chemical Education
Location: Bangkok, Thailand
Contact: Dr Somjai Wichaidit, The Secretariat - 12th ICCE, c/o Research Centre, Faculty of Medicine, Ramathibodi Hospital, Rama 6 Road, Bangkok 10400, Thailand
The theme of the Twelfth International Conference on Chemical Education will be Chemistry in Transition and it is hoped that the participants will interpret this in many different ways. This biennial Conference, to be held for the first time in South East Asia, is organised by the Committee on Teaching of Chemistry of the International Union of Pure & Applied Chemistry, and The Chemical Society of Thailand in cooperation with UNESCO. It is attended by chemistry teachers at both high school and university levels who wish to improve their teaching and to learn from one another techniques and experiences. A second circular including instructions for submitting abstracts and registration will be mailed in March 1992 to those responding to the address above.
January 3-8
International Conference on Science Education in Developing Countries
Location: The Amos De-Shalit Israeli Science Teaching Center, Israel
Contact: Conference Secretariat, ORTRA Ltd, 2 Kaufman St, PO Box 50432, 61500 Tel-Aviv, Israel (conference arrangements) or Dr Avi Hofstein, Department of Science Teaching, The Weizmann Institute of Science, Rehovot 76100, Israel (academic correspondence)
This international conference on the theme "Science Education in Developing Countries: From Theory to Practice" will review past experiences and achievements in science education and plan for the 21st century with a special focus on developing countries. The conference will feature plenary lectures, symposia, poster sessions, workshops, exhibitions, informal discussions, social events and local visits. Topics for symposia and plenary lectures will focus on current research on learning and teaching and its implications for (1) the learner, (2) the teacher, (3) the classroom, and (4) the curriculum.

June 27 - July 3
VII Pacific Science Inter-Congress
Location: Okinawa Convention Center, Okinawa, Japan
Contact: VII Pacific Science Inter-Congress, c/o Section of International Affairs, University of the Ryukyus, 1-Senbaru, Nishihara, Okinawa, 903-01, Japan
The symposium will be organised around the theme The Pacific: Crossroads for Culture and Nature and subthemes (1) Cultural Interchange among Pacific Peoples; (2) Speciation, Dispersal and Conservation of Species in the Pacific; (3) Towards Appropriate Technologies and Policies for Development and for the Conservation of Natural Environments in the Pacific. Scientific sessions organised by the Scientific Committees of the Pacific Science Association focus on a range of science disciplines and issues, including Science Communication and Education.

July
Conference 93
Location: Paris, France
Contact: Dr Jack Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong.
This worldwide conference, organised by ICASE in conjunction with Unesco and other international bodies including ICSU Committee on Teaching of Science, is the second phase of the three phase Project 2000+ (refer to September 1991 issue for more details of this project). A number of international and regional conferences will generate input into Conference 93. The theme of the conference addresses the issue of Scientific and Technological Literacy for All. Sessions will establish agendas for future action. The majority of delegate places will be filled by invitation.

ICASE ENDOWMENT FUND

Associations and individuals are invited to contribute to this fund to support the activities of ICASE

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Science Education Center, University of Iowa, Iowa City IA 52242, USA
Individuals US$15 per annum, Libraries US$30 per annum

Brenton Honeyman, Editor, The ICASE Journal
10 Hawken Street, Monash ACT 2904, Australia
Individuals AS$20 per annum, Libraries AS$40 per annum
Looking forward to 1992

By Brenton Hemony
ICASE Journal Editor

This year is packed with events and meetings which will continue to strengthen the ICASE network of member associations.

The year began with the release of the new ICASE Publication Who's Who in Science Education Around the World 1991 Edition. This first edition contains brief profiles on prominent science educators, their work, their projects and their interests. The information will help readers to contact colleagues in both developing and developed countries who may be working on projects of interest to them, who may be potential speakers at upcoming meetings or conventions, and who may be invited to work on collaborative projects. Copies have been distributed to ICASE member associations, institutions, centres, foundations and companies, and to international science education organisations including Unesco, and the ICSU Committee on Teaching of Science.

The ICASE Executive will be meeting in London during April. The long agenda reflects the growth in the number of programs managed by ICASE. Their remains a critical factor in the delivery of these programs - the continuing need for additional human resources! The development of a 5 year plan for the Association acknowledges this critical factor.

At the conclusion of the Executive Meeting, a number of members will meet to further the planning of Conference 93 'Scientific and Technological Literacy for All' to be held in Paris in July 1993. The planning team has been working closely with Unesco and other participating organisations to prepare for this big event – the second phase of Project 2000+ (a joint ICASE-Unesco initiative).

One of the key conferences which will link with Conference 93 is INCOTE 92, the International Conference on Technology Education. This pan-European event is an ICASE endorsed meeting, and is being held at Weimar in Germany from 26th April to 1st May. At this meeting, ICASE is conducting a symposium on 'Science and Technology Education – A Vital Link'. The symposium will highlight the debates surrounding the place of technology education in the school curriculum and, in particular, in school science programs. This meeting will also be considering the establishment of a world-wide technology education association – a development which is being followed closely by ICASE.

Another ICASE event in Germany is scheduled for 10th - 12th June at the University of Dortmund. The ICASE Research Seminar on Chemistry and Physics Education will continue to generate important outcomes in the tradition of the previous two events and will also provide a valuable input to Project 2000+ and Conference 93.

An ICASE Asian Symposium on 'Science Education for a Changing World' will be held in Sri Lanka during 2nd - 10th August. As a feeder event to Conference 93, the outcomes of this symposium will feed directly into Project 2000+.

A little later in the same month (17th - 22rd August), the Science Teachers Association of Nigeria is organising an International Seminar on a Conducive Classroom Environment for Science, Technology and Mathematics Education in Enugu, Nigeria.

October 14th has been designated as ICASE World Activity Day. On this day, schools around the world are encouraged to participate in special activities. This year, in concert with ISY (International Space Year), the activities will be on a space theme and will be appropriate for primary and secondary schools. ICASE member associations are encouraged to promote these activities as widely as possible to teachers in their country. Some special activities are outlined later in this issue.

The Second ICASE Industry-Education Seminar is being organised in Europe as a followup to the successful seminar held in 1990.

While all this activity is going on, ICASE is continuing to develop a range of publications. Science Education International continues to experience growth in subscriptions as it becomes more well known. Other publications are planned during 1992. And this is just the start . . . !

News from Jamaica

The Annual Meeting of the Association of Science Teachers of Jamaica (ASTJ) was held on 28th - 29th November 1991 in Kingston, Jamaica. The ASTJ is one of the oldest science teachers associations in the Caribbean and Latin America, having been established in 1950. It became a foundation member of ICASE in 1973. The theme of the 1991 Conference was 'Science for Young Jamaica - Partnership for Development'. In addition to reports from local projects for formal and non-formal science education, there were three plenary lectures by overseas visitors including: Mr Bill Aldridge, Executive Director of The National Science Teachers Association (NSTA), USA; Mr Dennis Chisman, Hon Treasurer, ICASE, UK; and Prof Napoleon Bryant, Xavier University, Cincinnati, Ohio, USA.

The new Chairman of the ASTJ is Ms Vilma McClennan of the UWIDITE Unit at the University of West Indies in Kingston, Jamaica. This, together with a newly-established interactive Learning Centre on the campus of the University of the West Indies, will provide a resource and library base for the Association and accommodation for meetings.

Review of Literature on Scientific and Technological Literacy

In preparation for the major UNESCO-ICASE Conference to be held in Paris during 1993 as part of Project 2000+, ICASE is completing a review of the literature on scientific and technological literacy.

Please send any articles or abstracts on these subjects to:
John E Penick
Science Education Center
789 VAN
University of Iowa
Iowa City, Iowa 52242
USA

All submissions will be acknowledged in the review.

Canada ROJ 1HO

These activities will be compiled into an ICASE publication.
A Caribbean Physics Syllabus and the History of Physics

by Peter Whiteley
Faculty of Education, University of the West Indies
Mona Campus, Kingston 7
Jamaica

Introduction
The majority of the English-speaking territories of the Caribbean obtained their political independence from Britain in the 1960's and 1970's. However, even after independence there continued to be reliance on the examinations set at Ordinary and Advanced level by British Examination Boards (mainly Cambridge and London). It became accepted that such reliance was not in the long term interest of the peoples of the Caribbean. A variety of cultural biases could be discerned in the syllabuses and examination papers and the lack of any substantial involvement of Caribbean educators in the process of examining tended to place limits on the quantity and quality of feedback from the examiners to the teachers and students concerned.

In order to address the issues mentioned above, amongst others, the Caribbean Examinations Council (CXC) was established in 1972 by the regional governments and now serves sixteen territories in the Caribbean region (CXC 1978, CXC 1982). Its mandate was to provide relevant secondary school-leaving examinations for candidates of age 16+ years and ensure that the standard of such examinations was regionally and internationally recognised.

Two levels of examination, Basic and General Proficiency, are offered by CXC, the former normally aimed at satisfying the needs of a school leaver who is to start work and the latter intended to provide a foundation for further study. The chemistry, biology and physics syllabuses were introduced in 1983 and first examined in 1985. These subjects were introduced at the General Proficiency level only. All three syllabuses have recently (1991) been fully revised. An integrated science syllabus, at both Basic and General levels, is available for those who need a more general science background.

The Development of the CXC Physics Syllabus
CXC syllabuses are developed by subject panels which consist of curriculum specialists from Ministries of Education of the territories involved, practicing teachers and members of staff from the regional universities. During the initial period of development wide-ranging consultation occurs which allows interested individuals and organisations to submit views to the panel. The intention is that syllabuses and examinations take account of the needs of the Caribbean, reflect the nature of the societies within the region and explore relevant regional issues. Science syllabuses and examinations might, for example, be expected to utilise Caribbean examples of the applications of science.

A separate committee of three persons is responsible for the setting of the examination papers each year.

Taba (1962) suggested that the first steps in planning a curriculum should be the diagnosis of needs and the formulation of objectives to satisfy those needs. The selection and organisation of suitable content would follow. However, in the case of the CXC physics syllabus (1985) it appears that its content was primarily influenced by the Cambridge and London Examining Board syllabuses which were in use in the Caribbean in the early 1980's. The structure and order of the topics in the CXC syllabus is such as to encourage what might be described as a 'traditional' approach to the teaching of the subject. The content is arranged 'vertically', that is, in the order of development of the individual topics and the teacher (or student) is left to make the 'horizontal' links across the syllabus that unify the subject at a more fundamental conceptual level. All the 'usual' topic areas are in the syllabus, that is, mechanics, heat, light, sound, waves, electricity and magnetism and modern physics. General objectives are stated for each section and for practical work, and content is outlined with specific objectives written in broad behavioural terms. Overall, sixteen aims for the syllabus are specified and these may be classified as three content-based aims, eight process-based and five of an attitudinal nature.

A novel aspect of the 1985 CXC physics syllabus was the introduction of aspects of the history of physics and the historical development of some of the central concepts and models. Part of this material consisted of accounts of the lives of scientists concerned. However, the more interesting material was that in which previous scientific models (which now might be described as 'discredited') had to be known and understood. The students also needed to be aware of some of the ideas and experiments that led to the acceptance of the new models - the process of change that Kuhn (1970) referred to as a scientific revolution when the paradigm within which scientific research is carried out is replaced by a more useful paradigm.

Three major paradigm shifts were embedded within the CXC physics syllabus. They were:
(a) Aristotelian to Galilean/Newtonian theory of mechanics
(b) Caloric to kinetic theory of heat
(c) Particle to wave theory of light

In each case the syllabus asked for knowledge of both a previous and the presently accepted paradigm. In (b) and (c) a knowledge and understanding of a crucial experiment which
supported the new model was also required.

In the revised syllabus some rearrangement of the content has occurred and most of the biographical details of the scientists removed. However, the majority of the historical material of the 1985 syllabus appears in the new syllabus. The introduction of such material appears to reflect (or even pre-date) general trends as there is now considerable international interest in the utilisation of the history of science in high school science courses.

Sherratt (op cit) in his historical review of the history of science in the science curriculum, listed some of the wide variety of roles that have been seen for the history of science:

(i) as a source of experiments that allow easy illustration of fundamental scientific principles
(ii) as a useful teaching aid for aspects of science that do not allow for an experimentally-based development
(iii) to provide moral training (presumably Sherratt is referring to the attitudes and values displayed by the scientists)
(iv) to demonstrate the cultural and humanistic aspects of science
(v) to teach about the nature and methodology of science
(vi) to counter over-specialisation

Sherratt also mentioned Cawthorne, a science teacher of the 1930's, who advocated that the student should project him or herself into the life of the scientist and thus see the historical facts "within a wider context of their contemporary intellectual and social background". The biographical details of scientist and a chronological statement of the scientist's work was not considered adequate history by Cawthorne.

Sanchez (1989) in his paper presented in 1989 at the major Florida State University Conference on the History and Philosophy of Science in Science Training, supported this viewpoint and suggested that it is important that students recreate and re-live the problematic situation that led historically to the revision of belief and understanding.

Sanchez suggested that the use of historical material may be 'implicit', that is, no mention need be made of historical names, places and dates but the teacher may introduce counter-arguments and new problem situations from which the student develops a new and better model.

With regard to the nature and methodologies of science, Sherratt (op cit) supported the arguments for pupils to understand the nature of scientific method and the consequent transient nature of scientific laws and theories. Overall it was recommended that science should be presented as a method and not merely as a collection of 'facts' and it was suggested that the history of science may often provide suitable material for the achievement of such a goal.

In his paper Sanchez (op cit) also noted that the inclusion of the history of science may change the sequence in which material is presented. He argued that there is no inherent reason that the organisation of the subject matter by an expert in the discipline is necessarily the best way for a novice to first experience the material. The learner's task may
better be seen as confronting his or her own ideas and models with those which have a more general acceptance.

Kenealy (1989) highlighted the importance of coherence in the outline of scientific material - he pointed out the apparent comfort the human mind takes in a coherent set of ideas even when 'wrong and scientifically unsound'. He saw historical material as offering the potential for developing such a coherence.

At the same 1989 Florida conference Lochhead and Dufresne (1989) advocated the use of 'historical dialogues' between, say, Aristotle and Galileo or Newton as a way of improving student comprehension. In another paper at this conference Solomon (1989) presented the possibility of utilising classroom drama in a 'Retrial of Galileo'. Solomon suggested that this might illustrate the difficulties of 'overturning' an old theory which has become a part of a society's way of thinking.

If the students learn about the historical models as well as the currently accepted model they may better see how the current theories more adequately explain the data. This benefit is only likely to result if the students are able to think from alternative perspectives. They need to go beyond the models and theories and discuss the arguments in favour of them. The historical material in the CXC syllabus may, therefore, be seen to have several uses including the following:

(a) The development of scientific methodology and attitude can be well exemplified by aspects of the work of Galileo, Newton, Faraday and Curie.
(b) The tentative nature of scientific theories may be demonstrated with reference to the changes in scientific understanding that have occurred. Students have a tendency to believe in some absolute scientific truth which is a misrepresentation of the nature of science.

(c) There is now much research (in what might be called a 'constructivist' tradition) that suggests that the conceptions that children possess prior to instruction, and bring to their science classes, have at least some, and often quite considerable, resemblance to historical scientific models.

As an example of this latter point it is worth noting that research evidence suggests that Aristotle still maintains a considerable number of followers. For example, Vinnent (1979) working in France, Belgium and Britain found widespread occurrence of alternative conceptions which were very resistant to instruction and had many similarities to Aristotle's ideas.

Although no substantial work on this topic has been conducted here in the Caribbean, work has now started (Whiteley, 1991). Also, the reports from the CXC examiners (CXC, 1985-91) have, on three occasions, highlighted the prevalence of Aristotelian or quasi-Aristotelian views in the candidate population for the CXC physics examination.

However, the decision to include historical material in the CXC physics syllabus has been resisted by physics teachers in the Caribbean. The teachers seem to have been generally

ICASE AWARD SCHEME

for outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.

ICASE Distinguished Service Award

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

ICASE Regional Service Award

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels.

ICASE Association Award

This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association.

Contact Dr Jack Holbrook, Executive Secretary ICASE
Department of Curriculum Studies, University of Hong Kong, Hong Kong
unfamiliar with the older, alternative models, the growth and development of science and scientific methodology and the nature of scientific advance. The CXC/USAID Secondary Curriculum Development project was the source of a useful booklet for teachers, "History of Physics" (Stahl, 1983); other sources of information are available but the attitude of teachers appears to remain largely negative. The teachers seem to need greater support to develop ways of utilising the historical material to help improve their students' conceptual understanding. Strategies might be outlined in which the material could help to provide a context within which students could debate the pros and cons of alternative ideas. In the case of the Aristotle/Newton paradigm shift most of the better arguments on the Newtonian side are far from direct observation and involve the extension of ideas and experimental results to a non-observable limit - as Galileo did when imagining situations with no friction. Further, the historical development of concepts may even help teachers to predict students' preconceptions and thus be better able to take the students' ideas into account while teaching - see, for example, Wandersee (1985).

Conclusion
In this article the development of the Caribbean Examinations Council physics syllabus has been outlined and the introduction of historical material noted. A variety of possible reasons for this inclusion have been mentioned. It has been suggested that parallels between student ideas and previously accepted models may advise the use of the historical material to help students clarify and change their own beliefs. The resistance of Caribbean physics teachers to the introduction of this material has been mentioned and it has been suggested that the teachers need greater support in order to better utilise the new material.

The National Commission on Education in its NATION AT RISK report of the early 1980s, served to alarm the United States that its public education system was in trouble. Since the advent of that report, over 250 additional national reports have been issued sounding similar concerns and recommendations to improve the educational system in the United States.

As a result, the United States has committed itself to making the 1990s the ‘education decade’. If improvement of education in the nation is to be effective, it must take place at the ‘grassroots’ level of operation - the classrooms of its schools. It must touch every child to impact on the future of the country. One area of focus on this complex and difficult issue is the need to improve the science education learning experience for its students. Student learning must go beyond the reading about science. It must include the doing of science, its processes and its relevance. By the year 2000, 85% of the available science and technology jobs in the country will need to be filled by women and minorities. Additional sectors of industry report similar shortages and concerns. Business and industry want graduates to: communicate, think and problem solve, negotiate and work within a team, read, write and compute. It has been seen as a time to move beyond the rhetoric of the reforms - the reports of the 1980s.

One school district of 5000 students saw and chose to address this need directly. The Glastonbury Public Schools district in Glastonbury, Connecticut, USA responded by developing several mentorship programs with local businesses and industries. The programs are a novel and exciting way for the business and industrial communities to become involved with students in grades 7-12. As part of their mentorship course work, students are exposed to real work experience programs in a variety of science/technology oriented businesses and industries. It is an opportunity for members of the working community in partnership with schools to help influence a student’s life in an exciting and highly motivating way. It is this component of the program which provides a high level of relevance to the subject being studied and the world of work in general. The program fosters career development, interpersonal skills, written and communication skills and knowledge-based growth.

How it all started
In a technological and information oriented climate, the influence of science is all encompassing. There was a definite need for students, especially those in science classes, to learn not only what scientists do, but also how they think. Having an opportunity to engage in a research project under the tutelage of a working scientist and/or technologist would provide a unique learning experience for students. The necessity to encourage students to commit themselves to scientific/technological careers and to provide them with opportunities to experience practical applications related to their classroom studies was also paramount. Finally, there was a need for a program which would help them to develop an enhanced sense of responsibility, build a positive work ethic and gain skill in adult interactions in a work based situation.

Given these needs, the Glastonbury mentorship model was initiated by a science teacher and a K-12 science supervisor, with the support of the high school principal. The science teacher and supervisor developed the basic mentorship model. The mechanics of the program were worked out by formulating a rationale and considering schedules, sites, transportation and credit, as well as responsibilities of students, the faculty advisor and the mentor.

The Mentorship Program
In 1988-89, the program was piloted for one semester. Twelve 11th and 12th grade students in a high achievement level biological science course participated in the project. They received classroom instruction in the principles of biological science and research until the middle of October. From mid October until mid December, a total of about seven weeks, the mentorship component of the course was implemented. During that period, on an average of two afternoons per week, students continued to receive in-school instruction for periods of 50 minutes per class. Three additional afternoons during the week, students left school at 11.30 am and went to their mentor establishment. There, they worked on-site for a minimum of 100 minutes per session. Since the class was scheduled during the last two periods of the day, hours away from school did not cause time to be lost from other courses. Also, this scheduling allowed for greater flexibility if there was a desire on the part of a student and his/her designated mentor to extend the on-site hours.

Prior to September, the teacher and supervisor secured the involvement of business and industry mentors for the program. Personal contacts known to the teacher and supervisor, telephone calls to individuals actively involved in
research activities, mentor recommendations involving other colleagues, student contacts and general referrals made by personnel officers were successful in developing a pool of opportunity for students. Once school began, the teacher/advisor worked with the students in the program to select appropriate research projects and methods. Students were paired with mentors based upon interest and need relative to their research projects. The mentor and teacher jointly planned and implemented a program for the student. The research mentor then worked with the student to help guide the development of the project. The teacher/advisor interacted with the sponsoring business or industry on a regular basis to monitor student progress and evaluate results. Professional release time was scheduled for the teacher to visit mentors at the job site.

Implementation of the Program

Once the student selected a project, the mentor was contacted and background references and readings were assigned. It was important that each project be within the capability of a novice scientist, but that it contain sufficient challenge so that the student would experience the real flavour of a research environment. Two approaches were tried and they were equally successful. Some students were incorporated into an on-going investigation which had one or more components that could be completed within a reasonable time and which would yield some definable result(s). Others selected self-contained studies in which specific objectives could be chosen. The common denominator in each mode was the opportunity to work independently, after proper instruction and supervision, so that the students acquired both the skill for good lab technique, as well as the confidence that the results obtained were reliable and accurate.

An example of a project in which a student participated in an on-going investigation was an analysis of the amount of a foreign metal ion incorporated into a respiratory protein before and after removal of the native metal from the active site. A self-contained project which students completed was an analysis of the mineral content of over-the-counter vitamin and mineral supplements to check for label accuracy and brand reliability.

The initial training sessions were the most labor intensive, requiring one-on-one discussion, examples and tracking of the steps leading to good experimental technique. None of

9
the students in the program had any prior exposure to a business or industrial research lab and each evidenced the timidity of entering a new and somewhat overwhelming arena. One approach that helped to reduce this anxiety was to provide students with their own (small) desk space, a place where they could go to write up results, read references, plan the next series of experiments and keep notebook and papers. The transition to an operating laboratory was made quickly because these students were not only bright, but also very enthusiastic about undertaking this experience.

Upon completion of the projects, the students wrote a research report submitted to both the mentor and the high school science teacher. Each then rated the student’s performance and the teacher assigned a grade. In addition, students were required to prepare and deliver a 15-20 minute presentation to their classmates which described the nature of their research experience.

An important component of the program was to let students see first hand that what is taught as supported fact is often based on imperfect and, in some cases, imprecise data. The primary function of the mentor was to ensure that the transition from class/lab mentality to a research environment was seen by the students as the next logical step in their science education. In our experience, the main reason why this partnership works is because of the time commitment made by the mentor. This time commitment is necessary to train the students in the methodologies they will use in their studies. It is important that they be well versed in the instrumentation used for their study and be encouraged to have confidence in their results.

Assessment and Outcomes

Upon completion of the course, different evaluation instruments were distributed to students and mentors. A series of questions and value judgements were asked and they were ranked on a Likert scale. In addition, an opportunity for comments about the operation of the program was provided at the end. The outcomes were stellar. Both mentors and students were enthusiastically supportive of the program and their only regret was that there wasn’t more time available for it. With this in mind, the Board of Education decided to increase the Biological Science Mentorship to a full year beginning in September 1989.

The Biological Sciences Mentorship is now in its third year. There continues to be a high level of enthusiasm and support for it among the mentors, students and in the community at large.

The mentorship program provides students with opportunities to apply and build upon their knowledge and skills secured in the formal academic setting of the classroom. It also allows them to explore working with adults and to develop adult role models. It truly is an opportunity for committed partners in business and industry to help influence a student’s life with particular attention to career development, work ethics and adult interaction. Research rookies are key to turning national report rhetoric into effective education.

Program Expansion

Given the success of the program in meeting its goals, the program has been expanded. A second course was developed in an alternating year schedule with the RESEARCH MENTORSHIPS IN THE BIOLOGICAL SCIENCE course. The new course titled RESEARCH MENTORSHIPS IN THE PHYSICAL/ EARTH SPACE SCIENCES course has offered additional research opportunities.

At the middle school level (grades 7 & 8), motivated students may elect to attend a semester research course one to two days a week after school in addition to their regular science class. Beside the classroom time, for two or more hours a week, the students work with mentors from the business/research community. The research projects are smaller in scope compared to the high school level but they allow the students initial exploratory research with professionals in the field.

In grades nine and ten, a seminar course has been developed. Students meet at the school in a seminar format with mentors from business and industry to focus on the components of a project as a process. Scientific process skills are an integral part of their area of study.

Conclusion

In their three years of operation, the 7-12 mentorship programs have provided the school district with over US$1,000,000 of in-kind consultant time. More importantly, students are gaining a new insight into what doing science is all about and who the people are that make it happen.

Additional information on the program is available by contacting Dr Ken Roy or Mrs Elizabeth Shamroth, c/o Glastonbury Public Schools, Glastonbury CT 06033, USA.

ISY
International Space Year
1992

500 years ago, Christopher Columbus sailed three small craft – the Nina, the Pinta and the Santa Maria – across the blue Atlantic Ocean of our planet to discover a new world. 35 years ago, Russian technologists suprised the world by launching Sputnik into the heavens beyond this Earth's atmosphere.

ISY, in a unique display of international collaboration, celebrates these historic achievements and initiates new ones. It promotes worldwide cooperation in space, addressing environmental issues of global concern, and increasing awareness of the economic benefits of space science and technology.

ICASE and ISY

The ICASE contribution to ISY is through two international projects:

Resource Materials for Science Teachers

Dr David Moore, ISY Project Officer for ICASE, is coordinating the production of a set of resource materials for teachers, in collaboration with the ICSU Committee on Teaching of Science. For further information, contact:

Dr David Moore

ICASE World Activity Day

Thursday 14 October 92
Theme for 1992: Space

Teachers and students in schools around the world are invited to participate in special activities focusing on the theme of space. Thursday 14 October 1992 is designated as ICASE World Activity Day. Member associations of ICASE are requested to encourage schools in their countries to share in this worldwide program on 14 October. The activities, which can be adapted to suit students at all primary and secondary levels, include: (1) Designing, constructing and testing rockets which operate on compressed air and water; (2) Calculating the Earth's diameter by measuring the length of the shadow cast by a stick; and (3) Writing a short essay (maximum 1000 words) on (a) space travel in the year 2092 or (b) life as a student in 2092 as a result of space technology.

See this issue for an outline of these activities. For further information, contact: Brenton Honeyman, ICASE Journal Editor, 10 Hawken Street, Monash ACT 2904, Australia.
Report on the Sixth International Symposium of IOSTE

by Joan Solomon, Oxford University Department of Educational Studies

This article is reprinted from The British Council's Science Education Newsletter 100, January 1992.

IOSTE (the International Organisation of Science and Technology Education) is a non-bureaucratic association of individuals from many countries who are interested in promoting science and technology education. It runs international symposia, and keeps its members in contact through occasional newsletters.

The venue for the sixth symposium in August 1991 was Palm Springs, USA. There were some 200 participants from 25 countries. The ideas we hatched will be quite enough to keep us busy in our separate countries until the 1994 symposium in Einthoven, Holland.

It would be impossible to describe all 30 sessions in the space of this article. I shall concentrate on four talks I found the most inspiring, important and imaginative innovations for science education.

The first talk was by Basil Jones and Adrian Kohler, two young men who were travelling through the USA gathering ideas for their television project which will use glove puppet characters to teach primary science concepts in black community townships of South Africa. They told us that although only 27% of homes have television, each set is watched by many children. They plan a series in which topics such as light and forces are explored by a group of children (four black and two white), without a teacher, all of whom have characters and different misconceptions. The idea of using cartoon 'thought bubbles' to illustrate the operation and change in the children's ideas was inspired. There will also be simple investigations using non-laboratory equipment. The last 10 minutes of each program will be devoted to a guest star -- a local sports hero or a scientist -- who will set a problem for the viewers to think about. The solution will be given at the beginning of the next program.

The second talk was quite different. It was concerned with teachers rather than directly with students, concentrating on finding good strategies for new technology in the classroom, and was presented by Maria Saez of the University of Valladolid, Spain. The question that this country faces, like many others, is how to get the maximum advantage out of the very limited numbers of computers and video players available for science lessons.

The research was carried out in an appropriate and interesting way, not by university lecturers but by teams of practising teachers carrying out the new strategies in their classrooms. The two lecturers were there to encourage the team of teachers, help them to develop research skills, and to organise and analyse the data produced so that it could lead to a holistic understanding of the teaching/learning process.

Finally, and perhaps most importantly, they supported the teachers in a kind of auto-evaluation of their experiences. While researchers in richer countries often bemoan the non-implementation of their research, this kind of investigation-on-the-job can and does lead to changes in lesson strategies brought about by the teacher-researchers as they explore and evaluate their work.

The third session was also extremely interesting; it was given by two Brazilian educators. At first I sat quietly listening, with only half a dozen others (the session was timetabled against a far more popular session by a Western educator), to the account of a well designed program of environmental and health education which probed children's notions of health, developed INSET courses for teachers, created new instructional materials, and encouraged children to use hygienic practices in order to lessen the likelihood of catching parasitic diseases.

These diseases include schistosomiasis, an infection of the liver that is endemic in some parts of the world, affecting between 8 and 10 million people in Brazil alone. Almost without being aware of the transition I found myself listening to a story of how this young associate researcher from Rio de Janeiro, Virginia Schall, had discovered a plant, Euphorbia splendens, whose latex is toxic to just those snails that carry the parasite. It seems that one part per billion of the active ingredient is lethal to the snails. This is a most
Physics Teaching: A Publication of the Chinese Physical Society

by Prof Mi Zihong
Department of Physics, East China Normal University, Shanghai 200062, China

Physics Teaching is one of the periodicals published by the Chinese Physical Society. Its Editorial Board consists of thirty four experienced university professors and high school teachers across the country. In addition, there is a Correspondent Team consisting of seventy eight government education officials in provinces and cities throughout the country. The journal is published monthly in Chinese, but with English subjects. An English version is now being published.

The Journal has a history of more than thirty years; the current name Physics Teaching was adopted in 1978. As a monthly periodical, the Journal aims to reform physics teaching, to exchange teaching experiences, to report new important discoveries in physics, and to introduce what is happening in physics education in foreign countries. Special columns include Teaching Research, Teaching Abroad, Questions Assigned and Solved, Physics Window, Teaching Jottings, Experiment Sidelights, Teaching Material, and Physics in Daily Life.

The Journal’s readers (and authors) are physics instructors and students in universities and in senior and junior middle schools. Libraries in most schools subscribe to newspapers and periodicals, hence, assuming that there is an average of 100 readers in each school, the number of people reading the Journal may be more than 4 million!

In order to promote countrywide research in senior and junior middle school physics and to strengthen teaching through exchange of experience, the Journal has convened occasional conferences. These have included the National Conference for Special Classification Teachers of Middle School Physics; the National Conference on Micro-Computer Aided Physics Teaching; the National Conference on Educational Theory and Practice; and Seminars on Natural Science Teaching in Shanghai and Hong Kong.

The Journal jointly publishes physics books such as Eight Lectures on Senior Middle School Physics and International Physics Olympiads which have proven to exert considerable influence in China.

Towards a European Curriculum: Implications for Science Education

A Report on the 1991 ASE Assessment Seminar

by Drs Jan Hendriks
European Representative
ICASE
The Netherlands

Approximately 80 delegates participated in the 1991 Assessment Seminar of the Association for Science Education, held in November 1991 at the University of York, UK.

The first of these events in 1988 aimed at promoting discussion of significant trends and issues in assessment, involving an invited delegation drawn from a variety of backgrounds and with varying experiences and perspectives. The 1991 seminar focused on looking forward in the European context.

In the European Community, there will be open migration; all certificates and examination results will need to be acceptable to all EC countries. Hence it is critical to exchange information about the educational situation between countries.

The ASE invited four representatives from the continent to describe the educational systems of their countries, and the Headmaster of the European School in Culham, Prof Hans Vonk, Free University in Amsterdam, spoke about what was happening at primary and secondary levels up to tertiary level admission in The Netherlands. Ms Nicole Herman, Lycée Roosevelt, Reims, shared interesting developments in primary and secondary education in France. Mr Jan Thorsten from the University of Oslo spoke about the situation in Norway. Prof Hans-Jurgen Schmidt from the University of Dortmund presented an overview of tertiary education in Germany. Mr T Hoyem, Headmaster of the European School in Culham, described the European School where pupils from different countries with various needs, meet each other in the one school.

Prof Jeff Thompson from the University of Bath, UK presented a
summary of the Seminar. One conclusion of the lectures and discussions was that there are significant differences in curricula and examinations not just between countries but, as in the case of Germany, also within some countries. There is a case for a common core curriculum - but who should decide? Is there are role for ICASE in this?

Bob Fairbrother chaired the meeting, which was organised by Colette Baird, Assistant Secretary of ASE. The Association for Science Education is to be congratulated for convening this important Seminar.

National Science Policy Making Body in Cameroon
by Kiteh, Augustin
GHS Nkambe
North West Province
Cameroon, West Africa

According to Unesco (1966), the correlation between economic development and science and technology is so high that one definition of a less developed country is simply 'a country without science and technology'. Science and technology education can contribute directly to a country's primary health and nutritional care, effective population control, and development of human resources for agriculture and industrial activities (Unesco 1981). It is realised nowadays that science and technology has a profound influence on the 'change' component of development (Unesco 1986). Science and technology education, suitably designed, is an inseparable component of a country's development effort.

The main problem in Cameroon has been to identify practical ways in which to structure education for science and technology so that its contribution to sustainable development is maximised. The successful

The Second International Conference on the History and Philosophy of Science and Science Teaching

The Second International Conference on the History and Philosophy of Science and Science Teaching follows and builds on the very successful first conference, funded by the National Science Foundation. It was held at the Florida State University in Tallahassee, Florida, USA in November 1989, and attracted 300 people from 20 countries. The second conference, to be held at Queen's University in Kingston, Ontario, Canada during May 11-15, 1992 will host 400 science teachers (including elementary science teachers), science teacher educators, educational policy makers, scientists, and historians and philosophers of science from more than 20 countries.

This conference will provide the second opportunity for members of these professional groups to meet and collaborate in investigating ways in which the history and philosophy of science has, and can contribute to the preparation of science teachers, the development of curricula, the enhancement of science education, and the development of a more scientifically literate community by making science and technology more accessible and attractive to young people.

The first conference focused on science teaching in the high school. For the 1992 meeting, the focus has been broadened to include science in the elementary school. David Hawkins, well known for his work not only in the history and philosophy of science but also in the development of elementary science curriculum (he is a former Director of the Elementary Science Study ESS), is Honorary Conference Chairperson.

The themes of the second conference, designed to build on the achievements of the first, include:

- Science, Technology and Society
- Curriculum Reform and Teacher Education
- Science Education and the Environment
- Scientific Literacy
- Exemplary Practice in Science Education and Science Teacher Education
- Values and Science Education
- Women in Science

Conference sessions will also incorporate exemplary practice, lesson materials, curricula and research results from many different countries.

A number of distinguished writers have been asked to prepare papers exploring these themes, and to facilitate collaboration between participants in interdisciplinary groups.

In addition to the invited papers, a parallel program of contributed papers will enable science educators, historians of science and philosophers of science to contribute to the program.

To maximise involvement and discussion among participants, papers will be published in journals and proceedings, and distributed prior to the conference.

For information about other conferences refer to the section Calendar in this issue
exploitation and assimilation of scientific and technical developments can only proceed with the support of interested and informed politicians and administrators in the Ministry of National Education in Cameroon. The responsibility for fostering this interest should rest with the Ministry of National Education.

It is critical that administrators within the Ministry of National Education have some understanding of the role that science and technology can play; however many administrators are not scientifically literate, nor are they critically aware of science related issues. They lack sufficient understanding about science and technology education, and therefore are unable to take up effective action relating to it.

With this as background, Cameroon would benefit from the setting up of a national science and technology policy making body such as an association for science education. Such a body could formulate national policy for science and technology education relevant to defined sustainable development objectives. The body could act in a unifying role to direct the efforts of local teacher groups working towards curriculum solutions.

The economic, social and cultural situation in Cameroon will clearly impact upon the objectives and resources of such a policy making body. Science and technology will play an important role in the socio-economic development of the country; Cameroon needs a clearly defined national science and technology policy aimed at systematically integrating science and technology into the formulation of objectives of national development plans. A significant index of Cameroon’s technological development is the country’s ability to use local technological capacity to produce local science equipment needs (that is, in the tools and instruments used, and in how knowledge is applied to the production process). Educational technology needs to be developed in close collaboration with those who are to use it. It must be capable of being built and maintained in the Cameroon itself. Even simple and inexpensive equipment can be intellectually powerful.

The absence of a national science policy making body in Cameroon hinders the formulation of a coherent national scientific and technological development plan. Such a body need not operate in isolation, but could link with other organisations such as the Association for Science Education in the UK or the International Council of Associations for Science Education (ICASE). This would provide essential exchange of ideas and experiences; dissemination of information about new materials, resources and systems; and the opportunity for Cameroon to obtain assistance in developing a new approach to science and technology education.

Teacher Self Evaluation

by John Penick
Science Education Center
University of Iowa, USA

Without evaluation, we improve only randomly, a process which might as easily cause regression. In evaluating, we compare actual outcomes to predict, examine progress towards goals, or analyze appropriateness of action. All competent professionals self-evaluate while performing their tasks (formative evaluation) as well as after task completion (summative evaluation). Without formative evaluation, we have to wait until it's too late to see if our process is appropriate. Without summative evaluation, we never reflect back on quality or whether the task was even necessary. In addition, competent professionals must evaluate continuously. A brain surgeon can't just take a peek occasionally to see if all is as expected. Teachers are not different; as teachers, we must continually self-evaluate. What question should I ask next? How should (or did) I respond? How well do they understand? Why doesn't Johnny pay attention? Am I doing the right thing? Teachers, like all professionals, self-evaluate. In fact, many would say that serious self-evaluation is what differentiates a true professional from other occupations. As teachers, our ability to self-evaluate allows our teaching and effectiveness to evolve to its fullest. Without it, we are doomed to mediocrity or worse.

While all teachers evaluate their teaching to some extent, the very best teachers have learned to observe consciously their teaching systematically and compare those observations to what they would like to see. Some people call this 'comparing the desired state to the actual'. Call it what you will; before you can see something, you must know and remember to look for it. A checklist such as this makes it easier and more systematic.

The checklist at the end of the article is based on goals and ideas from teachers in Portugal, Taiwan, Singapore, Russia, Puerto Rico and the United States. It reflects their understanding of their role, their needs of their students and their knowledge about the research literature. Their typical interest in being professional prompted the final section on "My Professional Attitude". While you can use the checklist without much elaboration, for those of you interested I want to provide a brief rationale and some of the research support for each item. And, by reading this part, you will learn some of the subtleties of each item as well as potential consequences of use or non-use of each.

About My Teaching

Rather than evaluating teachers based on student scores, most educators feel that the teaching comes first. Some students learn better than we do and others do well to learn anything positive. No matter, you can still look at your teaching to see if what you are doing should lead toward your goals. Of course, this implies you have overt goals. For this checklist, the stated goals for students were that they:

- Identify and solve problems
- Be self-motivated
- Be confident and independent
- Communicate effectively
- Apply science and knowledge
- Know how to learn
- Be creative
- View science as a way of knowing

With these goals, looking at the research literature allows you to determine the key elements in achieving them. Obviously, if you aren't working toward these particular goals, this checklist may not be appropriate for you. If so, modify it to better reflect your own goals.

Have I maximized intellectual freedom?

Percy Bridgemen, a Nobel Laureate in Physics, said "Science is doing your damndest with your mind, no holds barred". Richard Feynman, another Nobel Laureate in Physics, said "Science is a belief in the ignorance of experts". They both recognised that science is a search for evidence, patterns, ideas, and explanations. For a student to feel free to do science, they must have intellectual freedom, something very different from social freedom. While students can't just come and go as they please, if they can't think freely they will not be learning science as it is known to scientists. Intellectual freedom is increased by:

1. Asking questions which require more than memorised answers

While memory is certainly important, few other than idiot savants earn their living by demonstrating their memory. Truly successful adults use their knowledge, demonstrating
understanding. A continuous series of questions guides the most successful, whether a golfer asking "How should I hit the Ball?" to a surgeon asking "What will happen if I cut here?" And, besides, science is the land of questions as well as answers. Answers in science are temporary, based on what we know today with today's technology. With new questions we will surely have new answers tomorrow. Why memorise yesterday's information when tomorrow is just a few hours away?

2. Waiting sufficient time for responses

Consistently, research has informed us that teachers often wait only a second or two after asking a question before they answer it themselves, rephrase it, or direct it to another student. What kind of answer can a student formulate in two seconds? How long does it take to make up an answer for "How would you find out which coat insulates best?" Would you go out for a coffee a second time with an adult who asked YOU questions and waited only a second for a response? In addition, that same research indicates teachers actually give more time to the brightest students and the least time to the slow ones!

3. Seeking multiple response from students

With creativity as one goal and the tentative nature of science in mind, we always seek to get a variety of answers. This reduces the risk for students and increases the possibility that a given student will get to respond. At the same time, the slower students have more time to think of answers and all get to build on prior ideas. And, ideas are what we thrive on in science classes where intellectual freedom is the norm.

4. Accepting (rather than evaluating) responses

Research on thinking is clear; if you want students to produce a variety of responses you must not evaluate ideas as they are produced. First, ask a good question then wait. If you accept student responses by nodding, saying "OK", "alright", writing the response on the board, or in some other way indicating you have heard and accepted, more wait-time will prod other students into saying more. A very active teacher, one who stimulates students to think, will find that the combination of the right stimulus idea or question, good wait-time, and acceptance usually produces ten or more ideas. The Evaluation section (below) offers some ideas on how to appropriately judge the worth of the numerous responses.

5. Using student ideas in questions and statements

When someone used your idea they encourage you to do more. A teacher's use of your idea goes even further, giving legitimacy to both you and your thoughts. You can use student ideas by writing them on the board, asking a question about the idea ("OK, Lucas, if water could freeze at 75 degrees, what might happen to our cities?") or by asking the student to clarify ("Megan, what do you mean by 'synthesize'?"). This is exactly what we do in good adult conversation. Two adults conversing pick up the ideas of others and use them for the next statement. Most statements are linked and relate to each other. This is why we find good conversation stimulating and the time passes so quickly; our ideas are part of the conversation. We are both involved and necessary. Make student ideas a necessary part of the classroom conversation and they'll be more involved.

6. Evaluate responses based on consequences

Australia

Overseas: $12.50 for single poster (incl airmail)
Australia: $9.50 for single poster (incl postage)
Send cheques or money orders to 'Atomic Art' at the address above. Bulk order enquiries welcome.

Ideas are rarely inherently right or wrong. The true evaluation of an idea lies in its usefulness. If a student suggests making a better clay boat by mixing water with the clay, it’s easy for the teacher to save the student time by saying “Water will make the clay soft, it won’t work as well”. When the teacher evaluates for them, students lose all opportunity to evaluate for themselves and may well become dependent on the teacher. And, equally important, you, the teacher, may be wrong. How do you know the student is not on to something? Remember, “Science is a belief in the ignorance of experts.” Let the student try and see the consequence of his idea. This is a true evaluation.

If you have asked for ways to improve the city water treatment plant and make it look better, and the students have generated a long list (probably including “paint it purple”, “have snakes all around”, and “put a heavy metal rock group on the roof”) evaluation can also come from the students. An effective technique is to have students, in small groups, select five or six ideas that seem best or most possible right now. This usually eliminates the ‘fun’ responses. Now, you can have various small groups compare their lists, seeking to reconcile their differences. You can also ask them to rank order their ideas. From here, it’s a natural step to have them plan to bring about the changes. To be successful both students and teacher must learn to self-evaluate.

7. Have high expectations for all students
Research, over and over again, indicates a subtle pattern of classroom bias. Teachers give more encouragement, smiles, nods, time, and expect more of students perceived as being of high ability. Boys are rewarded for how well things work while girls are rewarded for how they look. High ability students get praise for academic efforts while those of low ability get praise for other activities. While it’s true that high ability students do usually perform better, evidence indicates students are aware of your expectations. This doesn’t mean you should have unrealistic expectations; just make sure you communicate to students that you have high expectations for each and every one of them and for yourself.

8. Model the goals and behaviours you expect of your students
Have you ever watched children playing “school”. What kind of teacher do they play? Why are they always authoritarian teachers? Are they modelling themselves after you? Many studies demonstrate that students copy their teachers’ behaviour. We even see this with our own children. If you want students to ask good, thought-provoking questions, then you must do the same. So, you also need to be seen as inquisitive, open, accepting, and communicative, indicating that you are a learner also. A
coach does not have to be better than the player and you don't have to be the all-knowing, super competent science star. Instead, you must indicate interest, understanding, and a desire for success, while helping students analyze, question, reflect and proceed.

9. Be consistent
Your pattern of behaviours tells much about you and a consistent pattern allows students to be more comfortable with you. They know what to expect. And, since students do pay attention to you, your pattern will become a model for students. For example, if you consistently approach new situations with questions, experiments, and a variety of ideas, your students will do the same. Research even indicates that teachers who dominate students have students who act domineering. What kind do you want to live with?

Are students doing science?
"Doing science" means far more than watching a demonstration, listening to a lecture, seeing a film, or even doing an activity. Learning requires action and the action must be both physical and mental. During a demonstration, students are passive, watching and listening and maybe even thinking. But, the real science comes when they go beyond the demonstration, seeking explanations, working with the materials and doing it themselves, modifying the demonstration. Science is doing and thinking, not just watching and listening. Even when doing an activity, if they follow explicit directions or have limited equipment, students may be able to "do" without any real involvement. Effective teachers continually ask themselves "Right now, are my students doing science?"

Are students applying their knowledge?
"What is knowledge if not applied?" We know well that we learn best when we use as we learn. Would you fly with a pilot whose training consisted of a series of lectures and films on flying? Applying what you know also causes you to learn more as you find you lack certain information or ideas. In the 1986 United States National Assessment of Educational Progress in Science, students who scored the highest on the content items reported applying science more than did lower scoring students. Students apply sciences when they construct devices, plan experiments, or even when they seek information from others. The key is that they are learning, not for an exam, but to use knowledge.

My professional attitude
1. Do I belong to a science teacher professional organisation?
Although you might be an excellent teacher, professionals have added responsibility in improving their profession by communicating with peers. Novice teachers attend meetings hoping to gain new knowledge. Experienced teachers must be there to provide it. Professional organisations speak for members and must have broad input to be truly representative. New initiatives undertaken must be staffed by competent professionals. An outstanding teacher is a professional who takes professional responsibilities.

2. Do I read two or more professional journals each month?
Journals are a profession's way of communicating with members. If you don't read them, their messages die quickly. Journals are also an easy way to stay current on events, topics, and happenings. In a recent study of teachers in exemplary programs, Dr Ronald Bonnsette (who edits the Science Teacher Education section) found that they read an average of two professional journals each month.

3. Have I voluntarily attended recent meetings or inservice for science?
Dr Eddy Hidayat of Indonesia, in a study of the best and worst science teachers in a number of United States districts, found that the best were eleven times more likely to have attended a voluntary inservice during the prior year. Effective teachers attend inservice, not to be totally enlightened, but to glean a few new ideas or reinforce an old one or two. They know that not all will be great but that most have something to offer a creative and analytical teacher.

4. Do I present my ideas at such meetings?
As professionals we have obligations to communicate our ideas with colleagues. Bonnsette's study found that most teachers in exemplary programs had presented sessions at inservice meetings. And, since you know well that you learn more when you teach than do in taking a class, these are teachers who are learning it even better.

5. Have I published any of my ideas or findings?
Publishing, though not expected of teachers, is the hallmark of the scholar. Why shouldn't a teacher be a scholar? Plus, if you really have worthwhile ideas, shouldn't they be disseminated widely? Remember, a journal is the means of communication within an organisation. If you don't communicate then you are not taking a full role in your own profession.

6. Am I working on an advanced degree?
Even though degrees do not make competence, they are a mark of a learned person. To others, a graduate degree signifies that you care, expend effort, and know something. Since earning a graduate degree takes time and study, we can also assume you are dedicated and perhaps more current in your knowledge than someone without. And, truly exemplary teachers continue taking courses for credit, even if they finish the degree.

7. Do I audio or video tape and analyze myself regularly?
Yes, your administrator or colleagues can observe you. But, until you can self-evaluate, you are dependent on them. Unless you self-evaluate, you must wait for analysis until after they watch. But, a successful person evaluates continuously and continually. While audio tape may work, the best way is via video tape, observation, and very specific analysis. By watching for specific behaviours on the part of you and the students, you can learn that you, like all professionals, self-evaluate.

Some final thoughts
Can you imagine a serious and effective coach who did not analyse the game in progress and then, with the players, review the game later? If available, every coach would video
tape. And, rather than saying "Nice game!" or "Play harder, Lucas," coaches teach players to observe rather specifically and plan for the next time. "Lucas, what happens when you hold the ball like that?" Self-evaluation, done regularly and with serious deliberation, always leads to positive changes. To be truly effective, you must learn to observe clearly. Often, this means labelling certain behaviours and looking for nuance. You, like the good coach, should seek predictable and desired patterns of behaviour, trying out new ideas for improvement. Self-evaluation is more than a hearty, 

"I'm a good teacher!" Real self-evaluation is knowledgeable and based on evidence; "I'm a good teacher because I..." Using a checklist such as this one will give you that evidence and knowledge.

TEACHER SELF-EVALUATION

How Good Am I? Some Questions To Ask Myself

ABOUT MY TEACHING

Do I maximise intellectual freedom by:
• Asking questions which require more than memorised answers?
• Waiting sufficient time for responses?
• Seeking multiple responses from students?
• Accepting (rather than evaluating) responses?
• Do I use student ideas in my questions and statements?
• Do I evaluate student responses based on consequences?
• Are my expectations high for all students, regardless of gender or perceived ability?
• Do I model the goals and behaviours I expect of my students?
• Am I consistent in my behaviour?

ARE STUDENTS:

• Doing science?
• Discussing science with each other?
• Applying their knowledge?

MY PROFESSIONAL ATTITUDE

• Do I belong to science or math professional organisations?
• Do I read two or more professional journals each month?
• Have I voluntarily attended recent meetings or inservice devoted to math or science?
• Do I present my ideas at such meetings?
• Have I published any of my ideas or findings?
• Am I working on an advanced degree?
• Do I video tape and analyse myself regularly?
Reflective Writing to Enhance Communication and Learning

by Ronald J Bonnstetter

In recent years many preservice teacher preparation programs have increasingly requested students to write about their student teaching or practicum experiences. These daily logs, without guidelines, can be little more than a listing of happenings. However, with assistance, a journal can provide valuable insights for both the instructor and the student author. As instructors we are faced with increasing class sizes that make it progressively more difficult to maintain regular and personal communication with each student. A well designed journaling process can provide this one-on-one dialogue.

A Journaling Scheme

The following structured response guidelines are divided into three categories - Reaction, Relevance and Responsibility. This 3R Reaction scheme closely resembles Bloom's domains of learning taxonomy - the cognitive, the affective, and the psychomotor. The difference between the two nomenclature is that the 3R Reaction scheme deals with the reaction of the affective domain first, rather than the cognitive, as does Bloom. The rationale for the difference in placement is so the student can become aware of his or her affective response, and then deal with the cognitive merit of the learning regardless of the positive or negative affect associated with it.

When writing a 3R Reaction the following guidelines are suggested:

Reaction (Affective Domain, To Feel)

What was the reader's response (favourable, unfavourable, or mixed)? Give at least one example from the experience to support the point.

Relevance (Cognitive Domain, To Think)

How pertinent is the event to the issue at hand (the conceptual framework of the event)? The reader should be able to recognize and discuss how specific or important (meaningful) the event is to the course or issue and give at least one example from the reading to support the point.

Responsibility (Psychomotor Domain, To Do)

How will the knowledge gained from the event be used in the everyday life of the reader? Give at least one example of a possible application in your personal or professional life; simulate in behavior terms.

For the past three years I have collected student written logs each Monday. I have asked students to use the 3R Reaction scheme to help them become more reflective teachers. These entries vary in length from a half to two pages. By waiting until Monday the students are far more likely to include thoughts from Friday classes or student teaching and tend to be more reflective in their writing. The disadvantage of a Monday collection is that each journal must be read and written comments must be made by the instructor quickly.

STOP PRESS

New element discovered!

Following hard on the discovery of Administratium, announced in Vol 2 No 3 of Science Education International, comes news of another inert element – Unitednatium.

At first, because of the similarity in composition and structure, it was thought to be an isotope of Administratium. However, it has now been shown to be considerably heavier, with an atomic mass number estimated to be around 365. There is some doubt and the exact figure may even be 366; the matter is likely to be resolved in 1992.

The considerable gap in atomic mass between Administratium and Unitednatium is giving rise to speculation that there may be still other elements in the series. A well-known English lady politician and sometime chemist is rumoured to have identified one which has been tentatively named Eurocommissar by her friends.

Source: An anonymous ICASE Award Winner
so journals may be returned.

These written comments can be brief notes written in the margins or longer responses at the end of the student entry. Most instructors request that separate journal notebooks be maintained which contain no other material and that these future teachers plan to maintain their journals and revisit these written thoughts from time to time.

Without the 3R Reaction Scheme or some other form of guidance, many first time journal entries do little more than tell what happened. Instructor margin comments can be used to express the need for greater depth or elaboration. For example, "Yes, but how did this make you feel?" or "What would you do differently next time?"

If the instructor is serious about having students share feelings, then a non-threatening environment must be created. This simply means that the journal should not be used by the instructor to reprimand a student and written comments should not be dogmatic but suggestive. For example, instead of saying "You should have used grouping for this activity" suggest alternatives, "I wonder how grouping the students might have changed the outcomes?".

Journal grading must also be non-coercive if student openness is expected. Most literature suggests that instructors simply record the completion of journal entries and not make subjective and limiting judgements concerning entry quality.

This format has been particularly useful for the undergraduate preservice teachers who, for the most part, have never been asked to be reflective in their work. The 3R Reaction Scheme can also be used to add structure to article reviews; especially for those students who need help understanding the role of reflective writing. As is true of any teaching strategy, if over used its effectiveness diminishes.

---

**Pasteur and Microbes**

**A Teacher Resource Book**

**Commemorating**

the 100th Year of the Pasteur Institute

1888-1988

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute. It contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few.

These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation.

Order by sending a cheque (payable to "ICASE") US$8.00 or £5.00 (add 25% postage and packing) to:

**STEPS**

The Stepping into Science Newsletter

The ICASE Project Stepping into Science is growing! On 3rd January, the Come and Share Workshop at the ASE Annual Meeting held at Sheffield University, UK attracted lively participation by delegates keen to learn of new activities for primary and elementary classrooms.

The second issue of STEPS (February 1992) includes several ideas presented at the workshop. One of them – The Texas Turkey Gobbler – is reproduced here.

A second ICASE Come and Share Workshop will take place at next year’s ASE Annual Meeting to be held at Loughborough University. Plan now to not only attend, but to bring along an activity to share.

For further information, contact Sue Dale Tunnicliffe, Project Officer, ICASE Stepping into Science Project, 18 Octavia, Bracknell, Berkshire RG12 7YZ, UK

---

**TEXAS TURKEY GOBBLER**

*Based on the activity in STEPS*

The Newsletter of the Stepping into Science Project

**You will need:**
- paper cup
- toothpick
- paper towel 7.5 cm square
- thin string 45 cm long
- water

**What to do:**
Set up the items as shown in the diagram. Wet the paper towel.

What do you think will happen if you pull the paper towel along the string? Pull the paper towel along the string. What happens?

Some more for you to explore:
Try this activity using different types of string, different paper and plastic cups, and different types of paper instead of paper towel.
Does the paper towel have to be wet? Experiment to find out.

Moving on Air
Some Improvements

John Stringer, Project Director of SATIS 8-14, UK, has written to the Editor to suggest some improvements to the "Moving on Air" activity developed by the SATIS Project and published on page 30 of the September 1991 issue of this journal. The improvements he has suggested arose during the trialling of these activities.

The air track (pictured opposite) works better with a small piece of plasticene stuck to the ring to give it stability.

The hovercraft (pictured below) is more controllable if you stick a piece of tin foil across the hole in the wheel, and make a small pin hole in it. A clothes peg on the neck of the balloon acts as a brake until you are ready to start.

(Editor's Note: The activities opposite and below incorporate these suggestions.)

Moving on Air - The Air Track

From SATIS 8-14
Association for Science Education, UK

Make an air track with a plastic drink bottle, using a compass point or thumbtack to make holes as shown.

Make a 'vehicle' by cutting a plastic ring from another larger bottle. Make sure the ring has no ragged edges. Stick a small piece of plasticene on the bottom of the ring. This makes the vehicle more stable.

Moving on Air - The Balloon Hovercraft

From SATIS 8-14
Association for Science Education, UK

Make a model of a Balloon Hovercraft as shown in the opposite diagram.

The hovercraft is easier to control if you stick a piece of tin foil across the hole in the wheel, and make a small pin hole in it.

Blow up the balloon and see how it moves. A clothes peg on the neck of the balloon acts as a brake until you are ready to start.

Can you make your hovercraft bounce off things?

Can you improve on the design? Try making a hovercraft using different materials.

New Logo for Stepping into Science Project

Carolyn Petty of the USA, a member of the Stepping into Science Advisory Committee, has designed a new logo.

Activities Book

The Stepping into Science Project is planning to produce an Activities Book as a resource for primary/elementary teachers of science. If you have activities to contribute for publication in such a book, or in the Stepping into Science Newsletter, please forward to Sue Dale Tunnicliffe, 18 Octavia, Bracknell, Berkshire RG12 7YZ, UK.
Stepping into Science
An ICASE Primary/Elementary Science Project

AIMS

Stepping into Science is an ICASE project which aims to:

• Establish an international network for teachers to share ideas on the teaching of primary/elementary science and technology.
• Provide activities and support for teachers, thereby encouraging them to include more science in the primary/elementary curriculum.
• Promote the value of science experiences for young children throughout the world.
• Facilitate professional development opportunities for teachers by including sessions on primary science and technology in regional and international conferences.

ACTIVITIES

The Stepping into Science Team is actively involved in a number of projects and activities including:

• Publishing STEPS, the Stepping into Science Project Newsletter. This newsletter contains ideas for class activities at various levels in primary/elementary schools, activities for children to do at home, comments by network members on issues, examples of children’s work, lists of helpful resources and contacts. ICASE acknowledges the contribution of Philip Harris in sponsoring STEPS.
• Contributing articles and ideas for the Primary Science Section in Science Education International, the ICASE quarterly journal.
• Compiling ideas and activities for inclusion in a series of sourcebooks on the teaching of primary/elementary science and technology.
• Coordinating a scheme to encourage children to participate in science and technology activities. Certificates of Participation have been produced, and are available for schools to use in rewarding students as they complete a number of activities. Certificates are colour coded in seven different colours, so that they can be used to acknowledge progress in science from early to advanced levels within primary/elementary schools. ICASE is grateful to BP (Oman) for sponsoring this scheme.
• Organising Stepping into Science workshops and displays of children’s work at national, regional and international conferences.

Closing the Educational Gaps Between Science, Technology and Society

by Paul DeHart Hurd

This excerpt is from an article by the same title published in Theory into Practice, Volume XXX, Number 4, Autumn 1991. Paul DeHart Hurd is Professor Emeritus of Education at Stanford University, USA.

Throughout history and currently, school science courses have been organised and taught as mirror images of research disciplines found in universities, such as biology, chemistry, geology, and physics. Typically, learning goals include knowing the structure and basic principles of each discipline.

Students are expected to acquire the vocabulary and language scientists use to communicate with other researchers. Learning activities are designed to encourage students 'to think like a scientist' and to acquire the mathematical and observational skills essential for doing so. The primary goal of science teaching in the upper grades has traditionally been to prepare students for college and a career in science.

This mode of science teaching has been challenged throughout the history of public education in the United States. The alternative view is to consider achievements in science in terms of benefiting the common good and fostering the welfare of individuals.

Instructional goals are seen as developing an understanding of the natural world and the acquisition of intellectual skills for living and participating in a culture that is increasingly characterised by achievements in science and technology.

The central goal for an education in the sciences in the 1990s is perceived as enculturation or scientific literacy. Over the past 200 years, the debate on the social nature of science has ripened into an educational vision that brings science, technology, and society (STS) into a common discipline. The current reform movement in science teaching calls for instructional goals and a supporting curriculum taught in a social and personal context.

World Activity Day

14 October 92

Celebrating International Space Year in schools around the world

Teachers and students in schools around the world are invited to participate in the special activities on the following pages focusing on the theme of space. Member associations of ICASE are requested to encourage schools in their countries to share in this worldwide program on 14 October. The activities, which can be adapted to suit students at all primary and secondary levels, include:

1. Designing, constructing and testing rockets which operate on compressed air and water
2. Calculating the Earth's diameter by measuring the length of the shadow cast by a stick
3. Writing a short essay on (a) space travel in the year 2092 or (b) life as a student in 2092 as a result of space technology

See the following pages for an outline of these activities. Member associations are encouraged to reprint these pages in their own journals and newsletters to encourage schools to participate.
UP, UP AND AWAY
WITH BOTTLES!

An Activity for Students in Primary and Secondary Schools across the World

The age of rockets is very modern, but the science which explains how a rocket works was understood hundreds of years ago. Rockets burn fuels in a chamber shaped like a bottle with a neck pointing down. The burning fuel produces large amounts of gases expanded by heat. The gases are forced down through the neck at high speed, forcing the rocket up in the opposite direction. Isaac Newton first explained it in this way – if there is a force pushing in one direction, there is an equal force pushing in the opposite direction!

Drill a hole in the rubber stopper and insert the metal nozzle. Attach the nozzle to the pump. Quarter fill the PET bottle with water. Fit the rubber stopper and nozzle firmly into the neck of the bottle. Place the bottle upside down on a launch pad such as a cardboard carton with a hole to support the neck. Pump air into the bottle until the air pressure inside pushes the stopper out the bottom. The force of the water pushing down causes a force pushing the PET bottle up. As water is ejected, the bottle becomes lighter, and it accelerates!

This Water Rocket activity uses plastic bottles to give you hours of fun exploring this important scientific principle.

You will need:
- plastic P.E.T. bottle
- rubber stopper to firmly fit the neck of the bottle
- bicycle pump
- metal nozzle (as used in inflating basketballs, etc)

Acknowledgement

This activity is adapted from Up, Up and Away With Bottles developed by Questacon – The National Science and Technology Centre, Canberra, Australia and published in SPACELINKS, Australian Science Teachers Association 1992.
Measuring Altitude

Measure the height of the rocket by making a cardboard quadrant marked with angles from 0 to 90 degrees.

Kneel down 25 metres from the launch position. Sight along the bottom of the quadrant to the rocket.

As the rocket goes up, follow it with your forefinger along the curve of the quadrant. When it reaches its highest altitude, read the angle where your finger has stopped.

Use the table below to find out the altitude of the rocket.

<table>
<thead>
<tr>
<th>Angle (Degrees)</th>
<th>0</th>
<th>10</th>
<th>20</th>
<th>30</th>
<th>40</th>
<th>50</th>
<th>60</th>
<th>70</th>
<th>80</th>
</tr>
</thead>
<tbody>
<tr>
<td>Altitude (Metres)</td>
<td>0</td>
<td>4</td>
<td>9</td>
<td>14</td>
<td>21</td>
<td>30</td>
<td>43</td>
<td>69</td>
<td>142</td>
</tr>
</tbody>
</table>

Extra things to try

- Does the amount of water in the bottle affect the altitude of the water rocket? Design an experiment to find out. A quadrant may help you to measure altitude during your experiment. The above instructions will help you to make and use a quadrant.
- Design some fins for the PET bottle rocket. Do fins improve the flight of the rocket? If so, how?
- Try designing and making other water rockets.
MEASURING THE EARTH'S CIRCUMFERENCE

An Activity for Students in Secondary Schools across the World

Some history
Contrary to popular opinion, not everybody before Columbus believed that the Earth was flat. In fact, a remarkably accurate measurement of the Earth's circumference was made in the 3rd Century BC by Eratosthenes — an astronomer, historian, poet and director of the great library of Alexandria. He read in a papyrus manuscript that at midday on a certain day of the year at Syene (now Aswan) vertical sticks cast no shadow, and the reflection of the Sun could be seen in a deep well. He tried the experiment at Alexandria (at the mouth of the Nile) on the same day of the year and found that shadows were cast by vertical sticks.

He reasoned that the Earth was spherical and calculated its circumference as follows. The angle of the shortest shadow cast at Alexandria on that day was 7 degrees, which is about one fiftieth of a circle. He then measured the distance between Alexandria and Syene. Some say that he hired a man to pace out the distance. Others say that he used the time taken for a camel to undertake the journey. The distance was found to be 5000 stadia — kilometres were not yet in vogue — hence the circumference was calculated to be 50 x 5000 = 250,000 stadia or 46,300 km. This figure was only about 15% larger than the currently accepted value.

The measurement activity
Try this activity on World Activity Day, 14 October 92. Hopefully it will be a sunny day. You will need:

- straight rod (1 to 2 m) on a stand
- ruler
- plumb-line
- flat level surface open to sunshine during the day
- chalk or similar to mark the surface
- 3 m length of string

Early in the day (about 9 am) set up the rod on a flat level surface. Use a plumb-line to ensure that the rod is precisely vertical. Mark the position of the shadow end. Repeat marking points at half-hourly or hourly intervals as convenient. You may wish to mark points more frequently near solar noon. It does not matter if a few points are missed.

Acknowledgement
This activity is reproduced from Honeyman B & Burfitt H (eds) 1985 Australian Science in Schools Week Resource Book Australian Science Teachers Association

At the end of the day, draw a curved line through the points to trace the path of the shadow. Using a string of fixed length extended from the base of the rod, scribe two arcs that intersect the shadow path (see diagram). Use the string again to scribe the intersecting arcs from the two intersections on the shadow path. From this determine the length of the shortest shadow.

Measure the height of the rod above the surface and, using values of tangents, determine the angle of the sun at solar noon. What fraction of 360 degrees is this angle?

Determine the the distance between the point of your observation and that point on the Earth's surface where the sun is directly overhead at solar midday. This can be calculated as follows. The declination (d) of the sun on any day during the year can be found from:

\[ d = 23.45 \sin \left(360 \frac{284 + n}{365}\right) \]

where \( n \) is the day number of the year. Substitute the value of \( n \) for the date you carry out this activity. A negative value will indicate the line of latitude south of the equator where the Sun is directly overhead.

From a map, locate this latitude and determine the distance along the meridian between your position and that latitude. Use the same reasoning as Eratosthenes to calculate the circumference of the Earth.
WRITING A SHORT ESSAY
LIFESTYLE IN 2092

An Activity for Students in Primary and Secondary Schools across the World

Primary Category
Ages 5 to 8
Maximum 250 words
Write a short essay on space travel in the year 2092

Secondary Category
Ages 13 to 16
Maximum 750 words
Write a short essay on life as a student in 2092 as a result of space technology

Primary Category
Ages 9 to 12
Maximum 500 words
Write a short essay on space travel in the year 2092

Secondary Category
Ages 17 to 20
Maximum 1000 words
Write a short essay on life as a student in 2092 as a result of space technology

Forward essays, preferably typed on A4 pages, to the nearest ICASE Regional Representative below. Certificate prizes will be awarded to the 20 best entries in each region.

Resources for Teaching Chemistry

Compiled by Peter E Childs and Marie Walsh

The Schools Information Centre on the Irish Chemical Industry has produced this publication as a service to practising teachers of chemistry. The guide to resources, published in November 1990, includes information on materials available from industry as well as on resources available from commercial sources. Booklets, posters, videos, slides, and software are listed in this directory.

Resources available from Irish companies are supplemented by resources from the UK, USA and other overseas companies. A number of museums and interactive centres are also listed in this 104 page directory. The directory can be purchased from:

Schools Information Centre on the Irish Chemical Industry
University of Limerick
Plassey, Limerick
Ireland

at the following cost:
- Cost within Ireland/UK: £3.00 per copy including postage & packaging
- Cost in other countries: £4.00 per copy including postage & packaging

Report on Third Nordic Conference on Science and Technology Education

The report on this Conference, organised by the Centre for Science Education of the University of Oslo and held in Norway in August 1991, is now available. The theme of the Conference was Science Education and the Environment. The 200 page report contains papers on various aspects of environmental science education, including details of the Baltic Sea Project and plans for a North Sea Project. Available for £5 plus 30% postage from the ICASE Hon Treasurer, Knapp Hill, South Harting, Petersfield GU31 5LR, UK.

NEW ICASE PUBLICATION

Who's Who in Science Education Around the World
1991 Edition

Who's Who in Science Education Around the World

Published by ICASE
With assistance from UNESCO

1991 Edition

This new ICASE publication, published with the assistance of UNESCO, contains brief profiles on prominent science educators, their work, their projects and their interests. The valuable reference book includes key women and men in many countries throughout the world who are contributing to science education at primary, secondary or tertiary levels.

The information will help readers to contact colleagues in both developing and developed countries who may be working on projects of interest to them, who may be potential speakers at upcoming meetings or conventions, and who may be invited to work on collaborative projects.

Copies at a cost of US$15.00 or £9.00 or A$20.00 including postage can be ordered from the Editor:

Brenton Honeyman, Editor
10 Hawken Street, Monash, ACT 2904, Australia

or

Dr Jack Holbrook, Executive Secretary, ICASE
Dept of Curriculum Studies, University of Hong Kong
Hong Kong

Dennis Chisman, Honorary Treasurer, ICASE
Knapp Hill, South Harting, Petersfield GU31 5LR, UK

What role do museums play in promoting the public understanding of science? This book of discussion papers looks at the museum as an educational resource, as a medium of communication, and as a message. Contributors are drawn from museums, visitor centres, and universities in the UK, France, and North America.

Museums and the Public Understanding of Science, John Durant (ed), Science Museum in association with the Committee on the Public Understanding of Science, 1992, ISBN 0 901805 49 1, £9.95 (plus £1.28 p&p for mail orders within the UK). To be published March 1992. Copies of Science Museum books are available by mail order from Dillons at the Science Museum, Exhibition Road, London SW7 2DD (payment with order). If you want to know more about our list, please write to Victoria Smith at the Science Museum.

Science, Mathematics & Technology for All: Towards a Better Society

Proceedings of the Sixth ICASE Asian Symposium published by Brunei Association for Science Education

The Symposium, organised by the Brunei Association for Science Education and ICASE in association with the Ministry of Education, Brunei Darussalam, was held at the Universiti Brunei Darussalam, 4-10 December 1989.

The recently published proceedings (234 pages) contain full papers for the 3 plenary sessions, and 20 other sessions. Abstracts of all other presentations are also given (full papers can be obtained from BASE or the ICASE Secretariat).

The keynote presentation by Prof John K Gilbert (University of Reading, UK) addressed the topic Educating the Science and Mathematics Teachers for All, and focused on the change in the nature and provision of school-level science and mathematics education underway in many countries, and the implications for teacher education.

Other papers which are included in this proceedings are 'Science and Technology: Some Perspectives' by D J Daniels of Brunei; 'Science Centres as Non-formal Agents for Science, Technology and Mathematics Education for All' by Leo W H Tan of Singapore; 'Science for All' by Jack Holbrook of Hong Kong; 'Science Technology and Society: Implications for Better Decision Making' by Lucille C Gregorio of Thailand; 'Images of Science and Technology' by Doug Hill of Australia; 'Projects in Science Technology Education: The Setting up of a Computerised Information Exchange' by K Riquarts & H Waldow of Germany; 'Difference in Concepts between Urban and Rural Children of Bangladesh' by I A Muttaqui and A J Ara of Bangladesh; and 'Role Play in Science Education' by Asoka Weerasinghe of Sri Lanka.
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1992

March 26-29
NSTA National Convention
Location: Boston, MA, USA
International delegates are invited to participate in the International Round Table - one of the many features of this large convention. Each country is provided one or more tables in a large room where delegates can display and present information on science education in their country. Visitors move from table to table, talking with the various representatives. Contact: John E Penick, Professor and Coordinator, Science Education Center, The University of Iowa, Iowa City, Iowa 52242, USA.

March 26-28
Les Journees Informatique et Pedagogie des Science Physiques
Location: France
Contact: F M Blondel, Informatique et Enseignement, Institut National de Recherche Pedagogique, 91 rue Gabriel Peri, 92120 Montrouge, France
This meeting on Informatics and Pedagogics in Science is being organised by l'Union des Physiciens (UdP), the Association of Physics and Chemistry Teachers.

March 29 - April 10
Seminar on Science Teacher Education
Location: King's College London, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This British Council International Seminar will focus on secondary level teacher education, although some aspects will be of interest to those involved in primary science teaching. Six areas will be addressed: What is the nature of science education for schools?; To what extent should teacher education reflect and shape societies' values and cultural traditions?; How can we aid their professional development so that science teachers have the skills they need in the classroom and laboratory?; What can the results of research tell us about new ways to approach children's learning and classroom practice?; How is the work of pupils, teachers and trainees to be evaluated?; How does the structure of national and regional administration affect the management of teacher education? There are vacancies for 30 international participants - practising teacher trainers, advisers, inspectors, organisers of professional development programs and policy maker.

April 26-May 1
International Conference on Technology Education - INCOTE 92
Location: Weimar, Germany
Contact: Dr D Blandow, INCOTE 92, Pädagogische Hochschule, Nordhäuserstraße 63, 0-5063 Erfurt, Germany
This conference, organised in collaboration with a number of organisations including ICASE and INISTE, aims to bring education and industry together to consider the goals, methods and organisation of technology education; share practice aimed at developing technological literacy enabling all people to contribute to a modern society; discuss the value of technological approaches for delivering other learning and enhancing human capabilities, and to establish an umbrella organisation for networking information and contacts. The majority of participants will be from European countries, with a few key people from other regions of the world. The principal language of the symposium will be English.

May 11-15
Second International History Philosophy and Science Teaching Conference
Location: Queen's University, Kingston, Ontario, Canada
Contact: Prof Skip Hills, Faculty of Education, Queen's University, Kingston, Ontario, Canada K7L 3N6
This conference follows the very successful First International Conference on History, Philosophy and Science Teaching held at Florida State University in November 1989. All conference papers will be published in advance of the conference.

May 11-22
Seminar on Developments in Primary Science Education
Location: Liverpool, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
This British Council Seminar will examine major concerns and activities in primary science in the UK as well as their international context and implications. Major research and development projects in the area of science and technology relevant to the primary phase will be represented, including Learning in science, Research into children's ideas, Contexts of learning, Out of school learning, Curriculum development and evaluation, Pupil assessment, and Teacher education. There are vacancies for 35 participants, including science educators and curriculum developers concerned with the primary phase.
June 10-12
ICASE Research Seminar on Chemistry and Physics Education
Location: University of Dortmund, Germany
Contact: Prof Dr Hans-Jürgen Schmidt, University of Dortmund, Department of Chemistry, Otto-Hahn-Straße, 4600 Dortmund 50, Germany
This symposium on empirical research in chemistry and physics education will focus on the methodology of empirical research in this field. There will be approximately 12 presentations each followed by a discussion period. The language of the symposium will be English. Presenters will be asked to send their paper beforehand, ready for printing as Proceedings through ICASE. Although there will be no seminar fee, participants will need to cover their own expenses.

July 6-10
CONASTA 41
Location: University of Western Australia, Perth, Western Australia
Contact: Nic Soufolis, Convener CONASTA 41, Science Teachers Association of WA, PO Box 222, Claremont, WA 6010 Australia (Fax +61-9-385-1509)
The Australian Science Teachers Association invites you to participate in the forty first annual conference of the Association. The theme of Science and our Economic Future will be addressed from the viewpoints of government, scientific research, applied science and technology, the environment, industry and commerce, and education. Outstanding national and international educators, scientists and classroom practitioners will present keynote addresses and workshops, and a variety of excursions will be offered. A comprehensive display of resources useful to science teachers will be presented by publishers, booksellers, equipment and computing companies.

July 22 - August 5
34th London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK, Fax 071-835-1070
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments in London, Oxford, Cambridge and other centres in southern England. Accommodation in London University Halls of Residence together with all meals and a supporting social program are included in the participation fee of £650.

August 2-10
Eighth ICASE Asian Symposium
Location: Colombo, Sri Lanka
Contact: Mr Asoka Weerasinghe
Hon. Joint Secretary, SLASME, Institute of Computer Technology, PO Box 1490, Colombo, Sri Lanka
Science educators are invited to attend the eighth ICASE Asian Symposium and enjoy the natural beauty of the country and the hospitality of the Sri Lankans. The Symposium, organised jointly by ICASE and the Sri Lanka Association for Science and Mathematics Education (SLASME), will feature outstanding speakers from many countries who will address the theme "Science Education for a Changing World". The Symposium aims to identify some of the changes affecting our daily lives and to discuss ways by which science education can respond to these changes. Subthemes include (1) technology, (2) appropriate technology, (3) environment, and (4) scientific literacy. Participants will be able to experience the world famous pageant "The Kandy Perahera" in Sri Lanka. 100-150 science and mathematics educators from all parts of the world, and 200-250 local delegates are expected to participate in this event.

August 31 - September 3
SCICON Biennial Conference of NZSTA
Location: University of Waikato, Hamilton, New Zealand
Contact: Neal Utting, Education Advisory Service, 4 Hill Street, Hamilton, New Zealand
The theme of SCICON for 1992 will be Science - Technology . . . A Partnership . Information and registration forms about the biennial national conference of the New Zealand Science Teachers Association can be obtained from the contact above.

September 19-21
Second General Conference of Teachers
Location: Poland
Contact: SNPPiT, Skrypta Pocztowa 62, 85-791 Bydgoszcz 32, Poland
This second General Conference on the theme 'Education, Environmental Protection and Industry' is being organised by the Association of Science and Technology Teachers (SNPPiT), Poland. Languages used will be Polish and English.

December 17-21
Twelfth International Conference on Chemical Education
Location: Bangkok, Thailand
Contact: Dr Somjai Wichaidit, The Secretariat - 12th ICCE, c/o Research Centre, Faculty of Medicine, Ramathibodi Hospital, Rama 6 Road, Bangkok 10400, Thailand
The theme of the Twelfth International Conference on Chemical Education will be Chemistry in Transition and it is hoped that the participants will interpret this in many different ways. This biennial Conference, to be held for the first time in South East Asia, is organised by the Committee on Teaching of Chemistry of the International Union of Pure & Applied Chemistry, and The Chemical Society of Thailand in cooperation with UNESCO. It is attended by chemistry teachers at both high school and university levels who wish to improve their teaching and to learn from one another techniques and experiences. A second circular including instructions for submitting abstracts is available in March 1992 to those responding to the address above.
January
ASE Annual Meeting
Location: UK
Contact: Annual Meeting Secretary, ASE Headquaters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated in Education in Science, a journal of the Association for Science Education.

January 3-8
International Conference on Science Education in Developing Countries
Location: The Amos De-Shalit Israeli Science Teaching Center, Israel
Contact: Conference Secretariat, ORTRA Ltd, 2 Kaufman St, PO Box 50432, 61500 Tel-Aviv, Israel (conference arrangements) or Dr Avi Hofstein, Department of Science Teaching, The Weizmann Institute of Science, Rehovot 76100, Israel (academic correspondence)
This international conference on the theme "Science Education in Developing Countries: From Theory to Practice" will review past experiences and achievements in science education and plan for the 21st century with a special focus on developing countries. The conference will feature plenary lectures, symposia, poster sessions, workshops, exhibitions, informal discussions, social events and local visits. Topics for symposia and plenary lectures will focus on current research on learning and teaching and its implications for (1) the learner, (2) the teacher, (3) the classroom, and (4) the curriculum.

April 21-25
International Conference on Geoscience Education and Training
Location: University of Southampton, UK
Contact: Mrs Esther Johnson, GEOED Conference Secretariat, Department of Geology, University of Southampton, Southampton S09 5NH, UK
The Association of Geoscientists for International Development (AGID) and the Commission on Geoscience Education and Training (COGEOED) of the International Union of Geological Sciences are convening this international conference with the support of ICASE. Themes include: geoscience education in schools; higher education; geoscience training for business, industry and public service; and public understanding of geoscience. The conference is open to all those with an interest in geoscience education and training - including practitioners and those involved in administration, course development, and the supply of resource materials.

June 27 - July 3
VII Pacific Science Inter-Congress
Location: Okinawa Convention Center, Okinawa, Japan
Contact: VII Pacific Science Inter-Congress, c/o Section of International Affairs, University of the Ryukyus, 1-Senbaru, Nishihara, Okinawa, 903-01, Japan

ICASE ENDOWMENT FUND

Associations and individuals are invited to contribute to this fund to support the activities of ICASE

The Symposium will be organised around the theme The Pacific: Crossroads for Culture and Nature and subthemes (1) Cultural Interchange among Pacific Peoples; (2) Speciation, Dispersal and Conservation of Species in the Pacific; (3) Towards Appropriate Technologies and Policies for Development and for the Conservation of Natural Environments in the Pacific. Scientific sessions organised by the Scientific Committees of the Pacific Science Association focus on a range of science disciplines and issues, including Science Communication and Education.

July
Conference 93
Location: Paris, France
Contact: Dr Jack Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong.
This worldwide conference, organised by ICASE in conjunction with Unesco and other international bodies including ICSU Committee on Teaching of Science, is the second phase of the three phase Project 2000+ (refer to September 1991 issue for more details of this project). A number of international and regional conferences will generate input into Conference 93. The theme of the conference addresses the issue of Scientific and Technological Literacy for All. Sessions will establish agendas for future action. The majority of delegate places will be filled by invitation.

July 28 - August 11
London International Youth Science Forum

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Project 2000+
Request for articles and reports on scientific and technological literacy

By John E Penick
ICASE Special Projects Officer

As part of the ICASE/UNESCO Project 2000+, focusing on developing scientific and technological literacy, we are collecting articles and reports related to scientific and technological literacy. These papers will be compiled into an annotated bibliography as well as a summary and analysis and distributed to science educators throughout the world.

To do this compilation, I am requesting your help in obtaining copies of articles or other works, published and unpublished, relating to six aspects of scientific and technological literacy:

1. The need for scientific and technological literacy: a rationale for scientific and technological literacy; demystifying science and technology; life long science and technology literacy; research into scientific and technological literacy; case studies and exemplars
2. Scientific and technological literacy for development
3. The teaching and learning environment for scientific and technological literacy
4. Formal and informal development of scientific and technological literacy
5. Teacher education for scientific and technological literacy
6. Assessment and evaluation for scientific and technological literacy

Please forward editorials, research papers, desired goals and action, and descriptions of programs. These do not need to be in English but, if they are not, it would be useful to provide an English abstract.

Please search whatever local and regional literature you have available.

This section provides news for the information of member associations, institutions, centres, foundations and companies. The Executive Committee encourages members to reproduce this section in journals and newsletters to communicate this information to as many as possible.

Russian Association of Biology Teachers joins ICASE

ICASE welcomes the Russian Association of Biology Teachers (RABT) as a Full Member. Alexander I Nikishov, President of the Russian Association of Biology Teachers has provided the following information about this new association:

The Russian Association of Biology Teachers is a non-government organisation. It was founded in 1991 to unite biology teachers, as well as others who contribute to the development of secondary school biology education. Any citizen of Russia, or citizens of other countries who participate in the activities of the Association, can become a member.

The objectives of RABT are to:

- provide support and assistance to teachers of biology in their work
- improve and develop school biology education
- upgrade the skills of biology teachers
- research, support and disseminate advanced pedagogical methods
- assist in the organisation of school competitions in biology; identify gifted children and extend their interests in biology
- provide gratuitous aid to boarding schools for children disabled at birth, and to orphans, by supplying didactic and popular scientific materials

RABT takes an active part in the development of school biology education by preparing educational and methodological materials on biology. More than 1000 educators from Russia, Belorus, Ukraine, Azerbaijan, Georgia, Lithuania and other countries are members, and the Association is linking itself with foreign and international education organisations.

For further information write to:
Dr Vjacheslav M Dushenkov, Moscow Pedagogical State University, Department of Zoology and Ecology, Kibalchicha 6, Building 5, 129278 Moscow, Russia.

Photo: John E Penick, ICASE Special Projects Officer. Dr Penick is Professor and Head of the Science Education Center at The University of Iowa, Iowa City, USA. Prior to 1989, he was the North American Regional Representative for ICASE. Dr Penick is a member of the planning committee for the ICASE/UNESCO Project 2000+.
ICASE Membership Continues to Grow

Association de Professeurs des Science Quebec
ICASE welcomes Association de Professeurs des Science Quebec (APSQ), the long-established science teachers association in French speaking Quebec, Canada.

Longman International Education

Cambridge University Press
Cambridge University Press, The Edinburgh Building, Shaftesbury Road, Cambridge, CB2 2RU, UK joins ICASE as a Company Member.

Both these publishers are very involved in science education throughout the world, and ICASE is pleased to welcome them into membership.

AKZO N.V.
AKZO, an international chemical company based in the Netherlands, with products ranging from salt, fibres, coatings, health care products and general chemicals, has recently become a Company Member of ICASE. ICASE welcomes AKZO into membership. The correspondent is:

Mrs (Drs) S C M de Maat
AKZO N.V.
PO Box 9300
6800 SB Arnhem
The Netherlands

Come and Share
A great success at ASE Annual Meeting
Sheffield University, UK
January 1992

The ICASE Stepping into Science Project, led by Sue Dale Tunnicliffe, made quite an impact at the Come and Share Workshop held at the ASE Annual Meeting in January earlier this year. The photo below shows some of the participants engaged in the exciting activities shared at this popular session. Another Come and Share Workshop is being planned for the 1993 meeting - plan now to take part!
Project 2000+
Scientific and Technological Literacy for All

by Dr Jack B Holbrook
Executive Secretary, ICASE

What should we teach in science (and technology) classes?

If we consider the science to be taught at the primary and junior secondary levels (basically the compulsory years of schooling), what is its purpose? What is the role of science education taught in schools today? Why do we teach science?

We can dismiss the arguments because the topic is in the curriculum or to pass the examination as that really begs the question and is no educational answer. Change the curriculum or examination and we change the outlook.

Project 2000+ is being initiated to raise a concern worldwide and to draw attention to the goals of science education, through science and technology education, for a literate society in the 21st century.

A past goal that has strongly influenced science teaching, especially in the selection of curricula materials at the compulsory years of schooling, is the wish to turn students into little scientists. The plan has been to train students to do as scientists do, to think as scientists think, and to have attitudes pertaining to scientists. But this often has little to do with everyday life, even if we add examples of the scientific principles to the end of teaching topics.

You may care to reflect on whether we teach mathematics to turn students into mathematicians, or history to turn students into historians, or technology to turn students into technologists. I suspect your answer would be, not really. In fact very few students go on to be scientists and few nations want so many scientists that they wish to teach the subjects to thousands of students every year solely for this purpose. So why should behaving as little scientists be a major goal for science education?

Project 2000+ as part of general education is being initiated to examine the role science and technology education is expected to play in providing basic education in the 21st century at a time when technological change is occurring at a faster and faster pace, and when science data is accumulating faster than traditional libraries can cope.

An important viewpoint that forms a basic premise for Project 2000+ is that science education as a school discipline must have educational aims that relate to the society and to the individual. These aims should bring science education and technology education closer and closer together, so much so that it is more appropriate to express these aims for both science and technology education together. The following defines a scientifically/technologically literate person (NSTA, 1990-91) and forms an appropriate starting point for discussion and expansion:

- uses concepts of science and of technology as well as an informed reflection of ethical values in solving everyday problems and making responsible decisions in everyday life, including work and leisure
- engages in responsible personal and civic actions after weighing the possible consequences of alternative options
- defends decisions and actions using rational argument based on evidence
- engages in science and technology for the excitement and the explanations they provide
- displays curiosity about and appreciation of the natural and human-made world
- applies skepticism, careful methods, logical reasoning, and creativity in investigating the observable universe
- values scientific research and technological problem solving
- locates, collects, analyses, and evaluates sources of scientific and technological information and uses these sources in solving problems, making decisions, and taking actions
- distinguishes between scientific and technological evidence and personal opinion and between reliable and unreliable information
- remains open to new evidence and the tentativeness of scientific/technological knowledge
- recognises the strengths and limitations of science and technology for advancing human welfare
- analyses interactions among science, technology and society
- connects science and technology to other human endeavours (eg history, mathematics, the arts, and the humanities)
- considers the political, economic, moral and ethical aspects of science and technology as they relate to personal and global issues
- offers explanations of natural phenomena which may be tested for their validity

Are these the most appropriate goals for science and technology education in the future during the compulsory years of schooling? They appear to fit with the expressed goal of education suggested at the World Conference on Education for All (WCAFE, 1990), addressing the issue of basic education, which pointed out that education is more than an end in itself. It is the foundation for lifelong
learning and human development on which countries may build systematically further levels and types of education and training.'

PROJECT 2000+, which has been initiated by UNESCO and the International Council of Associations for Science Education (ICASE) to draw attention to the poor state of science and technology education at the compulsory level of schooling in many countries, both in the developed and the developing world, focuses on the scientific and technological dimensions of this basic education in the context of education for all and initiates debate on the appropriate goals for science and technology education for all for the 21st century.

The project recognises that the above objectives are of little practical use in putting forward curricula, in training educators or in expressing learning practice either in the classroom or in non-formal settings. But such factors form areas of focus for the project.

In PROJECT 2000+ attention is initially drawn to:

(a) The Meaning of Scientific Literacy, Technological Literacy, and their Interrelationship

This focuses on the need to examine the nature of science and its relationship to literacy, the nature of technology education, the interdependence of science education and technology education, the interdependence of science education and technology education and vice versa, and the misconceptions held about the meaning and provision of technology education.

(b) A Rationale for Scientific and Technological Literacy

Scientific and technological literacy are essential for all, because of the increasing impact of science and technology on people's lives, individually and in relation to societal, citizenship, career and quality of life issues in the community, the state, and on a global basis.

(c) Demystifying Science and Technology

To demystify science and technology, they must become accessible to all. Fears that these subjects are hard and remote must be overcome, preferably by initiating children into using and thinking about science and technology concepts and processes at an early age.

In summary, PROJECT 2000+

• recognizes the growing need for a more scientifically and technologically literate society;
• clearly identifies ways of promoting the development of scientific and technological literacy for all;
• puts forward educational programs (formal and non-formal) in such a way as to empower all to satisfy their basic needs and be productive in an increasingly technological society;
• provides guidelines for the continuous professional development of science and technology educators;
• supports the development of a wide range of projects that aim to improve quality of life and productivity in society and that lead to promoting solidarity and cooperation in achieving scientific and technological literacy for all.

Wanted!

Science Activities Around the World

Examples of simple, hands-on science activities especially those with a local, or regional flavour

ICASE is compiling a book of Science Activities Around the World
Make sure your activity
and your name as the person submitting it is included

Send materials to John E Penick
789 VAN ALLEN HALL, THE UNIVERSITY OF IOWA
IOWA CITY, IA 52242-1478, USA
ICASE has been greatly encouraged by the comments from individuals and Science Teacher Associations on the suitability of Project 2000+. ICASE is now forging ahead in partnership with UNESCO to make the project a reality and to lay concrete plans for an international forum to be held in Paris, July 1993. ICASE hopes many educators linked with Science Teacher Associations will be able to attend the forum, even though, in total, only 500 participants are possible. Already steps have been taken to seek funding to assist those STAs where money is a problem, although nothing is finalised at this stage.

Your interest in this project is now being sought, especially of persons who would like to be involved in participating in the international forum and in helping science teacher associations to be involved in national developments at Phase 3. Please write to the ICASE secretary, Dr Jack Holbrook. ICASE is keen to invite persons with international involvement and those involved with national (regional) Science Teacher Associations.

Initiating Project 2000+

Project 2000+, an initiative of ICASE in partnership with UNESCO, has two main operational parts:

1. A five day working forum to be held at UNESCO headquarters, Paris in July 1993 seeking definition, resolution, and action, and

2. A coordinated sequence of meetings, national working groups, task forces and political action aimed at enhancing basic science and technology education for all, throughout the world so as to improve scientific and technological literacy.

For Project 2000+ to be successful, UNESCO, ICASE and other organisations worldwide plan to mobilise support to give proper visibility to the project. This visibility is to be enhanced by:

- contacting interested partners who could contribute financially, technically and intellectually;
- jointly planning and describing roles of each partner and the activities which need to be carried out in various phases of Project 2000+;

Project 2000+ will also initiate actions such as:

- drafting statements of a political and professional nature for discussion in the international forum;
- initiating pilot projects designing and implementing specific programs of teacher enhancement, research, and curriculum development;
- designing an evaluation component of Project 2000+;
- drafting guidelines for designing, implementing, and evaluating curricula and projects in the post-forum phase;
- completing databases suitable for fast, easy access of relevant research and editorial materials as well as teaching material for scientific and technological literacy.

Prior to the forum, information, experiences, and example materials related to scientific and technological literacy will be collected. Everyone involved with the forum will be expected to assist with this. Including the data collecting aspect, there are thus essentially three phases to Project 2000+.

---

**ICASE AWARD SCHEME**

*for outstanding contributions to international science education*

**Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.**

**ICASE Distinguished Service Award**

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

**ICASE Regional Service Award**

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels.

**ICASE Association Award**

This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association.

Contact Dr Jack Holbrook, Executive Secretary ICASE

Department of Curriculum Studies, University of Hong Kong, Hong Kong
Phase 1 - Planning, Information Gathering, and Initiating Pilot Projects

During Phase 1, the proposals for Project 2000+ will be further developed, funding sought, and materials collected. Systematic searches of the literature will produce summary documents on various aspects of scientific and technological literacy, including definitions, appropriate classroom climate, assessment and so on.

Additional information will be collected relating to education reforms, exemplary materials and practices, and projects aimed at satisfying basic needs (environment, health, nutrition), improving productivity (agriculture), and meeting basic demands created locally by the presence of industries. Examples of materials related to good classroom practices, good teacher education methods and good assessment and evaluative techniques will also be collected. This will include non-written materials such as slides, videotapes, computer programs, tape recordings and toys and games.

Projects which are designed to contribute to scientific and technological literacy will be piloted and preparatory work will begin on designing and creating databases which will support both discussion in the forum and plans for the post-forum phase.

Project 2000+ will include provision for disseminating information related to focus areas of Project 2000+. To do so requires:

- identifying and compiling relevant articles and activities from around the world;
- obtaining and preparing outcomes from relevant meetings prior to the forum to be held in July 1993;
- initiating the preparation of databases to compile and access information relating to scientific and technological literacy as well as the institutions and networks promoting such literacy.

Phase 2 - Discussing the Issues and Putting Forward Outcomes

Phase 2 will be an International Forum, held at UNESCO headquarters, Paris, in July 1993, to discuss issues identified during Phase 1 with a view to:

- issuing statements to effect political visibility for science and technology education for all as a requirement for both individual and national development;
- providing a framework for major programs of action in science and technology education involving Governments, Inter-Governmental Organizations (IGOs) and Non-Governmental Organizations (NGOs such as Science and Technology Teacher Associations);
- developing guidelines for designing, implementing and evaluating projects in Phase 3

During the International Forum in July 1993, persons with an interest in scientific and technological literacy will discuss evidence and issues. The forum will be expected to examine ways of seeking the development of scientific and technological literacy for all, paying attention to formal and non-formal educational opportunities while considering six specific Focus Areas as outlined below:

1. The Nature of and the Need for Scientific and Technological Literacy

Scientific and technological literacy are basic to any education for the 21st century. Without such literacy, citizens will be poorly prepared for learning to cope with an increasingly technological environment and lifestyle and thus:

- the need for scientists, politicians and other key personnel to be scientifically and technologically literate as a basis for decision making to be able to participate meaningfully in science-related political issues;
- the need for people to be functional in an increasingly technological environment; 'operate' in relation to machines; develop appropriate societal behaviour for the benefit of the individual, society and the environment as a whole;

2. Scientific and Technological Literacy for Development

Areas for consideration include national social, environmental and economic development with particular respect to:

- personal development including human and ethical values;
- quality of life issues such as sustainable development strategies, the environment, energy, population, and health;
- economic development, opportunities for employment at local, regional and national levels.

This particularly applies to:

(a) Life-long Science and Technology Literacy

As science and technology develop, now and in the future, efforts have to be made to prepare and sustain science and technology literacy throughout life. Efforts to promote public understanding of science and technology, for example through the media, in the local community, must complement formal education systems.

(b) Research into Scientific and Technological Literacy

Serious research efforts must begin to investigate needed basic concepts, the knowledge base, processes, and skills related to scientific and technological literacy. Further research must consider teacher education, learning environments, and career-related issues.

(c) Case Studies and Examples of Scientific and Technological Literacy in various settings

Descriptions of existing literacy programs and activities will stimulate discussion, research, and action. Such examples are essential for developing modes for educational development.

3. The Teaching and Learning Environment for Scientific and Technological Literacy

The ultimate goal of scientific and technological literacy is an individual who feels comfortable with and capable of learning and using science and technology. In developing this literacy, teaching must focus on the individual. Such focus requires a carefully planned and created learning environment. This learning environment includes:

- the role of the learner
- the role of the teacher
• the curriculum, and
• the physical environment where the learning is to take place

The desired role of the learner must be compatible with the nature of science and scientific literacy and what is known about how people learn. To be useful, this role must be carefully described and documented quite specifically.

Once the role of the learner is specified, a careful search of the literature should reveal appropriate teacher behaviour and actions which should lead to learners performing as desired. At the same time, a number of teacher roles and behaviours not desired will be identified. Combining these with a thorough analysis should lead to appropriate teaching strategies for enhancing scientific and technological literacy.

Since learners interact with the teacher in a context and physical locale, these too, must be designed for compatibility with the ultimate goal, scientific and technological literacy.

(4) Teacher and Leadership Education for Scientific and Technological Literacy

The teacher and/or leader is a key figure in the learning environment. Hence, the teacher's and leader's own education must be carefully planned to optimise the learning environment. Teachers (and others directing an environment for developing scientific and technological literacy) must consider and control the learning environment and their own behaviours. If this is to occur, the personal education of teachers, leaders and directors must be equally well-considered and implemented. Such consideration will probably include:

• necessary background knowledge
• knowledge about teaching and learning
• appropriate attitude and commitment
• competence with appropriate teaching strategies
• ability to select, modify, and design curriculum

To achieve these, programs for educating leaders and educators must have specific components which lead to the capabilities desired.

(5) Assessment and Evaluation for Scientific and Technological Literacy

Whereas assessment is most commonly used in formal school classrooms there is a need to use evaluation as a tool for accountability in all scientific and technological literacy programs. Educators need to assess regularly and meaningfully the academic achievement of their pupils. But, equally important, teachers must devise methods for monitoring their own teaching programs and the system in which they carry out their profession.

There are many issues to focus on, but attention should be drawn to:

• the need for valid assessment and evaluation for all desired goals (attitudes, creativity, the nature of science, application of knowledge), not just knowledge of concepts, vocabulary, and processes;
• the role of assessment and evaluation;
• public acceptability of appropriate assessment and evaluation;
• how such assessments/evaluations can be identified and monitored in formal and non-formal situations;
• use of formative as well as summative evaluation strategies;
• self-evaluation for users of technology;
• mechanisms for collecting relevant data;
• the role of evaluation agencies.

Assessment and evaluation should provide usable information for improving the quality of life and measuring the needs of a flexible workforce which can be more effective if scientifically and technologically literate.

(6) Non-formal Development of Scientific and Technological Literacy

While formal schooling provides a major mechanism for enhancement of scientific and technological literacy, non-formal (museums; science centres; zoos; science clubs, fairs and camps) and informal (the media, science magazines, events, art, music) also provide significant avenues for development. In fact, for adults and out-of-school youth, these may play the major role. Knowing these, serious proposals must consider:

• identifying, supporting and publicising non-formal and informal mechanisms;
• the education of personnel for non-formal and informal efforts;
• linking schools with non-formal and informal institutions, events and mechanisms;
• evaluating the effectiveness of various non-formal and informal approaches.

There is a wide range of institutions and organisations involved in informal and non-formal education. These include national academies of science, associations for the advancement of science, and science teachers' professional associations as well as literacy adult education and distance education programs.

With these aspects considered, the role of non-formal and informal education is anticipated to improve and complement that found in the more formal school setting. Simultaneously, adult scientific and technological literacy would be enhanced. And, since both non-formal and informal mechanisms involve mixed age groups, learning will be better viewed as a family and life-long affair.

Approximately 500 participants will convene in Paris in July 6-11, 1993. These will include:

• about 100 key science and technology educators, invited on the basis of their ability to provide support material, to assist and guide discussions. They will also have a significant role in the production of phase 2 products;
• about 100 science and technology educators invited because of their institutional affiliations and interest in initiating phase 3 developments;
• government-sponsored high level officials, associated with EFA national programs, and interested in phase 3
developments;

• persons from the media who can give the project and its aims prominence around the world and thus assist the project to make an impact during phase 3;

• industrialists and technologists (both indigenous and advanced) who can guide career aspirations and provide guidance for scientific and technological literacy in areas such as risk assessment, health and safety at the workplace, creativity and attitudes and adaptability towards 'new' technologies.

All participants would be placed in one of the 6 focus areas. Each focus group will include a diverse selection of individuals, having a rational balance of world regions, women and men, EFA representatives, STAs, teacher educators, non-formal education groups and others.

Phase 3 - Action Phase

Phase 3 will follow the forum. Encouragement will be given to set up special task forces involving Governmental and Non-Governmental Organizations, linked with groups working in the field of education for all, to design and supervise the implementation of projects at the national level. The international community, also made up of IGOs and NGOs, would play a multi-faceted role, serving as catalyst and broker while providing technical and logistic support and funding.

The global aspects of Phase 3 are anticipated to be:

• an international secretariat

• task forces

• support groups

• international communication network

• international databases

Post-forum action will involve:

• convincing countries that scientific and technological literacy is important and that greater efforts are needed for more relevant teaching and non-formal education;

• recognising the need and finding ways to support a greater degree of non-Government input into supporting teachers and non-formal education.

Internationally, efforts will also be made to improve scientific and technological literacy and make the project more visible by:

• publishing a project 2000+ periodical;

• mentioning projects that have been up and running in a region (crucial here is the link between development-implementation and classroom practice);

• stimulating small, regional working conferences where the process and results of projects are discussed and reviewed (reports to be published in the newsletter);

• initiating more teacher in-service programs (international organisations can help by providing examples of guidelines, source reference materials and lists of contact addresses);

• making known internationally more information and evaluative data on projects trialled around the world by making use of task forces; providing support groups to assist, if needed, in the design of projects appropriate for a system on the scientific and technological needs in the region and/or the necessary training for local personnel;

• assisting in the trialling of materials in countries by providing expertise support if needed through support groups; assisting the evaluation of trials and more extensive studies by providing expertise if need through the support groups; using international task forces to obtain the information needed for databases in support of national developments.

The local part of Phase 3 will be the National Programs operating at the Governmental, the Non-Governmental level or at both levels. These programs will be planned locally, directed locally, implemented locally and evaluated locally. The global components of Phase 3 provide support to the local groups.

The National Program will be Governmental, Non-Governmental, or preferably both Governmental and Non-Governmental. These will depend on the country and the mode in which developments are feasible but could be:

• a new policy for science and technology education;

• new curricula, implementation strategies, resource materials, assessment techniques for supporting formal, informal and non-formal learning;

• promotion of the need for and the status of science and technology education within the community using the formal school sector, the media, and greater community involvement;

• encouraging 'think and act' for greater scientific and technological awareness and literacy;

• promoting the need for greater concern for science and technology and in understanding the 'trade-offs' (good for some, bad for others!).

ICASE plans to actively support Science Teacher Associations (as important national NGOs) in assisting such programs.

According to Leyden (1984), about 43 percent of high school graduates in the United States will go on to college. Similarly, in Indonesia, about 43 percent of high school graduates are admitted to higher education (Isman, 1985). But far fewer students complete high school in Indonesia; in 1983/84, only 25% of youth aged 16-18 were enrolled.

To improve education in Indonesia, a 1975 curriculum reform was supported by a series of in-service programs for teachers, administrators, school supervisors, and headmasters. The program was reported to involve more than 18,000 school personnel during the period 1976 to 1979. Further orientation programs for teachers were carried out by a 'cascade' method where the central office trained the regional instructors and the regional instructors conducted regional courses for the teachers. Eleven such regional centers were established.

Several additional steps have been carried out to introduce reforms in science education in Indonesia: (1) establishment of the free textbook program; (2) building of science laboratories and the provision of specialized equipment; (3) a new curriculum which stressed hands-on student activities; and (4) planning for more orientation courses to help administrators, supervisors, and teachers to become familiar with the aims of the science education reform.

Another reform in 1984, after the Minister of Education and Culture signed a decree (SK. No. 04861 U 1984) regarding the implementation of the '1984 Curriculum', established two Senior High School Programs, the Core Program and the Electives. The Core Program consists of 60% of the whole high school program and is worth 134 credit hours. Included is biology, 2 semesters, worth 6 credit hours, and 14 other courses (Dep. PDK, 1984). The Electives prepare students to pursue higher education and enter the career world. The Electives consist of 40% of the whole program or 88 credit hours. There are two kinds of Electives, the A program and the B program.

The A program serves the second goal of high school education, that is to prepare students to study in higher education, especially in the university/institute. There are five groups of studies in higher level learning, physical sciences (A-1 group), biological sciences (A-2), psycho-sociological sciences (A-3 group), and cultural sciences and religion (A-4 group). The biological sciences program, for example, prepares the students to study biological sciences in higher level learning, in areas like agriculture, fishery, animal husbandry, medicine, biology. The students in biological streams must complete 22 credit hours of biology in 4 semesters (4, 6, 7 and 5 credit hour each). The B programs prepare students who want to seek jobs after high school graduation or to enhance their skills in vocational work. Unfortunately, the implementation of the B programs has been postponed because there is still lack of school facilities to support these programs. The decision as to whether a student enters the A or B program in the third semester is based on the student's performance in core programs. After finishing the third semester, students can transfer to another program if they want to change.

Beginning in 1984, the Indonesian government decided to use a new system for selecting new university students (freshmen) at forty-five Indonesian public universities (state universities), including 'open university'. This system, SIPENMARU (Sistem PENERIMAAN MAHASWA baru) or UMPTN (Ujian Masuk Perguruan Tinggi Negeri) has two ways of selecting freshmen; one is by taking the SIPENMARU test or UMPTN test, and the other is without a test, by a so-called 'talent scouting method'.

Isman (1985), stated that the major trends and issues in Indonesian education recently include:

(1) universalization of primary education
(2) a well-balanced curriculum with regard to academic and personality development with relevance to societal and national needs
(3) introduction of more flexible programs
(4) continuing commitments to the eradication of illiteracy and the improvement of practical basic skills
(5) the provision of facilities for continuing education for care development and self fulfilment
(6) awareness of the necessity to improve the quality of education.

From Isman's statement we can infer that Indonesian education still lacks:

(1) universal primary education
(2) balance in the curriculum with regard to academic and personality development as well as relevance to societal and national needs
(3) flexible programs

It also implies that problems of illiteracy, facilities for continuing education, and awareness of the necessity to improve the quality of education still exist.

The Indonesian Minister for Research and Technology, Habibie, stated after struggling for ten years Indonesia has
succeeded in achieving high technology as mastered by the advanced countries (Caraka, 1986).

The goal of REPELITA (the Five-Year Development Plan) indicates that at the end of the sixth REPELITA by the end of the 20th century, Indonesia must be ready to start an industrial state. It implies that education relevant to meet the needs of that era should be provided.

The sixth of the five-year development plans, requires that Indonesia should have enough scientists, engineers, and other skillful personnel who have adequate knowledge in science and technology. But, the Improving the Efficiency of Educational Systems (IEES) Study in 1986 reported that manpower analysis evidence indicates that Indonesian labor has not yet reached the level of skill required for industrial expansion (IEES, 1986 p. 320). Indonesia's 12 year attempt to support an aeronautic industry (Caraka, 1986) has proven that Indonesia's manpower is reliable and ready. However, more and more experts and skillful personnel in science and technology will be needed as successors to those currently employed as well as for expansion. This requirement can only be fulfilled by early preparation through providing scientific and technological knowledge appropriate to solve the designated problems of the future.

To do this, Indonesian science education goals need expansion. Revising the existing curriculum becomes a must if the goals of science education are to be adjusted or achieved. The teaching approach should also be modified to meet the needs and appropriate assessments conducted to ensure the achievement of the new goals.

The sources of technology are moving rapidly, contrary to the Indonesian educational plan. For these reasons, it is reasonable to scrutinize the inadequacy of Indonesia's current science curriculum and develop a new set of goals and ideas.

Current Indonesian science textbooks required for precollege students contain little information on new technologies, even while some of these technologies are a part of students' daily lives. Changes in science and technology should be followed by Indonesian science educators to enable them to inform their students about the most current applications of knowledge.

The Indonesian secondary education is divided into two levels, the lower and upper secondary, along with another division, general and vocational stream. Each level consists of a three-year program of study, equivalent to grades 7-9 and grades 10-12.

Hidayat (1987) showed that there was a positive increment in the Indonesian students' positive perception toward science, career awareness, and the usefulness of science from elementary to senior high school. But it seems that this positive perception is not accompanied by a higher achievement in science courses at the precollege level. Professor Nasution, the former rector of Bogor Institute of Agriculture, stated that the quality of candidates who were entering Indonesia's public universities in 1988 were not better than those of the previous years (Binadja, 1988). Nasution is so concerned with the quality of science education graduates in Indonesia that he feels a special school needs to be provided for science students. Unfortunately, a study conducted by Susilo (1986) supported this statement. Her study indicated that the prerequisite knowledge of biology for science education graduates entering the university is lower than what is expected or needed. The lack of teachers' capabilities in teaching science could be one of the reasons for the low quality of science education graduates in Indonesia (Van den Berg & Lunetta, 1986). Some science teachers in secondary schools were graduated from Diploma Programs that take only one to three years to complete after senior high school. According to a UNESCO study (1986), Indonesia devoted 1.5 hours per week to science at grades 1-2, 2.2 at grades 3-6, and 3.2 at grades 7-9. In technology, Indonesia devoted 1.5 hours per week at grades 1-2, 3.0 at grades 3-6, but no data are available for grades 7-9. These values were at or below the average values for the world. The broadest goal of secondary education in the next decade must be to deliver to the nation a skilled pool of

manpower with the knowledge and competence to add a substantial new industrial base to the Indonesian economy.

The introduction of the Outline of Instructional Program for Lower Secondary School (GBPPIPASMP - Ind, 1986) stated that the goals and functions of science education are to enable students to:

(1) master scientific concepts and their interrelationships
(2) utilize scientific methods which are supported by scientific attitudes, to solve problems students face in order to realize the dignity and the power of the creator (God).

In addition, the Outline also stated the following functions of science courses:

• to develop skills to gain, develop, and apply scientific concepts
• to develop (personal) attitudes and values
• to implant scientific attitudes into the students and train them to scientifically solve problems they face
• to make students aware of the importance of maintaining the environment and natural resources
• to make students aware of the order of the universe, its beauty, in order to appreciate and glorify the creator
• to provide students with basic knowledge for continuing their education to a higher level and apply it in their daily lives
• to develop students' intellect and creativity

The major goal of senior secondary education is successful preparation for further academic study at the university.

IEES (1986) study indicated that many schools report that for a variety of reasons they find it difficult to complete the full scope of the curriculum, including the science curriculum. There is a gap in the operational curriculum between what is intended and what is accomplished.

In practice secondary classes are organized in set groups of students. Teachers come to the class; students do not move except for laboratory courses. Classes range in size from 40 to 50 students. The gross ratio of students to teachers is about 15.4:1, while the face to face student/teacher ratio is 42:1. Face to face ratio is the actual ratio of the average number of students in a class taught by one teacher. The face to face ratio is more important than the gross ratio because this ratio represents the reality of a full-time teacher handling full-time students in approaching an international standard. It is not unusual, however, that a teacher teaches a class consisting of 50 students. Most classes are designed to accommodate 50 students.

The average class size in lower secondary school is 45. A group of students is assigned to the same class for instruction for one year and often for the entire three years of their time in the lower secondary school. The ratio of students to teachers in lower secondary school is approximately 18.9:1. But it must be noted that most of the 115,000 part-time teachers working in the private sector are double counted because most of them are also full-time teachers in public schools. It means that in reality the ratio may be greater than what is stated above.

In the lower and upper secondary schools the main textbooks for science classes are provided by the Ministry of Education and Culture. However, teachers are allowed to use other textbooks provided the textbooks cover the themes specified in the course content outline, and/or for enrichment purposes. The content is directed toward pure science practice rather than daily practice. Unfortunately, this means assignments that relate to inquiry methods are directed rather than letting the students use inquiry methods.

The current secondary level science curriculum, introduced in 1984, was also called the 1974 Update Curriculum. The total curriculum was officially put into action in the 1987-88 school year. The current curriculum, for upper secondary schools, offers the core and optional program (KurSMALPP-Ind). The core program is intended for students who plan to continue their education to the university level. The science core courses offered are biological science, chemistry, and physics. An optional program was designed for students who pursue a specific career after completing the secondary education.

About the Authors

John E Penick can be contacted at the Science Education Center, University of Iowa, Iowa City, IA 52242, USA.

Mohammed Amien can be contacted at Program Pasca Sarjana, IKIP, Yogyakarta, Indonesia.
500 years ago, Christopher Columbus sailed three small craft – the Nina, the Pinta and the Santa Maria – across the blue Atlantic Ocean of our planet to discover a new world. 35 years ago, Russian technologists surprised the world by launching Sputnik into the heavens beyond this Earth’s atmosphere.

ISY, in a unique display of international collaboration, celebrates these historic achievements and initiates new ones. It promotes worldwide cooperation in space, addressing environmental issues of global concern, and increasing awareness of the economic benefits of space science and technology.

**ICASE and ISY**

The ICASE contribution to ISY is through two international projects:

**Resource Materials for Science Teachers**

Dr David Moore, ISY Project Officer for ICASE, is coordinating the production of a set of resource materials for teachers, in collaboration with the ICSU Committee on Teaching of Science. For further information, contact:

Dr David Moore

Hatfield, Herts AL10 9AA, UK

**ICASE World Activity Day**

**Thursday 14 October 92**  
**Theme for 1992: Space**

Teachers and students in schools around the world are invited to participate in special activities focusing on the theme of space. Thursday 14 October 1992 is designated as ICASE World Activity Day. Member associations of ICASE are requested to encourage schools in their countries to share in this worldwide program on 14 October. The activities, which can be adapted to suit students at all primary and secondary levels, include: (1) Designing, constructing and testing rockets which operate on compressed air and water; (2) Calculating the Earth’s diameter by measuring the length of the shadow cast by a stick; and (3) Writing a short essay (maximum 1000 words) on (a) space travel in the year 2092 or (b) life as a student in 2092 as a result of space technology.

See the March 1992 Issue for an outline of these activities. For further information, contact: Brenton Honeyman, ICASE Journal Editor, 10 Hawken Street, Monash ACT 2904, Australia.
Second ICASE Symposium 
Education Industry Liaison

by Jan Hendriks
ICASE European Regional Representative

As announced in the December 1991 issue of Science Education International, the very successful symposium in Brussels in September 1990 which was organised by ICASE in conjunction with the European Chemical Industry, will be followed by a Second Symposium on Education Industry Liaison.

AKZO, one of the leading chemical and pharmaceutical industries in Europe, has offered to host this Second Symposium during two days at the end of November 1992. AKZO has recently joined the ICASE network as a Company Member (refer to ICASE News). The Second Symposium will be held in Arnhem, the Netherlands.

The themes of the Second Symposium will include:

- AKZO Education Industry Partnerships and Projects
- Evaluation and experiences from other education industry partnerships
- Extension of the scope of education industry interfaces with publishers, press, television, education museums, etc
- Followup activities (eg workshops)

Participants will be required to cover their own travel and accommodation expenses.

Participation will be by invitation only. Those interested in Education Industry Liaison and, in particular, Education Industry Partnerships, are invited to submit a letter of application. Letters of application should outline the applicant's interests and experiences in the field of education industry liaison.

Letters of application should be sent before 1st July 1992 to:

Jan Hendriks
ICASE European Representative
Konijnendal 3
7921 BM ZUIDWOLDE (DR)
The Netherlands
Fax 31-5287-2693

Successful applicants will be selected by the Organising Committee and invited before the end of July 1992.

Copies of the proceedings of the first symposium on Industry Education Liaison can be ordered from ICASE at a cost of US$7.50 or £4.50 plus 25% postage.

A New Approach to Teaching Science In Russian Secondary Schools

by Dr Vjacheslav M. Dushenkov
Moscow Pedagogical State University

Russian society is following the way of changes. The education system is a mirror reflecting this process of change.

Arising out of a school system where the ideologies are as one and where all educators are required to teach all students according to one program on any subject without attending to the various abilities and interests of students, there emerges a new approach. Until recently, a future novelist, a future industrial worker, a future manager, and a future biologist all studied the one science curriculum and science program. Now there are various types of schools and classes, and various curricula are being developed. This new approach needs new programs, courses, textbooks and new teaching strategies.

In recent decades, humankind has become an increasingly disruptive influence on a global scale. The survival of our civilisation and the whole planet depends upon whether or not our children will be educated so as to become ecologically literate. Our children need to be aware of the inter-connectedness of all levels of life, of living beings and non-living matter, of humankind as an integral part of the environment.

At present, we are establishing a recognition that the 'environment' is not 'out there' but everywhere! It is the
Entire context of our lives.
Environmental education provides the large picture of the interconnectedness between biology, technology and culture – much larger than these studies provide separately.
Environmental education is comprehensive and global. It can provide an education which includes the 'big picture' enabling us to make sense out of our 'jigsaw puzzle' world.

This goal – to provide an education with the 'big picture' of the world – is becoming more and more critical.

As a result of industrial growth after World War II, there was a great movement towards the cities. Many children grew up without a deep knowledge of the natural world. They experienced smog, dead lakes and dumps, but did not appreciate the beauty of young green leaves or the charming songs of a nightingale. Their lives did not connect with nature, its sustainability or its health. Hence they were not aware of it; their behaviour reflected the way they think about the environment. The primary focus of any environmental education program must be, therefore, to change the way people think about their relationship to the world in which they live. They must recognise that the global ecological system is essentially a single, integrated life support system, and that all of our natural and cultural systems are interconnected and interdependent.

Educators are challenged by the goal to develop an environmental program which integrates nature, culture, technology, people, ideas and feelings. This challenge has encouraged a group of Russian pedagog to try and develop such an integrated program for 5th to 7th grade children. The course was entitled General Science.

Why were these grades selected? In our school system, children begin school when they are 6 or 7 years old. They are taught for 3 or 4 years at primary school; during these years, they undertake a course entitled 'Environment'.

Environment Course
The main goals of this course are to:

- develop an appreciation of nature and phenomena of social life in order to understand the connections within the system 'humankind-nature-society'
- develop a comprehensive understanding of our own bodies, and the necessity for personal and social hygiene
- form an appreciation of moral and ethical norms of behaviour accepted within society towards nature, environments and people
- foster an interest in life, nature and social phenomena in order to develop an attitude of complicity, duty and care toward nature and people

The content and structure of this course has been developed with consideration for children's psychology in the 6-10 year age range which perceives the surrounding world as a whole. This is why the course includes both the habitant and social environment together so as not to hinder the formation of the notion of integrity of the whole environment.

For each grade, the Environment course units are as follows:

**Second Grade (68 hours)**
Unit 1 - You are a pupil of 1st grade
Unit 2 - Your health
Unit 3 - We and things around us
Unit 4 - Nature around us
Unit 5 - Native country

**Third Grade (68 hours)**
Unit 1 - Man and his health
Unit 2 - What surrounds us
Unit 3 - My friends: adults and children
Unit 4 - Man and nature
Unit 5 - Native country

**Fourth Grade (68 hours)**
Unit 1 - Introduction
Unit 2 - Man studies environment
Unit 3 - Locality in the region of school and its features
Unit 4 - Forms of land surface
Unit 5 - Natural sources
Unit 6 - Water and its role in nature and man's life
Unit 7 - Air and its significance for nature and man's life
Unit 8 - Natural and artificial communities

Unit 9 - People on earth
Unit 10 - The Earth as a space body

From 5th Grade, children begin secondary school. The General Science course was developed as a sequel of the Environment course.

General Science Course
The goals of this course are to:

- master scientific facts; notions; symbols; generalisations of physical, chemical and biological phenomena; their interrelations as the basis of nature
- form a scientific world outlook; knowledge about nature as a developing system
- develop knowledge of ecology, the role of people in nature, and of humankind as part of the biosphere
- develop a familiarity with the structure of the human body, the measures directed towards health protection, hygienic standards, hygienic and sexual education, formation of a healthy lifestyle
- focus on the significance of the natural sciences in the national economy and in conservation of nature
- develop creativity, ability to think logically, memory, speech, imagination, and observation skills
- cultivate emotions and feelings, will and persistence
- develop cognitive skills (ability to analyse and compare, to make conclusions, to explain phenomena) and practical skills (ability to use equipment, to conduct experiments)

The course is divided into three parts – one part per year. Three versions of the General Science 5-7 course were proposed. The one described here is entitled 'Nature and Man'. This course is appropriate for different types of schools and encourages a new way of thinking by focusing on global environmental problems.

**Part I - Fifth Grade**
The first part is devoted to the Earth as part of the Solar System; bodies living and non-living and substances on the Earth (molecules, atoms, elements in living and non-living bodies, spheres of the Earth); diversity of living beings on the Earth; man as a natural and
social being. This part provides the answer to the question "What can we find on the Earth?": The major thrust of this part is the interconnection of all bodies on the Earth, of living and non-living things.

Part 2 - Sixth Grade
The second part is devoted to all natural phenomena – physical, chemical, geographical, biological and social. Children study power, electricity, light, sound, and chemical reactions in nature, shaping these phenomena as environmental factors influencing living beings. Biological phenomena are shown through metabolism. Different types and processes of nutrition, respiration, excretion, reproduction, development and irritability are examined in plants and animals. Students learn about anatomy and the morphology of different living beings through the functions of these structures in metabolism. The final unit – social phenomena – shapes the role of mankind on the planet.

Part 3 - Seventh Grade
The third part focuses on natural systems, their connectedness, and development. The first unit is devoted to the system 'matter-energy' as a universal system. The second unit describes ecological systems – populations, communities (natural and human made), ecosystems, their structure development and responses to stress. The third unit is about the Earth's development as a global ecosystem. The unit 'Man and different systems' ends the course.

In all grades and throughout all units, science, art and folklore are incorporated in the same way. The course features poems, proverbs, and sayings about nature and its phenomena. Pictures by great artists illustrate textbook pages (for example, when explaining light phenomena, the problem of light distribution in the pictures of the impressionists is

**An Invitation to Kansas City**
**NSTA National Convention**
**March 1993**

**International Round Table**

Each year at the NSTA National Convention, the International Committee of the United States National Science Teachers Association (NSTA) hosts an International Round Table. At this 90 minute session, presenters from different parts of the world discuss their country’s science education programs.

Each presenter is provided with a table for a materials display. Those attending the International Round Table session visit the tables of countries they wish to learn about.

If you would like an official invitation to participate as a representative of your country, write to:

John E Penick  
Science Education Centre  
Room 789 VAN  
The University of Iowa  
Iowa City, IA 52242-1478  
USA

Participants will be required to arrange their own funding. The letter of invitation, and your name listed in the program, may help you as you seek funding support.

For information about other conferences refer to the Calendar section in this issue.
discussed).

When discussing the scientific problem of the origin of the Earth and life on it, some pages focus on science fiction literature, and on ancient legends and myths about this topic. The course describes how various nations have tried to recognize and explain this problem during the centuries. Hence, the course develops an understanding that science and art, science and social studies together lead us to a holistic view of our environment.

After the 3 year course ‘Man and Nature’, biology, chemistry, geography, and physics are studied for two years as separate subjects. Some students who are interested in science continue their education in this field. Those who don’t will have a new course ‘General Science 10-11’ to study – a new course which is under development. We would welcome other pedagogues joining us in this exciting work.

Report: 1992
NSTA National Convention

by Dr Ken Roy
ICASE North American Representative

Boston was the site for the National Convention of the National Science Teachers Association on 26-29 March earlier this year. This convention was the largest in the history of NSTA with over 18000 teachers, administrators, professors and others in attendance.

Available for participants were tours, short courses, expositions of science teaching materials, publication sales, seminars, affiliate-sponsored sessions and presentations by educators.

Special seminars were offered, including:
- Remote sensing of the Earth environment by Farouk El-Baz of the Center for Remote Sensing in Boston
- Building living ecosystems by Walter Adey of the Marine Systems Laboratory, Smithsonian Institution
- Advances in human genetics: recent discoveries and their implications by Aubrey Milunsky of the Boston University School of Medicine
- Global environmental change by Eileen L Shea of the National Oceanic and Atmospheric Administration
- Cancer connections: the food that we eat or the air that we breathe by Gary W Winston of the Department of Biochemistry, Louisiana State University
- Space and time: from Newton to Einstein and beyond by Abhay Ashokker of the Department of Physics, Syracuse University
- Paradigms for research and parables for teaching by Dudley Herschbach of the Department of Chemistry, Harvard University

There were over 1000 presentations on a variety of topics for Kindergarten teachers through university graduate school professors. Presentations focused on the issues of the day for practitioners in the United States. These included major national curriculum initiatives such as Project 2061 (AAAS); Scope Sequence and Coordination Project (NSTA); business education liaisons; funding; elementary programs in science education; computer interfacing; chemical safety; performance assessment techniques; hard core science; interdisciplinary science; trade books for elementary science; and much more.

Several ICASE activities were planned and held. Included were:

At the ICASE Executive Meeting, discussions were held with ICASE President Bob Lepischak, Executive Secretary Jack Holbrook, Special Projects Officer John Penick, and North American Representative Ken Roy.
ICASE President Bob Lepischak and North American Representative Ken Roy attended and represented ICASE at the NSTA International Committee meeting. ICASE Special Projects Officer Professor John Penick served as the chairperson of the Committee. Dr Gerald Krockover of Purdue University was named as the new chairperson of the International Committee.

The featured speaker for the ICASE International Luncheon was Professor Gerald Krockover of Purdue University. His presentation was titled Science Education: Reflections of the USSR.

At the CASE/ICASE Breakfast, the featured speaker was Dr Jack Holbrook, Executive Secretary of ICASE. He spoke about the Project 2000+ Conference which will be held in Paris, France during July 1993.

An ICASE exhibit booth was erected to share publications and international opportunities with participants.

The STS Approach Parallels Constructivist Practices

by Robert E Yager

Science Technology Society (STS) is defined by the National Science Teachers Association (NSTA) as the teaching and learning of science/technology in the context of human experience. Eleven features are offered by NSTA to describe STS approaches to teaching (NSTA, 1991). These features include:

1. student identification of problems with local interest and impact;
2. the use of local resources (human and material) to locate information that can be used in problem resolution;
3. the active involvement of students in seeking information that can be applied to solve real-life problems;
4. the extension of learning going beyond the class period, the classroom, the school;
5. a focus upon the impact of science and technology on individual students;
6. a view that science content is more than concepts which exist for students to master on tests;
7. an emphasis upon process skills which students can use in their own problem resolution;
8. an emphasis on career awareness, especially careers related to science and technology;
9. opportunities for students to experience citizenship roles as they attempt to resolve issues they have identified;
10. identification of ways that science and technology are likely to impact the future; and
11. some autonomy in the learning process (as individual issues are identified).

The Constructivist Learning Model is advanced as an explanation of how learners learn. Von Glaserfeld is one of the foremost constructivists who has offered the experimental, philosophical, and research base for constructivism. The model invites certain teaching approaches. These include:

1. seeking out student ideas before presenting teacher ideas or before studying ideas from textbooks or other sources;
2. encouraging students to challenge each other’s conceptualisations and ideas;
3. utilising cooperative learning strategies which emphasise collaboration, respect individuality, and use division of labour tactics;
4. encouraging adequate time for reflection and analysis;
5. respecting and using all ideas that students generate;
6. encouraging self-analysis, collection of real evidence to support ideas, reformulation of ideas in light of new experiences and evidence;
7. using student thinking, experience, and interest to drive lessons (this means frequently altering teachers’ plans);
8. encouraging the use of alternative sources for information both from written materials and live ‘experts’; and
9. using open-ended questions.

STS certainly has a curricular dimension. In fact, some refer to STS themes, topics, and courses (Bybee, 1986; Rubba & Wiesenmayer, in press). However, the curricular dimension does not distinguish STS from any other course or unit that may be offered to meet innovative goals. The instructional approach required of STS (see NSTA listing above) provides the explanation for the successes commonly reported for STS instruction (Yager, in press-a, in press-b).

The Project Synthesis research team offered a contrast of the instructional procedures found in a typical science class and those which would characterise an STS classroom. The list of strategies that should characterise an STS classroom also describes teaching techniques required for teachers interested in creating a classroom where constructivist practices can be seen. Table 1 (refer to following page) provides a list of these contrasts.

When STS instructional strategies are employed, student learning is enhanced. The mastery of student concepts is no better than it is in typical classrooms. However, significant advantages in favour of STS instruction occur in terms of student understanding and use of process skills, ability to use basic science concepts and processes, creativity skills (quality and quantity of questions, explanations, and prediction of consequences), and more positive attitudes concerning science classrooms, teachers, and careers. Figure 1 illustrates composite results which show student learning that has been measured in classrooms of Lead Teachers in the Iowa Chautauqua Program (Blunk & Yager, 1990).

The advantages of STS instruction likely occur because of the validity of the Constructivist Learning Model. The essential strategies that characterise STS teaching parallel the teaching procedures demanded by constructivism. If STS and Constructivist approaches are to achieve the potential envisioned by proponents, the reforms for which so many yearn will be realised. It will mean completely new roles for science teachers. These new roles will demand a teacher education vastly different from that found in most colleges and universities. It will require more experiences with STS and more opportunities for would-be teachers to structure their own meaning. It will require less remembering what students are told and more practice with questioning and personal actions as prospective teachers learn to deal with their own questions and how to learn to develop even better ones. These are skills that teachers must foster in their students - a task that many find threatening - even impossible without some experience in doing it themselves.

The Role of the Teacher in an STS Classroom

by John E Penick & Ronald J Bonnstetter

Teachers do make a difference and the STS classroom is no exception. Several studies of teachers in STS settings have revealed ten generalisations about their role. Effective and successful STS teachers:

Provide a stimulating, accepting environment

Students do best in an environment rich in human and material resources combined with numerous opportunities to initiate, study, and take action. Effective teachers do this by scheduling time for individual as well as group work and by expecting action, not just words or reading. Teachers encourage student decision making and action by not being content with mere knowledge and reports. Students can and will go a step further toward action if their teachers expect and encourage it.

Have high expectations of themselves and students

In addition to expecting students to go a step further, good STS teachers want these steps to lead to change. Change may be in learning or it may be resolution of a real problem. Teachers have different expectations as well, recognising that students have varying potential and that a student may perform quite differently in the STS situation. These high expectations carry over to the teacher as evidenced by their continual push to do more, gain more involvement, and see more resolution. Teachers with high expectations also see their role as more than a teacher of thirty students. They see their role as a larger one in a community context and as a model of active enquiry.

Are models of active inquiry

Exemplary STS teachers bring inquiry alive by presenting themselves as students, eager and willing to learn new ideas, skills and actions. By bringing new ideas to the class, by questioning and being open minded, these teachers are clearly models to be followed. They also model the thoughtful and rational approach to problem identification and resolution by being interested, seeking information, asking for evidence, and by taking action themselves. In essence, they are making their thinking, feelings, and approach to learning highly visible.

Expect students to question facts, teachers and knowledge

By making their approach visible, students easily see that science involves a degree of skepticism, as Richard Feynman put it, "a belief in the ignorance of experts". Not an assumption of being wrong, such a belief is a quest for evidence to support a fact, idea, or position. Students who have questions, seek answers, and who can provide evidence become active citizens with the same attributes. Certainly, these are the core of science literacy.

Stress science literacy

Teachers stress science literacy by demanding a rational and independent approach to science. Students are expected to seek, to question, to explain, and to apply their knowledge. Teachers are not content with just knowing words or skills, they insist that words be used to justify, defend, or clarify larger concepts or actions. Students must apply their knowledge before it truly becomes a part of them.

Want students to apply knowledge

Applying knowledge may be answering questions at the end of the chapter. But, effective STS teachers are never content with this alone. Calculating vectors in a pulley system does not have as much potential or is not as problematic for most students as does actually rigging a block and tackle. The same is true with societal applications where students seeking justification for a new community water treatment plant view their learning as vastly different than reading a standard text on the subject. In both instances, they can see their knowledge as it is being used, often outside the classroom.

Do not view the classroom walls as a boundary

Teachers want students and learning to go beyond the classroom. Any learning that is real must, by definition, continue with the student into the rest of their world. Obviously, these effective teachers see that both their students and their ideas have many opportunities to go beyond the classroom, via field trips, visits to resource persons and facilities, and using outside materials such as books, papers and ideas. At the same time, teachers invite community experts in, through the walls, offering new insights and perspectives on existing problems and often raising new ones.
Are flexible in their time, schedule, and curriculum

Bringing in outsiders is quite disruptive. Students find new ideas to pursue, old issues get sidetracked, and the teacher loses some control. And, an effective teacher takes advantage of this, changing as opportunity presents itself. Students learn but not always as the teacher anticipated nor on the same schedule. But, the stimulation, excitement and involvement lead to many new avenues of motivation and learning – for the teacher as well as the student.

Put in far more than the minimal time

Scheduling, shifting, coordinating, expecting, and planning all require time. We find that teachers in exemplary STS programs worry about time but focus that worry on finding more to devote to their classes and ideas. They tell us what time they have is fleeting, the days are not long enough to contain all they want students to be involved with. As a result, they put in hours after school and on weekends, striving to make their teaching all it can be.

Teachers do make a difference

While national assessment data indicate most students don’t like science, students from classrooms where teachers exhibit these generalisations feel differently. They like science, science teachers, and science teaching. They feel science is useful, now and in the future.

Effective teachers cause students to see uses for their science and give them confidence in their own ability to use and be successful with science. And, these teachers are eager for Monday morning.

These are the teachers we wished we had had and whom we continue to want for our children.

Teachers do make a difference and the STS classroom can add even more.

---

Pasteur and Microbes
A Teacher Resource Book

Commemorating the 100th Year of the Pasteur Institute
1888-1988

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute. It contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few.

These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation.

Order by sending a cheque (payable to "ICASE") US$8.00 or £5.00 (add 25% postage and packing) to:

Dennis Chisman
Hon Treasurer ICASE
Knapp Hill, South Harting
Petersfield GU31 5LR, UK
### TABLE 1

**How to be an effective teacher**

**Provide a safe, stimulating, accepting environment**

The classroom must be rich with books, magazines, newspapers, art, equipment, and artifacts. Equipment should be readily available for spontaneous use (often students don't know they need something unless they see it).

The teacher must stimulate with provocative and insightful questions and statements then, to encourage students, allow sufficient wait time and accept (with no evaluation) all responses. Rather than "good" or "No I don't think so", nod, say "OK what else", or get additional students to respond. Students must feel safe if they are to risk something new. It's never really safe if someone is evaluating you.

**Have high expectations of yourself and students**

Don't be content with last year or the norm; always go at least one step further. Let students know you have faith in them when they produce a report, go further and send it to your local newspaper. Don't grade on a curve.

**Be a model of active inquiry**

Bring in questions from your own observation, reading, and conversation. Take action to find out new resources and information. Be a learner. Let your students know you don't already know everything. Show your curiosity.

**Get students to question facts, teachers and knowledge**

First it must be safe. Then raise questions yourself, ask always for evidence supporting assertions or ideas. Put yourself in positions where students can successfully challenge you. Be willing to learn alongside them (see above). Play 'devils advocate', raising issues and questions even if you know them to be false.

**Stress scientific literacy**

Students who see you and themselves engaged as described above, will see and experience science as an active process of thinking and doing. As a result, they will come to rely on and expect their science to be useful personally.

**Get students to apply knowledge**

Use real-world problems and encourage your students to find other examples in their own lives. Provide time to discuss applications and evaluate these applications as well. Visibly apply knowledge yourself as you expect them to do the same.

**Not view classroom walls as boundaries**

Information as well as students flow in and out; take advantage of it. Reward students who bring ideas and information in and take solutions out. Do the same yourself by bringing in people and materials as resources; schedule group field trips and encourage individual students to make their own field trips. Teach students to use the library, write letters, and telephone sources. Get parents involved in the classroom and out of it as well.

**Be flexible**

Lesson plans are not religious documents. Feel free to postpone, ignore, change or delete. Watch for 'teachable moments' when you and your students can move ahead as learners. Use current events as they happen and help students to be 'investigative reporters'. A flexible student or teacher follows leads as they happen, not when scheduled.

**Put in more than minimal time**

Then, be more efficient; get students to do more of the work. We know of many classes where the students really do the lesson planning while the teacher plans the learning environment. But, it still takes time to develop your organisational plan and to have materials ready.

**Make a difference**

Trust yourself and your students. Look inward and ask "Is this best for my students and goals?" Study exemplars and most of all, study your teaching, making changes for the better. Your students will notice and appreciate your efforts.
The Infant Pedagogic Centre
in Antigua

by Sue Dale Tunnicliffe

The Infant Centre celebrated five years of existence in April 1992. It was set up following the infant co-ordinator's study leave in Israel. The philosophy is soundly rooted in the child as an active learner and acknowledging the experiences and knowledge which the youngster brings to his or her schooling.

Now in its second location, Newman Street, a short walk from the Ministry of Education itself, the centre has an office room and a front room which acts as a workshop room too. In these rooms are kept all the equipment.

Of particular note is the Science Centre Area which contains suggestions for classroom displays and activities and sourcebooks for the teachers to look at. In their recent publication *Ideas to Share* (Vol 2 No 8), the Centre shared ideas about setting up a science centre. These are reprinted here.

Most of the equipment in the Antigua Science Centre is low cost and locally available, including disposable plastic beakers, stirrers and sugar sachets from local hotels and catering containers from local airlines.

Establishing a Science Centre
Reprinted from *Ideas to Share* April 1992

A Science Centre is designed to provide children with the opportunity to learn about their world through investigation of what may be found in the school or home environment.

The materials and equipment in the Centre could be related to a particular theme or program, or they could be of general use, for other science activities carried out by teachers and children.

It is important to make observations, discuss processes, make predictions, and note outcomes. Children should look for and find the answers; the teacher should not tell them, but should act as a resource to help children think through and decide for themselves.

Every infant classroom should have a Science Centre where the child can:
- observe collections of objects and collections of pictures
- learn their names and normal usage
- handle them and observe them
- repeat the experiments the teacher has performed with the class
- experiment on his/her own
- display the collections he/she brings to school, and put away afterwards
- keep and take care of small animals such as fish, turtles, snails, crabs
- use his/her five senses – sight, hearing, touch, smell, taste

In setting up and presenting the Science Centre, the following needs to be considered:
- Provide the equipment, space and time for children to repeat the experiments themselves.
- Put up a bulletin board with pictures or objects related to the display.
- Have a place outdoors where children can sow seeds, dig, observe insects, etc.
- Have science materials children can touch, feel, listen to, and even taste.
- Science equipment should be simple and inexpensive.
Necessary supplies and equipment include:

- Collections of specimens from nature: pebbles, birds' feathers, shells, sea coral, seeds, seed pods, leaves, cones, coconuts, caterpillars, tree bark, insects, bird nests, bulbs, plants, tortoises, etc.
- Instruments for experimenting: magnet, magnifying glass, pulley, thermometer, balance, mirror, prism, clock, weather vane, barometer, bicycle pump, straw, wire, see saw, corks, nuts and bolts, measures, containers of water and sand, etc.
- Household materials which can be adapted for experimentation and for scientific observation: empty jars for terrarium or aquarium; jars and boxes of different sizes and shapes (glass, plastic, aluminum, foam and cardboard for observation boxes and planting seeds; see-through plastic for covers; pieces of rubber tubing for siphons; sponges, cotton wadding and blotters; cheese cloth and piece of wire for a net to catch insects; containers, pie plates and cake pans for experiments; combs, silk, woollen and fur fabrics for experiments and handling (also for static electricity); spools, string and wire for pulleys; salt, sugar, vinegar, soda, cloves, lime, flour, cornstarch for flavours and constructions.

Science activities

Science activities which foster the development of observation and an understanding of causal relationships:

- Leaf collection: press and preserve, play with dead leaves, rake them, pile them, make leaf prints with paint.
- Collect seeds: sort them, plant some, make seed pictures.
- Take care of plants: observe their growth, record in pictures and words.
- Observe birds and flowers for likenesses and differences: use pictures too.
- Prepare and observe plants which grow in a big terrarium bottle.
- Examine a collection of shells: sort them in many different ways - by colour, by size, by those alike and different, by broken or whole, by one part or two.
- Observe the sky and clouds for changes.
- Hold cloth up into the wind: observe and make comments, make a wind sock.
- Observe the sea and the waves: record daily for a week, with pictures.

More science activities

- Look at self in mirror. What do you see? Touch tip of nose, top of head, one eye, one ear. What do you see?
- Close eyes. Feel four objects. Comment on how they feel - smooth, cold, rough, furry, soft?
- Hold three objects which are arranged in order of heavieness, then lightness.
- Make two sets - living or non-living - from pebbles, toy car, seeds, rubber, sand, wooden block, flower, leaf, spoon, etc.
- Match babies to their adults using picture cutouts or toy animals - cat and kitten; calf and cow; chick and hen; etc.
- Name shapes - triangle, square, circle, rectangle. Explore classroom and schoolyard for like shapes. Record them. Make pictures of them.
- From a few different flowers, see which have smells and which do not. Compare colours and smells. Do the same kinds of flowers have the same number of petals?
- Describe the odd one out in sets (eg same colour pencils but one differs in length; nails and one screw; limes, one larger; shoes, one boot, etc).

Stepping into Science
An ICASE Primary/Elementary Science Project

AIMS
Stepping into Science is an ICASE project which aims to:

• Establish an international network for teachers to share ideas on the teaching of primary/elementary science and technology.
• Provide activities and support for teachers, thereby encouraging them to include more science in the primary/elementary curriculum.
• Promote the value of science experiences for young children throughout the world.
• Facilitate professional development opportunities for teachers by including sessions on primary science and technology in regional and international conferences.

ACTIVITIES
The Stepping into Science Team is actively involved in a number of projects and activities including:

• Publishing STEPS, the Stepping into Science Project Newsletter. This newsletter contains ideas for class activities at various levels in primary/elementary schools, activities for children to do at home, comments by network members on issues, examples of children’s work, lists of helpful resources and contacts. ICASE acknowledges the contribution of Philip Harris in sponsoring STEPS.
• Contributing articles and ideas for the Primary Science Section in Science Education International, the ICASE quarterly journal.
• Compiling ideas and activities for inclusion in a series of sourcebooks on the teaching of primary/elementary science and technology.
• Coordinating a scheme to encourage children to participate in science and technology activities. Certificates of Participation have been produced, and are available for schools to use in rewarding students as they complete a number of activities. Certificates are colour coded in seven different colours, so that they can be used to acknowledge progress in science from early to advanced levels within primary/elementary schools. ICASE is grateful to BP (Oman) for sponsoring this scheme.
• Organising Stepping into Science workshops and displays of children’s work at national, regional and international conferences.

More Activities to Investigate Principles of Rocketry

World Activity Day
14 October 92
Celebrating International Space Year
in schools around the world

Teachers and students in schools around the world are invited to participate in special activities focusing on the theme of space. Member associations of ICASE are requested to encourage schools in their countries to share in this worldwide program on 14 October. The activities, which can be adapted to suit students at all primary and secondary levels, include:

1. Designing, constructing and testing rockets which operate on compressed air and water

2. Calculating the Earth’s diameter by measuring the length of the shadow cast by a stick

3. Writing a short essay on (a) space travel in the year 2092 or (b) life as a student in 2092 as a result of space technology

See pages 27-30 in the March 1992 Issue of Science Education International for an outline of these activities. Member associations are encouraged to reprint these pages in their own journals and newsletters to encourage schools to participate.

In the March Issue of Science Education International, this column introduced some activities on the theme of space science. One of the activities Up Up and Away with Bottles challenges students to design water rockets which operate with compressed air and water. As a result of the interest in this activity, two further articles are included on this topic – The Sparklet Rocket and Newton’s Third Law and Extensions to the Bottle Rocket Activity.

The Sparklet Rocket and Newton’s Third Law

by Geoffrey Millar
Reprinted from SASTA Journal 85(2)

Section Editor’s Note: The attention of teachers is drawn to the safety precautions necessary when conducting this experiment.

One method available to the physics teacher to demonstrate the ideas described in Newton’s Third Law is with rocketry. The simplest rocket available is found as the common soda sparklet selling for a few cents in supermarkets. The sparklet contains carbon dioxide under high pressure for use in domestic soda siphons. For the sparklet to metamorphose into a rocket, a number of steps need to be taken.

The way to best show off the sparklet rocket is to run it along a tight guide wire. Thick fishing line can be used with excellent results. The sparklet will be suspended under the fishing line using a plastic drinking straw. Adhesive tape is used to connect the
sparklet to the straw. The problem is now to release the compressed carbon
dioxide from the sparklet.

A metal plug is used to seal the gas in
the sparklet. Under normal conditions,
this is pierced as the sparklet is
screwed into the siphon. Piercing the
sparklet has been the biggest problem
that I've had with the demonstration.
With the help of my lab assistant, a
solution was found to the problem of
reliable firing. Make a small nick in
the metal plug before mounting the
sparklet. To the plug end of the
sparklet, place a small sleeve of plastic
tubing about 1 cm long. Fill this with
plasticine, and insert a drawing pin
with its point sitting in the nick. The
'rocket' is now prepared for launch!

To launch, the sparklet needs to be
thrown along the guide wire backwards
so that it hits a support. If the blow is
sharp enough, the drawing pin will
puncture the sparklet. The carbon
dioxide will escape rapidly, propelling
the sparklet down the wire at high
speed.

The whole demonstration is best done
outside. The fishing line should be as
tight as possible without any knots.
The line should be as long as possible
(eg 30 or 40 metres).

As the sparklet becomes a fast moving
missile while travelling along the
wire, make sure there are no people in
front of it. In fact, all should be
behind the firing support!

There are many calculations that can be
made from measurements of the time
the rocket takes to cover a measured
distance. Here are some typical results.

**Acceleration**

This assumes a constant acceleration
over a measured distance. Measure
about 20 to 30 metres. Have students
with digital (easier to read) stopwatches
find the time of travel.

\[ s = ut + \frac{1}{2} at^2 \]

By substituting the following typical
values in the formula above (\( s = 25 \)
metres, \( t = 0.7 \) second, \( u = 0 \) m/s), it
can be shown that:

\[ a = 100 \text{ m/s}^2 \]
Extensions to the Bottle Rocket Activity

by Ronald J Bonnstetter

The March Issue of *Science Education International* contained a wonderful introduction to the world of rockets using simply a plastic bottle. I could not help but see a multitude of possibilities as I read that activity. I would like to suggest that each of us not only continue to share our ideas and activities, but invite others to take these ideas and share how they have altered or created extensions.

I have experimented with the concept of using plastic bottles as rockets for several years. The primary difference between the March Issue description and my most recent work involves controlling the pressure being added to the bottle. In other words, rather than simply corkscrewing the bottle and letting it launch at will, I hold the plastic bottle in place until I have the desired pressure. The design for this launch pad was published in the October 1991 National Science Teachers Association Scope Journal.

With control over launch pressure, and the ability to employ a count-down for launch, the possibilities for experimentation are almost endless. Let me offer just a few suggestions to get you and your students started. Once introduced to this learning tool, they will have many more wonderful ideas.

How do different sized bottles compare?

How will angling the launch pad affect the trajectory?

How would the rocket respond if mounted on a skateboard?

How might you decorate your rocket (lower elementary)?

How might you attach a parachute?

Design ways of transporting a payload (an egg?).

How could you safely illuminate the rocket for safe night flight?

How would altering the nozzle diameter affect altitude or velocity?

How could the rocket be modified to accommodate a horizontal trajectory?

What is the rocket's inertia at different points along its flight path?

How does varying the launch pressure or volume of water in the bottle affect velocity and/or altitude?

What are different ways of calculating maximum altitude?

What is the maximum time aloft?

How does the plastic rocket circumference vary with pressure?

How would streamers affect the launch?

What is its acceleration?

What is its maximum velocity?

What is the best way to attach fins?

How do you attach fins to make the rocket rotate?

How does rotation affect altitude and trajectory?

How does pressure, amount of water, use of nose cone, and fin arrangement affect acceleration, velocity and altitude?

How do 16 oz bottles compare to 2 liter bottles?

Calculate fuel and pressure needed to hit targets?

How could you make it produce noise during the launch?

How does altering the centre of mass affect performance?

Other ideas I would like to pursue include (1) how to interface photo gates to a computer to collect data on acceleration, or (2) how to cement a stack or series of 2 liter bottles together to form a super rocket.

I hope you have as much fun with this as we have had.

INTERNATIONAL COUNCIL OF ASSOCIATIONS
FOR SCIENCE EDUCATION

Who's Who in Science Education
Around the World

Published by ICASE
With assistance from UNESCO

This new ICASE publication, published with the assistance of UNESCO, contains brief profiles on prominent science educators, their work, their projects and their interests. The valuable reference book includes key women and men in many countries throughout the world who are contributing to science education at primary, secondary or tertiary levels.

The information will help readers to contact colleagues in both developing and developed countries who may be working on projects of interest to them, who may be potential speakers at upcoming meetings or conventions, and who may be invited to work on collaborative projects.

Copies at a cost of US$15.00 or £9.00 or A$20.00 including postage can be ordered from the Editor:

1992 ICASE Yearbook
The Status of Science Technology Society Reform Efforts Around the World

Edited by Robert E Yager

FOREWORD

Science Technology Society attracts even more attention than it did en years ago when it became a new focus for reform in a few nations like the United Kingdom, The Netherlands, and, to a lesser extent, the United States. Currently it is a focus in nations on every continent. For many it represents the most significant change seen in classrooms during this century. For some the reform seems slow – not to be realised to any degree before the year 2000.

This Yearbook has been prepared as a means of updating science educators and ICASE member societies around the world. Hopefully it will help coalesce the concept in all nations and provide support for emerging projects in other nations. The reports are offered in the spirit of providing a status statement. Also, information is included that can be used as evidence for STS as real reform. Hopefully such evidence will be useful for schools and the most innovative and creative teachers in science societies who are struggling with STS in their own situations. The Yearbook is organised as:

- STS definitions and rationales
- Examples of STS initiatives
- Evaluation of STS efforts
- STS moves in various nations

The authors all hope their contributions provide useful information and suggestions. They all hope that the Yearbook provides a needed record of where we are while also being controversial enough to promote debate and dialogue.

Electronics Teachers' Guide

No 40 in the Document Series on Science and Technology Education

Published by Unesco

This document, the second to appear on the teaching of electronics in the Science and Technology Education Document Series, has been prepared as part of Unesco's science and technology education program.

Electronics Teachers' Guide has been specially written by John Lewis for Unesco. Whereas most educators agree on the importance of including electronics within the school curriculum, there are conflicting views on how this should be done. The program of work was developed according to the following guidelines:

- The work forms part of a lower school physics curriculum. That represents the end of formal contact with physics for many students, hence the content has been devised to systematically progress towards this end point.

- The work is concerned primarily with the conceptual building bricks of electronics, using an appropriate level of complexity. The idea is to give a taste of how more complex units are built up from simpler building bricks, without making things too complicated.

- The work assumes that about 9 weeks (or 27 periods) will be available for the study of electronics within a Physics course.

- The work emphasises the ways in which electronics is used to perform useful tasks. This electronics course shows how electronic systems interact with the real world to control external devices.

What Research Says to the Science Teacher about STS

This volume, edited by Robert E Yager and published by the National Science Teachers Association, focuses upon research concerning STS with an emphasis on results of efforts in the US. It provides much additional information concerning emerging assessment and evaluation data of value and interest to the international STS movement. The publication is available by contacting:

Special Publications, National Science Teachers Association
3140 North Washington Boulevard
Arlington, Virginia 22201, USA
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1992

**June 10-12**
**ICASE Research Seminar on Chemistry and Physics Education**
Location: University of Dortmund, Germany
Contact: Prof Dr Hans-Jürgen Schmidt, University of Dortmund, Department of Chemistry, Otto-Hahn-Straße, 4600 Dortmund 50, Germany
This symposium on empirical research in chemistry and physics education will focus on the methodology of empirical research in this field. There will be approximately 12 presentations each followed by a discussion period. The language of the symposium will be English. A Proceedings will be published through ICASE.

**July 6-10**
**CONASTA 41**
Location: University of Western Australia, Perth, Western Australia
Contact: Nic Soufolis, Convener CONASTA 41, Science Teachers Association of WA, PO Box 222, Claremont, WA 6010 Australia (Fax +61-9-385-1509)
The Australian Science Teachers Association invites you to participate in the forty first annual conference of the Association. The theme of Science and our Economic Future will be addressed from the viewpoints of government, scientific research, applied science and technology, the environment, industry and commerce, and education. Outstanding national and international educators, scientists and classroom practitioners will present keynote addresses and workshops, and a variety of excursions will be offered. A comprehensive display of resources useful to science teachers will be presented by publishers, booksellers, equipment and computing companies.

**July 22 - August 5**
**34th London International Youth Science Forum**
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK, Fax 071-835-1070
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments in London, Oxford, Cambridge and other centres in southern England. Accommodation in London University Halls of Residence together with all meals and a supporting social program are included in the participation fee of £650.

**August 2-10**
**Eighth ICASE Asian Symposium**
Location: Colombo, Sri Lanka
Contact: Mr Asoka Weerasinghe
Hon. Joint Secretary, SLASME, Institute of Computer Technology, PO Box 1490, Colombo, Sri Lanka
Science educators are invited to attend the eighth ICASE Asian Symposium and enjoy the natural beauty of the country and the hospitality of the Sri Lankans. The Symposium, organised jointly by ICASE and the Sri Lanka Association for Science and Mathematics Education (SLASME), will feature outstanding speakers from many countries who will address the theme "Science Education for a Changing World". The Symposium aims to identify some of the changes affecting our daily lives and to discuss ways by which science education can respond to these changes. Subthemes include (1) technology, (2) appropriate technology, (3) environment, and (4) scientific literacy. Participants will be able to experience the world famous pageant "The Kandy Perahera" in Sri Lanka. 100-150 science and mathematics educators from all parts of the world, and 200-250 local delegates are expected to participate in this event.

**August 31 - September 3**
**SCICON Biennial Conference of NZSTA**
Location: University of Waikato, Hamilton, New Zealand
Contact: Neil Uting, Education Advisory Service, 4 Hill Street, Hamilton, New Zealand
The theme of SCICON for 1992 will be Science - Technology . . . A Partnership . Information and registration forms about the biennial national conference of the New Zealand Science Teachers Association can be obtained from the contact above.

**September 19-21**
**Second General Conference of Teachers**
Location: Poland
Contact: SNPIT, Strytuka Poczotowa 62, 85-791 Bydgoszcz 32, Poland
This second General Conference on the theme 'Education, Environmental Protection and Industry' is being organised by
the Association of Science and Technology Teachers (SNPPT), Poland. Languages used will be Polish and English.

December 17-21
Twelfth International Conference on Chemical Education
Location: Bangkok, Thailand
Contact: Dr Somjai Wichaidit, The Secretariat - 12th ICCE, c/o Research Centre, Faculty of Medicine, Ramathibodi Hospital, Rama 6 Road, Bangkok 10400, Thailand
The theme of the Twelfth International Conference on Chemical Education will be *Chemistry in Transition* and it is hoped that the participants will interpret this in many different ways. This biennial Conference, to be held for the first time in South East Asia, is organised by the Committee on Teaching of Chemistry of the International Union of Pure & Applied Chemistry, and The Chemical Society of Thailand in cooperation with UNESCO. It is attended by chemistry teachers at both high school and university levels who wish to improve their teaching and to learn from one another techniques and experiences. A second circular including instructions for submitting abstracts is now available from the address above.

1993

January
ASE Annual Meeting
Location: UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated in *Education in Science*, a journal of the Association for Science Education.

January 3-8
International Conference on Science Education in Developing Countries
Location: The Amos De-Shalit Israeli Science Teaching Center, Israel
Contact: Conference Secretariat, ORTRA Ltd, 2 Kaufman St, PO Box 50432, 61500 Tel-Aviv, Israel (conference arrangements) or Dr Avi Hofstein, Department of Science Teaching, The Weizmann Institute of Science, Rehovot 76100, Israel (academic correspondence)
This international conference on the theme "Science Education in Developing Countries: From Theory to Practice" will review past experiences and achievements in science education and plan for the 21st century with a special focus on developing countries. The conference will feature plenary lectures, symposia, poster sessions, workshops, exhibitions, informal discussions, social events and local visits. Topics for symposia and plenary lectures will focus on current research on learning and teaching and its implications for (1) the learner, (2) the teacher, (3) the classroom, and (4) the curriculum.

April 21-25
International Conference on Geoscience Education and Training
Location: University of Southampton, UK
Contact: Mrs Esther Johnson, GEOED Conference Secretariat, Department of Geology, University of Southampton, Southampton S09 5NH, UK
The Association of Geoscientists for International Development (AGID) and the Commission on Geoscience Education and Training (COGEOED) of the International Union of Geological Sciences are convening this international conference with the support of ICASE. Themes include: geoscience education in schools; higher education; geoscience training for business, industry and public service; and public understanding of geoscience. The conference is open to all those with an interest in geoscience education and training - including practitioners and those involved in administration, course development, and the supply of resource materials.

June 27 - July 3
VII Pacific Science Inter-Congress
Location: Okinawa Convention Center, Okinawa, Japan
Contact: VII Pacific Science Inter-Congress, c/o Section of International Affairs, University of the Ryukyus, 1-Senbaru, Nishihara, Okinawa, 903-01, Japan
The Symposia will be organised around the theme *The Pacific: Crossroads for Culture and Nature* and subthemes (1) Cultural Interchange among Pacific Peoples; (2) Speciation, Dispersal and Conservation of Species in the Pacific; (3) Towards Appropriate Technologies and Policies for Development and for the Conservation of Natural Environments in the Pacific. Scientific sessions organised by the Scientific Committees of the Pacific Science Association focus on a range of science disciplines and issues, including Science Communication and Education.

July 6-11
Project 2000+ International Forum
Location: Paris, France
Contact: Dr Jack Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong
This worldwide conference, organised by ICASE in conjunction with Unesco and other international bodies is the second phase of the three phase Project 2000+ (refer to article in this issue for more details of this project). A number of international and regional conferences are generating input into this international forum. The theme of the forum addresses the issue of Scientific and Technological Literacy for All. Sessions will establish agendas for future action. Attendance will be by invitation only (500 participants). Names are now being sought from a wide variety of organisations with an interest in science and technology education (see next page). The forum plans to issue statements to affect political visibility for science and technology education for all as a requirement for national development, and provide a framework for major programs of action in science and technology education involving governments, IGOs and NGOs.
International Forum

Scientific and Technological Literacy for All

Phase 2 of Project 2000+

Paris, France
6-11 July 1993

This International Forum is the Second Phase of Project 2000+, an international project on scientific and technological literacy for all, which addresses the following 6 focus areas:

1. The nature of, and the need for scientific and technological literacy
2. Scientific and technological literacy for development
3. The teaching and learning environment for scientific and technological literacy
4. Teacher education and leadership for scientific and technological literacy
5. Assessment and evaluation for scientific and technological literacy
6. Non formal and informal development of scientific and technological literacy

Attendance will be by invitation only and limited to 500 participants. Names are now being sought from:

- National EFA (Education For All) Groups
- National policy makers overseeing science and technology education
- INISTE centres
- Project coordinators and field workers for organisations
- Science and technology teacher associations
- Institutions, centres, universities and colleges involved in science and technology curricula, examinations and teacher education
- Science and technology out-of-school centres and organisations
- Non formal science and technology educational organisations
- Industrialists
- Persons from the mass media interested in Project 2000+

Organisations, associations and institutes are invited to submit names of suitable participants to the Project 2000+ secretariat before the end of September 1992. A short description of each person should also be included covering:

(a) activities of the person nationally (within organisation if appropriate)
(b) international involvement (at conferences, research, projects, etc)
(c) which Project 2000+ focus area is of greatest interest

Individuals can also apply. Individuals will be selected based on paper abstract, submitted by the end of September 1992, related to one of the focus areas.

Selection will take place at the end of 1992 and will be finalised by approval of the Steering Committee at the end of January 1993.

There will be a US$100 Registration Fee for each participant to help defray material costs. This will be payable to the Project 2000+ Secretariat on receiving the invitation. For further information, contact: Dr Jack B Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

1
Scientific and Technological Literacy for All

Phase 1 of Project 2000+

By Dr Jack Holbrook
ICASE Executive Secretary

Over the last few months many people have asked me the meaning of 'scientific and technological literacy'. My answer has tended to be, "If I had the answer, there would be no need for Project 2000+. In particular, there would be no need for the Phase 2 forum, one part of which will try to spell out the meaning(s) of scientific and technological literacy for all."

Others have suggested that the word 'literacy' is inappropriate in this context. My response has been, "Perhaps this is so, but what word is appropriate? Can literacy merely be applied to reading and writing, or does it overlap with common sense - and, if so, is not science and technology invading everyday life so much today, that it is virtually impossible to divorce it from common sense?"

Take a recent incident I experienced in Thailand. The driver taking me to a meeting stopped at a petrol station to fill up the vehicle with petrol. The driver, having a few moments of relaxation, lit up a cigarette and climbed out of the vehicle. Nothing happened (as I am here to relate the story) but how lucky was I? What risk was the driver taking? Is this part of literacy?

Project 2000+ (refer to earlier issues of Science Education International) is aiming to redirect science education away from its overwhelming reliance on the 'science for the scientist' approach for the compulsory years of schooling (and even well beyond). The project is encouraging the world community to view education in science and technology as critically important for 'general education'. It emphasises that the increasing developments in science and technology affecting our everyday lives put forward and many countries initiated task forces to put these resolutions into practice. But while science and technology were considered important, little was said during the conference about scientific and technological literacy. Project 2000+ follows up the Jomtien meeting and, through task forces during Phase 3 of the project, will move toward greater scientific and technological literacy.

The Phase 2 forum, planned for July 1993, is being held to consider in depth the meaning of scientific and technological literacy. The forum, however, will not stop there. Other groups in the forum will examine developmental needs, curricula needs, teacher and teacher education needs, assessment approaches needed and the role of non-formal and informal education programs towards attainment of scientific and technological literacy. Thus Project 2000+ is concerned not only with the meaning of this term, but also with how we go about achieving it and then, more importantly, developing and carefully evaluating national projects, research programs, development strategies, etc., that give direction to the achievement of a level of scientific and technological literacy for all that is commensurate with the needs of students and adults in the 21st century.

Phase 2 of Project 2000+ is thus being planned as 'how to' forum - how to teach; how to re-train teachers; how to assess; how to evaluate courses, textbooks and teaching materials; and how to link developments in school with developments in the community as a whole. The forum is not looking for the answer - but for good practices that can form the basis for the development of ideas elsewhere, and that can be linked with other developments across Project 2000+ focus areas to provide positive directions for countries around the world to undertake comprehensive scientific and technological literacy projects.

An important premise of the organisers of Project 2000+ is that much has been, or is now being developed,
written, discussed, and even taking place that can shed light on possible directions and approaches to be adopted. Such material is not necessarily universal, but may stem from national/sub-national projects and may encourage similar developments once educators share and appreciate such ideas alongside those generated in the Phase 2 forum.

It is to this end that attention is drawn to the important need for Phase 1 materials. Phase 1 is the collection of all materials that assist in better understanding of scientific and technological literacy, and the ways in which it can be achieved within school, outside school, through:

- new curricula
- the acquisition of resources
- different approaches or emphases on teacher or in-service education, including approaches to the way in which such education is developed and disseminated

- the modification to approaches, style, emphases and acceptance in the examining of students — a crucial concern in many countries around the world.

The single biggest factor inhibiting change in teaching towards greater literacy development around the world must surely be the manner in which students are assessed. The overwhelming reliance on summative, written examinations, overloaded with factual recall — often in the form of multiple choice items — must surely rank as a major target for reform in many countries. But how? Many countries have tried classroom assessment of various kinds that have involved teachers in increased administration, while others have adopted a non-aggregating, profiling system that the tertiary sector find difficult to understand and appreciate.

Phase 1 materials are thus vitally important. Your help is needed now to obtain these in the six focus areas of Project 2000+. While we have been steadily collecting research papers and journal articles on the need for and nature of scientific and technological literacy, also needed are materials related to assessment, evaluation, teacher education, classroom environments and development of strategies that bear on the manner in which students can be better equipped as the adults of tomorrow to cope in a scientific/technological world. The materials, in many instances, may not be solely related to science and technology. For example, teaching strategies involving role playing are not specific to science and technology.

Material is needed that is local as well as international. Internationally, these can be extracted from journals or conference proceedings. What about local developments, ongoing projects and procedures being developed or implemented in a region or country? How can we bring these ideas to the attention of the world community? Can you assist?

All types of materials are required, including booklets by science teacher associations on teaching ideas; videotapes on the development of new practices; slides that show the use of the environment, food, health, etc., in scientific and technological literacy development; project materials and assessment approaches. These can be sent to:

Prof John Penick, Science Education Center, University of Iowa, Iowa City, IA 52242, USA, (in particular, material related to the nature of scientific and technological literacy)

Emmanuel Apea, Chief, Science & Technology Education, Unesco Division for the Development of Education, 7 place de Fontenoy, 75700 Paris, France

Dr Jack Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong (soon moving to coordinate the Project Secretariat at Unesco Headquarters, Paris, France.)
New Member of ICASE
Earth Science Teachers Association

The latest member of the ICASE family is the Earth Science Teachers Association (ESTA) in the UK. This organisation was formerly the Association of Teachers of Geology. This association has about 900 members, most of whom are teachers in secondary schools, but includes members from all levels of education. The aim of the association is to encourage and support the teaching of earth science, whether as a single subject such as geology, or as part of science or geography. The ESTA issues a quarterly journal Teaching Earth Science and holds an annual conference in September. The 1992 Conference is being held in Cardiff, 18-20 September; the 1993 Conference will be held at the University of Leeds. There are also a number of working groups which provide information and support to teachers. These include primary education, curriculum development, syllabus and examinations, promotions, teacher training and fieldwork groups. The promotions group produces teaching materials such as colour slides and maps and other teaching aids.

The corresponding member for ICASE purposes is:

Dr Denis Bates
Editor, ESTA
Institute of Earth Studies
University College
Aberystwyth
Wales SY22 3DB
UK

Any members of ICASE interested in exchanging journals or receiving sample copies of Teaching Earth Science should contact:

Mr John Reynolds
Treasurer, ESTA
18 Gardiner Drive
Longton
Stoke-on-Trent, ST3 2RQ
UK

Longman International Education
New Company Member of ICASE

ICASE welcomes Longman International Education as a Company Member of ICASE.

Graham Taylor, Managing Director, has provided the following information about the activities of this major educational publishing company.

Longman International Education (LIE) publishes materials for the education systems in the developing world and for Africa, the Caribbean and the Arab World in particular. There are three main aspects to the work of LIE:

• new publishing;
• the provision of a publishing service; and
• the management of Longman's overseas companies.

Longman International Education's extensive backlist includes titles at all levels from pre-school to post-graduate level and in all subject areas. LIE continues to publish in the open market but now in addition often works in collaboration with Ministries of Education in the countries concerned to produce the materials they require for their school systems.

In the Arab World, the main emphasis is on the provision of English language teaching materials. Thus we supply courses for the entire school systems of Egypt, Sudan, Jordan and Oman.

In Africa, LIE publishes both in English and in indigenous languages, and in all subject areas.

LIE also publishes professional and vocational material for the developing world in general, as well as two fiction series Longman African Writers and Longman Caribbean Writers.

An increasingly important aspect of Longman International Education's work is to provide a publishing service for African and other publishing houses and Ministries of Education where such expertise is not yet available.

Lastly, LIE is involved in the management of the Longman subsidiary and associate companies in Africa and the Middle East.

For further information, contact:

Longman International Education
Longman House
Burnt Mill, Harlow
Essex CM20 2JE, UK

Project 2000+
Urgent Reminder

ICASE member organisations are reminded to collect and submit materials for Phase 1 as soon as possible. These materials will provide input to the Phase 2 Forum to be held in July 1993. Member associations are also reminded to nominate participants for the Phase 2 Forum.

Enquiries:

Dr Jack Holbrook, ICASE Executive Secretary
Dept of Curriculum Studies, University of Hong Kong, Hong Kong
1 The Nature of and the Need for Scientific and Technological Literacy

Scientific and technological literacy are basic to any education for the 21st century. Without such literacy, citizens will be poorly prepared for learning to cope with an increasingly technological environment and lifestyle and thus:

- the need for scientists, politicians and other key personnel to be scientifically and technologically literate as a basis for decision making to be able to participate meaningfully in science-related political issues;
- the need for people to be functional in an increasingly technological environment; 'operacy' in relation to machines; develop appropriate societal behaviour for the benefit of the individual, society and the environment as a whole;

2 Scientific and Technological Literacy for Development

Areas for consideration include national social, environmental and economic development with particular respect to:

- personal development including human and ethical values;
- quality of life issues such as sustainable development strategies, the environment, energy, population, and health;
- economic development, opportunities for employment at local, regional and national levels.

This particularly applies to:

(a) Life-long Science and Technology Literacy

As science and technology develop, now and in the future, efforts have to be made to prepare and sustain science and technology literacy throughout life. Efforts to promote public understanding of science and technology, for example through the media, in the local community, must complement formal education systems.

(b) Research into Scientific and Technological Literacy

Serious research efforts must begin to investigate needed basic concepts, the knowledge base, processes, and skills related to scientific and technological literacy. Further research must consider teacher education, learning environments, and career-related issues.

(c) Case Studies and Examples of Scientific and Technological Literacy in various settings

Descriptions of existing literacy programs and activities will stimulate discussion, research, and action. Such examples are essential for developing modes for educational development.

3 The Teaching and Learning Environment for Scientific and Technological Literacy

The ultimate goal of scientific and technological literacy is an individual who feels comfortable with and capable of learning and using science and technology. In developing this literacy, teaching must focus on the individual. Such focus requires a carefully planned and created learning environment. This learning environment includes:

- the role of the learner
- the role of the teacher
- the curriculum, and
- the physical environment where the learning is to take place

The desired role of the learner must be compatible with the nature of science and scientific literacy and what is known about how people learn. To be useful, this role must be carefully described and documented quite specifically.

Once the role of the learner is specified, a careful search of the literature should reveal appropriate teacher behaviour and actions which should lead to learners performing as desired. At the same time, a number of teacher roles and behaviours not desired will be identified. Combining these with a thorough analysis should lead to appropriate teaching strategies for enhancing scientific and technological literacy.

Since learners interact with the teacher in a context and physical locale, these too, must be designed for compatibility with the ultimate goal, scientific and technological literacy.

4 Teacher and Leadership Education for Scientific and Technological Literacy

The teacher and/or leader is a key figure in the learning environment. Hence, the teacher's and leader's own education must be carefully planned to optimise the learning environment. Teachers (and others directing an environment for developing scientific and technological literacy) must consider and control the learning environment and their own behaviours. If this is to occur, the personal education of teachers, leaders and directors must be equally well-considered and implemented. Such consideration will probably include:

- necessary background knowledge
- knowledge about teaching and learning
- appropriate attitude and commitment
- competence with appropriate teaching strategies
- ability to select, modify, and design curriculum
To achieve these, programs for educating leaders and educators must have specific components which lead to the capabilities desired.

5 Assessment and Evaluation for Scientific and Technological Literacy

Whereas assessment is most commonly used in formal school classrooms there is a need to use evaluation as a tool for accountability in all scientific and technological literacy programs. Educators need to assess regularly and meaningfully the academic achievement of their pupils. But, equally important, teachers must devise methods for monitoring their own teaching programs and the system in which they carry out their profession.

There are many issues to focus on, but attention should be drawn to:

- the need for valid assessment and evaluation for all desired goals (attitudes, creativity, the nature of science, application of knowledge), not just knowledge of concepts, vocabulary, and processes;
- the role of assessment and evaluation;
- public acceptability of appropriate assessment and evaluation;
- how such assessments/evaluations can be identified and monitored in formal and non-formal situations;
- use of formative as well as summative evaluation strategies;
- self-evaluation for users of technology;
- mechanisms for collecting relevant data;
- the role of evaluation agencies.

Assessment and evaluation should provide usable information for improving the quality of life and measuring the needs of a flexible workforce which can be more effective if scientifically and technologically literate.

6 Non-formal Development of Scientific and Technological Literacy

While formal schooling provides a major mechanism for enhancement of scientific and technological literacy, non-formal (museums; science centres; zoos; science clubs, fairs and camps) and informal (the media, science magazines, events, art, music) also provide significant avenues for development. In fact, for adults and out-of-school youth, these may play the major role. Knowing these, serious proposals must consider:

- identifying, supporting and publicising non-formal and informal mechanisms;
- the education of personnel for non-formal and informal efforts;
- linking schools with non-formal and informal institutions, events and mechanisms;
- evaluating the effectiveness of various non-formal and informal approaches.

There is a wide range of institutions and organisations involved in informal and non-formal education. These include national academies of science, associations for the advancement of science, and science teachers' professional associations as well as literacy adult education and distance education programs.

With these aspects considered, the role of non-formal and informal education is anticipated to improve and complement that found in the more formal school setting.

Simultaneously, adult scientific and technological literacy would be enhanced. And, since both non-formal and informal mechanisms involve mixed age groups, learning will be better viewed as a family and life-long affair. For further information contact:

The Other Side of the Classroom Climate Coin

by Olughbemiro J Jegede & Peter Akinsola Okebukola

The enormity of the task of implementing a science curriculum program often rests on the shoulders of the science teacher. Reduced to the classroom level, teachers attempt, on individual basis of student-teacher relationship, to communicate the ideas of science to learners in a way that the learning outcomes would be maximised.

In spite of all the very good tips about how best to teach science and especially in the age of inquiry and hands-on teaching, how many teachers still go home after a hard day's teaching, feeling everything but happy, confident and content that our students have really learned science?

If you think you are probably the only one that feels that way, a talk to the next science teacher and you would be surprised what little intrinsic reward we usually get from the strenuous and highly stressful effort and commitment we give to teaching science. For the teacher within a non-western and traditional society where the commonplace knowledge students acquire in the traditional setting is diametrically opposed to what school science teaches, this mismatch often creates a rift between the two worlds of science and culture with the learner being torn between the two.

To date, several studies have been carried out on classroom climate (Fraser, 1989). Within the psycho-social niche of the classroom environment, it has been found that factors like teacher support, teacher control and innovation, goal direction, cohesiveness, task orientation, to mention but a few, bear strong relationship to cognitive and affective outcomes of science education. While efforts have been directed at unravelling other variables that affect science teaching and learning, it does not seem that any concerted effort is being directed to study the socio-cultural niche of our science classrooms. Studies in this area are needed for two main reasons. The first is global in nature: culture, as the totality of all humans, does subsume every endeavour (and this includes science education) which we undertake. Science education is a cultural and human enterprise involving the transmission of cultural heritage of a people (Maddock, 1981; Gallagher and Dawson, 1984). Every investigation of human organisation ought to, therefore, tackle the socio-cultural framework. The second reason stems from our personal experiences as teachers of students in a non-western environment as well as of those in a western environment with a traditional background. Why is it that students in the categories mentioned above show certain traits which do not seem congruent with what is expected of

ICASE AWARD SCHEME

for outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.

ICASE Distinguished Service Award

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations

ICASE Regional Service Award

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

ICASE Association Award

This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Contact Dr Jack Holbrook, Executive Secretary ICASE

'normal' learners in science classes? For example, they hardly want, or display the urge, to ask questions in class; when forced to voice their opinions, some indicate that science has very little relationship with their daily life. Others think that the study of science is a weird, special activity requiring some magical and superhuman explanations.

To the science teacher who perhaps share the same socio-cultural background with this group of students, the issue is real but, nonetheless, frustrating. It is even worse and may be horrendous for the teacher with a western background who has to teach students of a non-western background. A typical case may be that of a permanent or Peace Corps science teacher of Western origin who finds himself or herself in a science classroom in Africa, Asia, South Pacific or the Caribbean. Such a teacher will find that these countries have a predominantly traditional environment characterised by ethos, values and beliefs quite different from what she/he is used to.

Based on our personal experiences as science teachers and teacher educators who have had to grapple with the effect of socio-cultural factors in the teaching and learning of science, we carried out studies to illuminate the socio-cultural aspects of the science classroom where an acute dearth of information has been noticed. The aims of the studies, carried out in Nigeria - the biggest and most populous African nation with a predominantly traditional society were:

- to develop an instrument, valid and reliable, for use in the study of socio-cultural factors in an African environment, and
- to investigate the socio-cultural predictors of outcomes of learning in science.

It was our belief that results from studies such as ours would not only add to the bank of knowledge on classroom climate, and particularly in non-western societies but provide useful information for teachers with a western background who find themselves operating in non-western classrooms. Similarly, teachers with culturally heterogeneous classes in a western environment with a good proportion of students from or within non-western background would also need more information for effective planning of science instruction.

In sum, the results of our investigations have led us to conclude that the following five predictors of socio-cultural influences in the learning and teaching of science in Nigeria are important for science teachers to be aware of.

**Authoritarianism**

This factor characterises the traditional society where the belief is strongly held that the older person, having been exposed to more life experiences, should be in a better position to appraise a situation and pass 'correct' judgement. The society frowns at a situation where the elder's point of view is challenged or questioned. On the basis of this, the elder asserts authority in decision making. It behoves the younger individual to accept without questioning, the directives passed down by the elder. This locus of authority of knowledge gets transferred into the classroom where the science teacher is seen as the elder who 'knows all' in matters relating to scientific facts, processes, principles and laws.

**Goal Structure**

This refers to the interaction pattern among the people of Africa which is predominantly of the co-operative kind. In the co-operative setting, the goal structure of individuals is directed at the same objective and there exists a high interdependence among the goal attainment of individuals. This contrasts very markedly with the individualistic competitive orientation school science portraits to learners.

**Traditional Worldview**

This relates to traditional beliefs and superstitions being used as the framework through which occurrences are interpreted. The society holds the notion that supernatural forces do have significant roles to play in daily occurrences. The younger members of the traditional society are supposed to grow up to learn and believe these without questioning. However, this creates conflict when that which is taught in the science classroom is not in agreement with the traditional worldview.

**Societal Expectation**

The success or otherwise of an individual within a community is developed and interpreted through the nature of interaction within a communal society. The behaviour of members in the community is invariable and intimately linked to, and governed by, that of the larger community. Hence, an individual, particularly a school child always reviews his/her achievement in school as a reflection on his/her home, friends and community.

**Sacredness of Science**

This pertains to conceptual interpretations of science. This is a pervasive view held by a large proportion of the African society in which the study of science is regarded as something special, requiring magical or weird explanation and incompatible with the thoughts of someone from a non-western society.

There is reason to believe that the currency of some of these factors may transcend international and regional boundaries particularly of Africa, Asia and the Americas (Gallagher and Dawson, 1984; George and Glasgow, 1988). This information might, therefore, prove very handy for teachers who are concerned about the comprehensive effectiveness of science teaching and are interested enough to know about the other side of the classroom environment coin.

Understanding the socio-cultural framework of a learner's mind is compatible with the emerging paradigm of alternative conceptions and constructivism in science teaching (Driver and Oldham, 1986). This will go a long way in helping to realise the five domains of science education as catalogued by McCormack and Yager (1989).

Discrepant Events
An Alternative Teaching Process
by
Dr Zoe Kavogli

Can you make successful teaching of primary science a little more possible?

Introduction
Discrepant events are events which are unexpected or surprising to the viewer.

Primary science has changed greatly during the past 10 years in Greece. At one time, most science teaching was focused on the content of science. Nowadays, national programs in science education shifts the emphasis away from content towards processes. What are processes? They are how a scientist works, thinks and investigates. In other words, it is a method of investigating.

As in most countries of the world, so in Greece, the typical primary teacher is responsible for many different subjects. Science is not the only concern and it is often the teacher's greatest weakness. As a result, success in primary science is not easy to achieve. Within the teaching process we try to make successful teaching a little more possible. We take away the complexity so often built into science teaching. We do not worry about how to teach the process approach. Discrepant events provide teachers with many simple, concrete and easy-to-use examples of events or situations that encourage good teaching practices.

'Discrepant events' was an experimental project taught to the postgraduate teachers and applied in various primary schools in Greece. The characteristics of matter, heat, energy, static electricity, magnetism, current electricity, sound, light, lenses and colour, air and air pressure, weather and climate, and flight through the air were studied and applied. This project was beneficial for both teachers and students. Especially teachers drew a lot of conclusions on an alternative way of teaching which provided more active learning in primary classrooms. This process approach included many specific skills such as careful observation, recording of data, predicting, graphing, estimating, formulating hypotheses, classifying information, comparing, measuring, inferring, generalising, and controlling variables. All of these are methods of investigating which are the core target of Primary Science in the Greek National Curriculum.

What is a discrepant event?
Everyone has seen water run downhill. The fact is hardly surprising or unusual. However if you were to see water run uphill, it would be entirely different matter! Water flowing against the force of gravity would be a discrepancy. Most people know that ice melts at 32 degrees F. However, if you were to see a beaker of ice melting at 10 degrees F, what would you think? Again there would be feelings of curiosity and surprise. This would be especially true when, upon closer inspection, frost is seen forming on the outside of the beaker while ice is melting on the inside.

Water is expected to run downhill, not uphill; ice is expected to melt at 32 degrees F, not 10 degrees F. These examples of discrepant events are often described as paradoxical, unexpected, and surprising. A discrepant event tends to produce a rather strong feeling in the observer. Generally, he/she will have an inner feeling of wanting to know and is curious, wishing to resolve the discrepancy in his/her mind. Adults and children will display a desire to resolve the unexpected. Certainly the enthusiasm of the latter will be even greater. Children will simply not rest until they find out why certain events occurred as they did.

It is obvious that when students are strongly motivated conditions are favourable for learning. Therefore, any method that helps generate this motivation is worthy of investigation. Thus discrepant events capitalize on the student's curiosity, helping him/her gain a better understanding of science.

Although there is considerable value in the use of discrepant events, it is obvious that these can not be developed for every topic or scientific principle. In the absence of an appropriate discrepant event, it is entirely acceptable to present non-discrepant events in which the students have a chance to observe or perform some kind of investigation. The main point to remember is that the event is used as an incentive to student involvement. Discrepant events are presented whenever possible, supplemented with non-discrepant events wherever needed.

How to use discrepant events in promoting the processes of Science
Discrepant events are quite useful when care is taken to initiate a lesson properly and time is allowed for student investigation. The teaching of lessons can become effective when the following three general steps are employed:

Set up the discrepant events
In this step the event or events are presented to gain attention, increase motivation, and encourage pupils to seek ways of solving the discrepancy. The stage for learning is set since pupils are confronted with questions or problems that they want to resolve.

Involve the children in solving the discrepancy
After the event has been properly introduced, the pupils will
be anxious to seek an answer. Pupils will often engage in purposeful activity in attempting to solve the problem or resolve the discrepancy. This is the ‘messing about in science’ phase of the lesson. Students will be active in observing, classifying, predicting, experimenting and doing whatever tasks are relevant to the investigation. In addition, it is likely that they will learn the bulk of the real content in the lesson.

Resolve the questions

Under an ideal setting pupils will gradually resolve the questions by their involvement in step two. By their activities and experiences they will find the answers to many of the questions posed by the discrepant event. Moreover, they will have learned something about how to observe, classify, and experiment, as well as other related science processes.

Even if pupils are not successful in finding all answers, they will be ready to benefit from a more traditional treatment of the topic. Their questions and comments can gradually be brought into line with the basic scientific principles that apply to a particular event. Even if the teacher merely explains the answer, the explanation will be of far greater value than a traditional explanation, because at this point children have made some personal commitment to the problem and have a vested interest in the outcome. This is far better than merely listening to an explanation of some abstract principle read in a book.

To make the three steps more meaningful, they will be used in the following examples:

**Example 1**

*Set up the discrepant event*

Place a coin under a clear glass tumbler and tell the children to watch the coin closely. It is easily visible when seen through the side of the glass. Now pour water into the tumbler and presto the coin disappears! Repeat several times to be sure that all can see.

An event such as this is of great value in motivating the child. Even adults who see this activity are generally quite surprised when the coin disappears and will want to know how it works. From this point on, the push or ‘wanting to know’ comes from the pupils.

*Involve the children in solving the discrepancy*

Students’ activities will include questioning, experimenting, reading, predicting, recording data, and theorising. Students will be sorting out the relevant from the irrelevant principles related to the event and are likely to cover a wide spectrum of the basic principles of science.

Resolve the questions

Students will gradually resolve their questions by their activity in step two. These questions are then placed in the proper context of the science principles which apply to the events. The disappearing coin is part of a lesson on the refraction of light which occurs when light moves at an angle from one medium to another. When viewed through the side of the glass, the light travels through several different mediums (glass, water and glass again) and is bent so much that the light from the coin does not escape through the side of the glass. When viewed from the top, however, it is still visible, because there are only two mediums to bend the light and the light is not travelling from one medium to another at much of an angle.

In this sample lesson, we used only a single event to keep things simple. In a typical classroom setting, we would probably present several related events, all pertaining to the same basic principles to fit into a continuous discourse.

Let’s trace the method through a second example.

**Example 2**

*Set up the discrepant event*

Set up three bottles as shown in Fig 1. Blow across the top of bottle A and note its sound. Ask students to predict whether it will have a higher or lower sound. Then blow
across the bottle B and observe that it has a higher sound. Now ask students to predict the sound of C. This time they easily predict that it will have a still higher sound; confirm their prediction by blowing across C.

![Image of three bottles](image)

*Figure 1 A paradox of high and low sounds can be produced by striking the suspended bottles and blowing across the mouth of each.*

Ask students to generalise. They will probably say that the higher the water in the bottle, the higher the pitch.

Produce the sounds several times so that everyone is sure of his or her observation. Then tell the pupils that we need to check just once more in a slightly different way to verify our observations. This time, instead of blowing, strike each bottle with a pencil. Surprisingly the tones will be just the opposite of what they were before! - The higher the water in the bottle, the lower the pitch.

**Involve the children in solving the discrepancy**

At first glance the discrepancy is baffling to children. They will want to reproduce the blowing and the striking tones to verify all their observations. Probably they will also test the bottles with varying amounts of water in them. Naturally, they will be sharing and comparing their theories and results.

**Resolve the discrepancy**

A single principle of sound explains both the first and second set of sounds from the bottles. A small mass (or quantity) of a substance will produce a higher pitch than a larger mass (or quantity). When air was blown across the bottles, the air was set into vibration, but not the glass or water. Therefore, the bottle with the least air had the higher pitch. When the bottles were struck, the mass of glass and the water set into vibration, not just the air. Our principle is applied again. The bottle with the least glass and water produced the highest pitch. In both cases the smaller mass produced the higher pitch and the larger mass produced the lower pitch.

As in the first sample lesson, this event should normally be supplemented with additional events all pertaining to pitch. The explanation would then receive a more thorough treatment and be better related to a continuous discourse.

Let us try a third example.

**Example 3**

**Set up the discrepant event**

Have available several tumblers and an aquarium or large jar of water. Give a set of two tumblers each to several committees of students and ask them to pour air from one tumbler to another.

**Involve the children in solving the discrepancy**

In this case, the event is not so much a discrepancy as it is a perplexing and interesting problem. At first, students will say it cannot be done. Tell them it can be done and see if they can discover how.

**Resolve the discrepancy**

The solution is very simple. Merely invert one tumbler and lower into the water leaving it filled with air. Lower the other tumbler under the water and invert it, filled with water. Then tilt the tumbler that is full of air so that the bubbles escape and rise into the tumbler that has no air. In this way, we can clearly see the air as it is transferred (or poured) from one tumbler to another (Fig 2).

![Image of air transfer](image)

*Figure 2 Pour air from one tumbler to another under water. This activity is related to one of the important properties of air. When this event is solved, the children will readily know that air is a real substance and occupies space.*

Again, as stated in the two previous examples, the lesson should generally be supplemented with several other related activities all pertaining to the same property of air.

One final comment is necessary. The three steps are important only insofar as they are useful in permitting teachers to acquire techniques that promote instruction of the process skills. The steps are really only generalised procedures for setting up the beginning, middle and end of a good lesson. They should not be regarded as restrictive in any way. Within the three steps, teachers should feel free to use a wide range of techniques in teaching any given lesson.

ICASE World Activity Day
Thursday 14 October 92
Theme for 1992: Space

Teachers and students in schools around the world are invited to participate in special activities focusing on the theme of space.
Thursday 14 October 1992 is designated as ICASE World Activity Day. Member associations of ICASE are requested to encourage schools in their countries to share in this worldwide program on 14 October. The activities, which can be adapted to suit students at all primary and secondary levels, include: (1) Designing, constructing and testing rockets which operate on compressed air and water; (2) Calculating the Earth's diameter by measuring the length of the shadow cast by a stick; and (3) Writing a short essay (maximum 1000 words) on (a) space travel in the year 2092 or (b) life as a student in 2092 as a result of space technology.

See the March 1992 Issue for an outline of these activities. For further information, contact: Brenton Honeyman, ICASE Journal Editor, 10 Hawken Street, Monash ACT 2904, Australia.
Indigenising the Science Curriculum in Ghana through the Science in Ghanaian Society Project

by Dr Joseph M Yakubu

Introduction

Richard Ingle and Tony Turner in their paper, 'Science Curricula as Cultural Misfits' (1981) state rightly that western science curricula imported into the Third World countries are both cognitive and cultural misfits. The consequence of this is that the young people who have received western formal education are, by and large, unemployable and de-acclimatized. They become cultural misfits. Rather than calling for the dismantling of schools or deschooling of society as Ivan Illich (1971) would suggest, science educators believe that the curriculum ought to be revolutionised. The 'Blackboard Revolution' or curriculum revolution is a world-wide process which started in the late 1950s. These years could be regarded as the years of Renaissance of science education. This consisted of the writing of new syllabuses and books, and devising new methods of teaching. The National Science Foundation of the United States of America set up projects such as the Physical Sciences Study Committee (PSSC). In Britain, the Nuffield Foundation set up the Nuffield projects in Biology, Chemistry and Physics.

In West Africa, this consisted of indigenising the curriculum. What do we mean by the term 'curriculum'? What do we construe the term 'indigenising' to mean? There is no agreed meaning of the term 'curriculum' but in this paper I construe it to mean as John Dewey defines it:

'... a selection of the kind of present experiences that live fruitfully and creatively in subsequent experiences' (Dewey, 1963).

If articulated this way, this definition will include those of Ralph Tyler (1949), Kerr (Lawton, 1973), Hirst and Peters (1970) and so on. It seems to have been agreed by all educationists that the characteristics of a curriculum should include aims and objectives, learning experiences, knowledge and evaluation.

The Oxford English Dictionary defines 'indigenising' to mean 'making natural to'. This implies that when we speak about indigenising the curriculum, we mean making it natural to our culture. It does not mean adopting or adapting these foreign curricula that have been in our societies since colonial times, neither does it mean just substituting local names for foreign ones in the syllabuses. It rather means that, with our knowledge of curriculum principles, science and our culture, we should be able to design curricula whose aims and objectives, learning experiences, knowledge, teaching methods and evaluation have their bases in our culture. My purpose in this paper is to describe and explain an attempt that is being made in Ghana to indigenise the science curricula.

The Science in Ghanaian Society Project: Its origin, rationale and objectives

The attempt at indigenising the science curriculum in Ghana is done through the Science in Ghanaian Society Project. The idea of using indigenous technology in science teaching came to me at a time when I became aware of the misfit between the teaching of science with foreign textbooks and the reality of the pupils' environments - natural, cultural and social. I noticed that the pupils became interested when a local example was used to illustrate a concept. They were then able to understand most of the ideas which I had to copy into my notebooks and learn by rote. I then decided to study science up to the School Certificate Level because I considered myself a brave boy who could tackle such an abstract subject as science which seemed to have nothing to do with my environment. This was a gamble, and I think that most of the pupils we teach science these days also take it as a gamble.

After years of teaching and study, my experiences and philosophy of science teaching have culminated in a project, the SGSP. Discussions were held with teachers and colleagues at the University of Cape Coast. Proposals were then written to look for funding in 1982. Fortunately, by August 1983, UNESCO and the British Council gave assistance in both cash and kind for the project to be started and the SGSP was started in December 1983.

Objectives of the SGSP

The objectives of the project were identified as follows:

- To study local industries in order to identify the scientific concepts and processes embedded in them
- To produce books on local industries and other aspects of Ghanaian culture relevant to science teaching
- To develop industry-oriented or interdisciplinary methods of science teaching
- To investigate ways of improving the image of the world of work of Ghanaian youth, especially senior secondary, junior secondary, and technical school leavers

The project at the moment is not to produce a course but resource material for both the teacher and pupils. As resource materials, the project books could be used to enrich the existing syllabuses. Later on, it should be possible to design a course from these materials, if the need arises. Providing the teacher with information and skills are of paramount importance in this project. Research in science education has indicated that the most serious problem of science teaching has something to do with the teacher's confidence or capabilities. Any attempt to improve the teacher's confidence...
will go a long way to improve the learning and teaching of science in our schools. Providing the teacher with information, new techniques of teaching and learning, are the strategies of the SGSP to improve the confidence of the science teacher.

Methodology of the SGSP
The project started investigating the indigenous industries because they are ubiquitous in the community. The case study method was found to be the most appropriate strategy to use. A case study is defined as an in-depth study of an instance (Kenny et al., 1984). An in-depth study of each indigenous industry was to be made. Since industries are interdisciplinary organisations, the interdisciplinary teaching method is the main method advocated and propagated.

The first phase of the project was to make case studies of indigenous industries and to develop interdisciplinary teaching methods. Practising science teachers in secondary schools and training colleges, and both District and Regional Science Organisers from all the regions were invited to participate in the first workshop of the project. Also invited to the workshop were representatives from the Department of Rural Development, the National Council for Women and Development, Technology Consultancy Centre, Kumasi, the Ghana Education Service Curriculum Research and Development Division and the Ministry of Science, Technology and Industry. Also invited were resource persons including economists, historians, appropriate technologists, scientists, social workers and industrialists.

At the first workshop in February 1984, the participants were taught how to make the case studies. They had two months to carry out the fieldwork using a format explained at the workshop.

A Writing Workshop was organised in April 1984. At this workshop each participant wrote up his case study and presented it for discussion. The presentation proved to be very lively and educative. The resource person gave comments that related to their fields of specialisation. All the comments were taken into consideration in the writing up of the case study books. The interdisciplinary methods of science teaching were explained and discussed. After the Writing Workshop, I wrote all the books. This meant doing a lot of reading and researching. Eventually 27 booklets were produced. This ended the first phase of the SGSP project. A report of the first phase of this project was written and sent to the sponsors – UNESCO and The British Council – together with sets of the 27 booklets. All the participants were given sets of the booklets. Copies were also sent to significant people in Ghana and abroad who would be interested.

In August 1985, I attended the Bangalore International Conference on Science and Technology Education for Future Human Needs. The SGSP books were exhibited and explained to the Industry Group of the Conference.

A third Workshop was organised in September 1985 for teachers who opted to try the books in their classrooms. The teaching methods were discussed and demonstrated. The booklets were also discussed critically. A questionnaire was given to each teacher to complete as he tried the booklets.

The completed questionnaires were returned by the teachers in 1986. The comments were noted. Two main suggestions came out. Some of the booklets were similar and could be brought together. The second comment was that the interdisciplinary methods are time consuming. It could disrupt the school timetable. There is the need to reconcile the pressure to finish the syllabus and the need to teach science for enjoyment and for life. These comments are being considered. The booklets are being reorganised into ten books. A fourth Workshop was organised to enable teachers to write examples of the interdisciplinary approaches for their colleagues.

The Philosophy of the SGSP
The philosophy of the SGSP is based on ideas of Robin Horton (1982). He distinguishes the African theoretical system of thought which he terms ‘Primary Theory’, from the western scientific system of thought which he calls secondary theory. He explains that the Primary Theory does not differ very much from culture to culture although the level of development of the theory will because experience is a variable factor. The Primary Theory embraces the world of human beings and enduring solid objects. It establishes the relationships between human beings and objects, among human beings, and between human beings and spirits. It is couched in personalised interpretations. The Primary Theory is also characterised by in-built ‘blocks to falsifiability’ (Shorupski 1976) which makes it appear to have the ability to explain everything. In this sense, indigenous Ghanaian thought is non-tentative and is unaware of its limitations. For indigenous people, there is always an explanatory framework for every phenomenon or problem encountered.

The Secondary Theoretical system, on the other hand, is based on intangible entities and establishes relationships between ideas and ideas. Horton’s ideas are evolutionist and he seems to assert a belief in universal culture especially the cognitive aspect he labels ‘theory’. The lower level of theory is the Primary Theory which exists in all cultures, and the Secondary Theory which is a higher level and resides in scientific thought. By implication, through cross-cultural exchanges, it is possible for the Primary Theory to be developed into a Secondary Theory. The Primary Theory exists because it is found to be efficaciously time-tested and not necessarily because of its age. Consensus is the method of legitimacy of the Primary Theoretical System while competition among rival theories is the method of legitimacy of the Secondary Theoretical System.

From this analysis, it appears that cultures which are stuck or ‘frozen’ by environmental constraints at certain stages of their development, from ‘primitive’ to advanced levels, can be ‘thawed’ to progress at their own rates. It seems to me that integration is an appropriate method by which this thawing process can happen. The indigenous technologies or actions seem to be the best media in which the Primary Theoretical system resides.

The SGSP studies the indigenous technologies or actions to identify the Primary Theory in them. Having done this, it reveals how the Primary Theory can be transformed in to the Secondary Theoretical level. The history of science (Williams 1976) tells us that the Roman craftsmen were
stagnant in their work because the Romans frowned on experimentation while the Arabs progressed in science because of their experimental techniques (e.g., Alchemy). The presence of the experimental technique removes the presence of blocks to falsifiability and therefore progress can be made. The SGPS therefore aims to infuse experimental techniques into the indigenous technologies.

Indigenous technologies are considered as issues-real problem areas in which not only ideas and techniques are at stake but also the economics, history, wealth production capacity, the environmental implications and social responsibility. For the interdisciplinary approach 'initiative, and originality in inventing and testing solutions together with thoughtful use of, and even extension of, one's resources of knowledge and skills, would be essential (Black, 1986). It is interesting to note that even though we are in a modern world of science and technology, the Ghanaiian population is still maintained by indigenous industries. For instance, the peasant farmer, using very simple techniques, still feeds us.

Appropriate interdisciplinary teaching methods termed industry-oriented methods have been developed for teaching the SGSP case studies. The industry-oriented methods include the following:

- Systems approach to science teaching
- Problem-Solving and decision-making
- Simulation Games
- Project Method
- Community Involvement Method
- Historical Method

**Systems approach to science teaching**

A system is understood here as an interconnected set of elements interacting and worthy of isolation for study. In this sense, a system has inputs and outputs or products. The inputs and the outputs can be seen but the interactions of the elements which lead to the product cannot be seen, producing a 'black box' situation. The factors which affect the interactions - variables - can be manipulated to produce a given form of product.

For instance, charcoal making (Book 1) can be used as an example. The charcoal pack is made up of layers of firewood, starting with larger logs at the bottom and ending up with smaller sticks at the top. The second layer is laid transverse to the first. The pack is then covered with fresh leaves of the plantain or cassava plant. This is then covered with sand to produce a mound. A gap is made at the bottom of the pack to allow air into it. The whole charcoal pack is regarded as a system and its inputs are the firewood and air. Fire is lit at the gap to set the firewood burning. The system is now a black box because we do not know how the wood is being turned into charcoal. However, we can identify the process that is going on inside it and then identify variables which we can manipulate to let the burning proceed the way we like. The variables are the passages of air into the system and out of it. Air enters through the main gap at the bottom and escapes through the top which is porous. The principle of hot air rises and cold air falls applies here. The cold air enters the bottom and the oxygen in it causes burning to take place. The hot air is lighter than cold air and therefore rises. A current of air into and out of the black box charcoal pack is set up.

If more air is allowed into the pack combustion becomes complete and ashes rather than carbon are produced. The controlled supply of air into the pack results in partial burning, distillation of the wood. In this process, the non-carbon components of wood are burnt off and escape as smoke leaving the carbon behind. Allowing very little air into the pack reduces combustion drastically. In such a case the charcoal will contain unburnt wood. Thus, by controlling the ventilation of the system, a certain quality of charcoal is produced.

In the systems approach the contents of test tubes, flasks, a whole process, a laboratory and so on are regarded as systems or black boxes. The factors which affect the interaction of the reactants in the system have to be identified and used as variables which can be manipulated to produce required products. The systems approach is actually the heart of the experimental technique.

**Problem-Solving and Decision-making**

'A problem exists when a threat or opportunity is recognised and one is not sure how best to act in order to counter the one or take advantage of the other.' (Suckling et al, 1978 p12)

In a developing country such as Ghana, there are threats of famine, desertification, and parasitic diseases. The problem is not that we are not aware of them but that we are not sure of where to find the solution. The SGSP tries to show how solutions to our problems are often found in our environment and indigenous technology. Identifying issues associated with them and basing our science teaching on them will go a long way to help us to transform them from a Primary Theoretical level to a Secondary Theoretical level. For instance, problems associated with energy resources (e.g., use of firewood and charcoal) can be tackled by posing a problem of a threat to our existence through desertification. Here, the SGSP Book 1 (Energy in Ghanaiian Society) will be the centre of the lesson.

Problem-solving is a systematic process comprising the following stages:

- Formulation of the problem to be clear and action-oriented.
- Interpretation of the problem laying out the scientific ideas and processes at stake and which need to be used.
- Generating courses of action; suggesting or conjecturing alternative solutions to the problem.
- Making a decision on which is the best solution considering its scientific, technological and social merits.
- Implementation of the selected solution keeping in mind the resources and constraints involved.

For instance, to understand desertification, the pupils must understand the concept of the ecosystem. Here again they are dealing with a system where interacting components are the producers, primary consumers, secondary consumers, decomposers, inorganic substances and energy. Again, this
becomes a black box. The problem is which factor is causing desertification? Most people depend on firewood and charcoal as fuel. How does this affect the ecosystem? Alternative solutions are suggested, including biogas production, transforming the indigenous stoves into more efficient ones and so on. Which of the alternative solutions is the best? Why is it regarded as the best solution? The implementation of a solution may include adult education, the production of the new type of stoves, or even new fuels.

This approach raises the level of consciousness of pupils who are the future policy makers, engineers and citizens. If they grasp the factors that underlie desertification now, we can have hope of arresting the fast rate at which desertification is proceeding. Similarly, pollution of soil, water and air, waste disposal problems in the cities, the short shelf-lives of vegetable oils, food preservation and so on can be problems which could be starting points for interdisciplinary science teaching.

**Simulation Game Approach**

A simulation is construed here to mean 'an operating representation of the central features of reality' (Ellington et al, 1979). A game is also construed here to mean a 'contest (play) among adversaries (players) operating under constraints (rules) for an objective (winning, victory) or pay off'. These definitions imply that the actual activities, out there in the society, are not played but that they are represented or acted in the classroom. The participants are actors in the game playing roles of certain people in real life situations. The SGSP Case Studies constitute a simulation of the real indigenous industries out there in the community. The pupils pretend to be the people working in these industries.

In the real world, competition is characteristic of industries as one industry tries to be the best in the world or country. Group work is very important in the simulation game approach, usually with each group representing a company. The best company will be the one that shows how it would use its technology, science, money, management and social responsibility will. The teacher also arranges to get someone from the real industry to judge and prizes are awarded.

In Ghana, pito brewing, a common activity, is one of the topics of the SGSP Book 4 (Fermentation in Ghanaian Society: Alcoholic processing and distillation). Groups of students represent Pito Brewing Companies, and groups try to show how they produce the best quality pito. Innovation such as preservation techniques, economic use of energy, and even marketing are considered. Continuing, gin could be another activity to be simulated. Gin can be distilled from the pito beverage, palm wine, fruits and molasses. Here again, priority is given to inventiveness and use of experimentation. Other case studies which can be simulated are industries (and issues!) related to fish smoking, gari production, vegetable oil extraction, farming, herbal medicine, or blacksmithing.

Games other than simulated case studies are used with shorter periods of time to play. For instance, Ludo, Snakes and Ladders, Monopoly, Oware, and cards can be adapted to teach certain concepts. For example, Snakes and Ladders can be used to teach about safety; Monopoly can be used to teach about how the productivity and growth of a company depends on the capability of its management.

Simulation games and games give the pupils the feel of being in certain situations even though they are not actually in those situations.

**Project Method**

A project is simply 'an extended piece of work on a fairly broad topic in which the pupil or group has a considerable degree of freedom in planning and carrying out investigations' (Hall, 1973). The project is actually another problem-solving and decision-making approach. The only difference is that the student or a group identifies their problem, generates his courses of action; makes his own decisions; observations, recordings, calculation, visits, interviews of people, hypotheses and tests.

Projects can be identified from any of the case studies on Energy (Book 1), Vegetable Oil Extraction (Book 2) Fermentation of Alcohol (Book 3) and Food Processing (Book 4). The experimental technique is central to the project work, providing opportunity for the pupil to learn how to experiment and think experimentally. This goes a long way toward infusing the experimental spirit which is lacking in the indigenous thought system into the pupil's explanatory framework. It also removes the barriers to falsifiability that exist in the primary theoretical explanatory framework.

**Community Involvement Approach**

An industry-oriented approach to science teaching is also community-oriented as the community and the school interact in such a way that each changes through the process. In developing countries the community is full of human resources or experts in various activities such as dyeing and weaving, brewing, herbal medicine making, soap and oil making, tanning, or blacksmithing. Since the teachers in the schools are not taught these activities during their pedagogical training they need to enlist the help of such cottage experts. The school will, in turn, help members of the community in other ways. Facilities such as buildings, library or football fields can be used by the community. The teachers can teach functional literacy including civic and health education to adults. Adult education thus changes from the learning of the alphabet to learning the meaning of existential situations of the community.

All the SGSP Case Studies lend themselves to the community involvement approach. Pito brewing, akpeteshie (gin) distillation, charcoal making, vegetable oil extraction, and food processing can be learnt by a community involvement approach. Health problems such as prevention of malaria, guinea worm and intestinal worm infestation, farming and so on lend themselves also to this approach.

Awareness is created in both the teachers and pupils, and also in the indigenous people of the community. Discussion and the appreciation of the views of others, a scientific attitude, is also created. Selection is a characteristic of science, but selection becomes impossible if plurality of ideas is not accepted. Open-mindedness may lead to the need to try-and-see or experiment and thereby remove the blocks to falsifiability that are inherent in the primary theoretical system of thought. Since the Ghana Government is advocating that all junior secondary schools should be
community schools, it is important that all teachers are made aware of what the community involvement approach is like.

Historical Approach to Science Teaching

Sherrat (1982) reports that in a presidential address, the President of the British Association for the Advancement of Science (BAAS) asserted that 'It is desirable ... to introduce into the teaching some account of the achievement of science and of the methods by which they have been attained ... There should be more of the spirit, and less of the valley of dry bones ... One way of doing this is by lessons on the history of science (BAAS, 1917 p 18-19)'.

Teaching 'the spirit of science' rather than 'the dry bones of scientific facts' is central to the philosophy of the SGSP. Although the case studies are not historical, they contain aspects of indigenous history which could be embraced in aspects of the history of science such as the development of concepts and methods. An attempt to draw parallels between indigenous thought and practice with science and technology may open our eyes to possibilities for improving indigenous thought and practices.

The historical approach can help the pupil to realize that scientific ideas are human constructions that form part of our culture. The primary theoretical explanations of the indigenous people are analysed in relation to a topic under discussion. For instance, in the indigenous explanations certain activities have their origins in hunters and fairies in the bush. A hunter encounters a fairy and is given the technology. These tales give the idea that the people do not know (and cannot explain) the origin of the technology and their 'blocks to falsifiability' will not allow them to say 'We do not know how such and such technology started'. Knowing the indigenous need for an explanation, the nature of scientific explanation can be discussed. Explanation through the agency of hunters and fairies suggests the diffusion of the technology from another society into the present one. Accidents can lead to discoveries, and there are examples of such in the indigenous experience.

The history of an indigenous technology can be discussed. For instance, I visited an Akpeteshie (Gin) Distillery near Cape Coast recently with my Masters students. One of the students asked whether they had tried fruits for distilling alcohol since they started production. They answered in the negative, and then he asked them why they did not do so. The answer was that it did not occur to them to try fruits and see what they would get since none of their predecessors thought of using a raw material different from the palm wine and sugar cane they had been using. From this discussion we realised that the Akpeteshie distillery is stagnant because of lack of experimentation. The historical approach can help us to identify what aspect of an industry can be transformed or what can be infused into the industry to bring about progress.

Visits to historical sites such as the ancient castles can be fascinating. For instance, the Portuguese came to the Gold Coast (Ghana) in 1482 and built a mighty castle as a trading fort which later became the main slave market. All the materials used in building the castle were imported from Portugal. The types of ships and navigational techniques of the day are discussed while building materials give an idea of the level of technology that existed in those days in Portugal. The factors which made it possible for the Portuguese to travel out to foreign levels are discussed and related to similar factors in Ghana.

The SGSP as a Strategy for Promoting National Development

Robin Clarke construes development to mean a 'process aimed at fulfilling mankind's highest aspirations' (Clarke, 1985 p 58). One may ask what Ghana's 'highest aspirations' are. This is stated very well in the Seven Year Development Plan (1964) which could be regarded as Dr Kwame Nkrumah's agenda for development. It was stated categorically that Convention People's Party (CPP) government aimed to 'establish in Ghana a strong and progressive society in which no one would have any anxiety about the basic needs of life, about work, food and shelter; poverty and illiteracy no longer exist and disease is brought under control; and where our educational facilities provide all the children of Ghana with the best possible opportunities for the development of their potentialities'. To strive to achieve these goals would rightly be explained as development.

There is a sense in which development can be understood to mean attempts to relieve people of their suffering by offering them aids of all kinds including food, health facilities and housing. Singer and others (1954) are of the opinion that progress is not motivated merely by the pressure of our needs but rather on the opportunities we have. This can be interpreted to mean that we cannot progress if we are merely desperate to relieve our present basic needs of food, health and shelter but we can progress only when we can identify what resources we have in our culture that we can try to improve with new techniques and knowledge. Such improved technologies will live with us forever if we are always improving them. Whether such improvements or transformation can be made or not, Clarke (1985) asserts that it depends on the knowledge available. He says that development is a measure of knowledge. The more scientific knowledge available, the more likely development can take place, the more likely the primary theoretical system can be transformed into the secondary theoretical system of science and technology. This implies that pupils should be helped to acquire scientific knowledge and techniques with which they can improve indigenous industries such as blacksmithing, vegetable oil extraction, food processing and preservation, dye stuff extraction, herbal medicine processing, salt making, fuel technology, or soap. These should be the objects of experimentation, hypothesising, and rational thinking of our pupils.

The SGSP Case Studies are portrayals of the opportunities that Singer and others are writing about. Our highest aspirations can best be realized through the opportunities we have, that is our indigenous technologies. The SGSP is therefore committed to educating pupils in science and technology for national development.
Conclusion

Clarke (1985) quotes Dr H B G Casimir, a past President of the Royal Netherlands Academy of Arts and Sciences as saying that science cannot be used for development. He was critical of the lip service by governments that science and technology are instruments of development. Ziman (1984) explains that science becomes an instrument when it acquires the status of a social institution ‘embedded in society and performing certain functions for society as a whole at par with other institutions associated with law, religion, political authority’. When so regarded, science and technology as an instrument or institution can be manipulated by politicians to satisfy their own ends rather than national aspiration. What Casimir is saying implies that national development ought to be synonymous with progress in science and technology. National development should be the same as science and technology development. This implies that to progress the government must give emphasis to science and technology education.

The question is what kind of scientific and technological development do we have in mind? The philosophy of the SGSP is that development of science and technology should be endogenous, that is, development that is internally motivated. This does not mean that external ideas should be excluded. What the SGSP advocates is the integration of the indigenous thought and practice with relevant imported science and technology. There should be a ‘grand titration’ of the two, as Joseph Needham (1969) explains. The SGSP is an example of a grand titration between indigenous Ghanaian thought and practice with foreign science and technology.

Acknowledgements

The SGSP has become a reality because of the encouragement of individuals and support organisations such as the following:

UNESCO, The British Council, the International Council of Scientific Unions – Committee for the Teaching of Science (ICSU-CTS), the International Council of Scientific Unions – Committee for the Teaching of Chemistry (ICSU-CTC) and IUPAC-CTC. I wish to render my sincere gratitude to all of them.

The present problem of the SGSP is with the publication of the eleven books of the project books. Support received so far has only helped to write the manuscript. The Ghana Universities Press needs money to print these books. Help is still sought to obtain money to publish the books.

The International School
Education for Children of all Nations

by John Stiles

Our world is increasingly a global community. In the recent past there has been an awareness that ties between countries have become stronger and national boundaries have become less defined. The iron curtain was dismantled more quickly than anyone thought possible, developing countries are negotiating contracts with super powers, and satellite communication is able to probe even the most remote areas of the Earth.

Efficient and relatively cheap air transport makes it possible to travel half-way around the globe within a day. Imagine the incredible fact that there are people alive today who were born before the first successful airplane flight and, thus, have witnessed the entire history of man's propelled journey into air and space!

With this increased mobility and cooperative development has come an increase in the number of people who frequently travel or move to other parts of the world than where they grew up. And these people increasingly are taking their families with them. Most families do not stay long-term in their new location; generally they return home or, in many cases, move on to another foreign post within three years or so.

The first group of people to make such a move on a large scale were American businessmen, diplomats and military personnel shortly after World War II when the USA found itself in the position of becoming the world's leading economic and military power. As the population of Americans living abroad increased in all parts of the world, the desire for American schools grew so that children would be able to continue their education in a familiar setting and be able to return home without falling behind in the American curriculum. Even though there were perfectly adequate schools available in many overseas locations, language differences and academic requirements were expected to be great enough that it was not perceived as beneficial for children to enrol in local schools. However, many parents did enrol their children in host country schools, and continue to do so in order to reap the many benefits that come with the knowledge of another culture and fluency in a second language.

Regardless of the perceived wisdom of the scheme, American-type schools opened up wherever a sizeable American population became established. Americans were then assured of an easy transition for their children, and a continuity in education which made it easy for children to return to US schools. This was often a 'selling point' used by companies luring prospective employees to work in foreign lands.

As American economic interests grew, the number of American schools increased throughout the world. From the first school in Mexico over one hundred years ago, the number of these schools has increased to number in the hundreds. Today, virtually every major city of the world has, or has had (many schools in war-torn countries have closed) at least one of these institutions. In addition, other schools, such as British, Swiss and French were established in foreign lands, although in smaller numbers.

Nearly one-fifth of these 'expatriate' international schools are affiliated with the United States Department of State, and were originally opened in capital cities to educate children of US citizens living abroad. More than 270 additional schools are run by the US Department of Defense.

By the 1980's other countries, especially European and Asian, had grown economically to challenge and compete with American interests. As a result, large numbers of non-American students enrolled in the American schools, and many - if not most - of these students went on to colleges and universities in the US.

But not all wanted an American education for their children. New schools often opened which had a more international (generally European) structure to the curriculum. From those who lacked the numbers or the financial means to open new schools, requests for courses which reflected various cultures resulted in a re-designing of the American school curriculum.

Many schools underwent so many modifications that in many locales the name was changed from 'American School' to 'International School'. The basic curriculum remained American, but was modified to meet the needs of non-Americans. One of these changes was the introduction of the Geneva-based 'International Baccalaureate' program, designed to prepare students for entry into European universities. A great number of international schools have adopted the program which can be made a part of the existing school curriculum. Other international schools have been formed primarily for European students; these schools can incorporate Americans generally more easily than American schools can incorporate Europeans because American universities in most cases do not
require specific curricula, only certain standardized college entrance examinations.

The name 'International School' reflects the growing number of students from various countries who attend the same institution. It is not uncommon for more than fifty nationalities to be represented in one school. Generally, Americans make up the largest percentage of these student enrolments but, increasingly, other countries have made their presence felt. The percentage of non-American students has risen, reflecting the trend of non-American economic influence world-wide.

Approximately half of the more than 800 schools for expatriate children are private institutions which receive funding from tuition fees (Broman and Brown, 1991). Most fees are paid by the companies which employ the parents, but there are some parents who pay the fees directly. In addition, many of the schools are supported by the United Nations, while still others are affiliated with religious organizations. These schools are subject to the laws of the host country.

In Thailand, for example, the head of a school, by law, must be Thai. Therefore, schools have a Thai 'headmaster' who is responsible for legal and business concerns, and a 'superintendent', a non-Thai who is responsible for curricular and instructional aspects of the school. The headmaster hires Thai personnel, while the superintendent hires non-Thais, usually the teachers and administrators, most of whom are American or European. Additionally, Thai children cannot attend these schools except for unusual circumstances such as those of mixed parentage or students who have lived outside the country for a number of years.

In Britain, a similar situation exists. Non-teaching personnel in 'American' or 'International' schools must be host country nationals, and are often hired by a Business Manager who is British, while the administrative and teaching personnel are hired by the Headmaster or Superintendent who is in most cases American or British.

Currently, there are six international schools in Thailand, each reflecting a unique educational need. In Chiang Mai, the International School uses an American-based curriculum. In Bangkok, there is a French School, a Japanese School, and a British School (Pattana) each structured to reflect the academic requirements of the parent country. Ruam Rudee International School recently had two campuses; one uses an American-based curriculum, the other Swiss, taught in German. This year, Ruam Rudee moved into a larger complex. The International School Bangkok curriculum is American-based but also offers the International Baccalaureate program for students bound for European universities. A new international school is planned to open in Bangkok in August of 1992. Its founders will model it on United Nations schools in Geneva and New York, with a flexible curriculum to meet the needs of students from all parts of the world. It will not necessarily be based on the American curricular model.

In the United States, international schools have existed for some time (The United Nations School in New York and the International School in Washington DC are two of the more well-known), but Japanese schools are now being opened or planned in areas where Japanese-based industry has brought large numbers of Japanese businessmen and their families. The international school concept has been successful in meeting the needs of temporarily displaced students world-wide, and by all indications will remain a viable force in education for some time to come. While the modifications will continue to reflect student populations and shape curricula, the schools themselves will be a comfortable and familiar 'base' for young people far from home. If the international schools and host country schools were to develop a cooperative venture, such as student and teacher exchange programs, the understanding between cultures would be enhanced and the lives of children even more enriched.

International Seminar Report
Empirical Research in Chemistry and Physics Education
10 – 12 June 1992

by Jan Hendriks, ICASE European Representative

In cooperation with ICASE, the University of Dortmund in Germany organised an interesting Summer Symposium. The first such summer symposium on Education in Chemistry in 1981 attracted little interest outside of the Federal Republic of Germany.

By cooperating with ICASE for the 1988 Symposium, the Summer Symposium was publicised worldwide. In recent years, the Dortmund Summer Symposium has developed into an internationally recognised meeting of researchers in science and mathematics education – a valuable source of information and ideas. The work and enthusiasm of Hans-Jürgen Schmidt, in particular, has been a key factor contributing to the success of the symposia.

In this year's Symposium, speakers from Australia, India, the Netherlands, Nigeria, the United Kingdom, the United States and Germany contributed to the program of lectures and discussions. About 80 participants focused on topics such as:
An Invitation to Kansas City
NSTA National Convention
March 1993

International Round Table

Each year at the NSTA National Convention, the International Committee of the United States National Science Teachers Association (NSTA) hosts an International Round Table. At this 90 minute session, presenters from different parts of the world discuss their country's science education programs.

Each presenter is provided with a table for a materials display. Those attending the International Round Table session visit the tables of countries they wish to learn about.

If you would like an official invitation to participate as a representative of your country, write to:

John E Penick
Science Education Centre
Room 789 VAN
The University of Iowa
Iowa City, IA 52242-1478
USA

Participants will be required to arrange their own funding. The letter of invitation, and your name listed in the program, may help you as you seek funding support.

For information about other conferences refer to the Calendar section in this issue

INFORMATION SHEET

Commonwealth Association of Science, Technology and Mathematics Educators (CASTME): Awards for science, technology and Mathematics teachers 1992/93

1. Introduction

The CASTME Award Scheme was started in 1974 when CASTME (then CASME) undertook to develop the former Guiness Award Scheme. Many entries have been received over the years since it started. It is certain that some schools and individual teachers have received major professional stimulus through its activities.

The awards are intended to encourage teaching of the social aspects of science, technology and mathematics, with particular reference to developing countries of the Commonwealth. The scope of the awards is interpreted broadly, and 'social aspects' includes the relevance of science, technology and mathematics curricula to

☐ local needs and conditions

☐ the impact of technology, industry and agriculture on the local community.

2. Eligibility

Teachers and officials (advisers, inspectors, etc) working in primary, secondary and tertiary education in Commonwealth countries are eligible to enter. Individuals or syndicates may enter.

3. Topics

There are no set topics for the competition. Reports of work carried out by the teacher or official should be based on personal experience and should include a substantial account of teaching and/or other educational work, such as curriculum development or programmes of teacher training. Entries based on ideas, proposals or general arguments which have not been tried out in practice are not acceptable.

An example of a recent prize-winning entry was entitled 'Using reed - a no-cost material - for science experiments in a rural middle school'. The author teaches in a rural school with no laboratory or commercial apparatus. He describes how he and his students developed a wide range of experiments and investigations using reeds gathered from a nearby swamp. Examples of activity-sheets are included, links with both the environment and the prescribed science syllabus explained, and the effects of the approach described and evaluated.

Each entry must be the original work of the entrant and must not have been published previously.

4 Awards

In addition to a small money prize donated by CASTME, a few travelling fellowships are sometimes awarded at the discretion of the judges. These fellowships, a gift of the Commonwealth Foundation, enable the prize-winners to follow a short programme of professional visits in a Commonwealth country. Edited versions of all winning entries may be published in the CASTME Journal and short abstracts of winning entries are printed in The British Council’s Science Education Newsletter. All prize winners will receive twelve months free subscription of the CASTME Journal. The judges are appointed by the Council of CASTME and their decisions will be final.
Judging is based on the following criteria

☐ evidence of originality and creativity
☐ evidence of use in practice and cost effectiveness (entries based on ideas, proposals or general arguments which have not been tried out are unacceptable)
☐ evidence of evaluation of the idea or material in use
☐ evidence of the social relevance of the project
☐ standards of presentation, organization and structure of the report

5. Presentation of the entry

Only one entry can be accepted from any one individual or syndicate.

Entries previously submitted to CASTME may not be re-submitted.

The entry must be written or typed on one side of A4 or quarto sheets of paper, and should not exceed 10,000 words in length. Reports in the past have mostly been between 2,000 and 5,000 words long.

Photographs and other illustrative material should be included wherever relevant, together with any other evidence that shows the ideas have been effective in practice. Pupil’s work may be included where possible.

Reference should be made to the source of information or of original experiments wherever this is necessary to a proper assessment of proposed modifications.

If a substantial part of an entry is being published or submitted as a thesis, this should be mentioned on the top sheet of the entry.

6. Registration and submission

Registration must be made before 30 November 1992.

Entries from registered candidates must arrive in the Education Department, Education and Science Division of The British Council before 1 March 1993.

Intending applicants should fill in a registration form. These can be obtained from

☐ Their local British Council Office
☐ CASTME Awards Scheme, c/o Education Department, Education and Science Division, The British Council, Medlock St, Manchester, M15 4PR, UK
Is Chemistry a Male Domain?

by John Beard, Charles Fogliani, Chris Owens & Audrey Wilson

Have your secondary science or chemistry students participated in a national quiz? Why not challenge them with a quiz lasting 60 minutes? In 1991, over 64000 students in 850 schools in Australia and the South Pacific participated in such a quiz.

The Royal Australian Chemical Institute introduced a National Chemistry Quiz in 1982, with two papers: a Senior Paper (Years 11 and 12) and a Junior Paper. A third paper (Years 7 and 8) was introduced in 1989, and a separate paper for Year 11 is being introduced in 1992. Schools from Fiji, Papua New Guinea and all States of Australia participate. The number of students taking the Quiz has increased from 8750 (150 schools) in 1982, to over 64000 (850 schools) in 1991.

Each paper in the Quiz is non-syllabus based and contains thirty multiple choice questions designed to stimulate interest in chemistry. While offering a challenge to students the primary function of the Quiz is enjoyment rather than formal assessment. Some questions are also presented as crosswords or word puzzles.

Certificates of Excellence (certificate and plaque) are awarded to students who achieve 100% in the Quiz, and Awards of Excellence (a plaque) are given for other outstanding results. About 40% of all participants receive a Certificate of Merit (10% High Distinction, 15% Distinction and 15% Credit).

Expressions of interest from teachers in Australia and overseas have led to the production of two books of categorised multiple choice questions from past Senior and Junior Quiz papers. The questions in these books can be used by teachers to produce tests and examination papers containing a balance of questions which have been categorised using Bloom's Taxonomy (Bloom, 1956). Questions are categorised as: knowledge (recall); comprehension; application; or analysis.

A typical example of a question classified as 'knowledge' is:

Valuable insights on teaching and learning may be gained from research and it is the aim of this section to bring significant research information to the attention of science teachers, with a view to helping them in their important work.

A student carelessly dropped 18M sulfuric acid onto some paper. The student noticed that, within a few seconds, the paper became blackened. In this reaction, the sulfuric acid is acting as:

- A dehydrating agent
- B an acid
- C a base
- D an oxidant

An example of a question classified as analysis is:

When milk powder is mixed thoroughly with black copper (II) oxide and heated in a test tube, water vapour is formed, together with a gas that turns lime water milky. Some of the copper (II) changes to copper. This shows that milk contains:

- A carbon
- B carbon and hydrogen
- C hydrogen
- D water

No questions from the two higher Bloom categories, synthesis and evaluation, are included in either the Quiz or the books. Questions in these categories usually require essay type answers, but the National Chemistry Quiz is restricted to multiple choice questions, owing to the difficulty of assessing such a large number entrants.

In comparing the performance of students in Years 11 and 12 on the 1989 to 1991 quiz papers, the percentage of Year 12 students who chose the correct answers nearly always exceeded the percentage for Year 11 students. This result is to be expected as Year 12 students have studied chemistry for an extra year. This has made it difficult to set a paper which is suitable for both Year 11 and 12 students, particularly as the Year 11 chemistry students in different states in Australia are taught various topics. To overcome this problem, a separate paper for Year 11 students, which will be more appropriate to their knowledge base, is being introduced in 1992, as mentioned above.

A more detailed examination of the performance in 1991 of final year secondary school students (Year 12) shows four questions where the overall performance was low (only between 15% and 30% correct responses). One of these, Question 20, involved reading the scale from a diagram of a burette. The question students found most difficult, however, was Question 26, and it involved the depression of the melting point of a pure substance by the addition of another substance. This was a question requiring only recall information and, as such, did not indicate lack of understanding or ability to reason.

The 1991 Senior Quiz Paper contained five questions classified as analysis.
Table 1: A summary of mean percentage of each Bloom category correct for the three 1991 papers. Values in brackets indicate number of questions in category.

</table>

(Table 1), which involved the highest cognitive skills of the four categories used. The students' performance on these five questions was quite good with Year 11 scoring 40.8% correct and Year 12 scoring 51.9%.

Fewer females than males in Years 11 and 12 participated in the 1991 Quiz, although more Year 12 Chemistry students are female (Australian Bureau of Statistics, 1990). In contrast more females than males in Years 7-10 participated in the 1991 Quiz. Table 2 (opposite) shows the percentage of males and females, and the mean percentage scores for each gender and year group in the 1991 Quiz. The males consistently achieved a higher mean score in the 1991 Quiz for all Years 7-12.

Application of a 't' test to the mean group scores, standard deviations, and number of students in each Year for males and females shows that the means for males and females are statistically different with p<0.001. The null hypothesis that there is no difference between the two scores is invalidated. In the 1991 Senior Paper males scored an average of 5.9% more than females in Year 12 on 27 of the questions and 5.5% more in Year 11 on 25 of the questions.

It is interesting to consider the significance, if any, of these results. For example, do the results mean that males are better at answering chemistry questions than females? Or are they simply an indication that a higher proportion of females in Australia who are weaker at chemistry are sitting for the Quiz? The samples of males and females taking the Quiz are not random or equivalent as only some schools out of the total national school sample are involved in any year, and most schools do not enter all their students. Table 3 (opposite) summarises the numbers of males and females in the top 150 for each year group in the Quiz, and it shows that the number of males is higher in each case.

Table 1 shows clearly that in each of the Quiz Papers the higher the Year Group (ie Year 12, 10 and 8) performed better than the lower Year Group. The increased achievement of the older students is not only on recall but also in the more important higher order cognitive skills. The origin of this increased understanding and chemical knowledge is not easily determined but it seems likely that the additional chemistry studied would be an influence. The significant increase in cognitive achievement in chemistry is

The Necessity of Variety in Teaching

Section Editor
Ronald J Bonnstetter
Center for Curriculum and Instruction
University of Nebraska
Lincoln, Nebraska 68588
USA

We all know that ideally we should individualise our instruction. Realising that in most cases this is not feasible, we tend to dismiss the goal and teach as we were taught or teach using approaches that best fit our own personal learning style. This column will review current learning theory research and point out the need to teach every major science concept using at least three learning approaches.

Over the years we have found that not only do people learn in ways that differ dramatically, but certain students understand only when material is presented using their preferred learning style. Reckinger (1979) found that if our students' learning style is oral, visual, kinesthetic, or any of the many combinations of diverse elements that make up personality and learning styles, their chances of succeeding in a science program that is dominated by lecture are close to zero. Recent studies suggest that the United States population may be 10-20% oral learners, 20-30% visual, and as much as 30% kinesthetic. In other words, at least half of US students learn best by doing.

And yet most teachers present information using their own preferred learning style. (Marshall, 1991). Local research on pre-service secondary science majors at the University of Nebraska have found that up to 80% of any given methods class can be classified as intuitive-thinkers while Myers-Briggs Guide to the use of type (1985) found less than 15% of secondary students are of this type. This means that most of our students need to experience a concept, while most of my future science teachers thoroughly enjoy mentally constructing knowledge. The fear is that these teachers will expect their students to learn intuitively. One can easily picture these teachers saying, "We don't have time to mess around with every concept in the book. Besides, the information is obvious and I don't have time to set up all that equipment."

There are several broad spectrum approaches to applying learning style information to teaching. The approach that may best fit our present limited knowledge and resources, takes into account the need to create diverse learning experiences in both curriculum design and instruction. According to Joseph Bogen (1975), most individuals rely on one information processing mode more than others, especially when approaching new learning. Bernice McCarthy (1990), suggests that several major learning styles should be addressed when introducing new concepts, thus allowing learners to experience the concept through their learning style strength and yet be stretched and challenged by other approaches.

In action this means that each new science concept should be presented using a minimum of three strategies that offer opportunities for visual learners, oral learners, and kinesthetic learners.

This section focuses on the pre-service and in-service education of science teachers, and aims to communicate ideas and strategies which will assist science teacher educators to enhance and enrich their pre-service and in-service programs.

Teach with variety

The philosophy of offering variety can prevent some of the problems of science teachers teaching only as they prefer to learn. A review of the literature makes several clear statements:

- Individuals learn in different ways or styles.
- These styles can many times be identified by some form of inventory or through direct observation.
- An individual's learning style makes a difference in how and what they learn.
- Individuals learn best when they are taught in a mode congruent with their individual learning style.
- Awareness of learning styles makes a teacher more receptive to student needs and problems.

By studying learning styles, teachers develop a better awareness of why some things work with some learners while not with others. At the same time, when diagnosing learning styles we must be careful not to over generalise and pigeon-hole students. Learning style research is not the only variable at work in our classroom.

Both teacher and learner must continue to work at being flexible and able to adapt to a variety of teaching methods and learning styles. By adapting our lessons to accommodate multiple instructional strategies, we are far more likely to teach to our students' preferred learning style. Let's not continue to only allow people who learn as we do to succeed in science. We can meet the needs of far more of our students by putting variety in our teaching.

Pasteur and Microbes
A Teacher Resource Book

Commemorating the 100th Year of the Pasteur Institute 1888-1988

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute. It contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few.

These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation.

Science Education in Primary Schools
Sri Lanka

by L S Kuruppu

This paper was presented at a Seminar preceding the 8th ICASE Symposium held in Sri Lanka.

Introduction

'The complete eradication of illiteracy and the assurance to all persons of the right to universal and equal access to education at all levels.' Thus says the Constitution of the Democratic Socialist Republic of Sri Lanka.

This has guaranteed the right of equal opportunities for education for all up to university level.

According to the 1990 school census, out of a total of 10100 schools, 96% had primary grades. This is an indication of the spread of Primary Education facilities throughout the country. The size of the school varies from less than 50 pupils to over 4000. These schools are mostly situated in the remote rural areas and in the plantation sector. 24% of the total number of schools fall into this category.

78% of schools have a student population of less than 500. School census reports show that male enrolment in the primary cycle is slightly higher than the female enrolment. Annually the enrolment rate has increased.

There are many reasons for this fact. There is a widespread interest about the schooling of the children, and in the new settlement areas, the number of schools has increased from 8100 in 1975 to 10100 in 1990 (School Census). As a result, there is now a school within two miles of every student in the country. Under the free education scheme no fees are levied from students in government schools. Text books have been given free to all students from Year 1 to Year 11 since 1980 and a free mid-day meal has been given since 1989. As a result, participation in education has increased.

The proposed free uniforms for all children from January 1993 will add to the improvement of participation rates. Participation in education has increased from 1.9 million in 1979 to 2.2 million in 1988 and 2.5 million in 1990 (School Census). The pupil cohort of 100 graduating from the primary sector has increased from 576 in 1971 to 911 in 1988. The number of years to graduation from primary level has decreased from 9.56 in 1971 to 6.11 in 1985.

Primary Science Education

Teaching science at primary level actually began with the introduction of a new subject called 'Nature Study' in 1954. This was the first policy decision at the national level to introduce science in primary schools. During the curriculum revision that took place in 1972, a new teaching strategy was introduced—integrated teaching, child-centred and emphasising the development of skills and attitudes as well as content. This new curriculum implemented a core subject 'Environmental Studies'. This paved the way for scientific investigations and the introduction of scientific method. This subject integrated basic concepts of Aesthetics, Creative Technological fields, Geography, History, Health, and Civics with science. The studies were based on eleven themes derived from opportunities and facilities available in the students' immediate environment.

During the next curricular revision (1982), which was based on the White Paper Proposals of 1981, the science component was separated from Environmental Studies and a new subject, called 'Beginning Science', was introduced at Year 4 level.

The content of this subject was selected to include simple terminology so that primary teachers would be able to create activities for the children. No textbook was made available and the children were expected to be involved in observations, explorations, collecting data and identifying scientific patterns in the environment. This child-centred teaching strongly reflected Piaget's work.

During the implementation of this

How you can help with Phase 1 of Project 2000+

Science teachers associations and other ICASE member organisations can play an important role in Project 2000+. Material relating to one or more of the following areas is needed:

- The nature of and the need for scientific and technological literacy
- S&T literacy for development
- The teaching and learning environment for S&T literacy

- Teacher and leadership education for S&T literacy
- Assessment and evaluation of S&T literacy
- Nonformal and informal development of S&T literacy

See note about where to send your contributions on page 3 of this issue.
program, certain issues became apparent. Firstly, it was difficult to orient the teachers to the new methodology in this program. Under privileged primary schools (24%) had very few teachers and fewer facilities with little motivation for implementing innovative learning programs. Although as many as 80% of primary children enter secondary education, many of them do not exhibit necessary attitudes and understanding of basic concepts.

National Seminar

SLASME Committee held a National Seminar on Primary Science as a pre-symposium seminar to the 8th ICASE Asian Symposium. The Director General of the National Institute of Education organised and financed this seminar. 20 teachers and senior Primary Science Inservice Advisors focused on the following areas:

* Impact of socio-economic factors on science education
* Primary science policy
* Innovative teaching methods including self-learning activities, guided investigation, dramatisation and role play
* Methods of evaluation

The teachers worked in eight groups each led by a District Inservice Advisor. In the six months prior to the seminar, trials were held in schools and the outcomes presented at the seminar. In the Keynote Address, the Director General explained how children must be set free to make their own discoveries and so achieve understanding. To achieve this, the teacher employs active exploration, investigation, and inquiry into the environment in which they live and work. Above all children need inspiration. The teacher's role is to make the learning experience more meaningful and inspiring to the child.

Impact of socio-economic factors on science education

This study was done to examine the relationship between the socio-economic status of the child and the achievement level of the child. A sample of students was selected randomly from seven education districts, and a survey made of their socio-economic background using a questionnaire. This data was then compared with their achievement in learning science.

The results indicated a strong correlation (78%) between socio-economic level and learning achievement, that is high achievers were generally of a high socio-economic level, whilst low achievers were from a low socio-economic level. Only 4% of high achievers had a low socio-economic background while 18% of the low achievers had a high socio-economic background. Where a low achiever came from a high socio-economic background, the parents were found to have comparatively low education levels. In the few exceptional cases of high achievers of a low socio-economic background, it is possible that the education level of the parent played a positive role. A past study of NIE (Entry Competency of Sri Lankan Children, NIE 1988, p.257) states:

'It is evident from the data that the occupation and education of parents does play an important role with respect to their children's educational achievement. Further it was revealed that it is the mother's education that matters the most . . .

Whatever the validity of the conclusions of this study, it opens up the opportunity to further probe into the factors influencing the learning of the Sri Lankan child.

Self-Learning Strategies

Guided observations

Children see many things, but only a few investigate these further. Teachers and facilitators can be of tremendous help in furthering the natural curiosity of children. For example, an after school Science Club activity might have a teacher probing the factors promoting the decay of leaves. Children might be assisted to investigate commonly held beliefs about the natural world – for example, two different varieties of the Jak tree may be distinguished by their falling leaves.

Workbooks with audio-tapes

An audio-tape can be used to give further instructions to children working through activities in a workbook. These kits can be used when the teacher is absent.

Crossword puzzles

The booklet suggests reading and experiments to do. The skills and knowledge that are gathered are used in solving the series of puzzles found in this kit.

Children learn in different ways

Various books have been produced under this project to add variety and interest to classroom work. Some of the books carry suggested assignments and overlay illustrations so that

What you can contribute to Phase 1 of Project 2000+

Guidelines for the type of materials to contribute to Phase 1 of Project 2000+ are as follows:

Do contribute teaching ideas for scientific & technological literacy, including videotapes, computer programs, examination papers, slides, questionnaire results relating to scientific & technological literacy (and curricula), position statements, etc.

Do not contribute material which is not applicable for learning in the year 2000, or material related to the advancement of content only, or current teaching materials that do not relate to science & technology education.

You may wish to establish a task force to help you with this task.

Please send contributions to the contacts listed on page 3 of this issue.
diagrams can be separated into their components – for example, the parts of a flower.

Guided investigations

The child's natural curiosity can be harnessed to motivate children in learning. Children may make an observation and a subsequent discussion might provide opportunity for them to make an hypothesis. Further investigations at times end up in wonderful discoveries as well as teaching the child the important skills of hypothesising and testing.

For example, a child found a household beetle and, observing it closely, he found some small creatures on its body. He, his friends, and even his parents, thought these were the young of the beetle. A teacher suggested further investigation and they discovered that their hypothesis was wrong - the small creatures were, in fact, bugs.

Researchers have identified the following features in children's investigations

- there is a process of logical thinking and reasoning that emerge from experience
- guidance could enrich or promote this process of observation and reasoning
- media, including textbooks can influence children's investigations
- often children's explanations are not perfect, but are very significant in arriving at conclusions
- achievement motivates children

Dramatisation and role play

Nature, which is full of patterns and cycles, is the true site for children's science. Once children observe and enjoy their natural surroundings they develop an enquiring and confident motivation towards learning. This can be enhanced by dramatisation which brings about the integration of Aesthetics and Language Development with Science. Various systems can be dramatised to great effect by children. The group presented a musical play on 'dispersal of seeds', on 'how an electric circuit works' and on 'how the different parts of a tree work together'.

Evaluation in primary science

Traditional evaluation is a drudgery for students. New techniques of evaluation are needed so that the love of learning is not destroyed. Some of the following are suitable alternatives for Primary Science.

- Role Play - the teacher, or group of children enter a class wearing masks symbolising objects and question the children about the topic presented. For example, a tree might ask children about its functions - children receive rewards for correct responses.
- Worksheets - children are given genuine specimens and a worksheet where questions are given. Colours are given to ascertain their performance level
- Observation - the teacher gives the children a few clues about a plant, an animal or an event. The children have to find it and subsequently complete a worksheet

Approaches to assessment include:

1. Manipulative skills/measurement – weighing balances have been improvised by the teacher. Students use them to find out the mass of objects provided. In a similar way, students can be asked to measure volume or length.
2. Skills in collecting/interpreting data – assignments can be given to student groups in advance. For example, what happens to a flower before it turns into a fruit? Daily observations can be recorded to provide continuous assessment. After the assignment is completed, the products are displayed for other children to see.

Conclusions

In Sri Lanka, as in many other countries, the teaching of science in primary schools is new. Hence, it is too early to set in concrete methodology or content of science at this level.

Recommendations

- Science education policy development must take into account living conditions, the richness of the environment, the benefits of learning science, and the contribution of science to the quality of life.
- Facilities/opportunities, in and out of school, must be available to engage children in investigative activities.
- The content and approaches to science in the primary school must be diverse and appropriate for the locality.
- Evaluation at the primary level should not hinder children's natural curiosity and activity.
- Innovative teachers are an asset to the teaching of science at the primary level. Teacher training programs need to provide teachers who are innovative.
- The innovative work by teachers should be taken into account for teacher promotion.

Mr L S Kuruppu is Director, Department of Primary Education, NIE, Sri Lanka.
AIMS
Stepping into Science is an ICASE project which aims to:
• Establish an international network for teachers to share ideas on the teaching of primary/elementary science and technology.
• Provide activities and support for teachers, thereby encouraging them to include more science in the primary/elementary curriculum.
• Promote the value of science experiences for young children throughout the world.
• Facilitate professional development opportunities for teachers by including sessions on primary science and technology in regional and international conferences.

ACTIVITIES
The Stepping into Science Team is actively involved in a number of projects and activities including:
• Publishing STEPS, the Stepping into Science Project Newsletter. This newsletter contains ideas for class activities at various levels in primary/elementary schools, activities for children to do at home, comments by network members on issues, examples of children’s work, lists of helpful resources and contacts. ICASE acknowledges the contribution of Philip Harris in sponsoring STEPS.
• Contributing articles and ideas for the Primary Science Section in Science Education International, the ICASE quarterly journal.
• Compiling ideas and activities for inclusion in a series of sourcebooks on the teaching of primary/elementary science and technology.
• Coordinating a scheme to encourage children to participate in science and technology activities. Certificates of Participation have been produced, and are available for schools to use in rewarding students as they complete a number of activities. Certificates are colour coded in seven different colours, so that they can be used to acknowledge progress in science from early to advanced levels within primary/elementary schools. ICASE is grateful to BP (Oman) for sponsoring this scheme.
• Organising Stepping into Science workshops and displays of children’s work at national, regional and international conferences.

Resources

Australian Chemistry Resource Book
1992 Volume
Edited by C. L. Fogliani

The 1992 Volume of the Australian Chemistry Resource Book is now available. This edition has been enhanced in response to a teacher survey conducted about the value of the 1991 Resource Book which is published annually on the occasion of Australian National Chemistry Week organised by the Royal Australian Chemical Institute. Teachers indicated that they found the book useful and that it should be continued to be produced. Although teachers were generally satisfied with the type of articles published, some indicated that they would like articles suitable for students in the junior years. This year, the Resource Book includes articles such as A Metal’s Tale and Chemical Bonding and the Structure and Properties of Materials which will be of general interest to junior students. The number of pages has been increased from 120 to 210 as a result of the positive feedback.

ICASE PUBLICATION
Who's Who in Science Education Around the World
1991 Edition

INTERNATIONAL COUNCIL OF ASSOCIATIONS FOR SCIENCE EDUCATION

Who's Who in Science Education Around the World

Published by ICASE
With assistance from UNESCO
1991 Edition

This new ICASE publication, published with the assistance of UNESCO, contains brief profiles on prominent science educators, their work, their projects and their interests. The valuable reference book includes key women and men in many countries throughout the world who are contributing to science education at primary, secondary or tertiary levels.

The information will help readers to contact colleagues in both developing and developed countries who may be working on projects of interest to them, who may be potential speakers at upcoming meetings or conventions, and who may be invited to work on collaborative projects.

Copies at a cost of US$15.00 or £9.00 or A$20.00 including postage can be ordered from the Editor:

Popularisation of Science and Technology
What Informal and Nonformal Education can do?
Edited by
Cheng Kai Ming & Leung Kam Fong

This publication is a report of an International Conference organised by the University of Hong Kong in cooperation with Unesco. The 205 page proceedings of the 1989 conference contains a selection of papers which focus on how nonformal and informal education can contribute to helping people achieve a level of scientific and technological literacy.

NOW AVAILABLE
1992 ICASE Yearbook
The Status of Science Technology Society Reform Efforts Around the World

FOREWORD
Science Technology Society attracts even more attention than it did in years ago when it became a new focus for reform in a few nations like the United Kingdom, The Netherlands, and, to a lesser extent, the United States. Currently it is a focus in nations on every continent. For many it represents the most significant change seen in classrooms during this century. For some the reform seems slow – not to be realised to any degree before the year 2000.

This Yearbook has been prepared as a means of updating science educators and ICASE member societies around the world. Hopefully it will help coalesce the concept in all nations and provide support for emerging projects in other nations. The reports are offered in the spirit of providing a status statement. Also, information is included that can be used as evidence for STS as real reform. Hopefully such evidence will be useful for schools and the most innovative and creative teachers in science societies who are struggling with STS in their own situations. The Yearbook is organised as:

STS definitions and rationales
Examples of STS initiatives
Evaluation of STS efforts
STS moves in various nations

The authors all hope their contributions provide useful information and suggestions. They all hope that the Yearbook provides a needed record of where we are while also being controversial enough to promote debate and dialogue.

Sourcebook in Environmental Education for Secondary School Teachers

Published by Unesco

This sourcebook (316 pages) is the product of a regional training course organised by Unesco in the Phillipine in 1989. Published in 1992, it contains knowledge base as well as pedagogical aspects of environmental education through presenting exemplary lesson plans and evaluation mechanisms.

Towards Formulating Goals, Aims and Objectives of Secondary Education for the Twenty First Century

Published by NIER

Published in 1991 (95 pages), this is the final report of the Regional Seminar on the Goals, Aims, and Objectives of Secondary Education in Asia and the Pacific which was held in Tokyo, Japan and organised by the National Institute for Educational Research (NIER).

To obtain this report, contact:
NIER
5-22 Shimomeguro 6-chome
Meguro-ku
Tokyo
Japan
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1992

September 19-21
Second General Conference of Teachers
Location: Poland
Contact: SNPPiT, Skrytka Pocztowa 62, 85-791 Bydgoszcz 32, Poland
This second General Conference on the theme 'Education, Environmental Protection and Industry' is being organised by the Association of Science and Technology Teachers (SNPPiT), Poland. Languages used will be Polish and English.

December 17-21
Twelfth International Conference on Chemical Education
Location: Bangkok, Thailand
Contact: Dr Somjai Wichaidit, The Secretariat - 12th ICCE, c/o Research Centre, Faculty of Medicine, Ramathibodi Hospital, Rama 6 Road, Bangkok 10400, Thailand
The theme of the Twelfth International Conference on Chemical Education will be *Chemistry in Transition* and it is hoped that the participants will interpret this in many different ways. This biennial Conference, to be held for the first time in South East Asia, is organised by the Committee on Teaching of Chemistry of the International Union of Pure & Applied Chemistry, and The Chemical Society of Thailand in cooperation with UNESCO. It is attended by chemistry teachers at both high school and university levels who wish to improve their teaching and to learn from one another techniques and experiences. A second circular including instructions for submitting abstracts is now available from the address above.

November 11-12
Second ICASE Education-Industry Symposium
Location: AKZO Centre, Arnhem, The Netherlands
Contact: Drs Jan Hendriks, ICASE European Representative, Konijnpad 3, 7921 BM Zuidwolde (DR), The Netherlands, Fax 31-5287-2693
AKZO, one of the leading chemical and pharmaceutical industries in Europe, is hosting this second symposium on Education-Industry partnerships. The program consists of 4 half-day themes: (1) New and current projects; (2) Models for evaluating partnership programs; (3) Extending partnerships to involve publishers, media, museums; (4) Workshops to define future priority areas. Participation by invitation only.

1993

January 3-6
ASE Annual Meeting
Location: Loughborough University, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated in *Education in Science*, a journal of the Association for Science Education.

January 3-8
International Conference on Science Education in Developing Countries
Location: The Amos De-Shalit Israeli Science Teaching Center, Israel
Contact: Conference Secretariat, ORTRA Ltd, 2 Kaufman St, PO Box 50432, 61500 Tel-Aviv, Israel (conference arrangements) or Dr Avi Hofstein, Department of Science Teaching, The Weizmann Institute of Science, Rehovot 76100, Israel (academic correspondence)
This international conference on the theme "Science Education in Developing Countries: From Theory to Practice" will review past experiences and achievements in science education and plan for the 21st century with a special focus on developing countries. The conference will feature plenary lectures, symposia, poster sessions, workshops, exhibitions, informal discussions, social events and local visits. Topics for symposia and plenary lectures will focus on current research on learning and teaching and its implications for (1) the learner, (2) the teacher, (3) the classroom, and (4) the curriculum.

March 21 - April 2
Science Education in a National Curriculum: An International Symposium
Location: University of York, UK
Contact: Your nearest British Council Office or Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN. There are vacancies for 30 participants.
Topics include: building a national curriculum; new science curricula in secondary schools; styles of curriculum development; evaluation of science curricula; impact and research on developments in science curricula; student assessment; changing demands for staff development; links between industry and science education; the role of national and international agencies in science education.
March 25-30
Sixth International PATT Conference
Location: Motel Eindhoven, The Netherlands
Contact: dr. Marc J de Vries, Pedagogical Technological College, PO Box 826, 5600 AV Eindhoven, The Netherlands, Fax 31-40-440045.
The aim of this conference is to exchange ideas and information on theoretical and practical implications of the implementation of environmental issues in technology education according to the subthemes: (1) Pupils' attitudes towards technology and the environment; (2) Environmental issues in primary and secondary technology education; (3) Gender aspects of environmental issues in technology education; (4) Environmental issues in the education of technology teachers. Registration forms and abstracts of papers should be sent before 1 November 92.

April 21-25
International Conference on Geoscience Education and Training
Location: University of Southampton, UK
Contact: Mrs Esther Johnson, GEOED Conference Secretariat, Department of Geology, University of Southampton, Southampton S09 5NH, UK
The Association of Geoscientists for International Development (AGID) and the Commission on Geoscience Education and Training (COGEOED) of the International Union of Geological Sciences are convening this international conference with the support of ICASE. Themes include: geoscience education in schools; higher education; geoscience training for business, industry and public service; and public understanding of geoscience. The conference is open to all those with an interest in geoscience education and training - including practitioners and those involved in administration, course development, and the supply of resource materials.

June 27 - July 3
VII Pacific Science Inter-Congress
Location: Okinawa Convention Center, Okinawa, Japan
Contact: VII Pacific Science Inter-Congress, c/o Section of International Affairs, University of the Ryukyus, 1-Senbaru, Nishihara, Okinawa, 903-01, Japan
The Symposium will be organised around the theme The Pacific: Crossroads for Culture and Nature and subthemes (1) Cultural Interchange among Pacific Peoples; (2) Speciation, Dispersal and Conservation of Species in the Pacific; (3) Towards Appropriate Technologies and Policies for Development and for the Conservation of Natural Environments in the Pacific. Scientific sessions organised by the Scientific Committees of the Pacific Science Association focus on a range of science disciplines and issues, including Science Communication and Education.

July 5-9
CONASTA 42
Location: Sydney, Australia
Contact: Jenny Jones, Convener CONASTA 42, PO Box 787, Potts Point, NSW 2011 Australia
The Australian Science Teachers Association invites you to participate in the forty second annual conference of the Association. The theme of 'Science – Teaching it Better!' aims to highlight the part that teachers can play in fostering in their students an interest in and understanding of science. Four subthemes will deal with both primary and secondary issues: (1) Science updates - recent exciting developments and their impact; (2) Science education research - what it has to offer the classroom teacher; (3) Science teaching for effective learning - how do we engage minds in the classroom?; (4) National initiatives. The program includes theme lectures, interactive workshops, seminars, field workshops, 'wandertimes' and poster presentations. A comprehensive display of resources useful to science teachers will be presented by publishing, audiovisual, equipment and computing companies.

July 6-11
Project 2000+ International Forum
Location: Paris, France
Contact: Dr Jack Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong
This worldwide conference, organised by ICASE in conjunction with Unesco and other international bodies is the second phase of the three phase Project 2000+ (refer to article in this issue for more details of this project). A number of international and regional conferences are generating input into this international forum. The theme of the forum addresses the issue of Scientific and Technological Literacy for All. Sessions will establish agendas for future action. Attendance will be by invitation only (500 participants). Names are now being sought from a wide variety of organisations with an interest in science and technology education (see next page). The forum plans to issue statements to affect political visibility for science and technology education for all as a requirement for national development, and provide a framework for major programs of action in science and technology education involving governments, IGOs and NGOs.

July 27 - August 10
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.
International Forum

Scientific and Technological Literacy for All

Phase 2 of Project 2000+

Paris, France
6-11 July 1993

This International Forum is the Second Phase of Project 2000+, an international project on scientific and technological literacy for all, which addresses the following 6 focus areas:

1. The nature of, and the need for scientific and technological literacy
2. Scientific and technological literacy for development
3. The teaching and learning environment for scientific and technological literacy
4. Teacher education and leadership for scientific and technological literacy
5. Assessment and evaluation for scientific and technological literacy
6. Non formal and informal development of scientific and technological literacy

Attendance will be by invitation only and limited to 500 participants. Names are now being sought from:

- National EFA (Education For All) Groups
- National policy makers overseeing science and technology education
- INISTE centres
- Project coordinators and field workers for organisations
- Science and technology teacher associations
- Institutions, centres, universities and colleges involved in science and technology curricula, examinations and teacher education
- Science and technology out-of-school centres and organisations
- Non formal science and technology educational organisations
- Industrialists
- Persons from the mass media interested in Project 2000+

Organisations, associations and institutes are invited to submit names of suitable participants to the Project 2000+ secretariat before the end of September 1992. A short description of each person should also be included covering:

(a) activities of the person nationally (within organisation if appropriate)
(b) international involvement (at conferences, research, projects, etc)
(c) which Project 2000+ focus area is of greatest interest

Individuals can also apply. Individuals will be selected based on paper abstract, submitted by the end of September 1992, related to one of the focus areas.

Selection will take place at the end of 1992 and will be finalised by approval of the Steering Committee at the end of January 1993.

There will be a US$100 Registration Fee for each participant to help defray material costs. This will be payable to the Project 2000+ Secretariat on receiving the invitation. For further information, contact: Dr Jack B Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong.
Extending and improving education in science for all children and youth by assisting member associations throughout the world

Australia
Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

1992 ICASE Distinguished Service Award presented to Samuel 'Tunde Bajah

The 33rd Annual Conference of STAN (Science Teachers Association of Nigeria) during August 1992 was the venue for the presentation of this prestigious award.

The Distinguished Service Award was awarded to Professor Bajah for his career history of distinguished service to international science education through his involvement in international activities of local, regional and global science education organisations. He becomes the first person from Africa to be awarded this honour, and joins a distinguished band of 9 previous recipients of this award.

In his acceptance speech, Professor Bajah said

"I ... receive this award with the greatest humility. I receive it for this great country which over the years has provided the arena for my exploration into science education; for my university, Ibadan, for the academic challenges it gave me; for my secondary school, Hussey College Warri, for the foundation it gave me in science; for my little village, Ugwuangwe, for the constant reminder to me that even small can be excellent; for my mother, Omeresan, of blessed memory who like most Iskiri women invested all she had to see me through school; for my wife, Ag, children and friends who kept putting the pressure of reassurance in my activities. I receive it for STAN, the Association I was privileged to serve and which had the confidence to dare ICASE with my credentials. Finally, I receive this prestigious honour, the first to Nigeria on behalf of humanity and all it stands for."

Photo below: Professor Samuel 'Tunde Bajah, FSTAN, the winner of the 1992 ICASE Distinguished Service Award

Fiji Association of Science Teachers joins ICASE

ICASE welcomes the Fiji Association of Science Teachers (FAST) as a Full Member. Vijendra Prakash, Secretary of FAST has provided the following information about this new association:

FAST was officially launched in December 1991 (having been formed as an interim body in August of that year) by the Permanent Secretary for Education. The launch also featured a display of resources and teaching aids.

In April of this year, the Association issued its first newsletter to help inform the public about the Association's activities and progress. In September, the Association was given an opportunity to address the Fiji Principals’ Association. At this meeting, FAST shared its goals and invited principals to support the Association by encouraging their staff to join FAST.

Future plans include:

- an annual convention on 20th January 1993 featuring key speakers and a display
- increasing membership throughout the nation, and forming branches at district level
- negotiating with the Government to declare one day each year as a Science Open Day. The day will enable institutions to organise science activities for the public
- organising science quizzes and oratory contests for various school grade levels
- publishing a science journal three times per year

Although young with limited finances, the Association is very active.

For further information write to:
Vijendra Prakash
Secretary
Fiji Association of Science Teachers
PO Box 8018
Nakasi
Fiji
PROJECT 2000+
International Forum

UNESCO Headquarters, Paris
5 - 10 July 1993

Will your Science Teacher Association be represented at this forum which will consider the way to launch the main phase for Project 2000+? Should you be present?

ICASE would like to hear from you if

• You can represent an organisation such as a Science Teacher Association which is interested in Phase 3 of the project (see article on Project 2000+ in this issue).

• You are interested in submitting a paper abstract (200 words) on one of the themes in the forum. If you have an interest, please take note of the important statement below.

• You are involved in on-going projects related to the theme of the forum. It is important that the forum is aware of all development in projects around the world which build on rather than duplicate such efforts.

The goal of Project 2000+ is improved scientific and technological literacy for all in the 21st century throughout all countries of the world.

Please note that the International Forum is not a conference in the normal sense where papers are presented. The forum is a discussion session to work on outcomes and recommendations to launch the third and most important phase of the project. The papers are needed as background material to illustrate the latest thinking for the various focus areas. As such, these papers play an extremely important role in the development of the project as a whole and only papers relevant to a focus area (as suggested by focus area leaders) will be solicited as full papers.

For further information, contact

Dr Jack Holbrook, ICASE Executive Secretary
UNESCO Science & Technology Education Unit
7 place de Fontenoy, Paris, France (Fax +33-1-40 65 94 05)

Photo right: Some of the local participants at the Eighth ICASE-Asian Symposium held in Colombo, Sri Lanka, 2-10 August 1992. This conference, organised jointly by ICASE and the Sri Lanka Association for Science and Mathematics Education, addressed the theme 'Science Education for a Changing World'. See the report in the section 'Science Education Around the World' in this issue.
Project 2000+
Revisited

by Dr Jack B Holbrook
Executive Secretary, ICASE

This article is intended as an addition to the rationale and description of Project 2000+ as featured in the June 1992 issue of Science Education International. It includes greater information on how persons can assist the Phase 1 data-gathering stage and participate in the International Forum (Phase 2) to be held in Paris, July 1993.

Project 2000+ International Forum

Project 2000+ is to be launched by seeking definitions, adopting resolutions and putting forward plans of action for the achievement of scientific and technological literacy worldwide at an international forum to be held in July 1993.

This forum differs from many conferences in that attendance is by invitation. Furthermore, participants are being asked to look forward to the way Project 2000+ should develop and the guidelines that need to be put into place, rather than to present and discuss papers. The forum is not intended as a time when researchers will inform of their work or developers will give a presentation on their curricula. Although there will be a few keynote speeches, these are designed to initiate the discussions and to put the project into perspective. There will also be room for a few paper presentations, but these will be carefully chosen by leaders of the 6 focus areas (described in the June issue) so that they are particularly supportive and relevant to the discussions and deliberations that will take place.

There will be plenty of room for papers, conference reports, etc to be distributed and read by participants before attending the forum. Some invitees, especially those recommended by a Science Teacher Association, would be expected to participate in the discussion and play a much greater role in post-forum activities launching Project 2000+ in their own country.

There will be room for displays and other presentations such as film-shows, playing of videotapes, showing of slides, computer programs, etc by all participants. This will be very much encouraged to illustrate the types of developments and projects that are actually taking place and which could have very important bearings on Project 2000+. A viewing room will be specially set aside throughout the forum for this purpose and agencies, industry, science education organisations and other bodies would be invited to supply suitable materials.

But the main focus of the forum will be to launch Project 2000+. This phase of Project 2000+ will be national programs, that is developments at a pilot or pre-pilot stage in as many countries as possible. These need to bear in mind that the year 2000 should see the implementation of relevant scientific and technological literacy curricula for at least the compulsory years of schooling.

Each country will have its own timetable, its own agenda and its own priorities and way of working, but within this, the Project 2000+ secretariat will fulfil a supportive and coordinating role. It is anticipated that in many countries use of existing ‘Education for All’ (EFA) task forces will provide the impetus for development. Other countries may see the Science Teacher Association playing an important role, or the INISTE centre, or other institutions.

But whatever pattern or patterns are chosen, the important factor that should emerge is that it is a partnership, a partnership between Government and NGOs (non-Governmental Organisations such as Science Teacher Associations).

New Address for ICASE Executive Secretary

Please note that, as from 1 January 1993, all correspondence for the ICASE Executive Secretary should be addressed to:

Dr Jack B Holbrook
ICASE Executive Secretary
Science and Technology Education Unit
UNESCO, 7 place de Fontenoy
75700 Paris, France
Involvement of NGOs (WCEFA, 1990)

Statement of principles for the involvement of NGOs in World Conference on Education For All follow-up activities with non-NGO bodies (abridged statements):

- NGOs shall be part of all formal structures for the implementation of programs at all levels: local, national, regional and international from the outset, particularly in the development and implementation of national plans.
- NGOs shall choose their own representatives within suitable guidelines
- Subsequent major meetings and conferences shall include NGOs as full delegates.

These are suggested statements of principles for project 2000+

Phase 1 of Project 2000+

The Forum is not intended as a conference in the normal sense. It is not intended as an occasion for science and technology educators to let the world know about their research and developments. That is the role of Phase 1.

Phase 1 is the gathering of previous conference outputs and developmental research and teaching materials that are geared to the attainment of scientific and technological literacy for the 21st century. Such materials are being gathered for all focus areas. Articles and reports are now being collated by Professor John Penick, ICASE Special Projects Officer (see June journal, page 2), but other materials such as project documents, videotapes, and other teaching resources are also being solicited and will be compiled by the project secretariat and the focus area leaders to provide input into the international forum.

It is difficult to give a full description of the materials that would prove useful as these are far ranging and very diverse, but as a simple working definition it is suggested that Phase 1 materials are 'materials that support the work of the forum in providing guidelines, definitions, outcomes and exemplars for national bodies to begin the task of developing and implementing scientific and technological literacy programs in the years ahead. Examples of materials related to good classroom practice, good teacher education methods and good assessment and evaluative techniques are especially relevant.

In some cases, useful Phase 1 material may be available associated with a project, especially if the project is related to indigenous technology. In other cases, the materials may be stand-ones, or material that is a collection of examples. The materials will only be useful if they relate to a student trait, that is student involvement is indicated in some way.

Wanted!
Science Activities Around the World

Examples of simple, hands-on science activities especially those with a local or regional flavour
ICASE is compiling a book of Science Activities Around the World
Make sure your activity and your name as the person submitting it is included

Send materials to John E Penick
789 VAN Allen Hall, The University of Iowa
Iowa City, IA 52242-1478, USA
Where does the material come from? One suggestion is that useful material will exist in journals, bulletins, newsletters and especially in in-service teaching notes of course tutors, or in small scale projects initiated by a teacher or group of teachers. If the science curriculum is very innovative in your country, then the current teaching will be appropriate (but this is not really anticipated as it belies the need for project 2000+).

An indication of materials that would not be useful may provide additional guidelines. It is suggested that the following are not helpful:

- Science (or biology, chemistry, physics, earth science) teaching materials that do not have a societal/technological relevance
- Experimental materials that do not have a societal/technological relevant attributes
- Assessment materials that do not measure societal/technological relevant attributes
- Factual material (unless it is supportive of student centred activities such as role playing/debating, initiating an investigation).

If you would like to submit materials, be part of the Project 2000+ forum, or simply wish to gain further information, please write now to Dr Jack Holbrook, Science and Technology Education Unit, UNESCO, 7 place de Fontenoy, 75700 Paris, France.

**ICASE AWARD SCHEME**

_for outstanding contributions to international science education_

_Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below._

**ICASE Distinguished Service Award**
This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations

**ICASE Regional Service Award**
This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

**ICASE Association Award**
This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

UNESCO Science & Technology Education Unit, 7 place de Fontenoy, Paris, France
The Present and Future of Science Education in Pakistan

by William J Boone & Alyas Qadeer Tahir

Since the creation of Pakistan in 1947 there have been numerous science education curricular revisions. However, these past efforts have often been characterised by rote memorisation and the recall of facts. In an effort to make sweeping changes within science education the Pakistani Ministry of Education conducted a science education needs assessment during the years 1984-85. The results highlighted the lack of qualified science teachers, administrators and supervisors at both the school and college level. School level science was found to be often taught by those who are professionally inexperienced as well as those who are uncommitted and unmotivated toward science teaching. As a result, the quality of science education was diminished and pupils were not achieving their potential. Furthermore, the assessment suggested that no matter how high the present quality of university teaching and research in science, the system was weakened by inadequate school science teaching.

In reaction to this study, the Ministry of Education began a multi-faceted science education reform project with funding from the Asian Development Bank. When the project is fully implemented in March of 1993 it should serve as a model for other developing countries that have to confront problems of national assessment, multiple languages, often inadequate teacher training, and a lack of science supplies. In the following sections of this paper the structure of science education in Pakistan will be briefly outlined, as well as the major components of the present far reaching reform effort.

At the elementary school level (grades 1-8) science is compulsory. At this stage science is presented so a range of science topics (chemistry, physics, biology) are introduced to pupils. Commonly elementary pupils at each grade learn their science from one teacher. Therefore elementary teachers must be well versed in all of the sciences. At the secondary level (grades 9-12) the amount of science presently taken by individuals depends on whether or not pupils choose to major in the sciences or the humanities. If a science major is selected, then pupils take classes in physics, chemistry, biology and mathematics. Those pupils who select a humanities concentration are all required to take a general science class. At this level one teacher commonly instructs both chemistry and biology, whereas physics and mathematics is usually taught by a different teacher.

The Reform Effort

Many aspects of the present nationwide reform effort are noteworthy. First, the Institute for the Promotion of Science Education and Training (IPSET) has been established in Islamabad, the capital of Pakistan. Additionally, four regional science education centers have been set up in each of Pakistan's four provinces (Punjab, Sindh, North West Frontier Province, Baluchistan). In addition to the development of these centres, care is being taken to improve the science facilities at schools within each province.

Furthermore, a cadre of master science teachers have attended a four week staff development training workshop so that they may train less experienced teachers. Since science supplies are often lacking in many of the nation's schools this project included the development and distribution of over 4000 science kits for middle school level teaching. The included table lists major components of the reform effort.

Another exciting and challenging aspect of this reform is its guiding goal of fostering a concern for pupil learning through application of concepts – this is quite a change from the 'traditional' outlook toward science education practised in many developing countries. This interest in both pupil and teacher application and synthesis of science material is being used to develop new curricular materials (textbooks, pupil manual, and teachers guides) as well as a national test item bank. Pakistan's current science education reform effort should be a helpful model for other countries in that it involves a coordinated effort among teacher trainers, active instructors, kit developers, textbook authors, and psychometricians. Furthermore, the structure of the reform effort (four regional centres, one national centre) will enable the work of regional sites to be monitored and will facilitate the sharing of information among the regional headquarters.

The reform effort being implemented in Pakistan is both exciting and difficult. Not only do science educators in Pakistan have to consider the infrastructure of local schools, and the logistics of nationwide testing, but there is the considerable complication of having to accurately translate texts, manuals, guides and test items into two different languages! However, even with these hurdles to clear the work now being carried out in Pakistan represents a proud step for science education. Now science education will be led, coordinated, monitored, and supported over the long term. This should help increase the supply of scientists and technologists, and will also result in better informed citizens.

A table summarising the major components of the present science education reform project appears on the following page.

About the authors

Dr William J Boone is Assistant Professor of Education at Indiana University. He can be contacted at Education 3068, Indiana University, Bloomington, Indiana 47405, USA.

Alyas Qadeer Tahir comes from the Institute for the Promotion of Science Education and Training, Islamabad, Pakistan, and can be contacted at the School of Education, Indiana University, Bloomington, Indiana 47405, USA.

Role Play
In Science Education

by Asoka Weerasinghe

Reprinted from the Proceedings of the 6th ICASE-Asian Symposium

Abstract
The paper discusses the importance of open discussions when inculcating moral and ethical values in pupils, during science lessons and recommends the use of role-play exercises as a method by which pupils could be drawn into open discussions. Advantages and disadvantages of role-play exercises, and methods of conducting role-play exercises have been included in the paper. A case study of a very interesting role-play exercise, which was conducted in a science class at a secondary school in Sri Lanka, has also been included in the paper.

Introduction
Looking back on the history of science education some important landmarks can be identified. During the initial stages the emphasis was on learning 'scientific facts'. This lead to the stage where importance was given not merely to knowing facts but also to understanding their relationships and formulation of generalisations, and theories, connected with them. The next stage was characterised by the 'investigatory approach' to science education, where in addition to the earlier trends, importance was given to methods of gathering data, and coming to conclusions. Further evolution of the development of science education was characterised by the introduction of the social importance, of what was learnt during science lessons. This could also be termed as 'Science Technology and Society Education' (Solomon 1988; Gorbman 1971). One of the most recent developments of science education can be identified as the introduction of ethical and moral implications, of that which is learnt during science lessons. The outcomes of the conference organised by ICSU on 'Science Technology and Future Human Needs', held in Bangalore in India during 1985, may have influenced this particular twist in the evolutionary process of science education.

The following were included amongst the important aims of the conference:
- to stimulate an awareness of ethical and social dimensions in science education
- to present selected problems: intrinsic, ie linked with science itself, and extrinsic, ie linked with its role in development
- to provide information on the efforts being made to deal with ethical and social problems in the practice of science education (Frazer and Kornhauser, 1986)

Each of these evolutionary trends were characterised by the introduction of different teaching and learning strategies. The earliest teaching strategies included, mainly the imposition of knowledge by the teacher, by the lecture method. Here the teacher played the dominant role in science lessons. As newer science education programs developed, the emphasis shifted more towards pupil centred activities, such as science project work which required investigatory work by the pupils.

Inculcating ethical and moral values during science lessons
Creating an awareness of the moral and ethical implications of that which is learnt in the science classroom, in the pupils is a difficult task. This cannot be done by mere imposition of knowledge by lecturing, as this will tend to indoctrinate the pupil. Developing ethical and moral values involve developing in the pupils, a value system which deals with what is good and what is bad, and also with what to do and what not to do. Such a value system cannot be built by the use of classroom activities traditionally used by science educators, as most of those methods may tend to indoctrinate the pupil. Desirable value systems are built, when there is no indoctrination, and when the individual builds that system intrinsically through one's own personal development. Development of value systems in a person takes place gradually, along with one's physical, mental and intellectual development. It is therefore important to help pupils to develop and work out their own value systems according to their level of mental and intellectual development. One important strategy to develop value systems in the pupils is by open discussion with teachers and peers (Furth 1979).

Open discussions and Sri Lankan culture
In a country like Sri Lanka open discussions between pupils and teachers may pose a problem. Firstly, learning strategies seem to be mainly geared towards memorisation of facts. This is not only because of the strong emphasis, and the back-wash effects of written examinations in the country, which tend to assess mainly cognitive knowledge (Dore 1976; Lewin 1984), but also traditionally a learned person in the Sri Lankan culture is considered to be a person who can commit to memory a large amount of knowledge. For example, a learned Buddhist monk, during the time of Sinhala Kings (ie before 16th century), was considered to be a person who could recite the Tipitaka, (an important Buddhist text) by memory. Secondly, the teacher of the 'Guru' in the Sri Lankan culture is held in very high esteem not only by the pupils but also by the society, as a fountain of knowledge. Under these circumstances, pupils may feel
reluctant to challenge, question, argue and discuss what has been taught by their teachers, and enter into open discussion with them.

**Introduction to role-play exercise**

An effective way of making pupils participate in open discussion is by introducing role-play exercises, where pupils are asked to act particular roles and react to simulated situations (Frazer 1986). The Dictionary of Education, explains, role playing as '... an instructional technique involving a spontaneous portrayal (or acting out) of a situation, condition or a circumstance, by a selected number of a learning group'. As Taylor & Worford (1978) pointed out '... all that is required of role playing is for the participant to accept a new identity, step inside someone else's shoes and act and react appropriately'.

Role-play has a subtle appeal to the emotions. It is similar in many ways to rhetoric discourse. Therefore role-play exercises share with the rhetoric the ability to sway opinions, and influence judgements, which are important in moral and ethical development of a person. Straight-forward debate or pedagogy may not be sufficient in this development.

Role-play was initially an exclusive claim of drama teachers, and it was later extended to subjects like languages and social studies. It has been found that role-play comes easily into learning situations, and it is in fact as natural as breathing. This is perhaps why social workers, counsellors, personal managers, have been seen to use it extensively. The utility of role-play as a learning method is undeniable and much is to be said for making role-play a technique available to teachers in all subjects as a valuable educational resource. Role-play has only just begun to infiltrate the science classroom, and this was almost unknown to science classes in the past (Solomon 1988). In the Sri Lankan situation role-play does not tend to destroy the traditional teacher-pupil (Gola-Gola) relationship. Even if the pupil behaves in a traditionally unacceptable manner, questioning and arguing with the teacher will be acceptable because the pupils and the teacher know that pupils are only play acting.

**Advantages of role-play exercises**

As stated by Jones (1979), there are many other advantages of role play exercises. The following list of advantages of role play have been compiled with reference to Jones, and the experiences of the author of this paper.

- Role playing helps pupils to express feelings and attitudes and to discuss them, thereby changing their attitudes where necessary, and helping in the maturation of their personalities.
- The pupils are encouraged to feel a situation rather than intellectualise about it.
- Role playing is a safe substitute for some real life situations. Sometimes real life experiences can be hard and bitter; mistakes that happen in real life may leave painful scars. During role-play, mistakes that one makes do not matter, and they do not leave bitter scars. Yet one can learn from them.
- Role play stimulates creativity, and critical thinking.
- Role play helps to develop social skills in that it makes one choose carefully words, gesture and approach.
- Role play helps as a powerful motivating factor for pupils to study.
- Role play helps the teacher to make a comprehensive evaluation of the pupils, in the cognitive, psychomotor and affective domains. For example the knowledge gained by the pupils in connection with a particular role will help the teacher to assess the cognitive abilities of the pupils. Their skills and abilities to debate can also be assessed, while their attitudes can be observed, as they react according to their roles during the role play exercise.
- Role play helps pupils organise thoughts and responses instantly, while reacting to the situation in question.
- Role play helps pupils remain calm in the face of adversity or pressure.

**The disadvantages of role-play exercises**

- What happens during a role-play is anybody's guess. It may however be possible to bring greater structure into the exercise by using pre-determined objectives.
- Pupils sometimes over emphasise or under emphasise particular roles and take the lesson along unintended paths.
- Pupils with talent may monopolise the situation.
- Pupils may be carried away in their roles and this may lead to disruption of the class, or become a distraction to the learning situation.
- Shy pupils or pupils with speech problems may not like to learn this way.
- Role play may be beneficial only to the persons actually participating, unless attempts are made to draw the whole class into it.

**Methods of conducting role-play exercises**

Role play can be structured or unstructured, the latter is something that would occur spontaneously during a lesson. For example during a science class on nutrition, the discussion steered towards a prominent television advertisement which highlighted the value of a brand of imported powdered milk. Some pupils wished to know whether fresh milk, or locally manufactured powdered milk was inferior. The teacher asked two pupils to take roles as a salesman of foreign milk powder, and as a salesman of local milk powder, and present their cases to the class. The arguments presented by them were helpful to the pupils in the class in providing opportunity for deeper consideration of the issue and equipping them to come to a conclusion of their own.

Structured role play exercises need more planning. The roles should be carefully worked out. The situation has to be carefully planned. Preferably the teacher should put all these details on paper. Roles should be allocated well in advance so that pupils can study their roles, collect relevant facts and plan what they should say during the role play exercise. The teacher may even coach the pupils separately. It may also be helpful in certain instances to get all the participants together and discuss their roles. Non speaking roles also may be given to the pupils in an effort to draw in more pupils to participate. Technical aspects such as tape recording the
proceedings can also be given to the pupils. See figure 2 for a flow chart which shows the details regarding arrangements of a structured role play exercise.

Identification of a suitable issue or a topic to be discussed during the role play exercise

- Plan the situation where the issue or the topic would be discussed. Define the roles for the exercise. The talent available, and the needs of the issue should be kept in mind.
- Call for volunteers for the roles.
- Allocate the roles to the volunteers. Try to match roles with their characteristics.
- Discuss with all the volunteers details regarding the issue or the topic.
- Give time to the participants to study their roles and gather information regarding their roles.
- Find strategies to involve other pupils in the role play exercise eg newspaper reporters.
- Make arrangements to tape record the exercise.
- Conduct the role play.

- Discuss the learning outcomes of the exercise with the whole class.
- Arrange re-enactment of roles where necessary.
- Plan suitable written work for the pupils.
- Make arrangements for the pupils to listen to the tape recording of the exercise.

Post role play activities

Role play activities do not end with the actual classroom enactment of roles by the pupils. It is equally important to analyse what happened during the role play exercise and determine what should be learnt. This can be done by further discussions and if necessary by re-enacting useful and important parts of the role play exercise. Listening to the tape recording of the proceedings of the role-play exercise will also be invaluable post role-play activity. The recording will not only help to further reinforce what was discussed, but it can capture useful and provocative experiences which will be a stimulant for role playing sessions on a later occasion (Pirrie and Dalgell-Ward, 1962). Refer to Figure 1 for a case study of a role play exercise, which was conducted in a Sri Lankan science class.

Figure 1

Case study of a structured role play exercise conducted in a Sri Lankan science class at secondary school level

A very interesting role play exercise was conducted by the teacher and pupils in a Sri Lankan secondary school science class. The issue to be discussed was the fate of an urban nature reserve situated very close to the school. Should this reserve be conserved or should it be used for other purposes? The school (Trinity College) is situated in Kandy. At the beginning of this century the area was about 400 hectares but it was now reduced to 100 hectares due to people forcibly acquiring the land from time to time for housing and agriculture.

The individuals taking part in the discussion, supposedly held at the Town Hall of Kandy, included persons from different interest groups with differing ideas regarding the reserve’s future. Those taking part in the role play took on pseudo names in keeping with their roles. Some of the names were funny, making the exercise more enjoyable to all. Figure 1 includes the list of characters in the exercise, their designations, and the main thrust of their arguments. It also shows some of the interactions that took place during the role play.

The rest of the class took part in the exercise as media people, representing the press, radio and television. Some pupils helped in the technical aspects, such as tape recording.

Each of the participants was requested to write a report on the arguments presented by them for the role play exercise, while the others were requested to write reports for their newspaper, journal, radio or television.

An interesting feature of this exercise was that it was an excellent example of making pupils aware of moral and ethical issues involved in conservation. The issue being linked with science itself, dealt with extrinsic issues such as development, leisure and even meditation. Therefore role play exercise was in keeping with the aims of the Bangalore conference.

Another interesting feature is that the issue discussed was a real one. Pupils may have been already aware of these issues, as various aspects of this issue were discussed by the press, radio and television. While role playing exercises can be made up, they are more powerful if real life situations are used.
Figure 2

The manner in which participants in the role play exercise interacted with each other.
Figure 3
Flow chart indicating various stages in organising a role-play exercise

Identification of a suitable issue or topic to be discussed during the role play exercise
Plan the situation where the issue or topic would be discussed
Define the roles for the exercise, keeping in mind the talent available and the needs of the issue
Call for volunteers for the roles
Allocate the roles to the volunteers, trying to match roles with their characteristics
Discuss with all the volunteers, details regarding the issue or the topic
Discuss details regarding each role separately with the participants
Give time to the participants to study their roles and gather information regarding their roles
Find strategies to involve other pupils in the role play exercise, e.g. newspaper reporters
Rearrange the furniture of the class to suit the situation, e.g. courtroom
Make arrangements to tape record the exercise
Conduct the role play exercise
Discuss the learning outcomes of the exercise with the whole class
Arrange re-enactment of roles where necessary
Make arrangements for the pupils to listen to the tape recording of the exercise
Plan out suitable written work for the pupils

Conclusion
Role play is a powerful educational force, and skilfully used it can provide groups of all ages, in any subject area, insights, laborious or even impossible to achieve by other means.

Reflections of Russia

by Gerald H Krockover

Adapted from the ICASE Luncheon Address
NSTA National Convention, Boston USA, March 1992

I am celebrating my 28th year in the field of science education and during those years I have had the opportunity to travel to numerous countries around the globe. But none of those trips was more exciting than the opportunity I had during the summer of 1991 to visit the former soviet union with 350 educators from American, Canada and Britain as part of a National Science Teachers Association sponsored trip.

As we prepared for the trip there was a great deal of excitement along with anxiety regarding what we might encounter and what might happen to us during our ten day visit. The excitement peaked when many of us gathered at Kennedy International airport in New York prior to flight across the Atlantic. We discussed our hopes and aspirations for a positive interaction and we talked about the presentations we would each be making during our visit to Moscow State University.

Upon arriving at the airport in Moscow it was quite evident to us that we were entering another era and that we were beginning a vastly different educational experience. The greetings from our student and faculty hosts were enthusiastic to the least. It became evident to me that our visit was going to be extremely successful and most enjoyable. Interaction between educators from both countries began almost immediately and friendships emerged as dialogue on education began and we shared our hopes for the future.

My session was scheduled for one of the afternoon periods. I am not usually very nervous with respect to making presentations since I have made literally hundreds of them. However, as I approached my presentation room I was becoming quite nervous. Would the teachers like what I had to say? Would they be able to understand my terminology? And, would they ask questions? As I entered the room I noticed that it was full and I began to get really nervous. The room was approximately 80% full with Russian educators. There was a slight problem - there was no translator for the session!

One of the American teachers I have worked with over the past five years volunteered to go out into the hallway and find a translator. She located a research chemist from Siberia who spoke excellent English and who volunteered to become my translator. She has since become a close friend.

Our session was lively; the Russian educators enjoyed it immensely and asked lots of questions. As I participated in other sessions, I found the same reception regardless of whether it was a Russian or a US presenter. As the days progressed, the dialogue became more focused with discussion about educational opportunities and the need for a continuing dialogue.

As an outgrowth of these experiences, I would like to recommend an article in the November/December 1991 Journal of Teacher Education entitled 'World Wide Issues and Problems in Teacher Education' by Howard B Leavitt, Director of the Council on Global Perspectives for the Professions, Amherst, Massachusetts. The article which is from his new book Issues and Problems in Teacher Education: An International Handbook, deals with many of the topics that we discussed with our Russian colleagues, and clearly delineates the specific problems relating to Russian education. These include:

- The recruitment of the most promising teaching talent and the competitiveness that exists from other more lucrative and more prestigious professions
- The content of teacher education - the discussion centred around the tensions that exist between the university ideal of knowledge for the sake of pure scholarship and the public school's interest in knowledge for practical purposes.
- Governance and quality control. This area can be summarised with the question, 'To what extent should the jurisdiction of teacher education and quality control be the province of central government as opposed to state or local administrations? ' When teacher education is perceived to be weak, when criticisms of teacher education institutions are publicised, and when economic recessions diminish funding for teacher education, public pressure is likely to build for state or national governments to intercede. Such interventions tended to diminish the authority for institutions for teacher education by imposing specific curriculum and certification requirements.
- Research was also discussed extensively with our Russian counterparts. Again a question best summarises discussion: 'To what extent should basic research be undertaken in contrast to research that can be immediately applied to the development of a program policy?' There appears to be a growing consensus world-wide that research and teacher education should become more action oriented and address policy issues related to improving the quality of programs at greater cost effectiveness.

- Professionalism. In many countries around the world teaching is treated as a semi-profession due to, among other things, the lack of a strong knowledge base, teachers' limited autonomy to make professional decisions, and accountability to superiors rather than to the profession.
- The notion of what is a teacher educator? This can best be highlighted by the question, 'To what extent should the activities of teacher educators reflect their connection with higher education traditions of research and scholarship rather than the responsibilities for preparing teachers to teach and
inducting them into the profession?'

• In-service education. This seems to be a problem world-wide because of the difficulty in coordinating pre-service and in-service education as well as providing coherence to countless problems of different types, organising efforts which take place by countless institutions, and a variety of goals that seem to be constantly moving. This problem tends to be magnified when a financial crisis exists. As a result, the world picture of in-service education is that of a huge variety of programs with on-again, off-again quality that trivialises both the concept of life-long learning for teachers and the process of induction into the teaching profession.

It appears that three major issues related to teacher education and to education in general, will have to be faced with respect to the restructuring of the Commonwealth of Independent States of the former Soviet Union. This includes the fact that teacher preparation takes place in three distinctly different institutions: secondary school institutions, pedagogical institutions, and universities. The major differences in the degree to which these institutions instil professional commitment and the ability to teach make it difficult to initiate nationwide reforms in such a fragmented system.

The second issue deals with attempts to liberalise a formalistic teacher training plan where the balance between academic courses and pedagogy is overwhelmingly tilted towards the former, especially in universities.

The third issue that will have to be dealt with concerns the neglect of financial support of education and the welfare of teachers. Low salaries, poor benefits and difficult working conditions, and buildings, equipment and curriculum materials which are deficient by any international standard, have produced a crisis in education. A severe shortage of competent teachers with a long-term commitment to teaching also exists.

Distracted by other more pressing aspects of reform, the governments of the former Soviet Union have only recently begun to grasp the enormity of the problems of producing an educated citizenry capable of achieving the commonwealth's new goals.

**Project 2000+**

**Scientific and Technological Literacy for All**

Calling all science teacher associations around the world

Are you aware of Project 2000+, an initiative of ICASE and UNESCO?

ICASE is now calling on all science teacher associations around the world to begin planning to unite with national institutes, science centres and other appropriate bodies to promote Phase 3 of this project.

Phase 3 is the major part of the project and will begin in earnest following the Phase 2 International Forum to be held in Paris, July 1993. Phase 3 consists of projects initiated and carried out in a country. They may be national in scope, or smaller regional projects.

Their purpose is to enhance scientific and technological literacy for all.

National task force groups may be set up to initiate cooperative developments among a number of interested partners. Governments may be involved – UNESCO will certainly be encouraging this. Regardless of whether there is any other support, ICASE will be behind the association offering whatever help it can.

But we have heard all this before!

An important aspect of Project 2000+ for better science and technology education is that far greater stress will be placed on IMPLEMENTATION and EVALUATION factors. These require teacher involvement – hence the importance of science teacher associations to be enthusiastic about Project 2000+.

Research has shown that current practices have been putting much emphasis on creating and developing intended curriculum, but that what is actually implemented is a far different picture. Much intending curricula advocate student-centred classrooms, highly trained and enthusiastic teachers, enlightened and varied teaching approaches and extensive feedback taking place in the classroom.

Reality shows teacher-centred, expository approaches that can, in many instances, hardly be called ‘teaching’.

If there is a way to change this, then the secret lies with the teachers. Implementational change is in the hands of teachers. Getting teacher support for implementational change is crucial. No support, no change! No science teacher involvement, no ICASE involvement!

ICASE stands for the creation of better curricula that promote scientific and technological literacy, the development of values, and the development of scientific and technological skills – and not merely the assimilation of a depth of factual information. ICASE supports the outcomes of the Bangalore conference (held in Bangalore, India in 1985) and its thematic approach. ICASE supports STS teaching and its incorporation of values. ICASE supports constructivism and research into the manner in which children learn science.

Project 2000+ is to effect these changes at a national level. The project secretariat is being set up now. It is waiting for your call... let ICASE help you with your Phase 3 project.

**INCOTE 92**

**International Conference on Technology Education**

Weimar, Germany

25-30 April 1992

by Dr J Holbrook

This conference was organised by Professor D Bladow, Pedagogische Hochschule Erfurt and Technische Universiteit Eindhoven, with the help of a number of international and European organisations.

A notable outcome of this conference was the creation of WOCATE (World Council of Associations for Technology Education), an umbrella organisation designed to link technology education associations around the world. Kevin Morgan (Australia) was elected as the first chairman with Professor Bladow as secretary. It was agreed that the secretariat would be based at Erfurt, Germany.

The conference drew attention to the very wide interpretation being placed on technology education around the world. In many third world countries there is little difference between technology and technical education, and both are related to the promotion of indigenous technology as a craft related exercise. Technology is seen as an end product and the skills are design and construction related.

In other countries, technology education is closely aligned with design, and is a problem solving process course where home technology and computer technology are integrated with areas geared to the utilisation of materials such as wood, metals and...
plastics.

It was striking to note the strong expressions dissociating technology education from science education. Whilst many speakers drew attention to the cross curricula nature of technology education and the links with economics, language studies and even history, links with science were quickly dismissed and, instead, differences dwelt on. Such differences were hard to reconcile without taking a very 'pure' approach to the teaching of science subjects.

Areas covered by papers on the themes of the conference were:

Strategy transfer – the interchange of experiences of technology education between eastern and western countries

1. Technological competencies, curriculum frameworks and teaching methods

In the area of stages of transfer, papers were presented on idea generation, identification, evaluation and assessment; communication; and a transfer strategy for conferences.

In the area of competencies and curriculum frameworks, papers were presented on the interdisciplinary nature of technology education and the links with science and other subjects; the situation of process skills not being clearly understood; the need for attention on design, development and implementation of technology education; and the need for an agreed philosophy.

In relation to primary school approaches, papers were presented on the philosophy behind technology education at this level; theoretical models; methodologies; and the need for a separate section on this area at the next conference.

Papers were presented on views and effects on high schools, focusing on topics such as: the necessity for a program for all youth to build confidence to learn from/with technology; and the need to define the scope to consider the inclusion of areas such as environment, or employment and livelihood.

In summary, there is a need for more dialogue and research; environmentally astute technology education courses; and the relating of technology education to culture and economic realities.

2. Technology teacher education

Papers were presented on philosophy, content, structure, pedagogy, quality, cooperation, breadth/flexibility, and research. The papers suggested the need to strengthen the societal interface, future planning, networks, and the politics of change.

3. Assessment and testing of technological competencies

Papers were presented on the topics: what to assess; capability in the process of task identification; recognition of importance of values and attitudes; ability to identify, seek out and apply knowledge and skills; the analysis of process in several ways; and the need to assess whole rounded performances in view of the learning process being more than the sum of its parts.

4. Technology education. advanced technology, industry links and the interface with environmental understanding

Papers were presented on: emphases on environmental issues; technological progress and science, social or child orientations; social orientation and an emphasis on discovery learning; and the trend to use problem solving as the starting point for socially oriented programs.

Technology, creativity and innovation

1. Role of technology education in developing human resources

Papers reflected the following viewpoints: all need technological literacy; the need for a skilled workforce not only in terms of technological capability, but also in terms of affective skills and values; technological capability in terms of flexibility, multidisciplinary creativity, team spirit and foresight.

2. The methodology of technology

Papers reflect the following: a general lack of insight into methodology; the need for methodology to be determined by particular groups of students and by teaching/learning aims; new technologies promoting new methodologies; awareness of available tools; the need for methodologies to be relevant; and the management of the physical environment.

3. Evolution of the nature of the human-technological interface

Papers reflect the following: the dynamic relationship of the human-technology interface; the greater sophistication of relationships as technology depends less on natural resources and unskilled labour, and more on human capability; the synergistic relationship impacting both positively and negatively on technology and individuals; the growing concern about the negative, indiscriminate use of technology; the need to account for local customs when transplanting technology; the need for educators to teach technology uses without compromising the need to be future oriented; the need for proactive approaches to technology change and the consideration of ethics in technology education strategies.

4. Human creativity, interests and technology activity and the means of overcoming barriers to technological thinking

A technology learning environment is one where the perceived realities interface with the external world and the internal landscape of the student. Barriers to this are the over challenges of the external world and the internal landscape. Also the under challenges of the external world and internal landscape pose a problem if activities are not challenging. Ways of overcoming barriers include: integration of technology, creativity and tools imagination; development of hardware/software for the external world and for the internal world.

Philosophy of technology

Papers were presented on: clarification of key philosophical terminology; identification of useful conceptual frameworks; evolving philosophical trends; uniqueness and commonalities among countries; differences between science and technology; and the uniqueness of technology knowledge.
Summary

This conference showed that the current trend in the developed world is towards the creation of a subject called technology in which problem solving skills are paramount. The subject is easily linked with design, and widened to incorporate areas such as home economics and informatics. It concentrates on solving real life concerns by practical means. As such, it lacks a theoretical base and has not yet penetrated into the less developed countries. When it does, I see the dilemma being whether it should be separate from or combined with a reconsidered science education program. The latter may be very attractive in terms of relevance, promoting indigenous technologies, and needing less specialised and costly facilities.

An Invitation to Kansas City
NSTA National Convention
March 1993

International Round Table

Each year at the NSTA National Convention, the International Committee of the United States National Science Teachers Association (NSTA) hosts an International Round Table. At this 90 minute session, presenters from different parts of the world discuss their country's science education programs.

Each presenter is provided with a table for a materials display. Those attending the International Round Table session visit the tables of countries they wish to learn about.

If you would like an official invitation to participate as a representative of your country, write to:

John E Penick  
Science Education Centre  
Room 789 VAN  
The University of Iowa  
Iowa City, IA 52242-1478  
USA

Participants will be required to arrange their own funding. The letter of invitation, and your name listed in the program, may help you as you seek funding support.

For information about other conferences refer to the Calendar section in this issue.
Eighth ICASE Asian Symposium
Sri Lanka
2 - 6 August 1992
Report by Dr J Holbrook

The 8th ICASE Asian Symposium was jointly sponsored by ICASE, SLASME, NIE and the Sri Lankan Ministry of Education and Higher Education.

The symposium's main theme was Science Education for a Changing World. Sub-themes were (1) high technology; (2) appropriate technology; (3) environment; (4) scientific literacy.

SLASME hosted the 8th ICASE-Asian Symposium at the National Institute of Education (NIE) in Colombo. There were about 100 participants from Sri Lanka and other Asian/Australasian countries. The subthemes were introduced by the main speakers and other papers were presented on the theme of the symposium. Discussion sessions covered the manner in which science education can contribute to a changing world. The proceedings of this symposium will be published.

SLASME is to be congratulated in hosting this symposium and showing what is possible with a small band of enthusiastic members. Although a small association, SLASME managed a very friendly and interesting meeting, and the overseas participants were well looked after. This meeting between overseas science educators and local science teachers was of particular significance. Thanks go to UNESCO and AIDAB for financial support. The British Council for supporting two of the main speakers, and to the Sri Lankan sources of financial aid, especially the Ministry of Education.

Summary of Recommendations of the Group Discussions of the 8th ICASE Asian Symposium

By Prof V K Samaranayake, SLASME

Four discussion groups met separately and made recommendations that were later approved at a plenary meeting. The recommendations are summarised as follows.

Group 1 – Environmental education
The aims should include the development of perspectives on environment based on a variety of considerations including aesthetic, biological, geographical, and physical; and the development of action to solve environmental problems including those for improvement and protection of the environment. The strategies should include the use of regional resource centres and the making of changes in curriculum and examinations.

Group 2 – Science and mathematics education
The group made a large number of recommendations which they placed under five headings:

- Inservice training programs should be re-organised.
- Assessment procedures must be reconsidered.
- Active learning by pupils should be encouraged by means of activities such as games, projects and roleplay.
- Parental involvement should be increased.
- Pre-school experiences in science and mathematics learning should be encouraged.

Group 3 – Science and mathematics literacy

- Innovative questions should be used in examinations.
- Dissemination of information relating to projects by students and

Photo (above): Professor Wynne Harlen from the UK addressing the 8th ICASE-Asian Symposium. About 100 local and overseas participants joined this successful symposium held in Colombo, Sri Lanka, 2-6 August 1992.
teachers.
• Developments of contacts between journalists and teachers.
• Schools should hold science days on which the community can visit the school and learn from the exhibits, plays, talks, etc.

Group 4 – Technology
The group identified seven priority topics and selected three of them for detailed discussion including the preparation of estimates for setting up working projects to achieve the proposals. The three projects were:
• National newsletter on science and technology education
• Making technological models and using traditional toys and games in primary schools
• Traditional technology: case studies of appropriate and environment-friendly technology

Report
The 8th ICASE Asian Symposium was organised by the Sri Lankan Association for Science and Mathematics Education (SLASME). Three other events were also held in conjunction with this symposium:
• Pre-symposium workshop on primary science
• Annual session of SLASME
• Roundtable on environmental education
All four events were co-sponsored by the National Institute of Education, Sri Lanka, which was also the venue for the events. The events were organised by special subcommittees of SLASME, enlisting the support of others drawn from the NIE, the Ministry of Education, the Ministry of Foreign Affairs, and the Ceylon Tourist Board.

The events were financed by UNESCO Paris, UNESCO Bangkok, the Australian International Development Assistance Bureau (AIDAB), the NORAD program of the Ministry of Environment & Parliamentary Affairs, the Natural Resources Energy and Science Authority of Sri Lanka (NARESA) and the Institute of Computer Technology of the University of Colombo. Local costs were met by SLASME.

Participants
Foreign participants came from Australia, China, England, Hong Kong, Iran, India, Malaysia, Maldives, Philippines, Thailand and USA.

Program
Papers were presented on the following themes:
• Environmental education
• Science and mathematics education
• Science and mathematics literacy
• Technology

Careful analysis and detailed discussion culminated in the following recommendations:

For the formal system of education
• to provide opportunities to acquire knowledge, values, attitudes, commitment and skills needed to improve and protect the environment.
• to encourage pupils to examine and interpret the environment from a variety of perspectives such as physical, geographical, biological and aesthetic.
• to arouse pupils’ awareness and curiosity about the environment and encourage active participation in solving environmental problems.
• to encourage teachers to use a variety of teaching strategies with material supplied through education authorities.
• to include problem solving, practical work, investigations, consolidation, exposition, discussion and display in the teaching strategies and change the assessment procedure to emphasise the same.
• to include innovative problems/questions demanding innovative answers in the national examinations.
• to undertake studies with the
The collaboration of the National Institute of Education, and the Department of Examinations on framing questions of the above type.

• to re-organise the in-service training program at all levels in the education system to achieve its goals.

For the non-formal system

• to involve parents through the School Development Societies to examine closely the educational activities of the pupils.

• to publish a series of booklets to disseminate information on out-of-school activities of pupils and teachers.

• to strengthen the contact between science teachers and media personnel.

Achievements

These include the motivation and stimulation of local teachers by exposing them to the work being done by others in the field of education in science and mathematics elsewhere in the world.

The presentations at the primary science workshop involved hands-on experiences of primary science for teachers who did not have a science background. If follow-up work is done on this by the National Institute of Education and SLASME, this could give the impetus to enhance science education at this level by leaps and bounds.

By setting apart one evening for CASTME, SLASME was able to give recognition and publicity to Sri Lankan CASTME award winners.

They made short presentations of their award winning works at the ICASE Symposium. By this exercise it is hoped that more teachers have been inspired to indulge in innovative work that will lead to improvements in the teaching learning situation in Sri Lanka.

SLASME has been able to harness the fullest cooperation of a number of government organisations, such as the Ministry of Education, the National Institute of Education, the Institute of Computer Technology of the University of Colombo and even the Ministry of Foreign Affairs and the Ceylon Tourist Board which do not normally become involved with the formal system of education.

33rd Annual Conference of STAN
Science Teachers Association of Nigeria
17 - 22 August 1992

33rd Annual Conference of STAN
Enugu, Nigeria
17-22 August 1992

The theme of this year’s conference was Conductive Classroom Environment for Science, Technology and Mathematics Education.

The Conference was declared open by the Executive Governor of Enugu State, His Excellency Dr Okwesili Eze Nwodo. The STAN President, Dr U M O Ivovi, FSTAN focused on the ‘Crisis in our Classrooms’ in his address and urged studies of effective classroom practices for the teaching of science.

Highlights of the conference were:
• the award of Fellowships of STAN to six distinguished members of STAN;
• the Master Project Award;
• Formation of a Science Technology and Society Panel of STAN; and
• the presentation of the ICASE Distinguished Service Award to Professor Samuel Tunde Bajah, FSTAN. This was in recognition of his career of distinguished service to international science education. Sam becomes the first person from Africa to be awarded the ICASE Distinguished Service Award, and joins an exclusive band of 9 recipients of this prestigious award.

Seminar on Curriculum Development for Secondary School Chemistry in P R China

by Dr J Holbrook

From 19th - 28th July, I conducted a seminar on behalf of UNESCO in Kunming, China for a group of 15 curriculum researchers, university professors and members of the People's Education Press. This proved to be a very interesting undertaking and I ended up doing much more and even teaching a summer school class in Yunnan Normal University on the virtues of problem solving and decision making activities. It was surprising how quickly 2 hours passes when everything that was said needed translating, and the overhead projector was not functioning as well as one would like. I very much enjoyed the experience.

The seminar itself focused on trends in chemical education and inevitably covered the need for more relevant curricula, science technology society developments, and the development of chemistry curricula. Also considered were teacher education needs and the issue of examinations, which teachers face in all countries where competition to enter tertiary institutions is great. I was able to illustrate alternative ways of sequencing the curriculum, particularly when it is accepted that a fundamental first chemistry approach is not particularly necessary and does not provide any more of a logical sequence for students than approaches which take on a more societal slant.

Much of the topics covered had a direct bearing on the thrust of Project 2000+ and it was encouraging to see the interest expressed in this project by the participants. It seems that Project 2000+ is coming at a very appropriate time for China as a new curriculum for 3rd year (grade 9) middle school chemistry begins in 1995, and developments in chemistry curricula for grades 10 upwards will begin shortly.

The seminar covered five main topics – trends in chemistry teaching; the STS movement; development of curriculum guides and textbooks; activities appropriate for new trends in chemistry teaching; and, finally, a look at assessment. The last topic was specifically included as the participants voiced this as a very strong deterrent for the introduction of more socially and technologically relevant teaching. The examination is seen as a major hindrance to the widening of skills taught in the classroom such as problem solving and decision making. Nevertheless, the inclusion of socially worded structured questions and the inclusion of relevance of chemistry to daily life was seen to be appropriate and fairly straight forward to incorporate. The concern came much more with suggestions of internal assessment, particularly with respect to the large class sizes experienced in China. This is an area for more research but the experiences in assessing large classes in experimental skills by internal assessment in Hong Kong were given to show the feasibility of such developments. The ideas on assessment did not stop there, however, as a brief look at criterion referenced assessment in a socially relevant area such as food additives was included to stress the idea of assessing from a 'can do' perspective rather than taking the more negative, penalising approach usually associated with norm referenced testing.

While looking at the range of activities, the Chinese participants became very involved with a role playing session on action to take in an electroplating factory where there had been a serious accident. This proved to be a highlight of the whole seminar.
A look at two minority families and their beliefs about who can become a scientist

by James E Nesbitt

Introduction
The implicit, as well as the explicit, interactions that take place between a parent and child constitute some type of an educational experience for the child. According to Olmstead (1991), parents are teachers everyday they interact with a child. This parent-as-teacher role begins at birth. The messages that parents convey to their children about educational issues are lessons that sometimes serve to discourage, rather than encourage a child. These messages may be influenced by a parent’s own educational experiences or by a parent’s ‘perceived’ sense of hopelessness. Within the minority community, some parents devalue education because education did not provide them with social and economic mobility. These disadvantaged parents may not be an advocate for education, while other minority parents in similar circumstances, may place an even greater value on education. How is it that minority parents from similar socio-economic backgrounds share contrary beliefs about the value of education for their lives and the lives of their children?

The historical context
The factors that influence the way some minorities perceive themselves have a historical foundation. Historically, these social conditions include: discrimination, poverty, lack of educational opportunities, and the struggle for civil rights (Looney, 1988). These factors still play a significant role in the development and the individual’s perception of self or one’s identity.

According to Looney (1988), identity deals specifically with an individual’s awareness, values, attitudes, and beliefs about oneself. Identity can also be described as a way of living – a way of viewing the world and interacting with the environment (Looney, 1988). Individuals who develop a positive identity, although confronted by these historically-rooted conditions, have established a philosophy about self that transcends the boundaries of these controlling factors. These individuals possess a positive self-concept. A self-concept that is supported by a world view or belief that the locus of control of one’s life exists within the individual. These are the individuals who encourage, rather than discourage their children, even when their educational experiences have not led to social and economic mobility.

Philosophical context
The 'constructivist' model offers a perspective or a way of understanding how individuals make sense of their world. Research findings resulting from this perspective have profound implications for the way in which science instruction is carried out (Saunders, 1992).

This model states that knowledge is socially-constructed. The meanings that individuals construct from events and experiences in their lives are understood within a socio-cultural context (Stewart and Mickunas, 1974). The interpretations of these experiences are processed through a cultural filter. The prior knowledge, values and beliefs of individuals have been shaped by their experiences. Since experiences are products of the human mind, they are by nature subjective. This subjective world is the basic context of human action (Stewart and Mickunas, 1974). This subjective world forms our worldview. This worldview is shaped by many cultural factors.

The constructivist model provides a theoretical framework for describing and interpreting data from a contextual or cultural perspective. As stated earlier, this model has implications for how we teach science and also for how students and parents make decisions about educational issues.

This approach offers students an educational experience more closely related to their reality. If students and parents experience science in a meaningful way, then hopefully the value of science in their lives will increase and as a result, their perceptions of 'Who can become a scientist?' will reflect a global view.

Beliefs about 'Who can become a scientist'

During my second year doctoral seminar, I interviewed two 8th grade minority students from my 1989-90 inner city science class. The mothers of these two young men were also interviewed. The purpose of this project was to assess the beliefs of these individuals regarding the question 'Who can become a scientist?'. Beliefs held by students will influence the role of science in their lives. Beliefs communicated by parents are factors that help give meaning to the student’s beliefs. The interviews revealed that these two families held opposing views on the issue of 'Who can
become a Scientist?”. One parent and child revealed a sense of powerlessness, while the other parent and child felt some measure of control over their lives in relationship to this issue.

Discussion

During the interview, one inner-city mother revealed examples of a negative attitude when she was asked her beliefs about ‘Who can become a scientist’. This mother held discouraging views about the possibility of her son, or for that matter any minority child from her community, becoming a scientist. She felt that some minority children don’t have the intellect or might even find science boring (Nesbitt, 1990).

In further conversation, this same mother revealed that science was not one of her strong points when she was in school. She stated that she does not want to present science as an easy endeavour, in case her son decided to go into science and couldn’t make it. Finally, she stated that as a minority parent she realised there are limits to what her son can do (Nesbitt, 1990).

The second mother held favourable attitudes toward science and believed that anyone could pursue a career in science, if he/she is provided with a nurturing experience early in life. She felt students from her community do not consider a career in science because there are no role models in the community. She stated that she is always telling her son how he can do anything and be anything he wants to be if interested. She, along with a friend, suggested that community science experiences be provided for the children. This suggestion led to the organisation of a community science program for the children of the community.

The interesting point is that the two mothers had sons who attended the same middle school and the two families lived in the same community, yet these mothers held opposing viewpoints on this issue. The mother with the encouraging comments believed that minority status should not be a deterrent to assuming a career in science, if opportunity presents itself to any individual who has received adequate preparation. Her son, also, stated that he believed anyone could become a scientist. It is the responsibility of the parent and the teacher to help children develop a positive self-concept. Hill, Pettus, and Hedin (1990) state that self-concept and a feeling of self-efficacy are two important personality variables that are related to an interest in science and mathematics.

The other young man in the interview shared the same discouraging comments as his mother. He did not possess a positive self-concept about going into science. He stated that he could not imagine himself as a scientist and told me that only the smartest students become scientists. I asked him why couldn’t he become a scientist and he replied, ‘scientists are too smart’.

If our educational goals include providing under-represented groups access to the field of science, then it is critical that we understand the beliefs they adhere to when they reflect upon the question, ‘Who can become a scientist?’

Implications for educational practice

Menacker, Hurwitz and Weldon (1988) concluded from their study of Chicago elementary schools that most inner city parents had negative school experiences themselves and did not see the school as a ‘place of hope’ for their children. The work of Ogbu (1983) might offer an understanding as to why some individuals commit to a feeling of hopelessness and a lack of control over their lives. Ogbu (1983) identifies two mental frame of references. One is the 'castelike' minority who is caught in a web of inferiority and self-defeat that discourages one from living up to his or her potential. The other is the 'immigrant' minority who sees education as a golden opportunity. Parents who assume the former way of thinking about educational issues are perpetuating this feeling of hopelessness in their children. Their beliefs influence the way their children view the world.

Ogbu (1983) further argues that whenever a subcultural minority has historically experienced caste-like restrictions in its access to legitimate power and status within a dominant culture, the adult members of the subculture develop different, largely negative, cultural attitudes toward such settings – attitudes that may be transmitted to its children.

It might even be easy for some educators to conclude that parents who exhibit a feeling of hopelessness or who have a discouraging attitude are parents who don’t value education, when in reality, other factors may be operating. According to Greenwood and Hickman (1991), some parents feel powerless to influence the school. Other parents believe they do not have knowledge or social skills (Greenwood and Hickman, 1991).

The obvious conclusion is that there is an apparent need to strengthen the lines of communication and relationships between the school and the home, or more specifically, the teacher and the parent. Discouraging parental attitudes can undermine the efforts of the teacher and the schools whose role is to provide a positive and encouraging learning environment.

The research on parent involvement suggests clearly that the home has at least as much influence on student learning and behaviour as does the teacher and the school (Greenwood and Hickman, 1991). Meaningful parent participation is essential for effective schooling (Comer and Haynes, 1991). Therefore, at a time when substantial efforts have been placed on encouraging more minorities to go into science, it is definitely desirable and advantageous to involve parents in our efforts, especially parents whose experiences have caused them to have a feeling of hopelessness. The messages that these parents convey to their children, many times, may be messages that are not consistent with our educational goals.

PROJECT 2000+

Phase 1 Materials

Can you help?

To ensure that Project 2000+ takes note
of all developments around the world,
can you help by bringing our attention
to any relevant materials that exist?

Of interest is material related to the 6 focus areas.
Please indicate which focus area.
The material may be journal articles, research papers,
material from projects, teaching or assessment ideas,
or local resource materials that have a bearing on
scientific and technological literacy
in the 21st century.

Non written materials are also very relevant,
including videotapes. The criteria is that
they relate to scientific and technological literacy
for the 21st century.

Please send any material
that you consider to be relevant to:

Dr Jack Holbrook
Project 2000+
Science and Technology Education Unit
UNESCO
7 place de Fontenoy
75700 Paris
France

If it is not possible to send the actual materials,
please let us know about them and
where they can be obtained.
Materials should be in English or French.
If materials are in another language,
please send with a short abstract in English or French
which describes the content.

Don't forget that materials, articles, etc
should be forward looking
and be capable of being relevant in the 21st century.

Project 2000+ is looking at the 21st century.
The Good Primary Science Teacher: What some Bruneian school children say

by Cynthia P Tendencia
Universiti Brunei Darussalam

Introduction
Teachers normally find some difficulties in giving a quick, spontaneous response when confronted with the question 'Are you a good teacher?' The Asian woman is quite demure in responding to this. Thus, the problem of who we should ask about the teacher, arises. Well, why not ask the schoolchildren. So, in an attempt to have a picture of a good primary science teacher as perceived by Bruneian schoolchildren, 140 of them from seven elementary schools were asked to respond in written essay form to an assumed situation wherein they had to describe the primary science teacher they would like to have.

The essays were analysed initially to identify the acts, attributes, behaviours and other characteristics of the chosen science teacher. These were tentatively labelled 'descriptions'. Then these descriptions were grouped and main headings were evolved which eventually were used as the three major categories of descriptions: (1) teaching skills; (2) personal qualities; and (3) discipline. Interviews were later conducted to verify the interpretations of the descriptions.

What is a good primary science teacher?
'I want a teacher who is very kind and gentle. I don't want her to be late for school to teach science. She should do interesting and exciting experiments. I like her to be fair to us and teach us very well. If she teaches us about animals or plants, I want her to bring to school some pictures or samples of what we have studied. I would like her to stop naughty pupils from fighting and destroying our experiments.'
(Md Erwan, 11 years old)

In the children's description of their preferred primary science teacher, there was greatest mention of the teacher's teaching skills, followed by personal qualities and then by discipline.

Primary science teaching skills
A total of 18 descriptions of teaching skills were derived from the essays.

These are summarised under 12 categories shown in the table below.

This article is an excerpt from the article of the same title published in the Proceedings of the 7th ICASE Asian Symposium.

| Teaching skills of a good primary science teacher as identified from 140 essays of Bruneian schoolchildren |
|---------------------------------------------------------------|---------------------------------------------------------------|
| **Skills** | **Rank** |
| Asks questions; allows children to also ask questions | 29 5 |
| Explains clearly and communicates well | 85 2 |
| Gives fair marks and grades | 4 11 |
| Gives notes, exercises, assignments, homework, project work and tests | 38 4 |
| Gives rewards and treats to those who do well in class and exams | 2 12 |
| Makes lessons interesting with stories and jokes | 20 7 |
| Manipulates science apparatus | 6 10 |
| Provides extra class, revision, tuition and remediation | 7 8.5 |
| Records interesting events in class like taking snap shots | 7 8.5 |
| Supervises individual and group work, points out mistakes; helps children at work | 28 6 |
| Uses experiments, field trips and visits, demonstration and activities | 133 1 |
| Uses audio-visual aids | 53 3 |
International Model Solar Car Challenge

On the lonely stretches of the sunburnt Stuart Highway in November 1993, vehicles powered only by the sun will slip through the air at speeds in excess of 100 km per hour in the Darwin - to - Adelaide World Solar Challenge in Australia.

This international event has been an unqualified success. The race has also generated tremendous interest among students throughout the world in not only these novel vehicles, but also in the many other renewable energy technologies.

In response to this interest, another event for our younger inventors will be held in conjunction with the 1993 World Solar Challenge.

The 1993 International Model Solar Car Challenge will bring together students from all over the world in a special competition to test their model vehicles powered by solar energy.

This event follows the successful Victorian-based Model Solar Car Challenge in 1990 and 1991. Teams in almost all Australian states and territories will hold state-based events to qualify model solar cars for the international event.

The success of these events will provide a significant representation by all Australian states and territories at the International Model Solar Car Challenge in 1993. New Zealand students will also participate as well as students from Japan, Europe and the US.

Why solar cars?
Teachers and students are looking for innovative ways to teach and learn about environmental issues. One of the most pressing environmental issues is the use of fossil fuels and the resulting problems of pollution, atmospheric change and resource depletion. One of the key solutions to these problems is the development and utilisation of energy-efficient and renewable energy technologies.

Generating electricity from solar cells is an emerging and important renewable energy technology. Many scientists have been successful in improving the technology of solar photovoltaic cells and believe that they have an important role to play in meeting the energy needs of our society.

Students need to be aware of the potential of photovoltaics and other forms of renewable energy so that they can make informed decisions about energy choices as they become the adults of tomorrow.

The 1993 International model Solar Car Challenge fits easily into science and technology studies where students design, construct and test model solar cars. The event and project can also develop links with Social Education, Environmental Education and Geography areas, while also providing a high degree of student motivation.

Students involved in previous model solar car activities have shown substantial personal development with organisational skills, co-operative group work, research skills and report presentations.

Project materials
An innovative package of materials has been developed to facilitate the construction and testing of model solar cars in a school-based multi-disciplinary activity. The package of materials includes a solar module, resource book and videotape, and provides a broad range of photovoltaic experiments and activities to be incorporated into on-going school programs and curricula. A practical guide is also available using ideas generated in the 1990 and 1991 events.

NEW ICASE PUBLICATION

Sustainable Development for a New World Agenda

PROCEEDINGS
OF A CONFERENCE

Winnipeg, Manitoba
Canada
October 17-20, 1990

Edited by John E Penick
and John R Stiles

This new publication, published jointly by STAM, CASE and ICASE, is a serious look at sustainable development and important reading for anyone involved in teaching, curriculum development or developing in-service teacher education courses.

Copies at a cost of US$10.00 including postage can be ordered from:

Dr Jack Holbrook, Executive Secretary, ICASE
Science and Technology Education Unit
UNESCO, 7 place de Fontenoy
75700 Paris, France

or

Dennis Chisman, Honorary Treasurer, ICASE
Knapp Hill, South Harting, Petersfield GU31 5LR, UK

John Penick, Science Education Center
University of Iowa, Iowa City IA 52242, USA

Evhan Uzwysyn, Home Schooling Office
1970 Ness Avenue, Winnipeg, Manitoba, Canada R3J 0V9

Cheques payable to "ICASE"

One of the major sections in this new publication includes papers on Education for Sustainable Development.

Topics include:

• The links between education and sustainable development

• Environmental education 1972-1992

• National round-table on the environment and the economy

• Mandates for environmental education

• Point of view on environmental education

• Education for sustainable development

• Geology education and science development in less developed countries of the world

• STS - environment - problem solving

• Beyond STS science education - adding the environment: a Saskatchewan approach

• Hazardous waste education in elementary school

• Exemplary environmental programs in the United States

• The world in the hands of children

• The future direction of sustainable development in the curriculum

These and other topics dealing with environmental problems and solutions will be of interest to teachers, curriculum developers and teacher educators.
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1992

December 14-17
14th Biennial Conference of the Asian Association for Biology Education
Location: Deakin University, Melbourne, Australia
Contact: Peter Brown, Convenor, AABE Conference, Deakin University, Rusden Campus, 662 Blackburn Rd, Clayton, Victoria 3168, Australia.
Anyone with an interest in biology education and environmental management is invited to attend. The theme is ‘Environmental Management in Asia – Training, Education and Research’

December 17-21
Twelfth International Conference on Chemical Education
Location: Bangkok, Thailand
Contact: Dr Somjai Wichaidit, The Secretariat - 12th ICCE, c/o Research Centre, Faculty of Medicine, Ramathibodi Hospital, Rama 6 Road, Bangkok 10400, Thailand
The theme of the Twelfth International Conference on Chemical Education will be Chemistry in Transition and it is hoped that the participants will interpret this in many different ways. This biennial Conference, to be held for the first time in South East Asia, is organised by the Committee on Teaching of Chemistry of the International Union of Pure & Applied Chemistry, and The Chemical Society of Thailand in cooperation with UNESCO. It is attended by chemistry teachers at both high school and university levels who wish to improve their teaching and to learn from one another techniques and experiences.

January 3-8
International Conference on Science Education in Developing Countries
Location: The Amos De-Shalit Israeli Science Teaching Center, Israel
Contact: Conference Secretariat, ORTRA Ltd, 2 Kaufman St, PO Box 50432, 61500 Tel-Aviv, Israel (conference arrangements) or Dr Avi Hofstein, Department of Science Teaching, The Weizmann Institute of Science, Rehovot 76100, Israel (academic correspondence)
This international conference on the theme "Science Education in Developing Countries: From Theory to Practice" will review past experiences and achievements in science education and plan for the 21st century with a special focus on developing countries. The conference will feature plenary lectures, symposia, poster sessions, workshops, exhibitions, informal discussions, social events and local visits. Topics for symposia and plenary lectures will focus on current research on learning and teaching and its implications for (1) the learner, (2) the teacher, (3) the classroom, and (4) the curriculum.

March 21 - April 2
Science Education in a National Curriculum: An International Symposium
Location: University of York, UK
Contact: Your nearest British Council Office or Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK.
There are vacancies for 30 participants. Topics include: building a national curriculum; new science curricula in secondary schools; styles of curriculum development; evaluation of science curricula; impact and research on developments in science curricula; student assessment; changing demands for staff development; links between industry and science education; the role of national and international agencies in science education.

1993

January 3-6
ASE Annual Meeting
Location: Loughborough University, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event have been circulated in Education in Science, a journal of the Association for Science Education.

March 25-30
Sixth International PATT Conference
Location: Motel Eindhoven, The Netherlands
Contact: dr Jean de Vries, Pedagogical Technological College, PO Box 826, 5600 AV Eindhoven, The Netherlands, Fax 31-40-440045.
The aim of this conference is to exchange ideas and information on theoretical and practical implications of the implementation of environmental issues in technology
education according to the subthemes: (1) Pupils’ attitudes towards technology and the environment; (2) Environmental issues in primary and secondary technology education; (3) Gender aspects of environmental issues in technology education; (4) Environmental issues in the education of technology teachers.

April 10-24
Edinburgh International Science Festival
Location: Edinburgh, UK
Contact: Edinburgh International Science Festival Ltd, 1 Broughton Market, Edinburgh EH3 6NU
The program for the fifth Edinburgh International Science Festival will span many themes ranging from the environment to space, and high technology to health but, perhaps most importantly, each of the 300 plus public events will explain – in jargon free language – how topical issues within each theme affect everyone. A major international conference focusing on initiatives taken by a wide range of organisations, in many different countries, to improve communications between scientists, the media and the public will be one of the highlights.

April 21-25
International Conference on Geoscience Education and Training
Location: University of Southampton, UK
Contact: Mrs Esther Johnson, GEOED Conference Secretariat, Department of Geology, University of Southampton, Southampton S09 5NH, UK
The Association of Geoscientists for International Development (AGID) and the Commission on Geoscience Education and Training (COGEOED) of the International Union of Geological Sciences are convening this international conference with the support of ICASE. Themes include: geoscience education in schools; higher education; geoscience training for business, industry and public service; and public understanding of geoscience. The conference is open to all those with an interest in geoscience education and training - including practitioners and those involved in administration, course development, and the supply of resource materials.

June 27 - July 3
VII Pacific Science Inter-Congress
Location: Okinawa Convention Center, Okinawa, Japan
Contact: VII Pacific Science Inter-Congress, c/o Section of International Affairs, University of the Ryukyus, 1-Senbaru, Nishihara, Okinawa, 903-01, Japan
The Symposia will be organised around the theme The Pacific: Crossroads for Culture and Nature and subthemes (1) Cultural Interchange among Pacific Peoples; (2) Speciation, Dispersal and Conservation of Species in the Pacific; (3) Towards Appropriate Technologies and Policies for Development and for the Conservation of Natural Environments in the Pacific. Scientific sessions organised by the Scientific Committees of the Pacific Science Association focus on a range of science disciplines and issues, including Science Communication and Education.

July 5-9
CONASTA 42
Location: Sydney, Australia
Contact: Jenny Jones, Convener CONASTA 42, PO Box 787, Potts Point, NSW 2011 Australia
The Australian Science Teachers Association invites you to participate in the 42nd annual conference of the Association. The theme of ‘Science – Teaching it Better!’ aims to highlight the part that teachers can play in fostering in their students an interest in and understanding of science. Four subthemes will deal with both primary and secondary issues: (1) Science updates – recent exciting developments and their impact; (2) Science education research – what it has to offer the classroom teacher; (3) Science teaching for effective learning – how do we engage minds in the classroom?; (4) National initiatives. The program includes theme lectures, interactive workshops, seminars, field workshops, ‘wandertimes’ and poster presentations. A comprehensive display of resources useful to science teachers will be presented by publishing, audiovisual, equipment and computing companies.

July 6-11
Project 2000+ International Forum
Location: Paris, France
Contact: Dr Jack Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong
This worldwide conference, organised by ICASE in conjunction with UNESCO and other international bodies is the second phase of the three phase Project 2000+ (refer to article in this issue for more details of this project). A number of international and regional conferences are generating input into this international forum. The theme of the forum addresses the issue of scientific and technological literacy for all. Sessions will establish agendas for future action. Attendance will be by invitation only (500 participants). Names are now being sought from a wide variety of organisations with an interest in science and technology education (see next page). The forum plans to issue statements to affect political visibility for science and technology education for all as a requirement for national development, and provide a framework for major programs of action in science and technology education involving governments, IGOs and NGOs.

July 27 - August 10
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.
International Forum

Scientific and Technological Literacy for All

Phase 2 of Project 2000+

Paris, France

6-11 July 1993

This International Forum is the Second Phase of Project 2000+, an international project on scientific and technological literacy for all, which addresses the following 6 focus areas:

1. The nature of, and the need for scientific and technological literacy
2. Scientific and technological literacy for development
3. The teaching and learning environment for scientific and technological literacy
4. Teacher education and leadership for scientific and technological literacy
5. Assessment and evaluation for scientific and technological literacy
6. Non formal and informal development of scientific and technological literacy

Attendance will be by invitation only and limited to 500 participants. Names are now being sought from:

- National EFA (Education For All) Groups
- National policy makers overseeing science and technology education
- INISTE centres
- Project coordinators and field workers for organisations
- Science and technology teacher associations
- Institutions, centres, universities and colleges involved in science and technology curricula, examinations and teacher education
- Science and technology out-of-school centres and organisations
- Non formal science and technology educational organisations
- Industrialists
- Persons from the mass media interested in Project 2000+

Organisations, associations and institutes are invited to submit names of suitable participants to the Project 2000+ secretariat. A short description of each person should also be included covering:

(a) activities of the person nationally (within organisation if appropriate)
(b) international involvement (at conferences, research, projects, etc)
(c) which Project 2000+ focus area is of greatest interest

Individuals can also apply. Individuals will be selected based on paper abstract, submitted by the end of September 1992, related to one of the focus areas.

Selection will take place at the end of 1992 and will be finalised by approval of the Steering Committee at the end of January 1993.

There will be a US$100 Registration Fee for each participant to help defray material costs. This will be payable to the Project 2000+ Secretariat on receiving the invitation. For further information, contact: Dr Jack B Holbrook, ICASE Executive Secretary, Science and Technology Education Unit, UNESCO, 7 place de Fontenoy, 75700 Paris, France.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

ICASE Secretariat moves to Paris

The intensity of work associated with the major ICASE/UNESCO initiative, Project 2000+, continues to increase as Phase 2 of the project draws nearer.

In order to facilitate the planning and organisation of the International Forum which will form Phase 2 of Project 2000+, Dr Jack Holbrook has moved from Hong Kong to Paris. The International Forum, which will be held at UNESCO headquarters in Paris, 6-10 July 1993, will involve 500 invited delegates, including representatives of ICASE member associations.

ICASE World Activity Day

Accompanying the June issue of Science Education International will be a special feature reporting some of the activities of World Activity Day which was held throughout the world on Thursday 14 October 1992. The activities focused on the theme of space, on the occasion of ISY (International Space Year).

The Editor has received several essays which have been selected by member associations and ICASE regional representatives as worthy of publication. The best of these will be published in this special feature. Certificates have been sent to through regional representatives to the students who wrote the winning entries.

The Editor has also received a report by students who conducted the activity to calculate the Earth's diameter.

If member associations have not yet passed on any entries, reports, etc to the ICASE regional representatives, please do this now so that these can be incorporated into the special feature. Alternatively, send entries, and any reports of World Activity Day in your area direct to:

Brenton Honeyman
Editor, Science Education International
10 Hawken Street
Monash ACT 2904, Australia

Member associations are requested to assist with nominating individual women and men who have made a significant contribution to science education at the primary, secondary or tertiary levels. It is hoped that in this second edition, there will be many more entries by educators from developing countries, and from officers who are making a substantial contribution through their science teacher association, etc. Either copy the form distributed with the December 1992 issue of this journal and send it to your nominees, or provide the Editor (Brenton Honeyman, 10 Hawken Street, Monash ACT 2904, Australia) with names and addresses so that forms can be sent.

New Subscription Rates
for Science Education International

Since the first issue of the ICASE Journal in March 1990, individuals and libraries have been subscribing to Science Education International.

Due to increasing production and postage costs, 1993 subscription rates have been increased to:

**Individual**
- £10.00
- US$17.50
- A$22.00
- CAN$20.00

**Library**
- £20.00
- US$35.00
- A$44.00
- CAN$40.00

Subscriptions can be forwarded to:
(chques payable to "ICASE")

The ICASE Commitment to Primary Science

The ICASE Stepping into Science Project, led by Sue Dale Tunnicliffe, continues to widen its impact in many places around the world. A Stepping into Science Newsletter, available on a subscription basis (£5, US$8, A$10 or Can$9), assists the project to share news of events and ideas for primary classrooms. The photo below shows Sue Dale Tunnicliffe conducting a Stepping into Science workshop at Cincinnati University during October 1992.
International Specialist Seminar

**Science, technology and society - appropriate science education for the twenty-first century**

*6-16 September 1993, Oxford*

This seminar will build on the highly successful course held in Oxford in September 1990, and yet it will be self-contained for those who are new to this field of science education. It will be directed by Dr Joan Solomon, University Lecturer in Research at the Department of Education Studies and author of several books on Science, Technology and Society. Mr Terry Allsop, Lecturer in Chemistry Education at the Department, will be tutor to the course.

The following issues will be among those discussed:

- The nature of STS as education
- Objectives and the evaluation of courses
- Information knowledge and Public Understanding of Science
- Industry and STS
- STS in developing countries
- Law, values and decisions about the environment
- New curriculum materials
- Teachers and in-service education

This seminar is intended for experienced science teachers, educationists, and government officials involved with curriculum planning and implementation and inservice work with teachers.

There are vacancies for 30 participants.

Seminar fee: £950; accommodation charge: £490; total fee: £1440.

The seminar will be held at the Department of Educational Studies, University of Oxford. Participants will be accommodated in single study bedrooms at the nearby Lady Margaret Hall, one of the university colleges. Bathroom facilities will be shared.

*Further information and application forms are available from local British Council offices or from Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK (telephone: +44 (0)71 389 4264/6252/4162; fax: +44 (0)71 389 4154).*

Disturbing the Boundaries
The Science/Literature Membrane

by Peter Lumb & Paul Strube

Abstract

A collection of over 200 short stories, written for the National Short Story Competition of the RACI, are examined for what they reveal of students’ images of science and scientists. A discussion of the place of science in fictional writing is carried out, using material from actual stories. This is placed in the context of other research on students’ perceptions of science, and has implications for concerns about gender in science education.

Science remains an activity that is highly competitive, macho and exclusive.
(Suzuki, 1987, 157)

Introduction

Constructivist theories of learning have encouraged us to look for the connections learners make when information is received. In science education, we have naturally tended to concern ourselves with the connections between scientific concepts. Research is beginning to uncover the connections between incoming scientific information and non-scientific content of the mind (Gunstone, 1990). Concept maps have been valuable here, showing the kinds of connections that are made when such words as ‘energy’, ‘force’ and ‘living’ are explored.

From 1988 through the current year, the authors have organised a short story competition for science students in Australian secondary schools. Sponsored by the Royal Australian Chemical Institute as part of its National Chemistry Week activities, the competition is based around writing a fictional short story in which chemistry played a major role. (Strube, 1989)

An objective of the competition was to stimulate imaginative interest in science, and to provoke thought among students about the ways in which science was contiguous with real and imaginative experience. Certainly, the products of this short story competition have suggested that science stories provide rich possibilities for humanistic exploration. The competition revived ideas about the ‘two cultures’; they seem clearly evident, and separate, in many of these stories. Both cultures, it seems, have much to gain if science teachers feel able to involve humanities teachers and secondary students in a joint writing enterprise. On the whole, stories from English classrooms are quite different to, and remote from stories from science classrooms. The two cultures are so distinct in many students’ minds that ideas must be written in two separate styles, which cannot be reconciled even within the one story.

This paper looks at the over 229 short stories entered in 1988 and 1989. It examines them for their images of science and of scientists portrayed. There was no attempt to instruct the authors to present what they truly believed scientists are like, and so the views represent how student authors ‘choose’ to portray scientists.

Nevertheless, there are some interesting revelations about the way scientists are imagined by students, and about the social world they inhabit. Attitudes, values and behaviours of (mostly) male scientists appeared consistently and clearly in student stories.

In order to see if these results were generalisable, it was necessary to conduct a literature survey. An attempt was made to uncover other people’s work on the image of scientists in society and to place the secondary students story findings alongside these. Were these other images as strong and consistent as those of the secondary school writers?

The stories

Below are some of the findings from the short story competitions.

• In 1988, 117 stories were submitted, and in 1989 there were 112. The stories came from all Australian states and all year levels were represented, although in the 1989 competition 45% of stories came from year 7 students. In both years relatively few year 12 students have entered.

• There were about the same number of stories submitted by females as by males in 1988, but in 1989 about 66% were submitted by females.

• About one third showed two distinct and unintegrated styles. These were literary fiction style, for example comic book, war, adventure, mythical morality, adventure, romance and adolescent social realism. These literary styles were often alongside classroom or school science textbook styles. This was less noticeable in 1989 because, it would seem the large number of year 7 authors had not assimilated a science-note style into their repertoire of writing style skills.

• In terms of writing craft the stories frequently appeared to be ‘rough draft’ quality. While sentence structure, paragraphing, and spelling skills were in place, the vast majority of stories hung together poorly. They lacked the usual techniques which published short story writers adopt, and which secondary English teachers expect to see from experienced readers and capable writers. (For example, surprisingly few stories had economically but clearly developed characterisation. Few had a clear sense of place or time. Few cohered as stories with a development of tension, then resolution or satisfying mystery, while few had surprising relationships, were witty or particularly funny.)
• However, the fundamental ideas for the stories were often very clever or unusual, given the author's experience in English classrooms. These stories did represent a very different imaginative territory.

**View of sciences/scientists found in the stories**

The stories reveal much about women and girls, and men and boys, and the way they are perceived to relate to each other, (or not), in story contexts which must contain science in society. The stories allow confirmation of other findings about science and its place in society, and thus in education. From these stories it seems that science is associated with men and masculinity. Regardless of who writes the story, women tend mainly to appear in very traditional nurturing roles.

Science seems 'penned-off' in two significant ways. First, for many students, (about one third), it was impossible to get their characters to discuss science processes or to 'play with' or argue scientific ideas, in any kind of sociable way. Textbook notes had to be inserted in the place of dialogue. This proportion of stories is even more striking as so many stories were set aside from consideration because they simply didn't contain science at all.

Second, and more obvious, science appeared as 'highly competitive, macho and exclusive'. Boys, quite literally, can't imagine girls or women doing science that is in any way connected with a laboratory, and barely at all outside a laboratory. (cf Table 1 No 4, 8). No boys in any age group wrote stories with females as protagonists or with female-only characters. (cf Table 1 No 6).

Girls who submitted stories, can't usually imagine girls or women who are involved in scientific activities, or having other than traditional family, nurturing roles. (cf Table 1 No 4).

Boys and girls, however can imagine men and boys being involved in laboratory science and, in addition, using science in a great variety of active, adventurous ways. Fifty percent of our male authors had men in laboratories, and seventy five percent had male leads and almost exclusively male characters populating the cast. Only occasionally did a 'token' female appear in any of the male authored stories.

Over the years of the competition boys and men did science as detectives, barristers, business men, hunters and gatherers, crooks, soldiers, spacemen, school boy adventurers, as tourists in predicaments, journalists, famous scientists, professors, fathers, farmers, and science teachers. By contrast, of the two 1988 female authored stories with woman laboratory scientists, one begins apologetically, as follows:

"Samantha woke up feeling very excited, as today was the day she was doing an important experiment (well to her anyway!) at her laboratory."

Among the 1988 stories, of the girls or women who do science outside the laboratory, in two stories perfume is manufactured and sold, farm animals' deaths are explored by a woman farmer, a cure is found for chocolate addiction, Coca-Cola poisoning is remedied, and there is a love story and a detective at work. Among the 1989 stories by female

| TABLE 1 | **Australian Secondary Science Short Stories 1988, 1989** |
| --- | --- | --- | --- |
| **Story (N=229) Characteristics** | **Female author** | **Male author** |
| | 60.8% | 39.2% |
| 1 Chemical fantasies, ie chemicals with personal qualities | 26.6% | 21.6% |
| 2 Nuclear horror, usually set in the future | 4.9% | 5.7% |
| 3 Domestic/family science, science in cooking, hair care, perfume making, etc | 38.8% | 6.8% |
| 4 Women in roles outside the family, excluding school girl role | 16.5% | 4.5% |
| 5 Male lead, mostly all male characters, including narrator when indicated | 36.3% | 75% |
| 6 Female lead, mostly all female characters, including narrator when indicated | 17% | 0% |
| 7 Men as laboratory scientists | 8.2% | 50% |
| 8 Women as laboratory scientists | 4.1% | 1.1% |

*Note: Stories often had more than one of the characteristics listed*
authors, there were girls or women who were torture victims, or who were dying, two young scientists (who were 'taking the micky out of a chauvinistic male professor-boss'), an English teacher, a number of science teachers, a maid, a President of the United States of America and an oil rig worker.

Among male authors in 1989, there was one female scientist, and two female science teachers. Other females appeared as wives or sisters (no girl-friends!). Stereotypical behaviour abounds. Men and women seldom interact, and almost never interact co-operatively or equitably.

Wider findings

When primary school children in a number of countries are invited to draw a scientist, and these drawings are scored with a standardised 'Draw a Scientist Test' procedure, the following picture emerges — refer to Table 2 below.

Chambers' findings held constant in large samples in Canada, the USA and Australia. In total, 4807 students were involved, 49% of whom were girls. No boys drew women-as-scientists and only 28 girls did. Australian secondary age student writers, several years on, have almost identical images of science and scientists although more science gets done in the stories outside laboratories.

In a literature review, McDonald and Bridgstock (1982) create a composite picture of scientists. The following attributes are central and persistent.

In general scientists are seen as possessing the positive qualities of intelligence and dependability and to be valuable and hard working. However, they were also seen to be cold, emotionally inhibited, rather boring, unsociable and unimaginative.' (McDonald & Bridgstock, 1982, 75)

McDonald and Bridgstock used qualitative, open-ended interviews with a sample of 55 Australian tertiary students, in an attempt to determine whether or not the strength of previous stereotypes was an artefact of the tools used.

These authors state that the opinions offered by student respondents were a good deal milder than expected. The 'icy-robot' image was confirmed, and generally students viewed scientists as 'conservative, or narrow-minded, male chauvinistic or tending to stick together.' (ibid, 1982, 77)

They also report that in Australia the image of the scientist has become entangled with that of the 'Ocker'.

The samples of interviews included in their article hardly seem to indicate a 'milder' stereotype; eg 'ocker-macho loudmouth engineer type'; 'proper Australian males who swear, drink and screw a lot'; 'basically conservative in their way of dress, political beliefs and attitudes to women and ethnic groups'. (ibid, 1982, 78)

The authors conclude that:

'The results seem to confirm that the 'core' of the scientific image exists, though in a somewhat milder form than it has usually been portrayed. The 'core' has however picked up some additional attributes that can hardly be regarded as favourable; they include the 'male chauvinist' tag for scientists and at least in Australia - the association with the Ocker image.' (ibid, 1982, 78)

Emens McAdam (1990) examined 200 books written for children and young adults, in an effort to uncover the image of the scientist they portray. She decided that 'the wild extravagances described in books are seldom met in real life'.

Chambers, 1983, 256
(McAdam, 1990, 104). This is consistent with the author's earlier (unpublished) research, that 'there is a definite stereotyped image of scientist in the minds of children and ... that this closely corresponds to the image in fiction that is read by children at that age' (ibid, 1990, 104).

From the literature surveyed, the image of the scientist is strongly and persistently negative and intensely male.

Conclusion
Our involvement with the secondary science stories suggests that science and humanities teachers would do well to explore the social context of science if they, and their students, are to come to grips with negative student perceptions of scientists and their work. There was nothing neutral, objective or value free in the way scientists were imagined in students' stories.

**ICASE AWARD SCHEME**

for outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.

**ICASE Distinguished Service Award**
This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations

**ICASE Regional Service Award**
This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

**ICASE Association Award**
This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Contact Dr Jack Holbrook, Executive Secretary ICASE, Science & Technology Education Unit UNESCO, 7 place de Fontenoy, 75700 Paris, France
Science Activities to Develop Transcultural Understandings

by M Gail Hickey

Teachers of young children are often quite adept at helping students see connections between and among academic disciplines. These teachers provide imaginative learning experiences which immerse students in the study of a particular topic. One example is the Culture Kit.

Culture Kits

By definition, a Culture Kit is a portable, self-contained 'museum-in-a-box' used by students as they learn about another culture (Hickey, 1992). Each Culture Kit is designed so that students can learn independently or in pairs at their own pace.

In keeping with the Salad Bowl perspective of multicultural education, the emphasis of the Culture Kit is on similarities among and between cultures. When students develop an awareness that:

• all people communicate with one another in a variety of ways;
• all people create stories, music, and crafts which communicate their culture;
• all societies have formal or informal governments and economic systems;
• all societies record peoples' imagining of fantastic beings and fanciful themes; and
• all people celebrate special times in their lives;

through exploring materials and completing activities contained in the Culture Kit, they learn to develop appropriate attitudes about cultures other than their own. With proper planning, they also explore a variety of science concepts and understandings in the process.

Teachers can easily make their own Culture Kits. Materials and activities such as the following should be included:

• a map of the country or area
• maps depicting the country or area within the larger geographic context (France in the larger context of Europe, for example)
• travel brochures
• post cards
• information about national flags, mottos, songs, etc
• examples of coins or other money
• souveniers of all kinds
• travel diaries and/or trip itineraries
• menus, candy wrappers, etc with words and phrases printed in the native language of the country
• photographs
• activity cards directing students to examine materials, explore scientific concepts, and/or research supplementary resources

Materials and activities should be attractively designed and displayed in a portable, durable container. If the container itself is attractively decorated with pictures and words that represent the culture being depicted, students will want to investigate it. Ultimately, students themselves may want to make a Culture Kit of a country or place they have visited.

Some teacher-tested examples for scientific learning

Example – Japan

Include a package of dried seaweed (can be obtained at Oriental food stores). Many Japanese recipes incorporate seaweed, yet children of other cultures usually have not considered seaweed either a source of nutrients or flavor. Encourage students to explore how seaweed is valued and utilized in the Japanese culture.

Example – Mexico

Woven rugs, blankets, ponchos, and other clothing are often seen in Mexico. Include an example of a woven item in the Culture Kit, along with some background reading depicting how weaving is done and with what materials. Provide materials and instructions for children to create their own ‘woven’ project, using bright colours to develop a pattern. Also, include an Aztec calendar. Have students develop their own Aztec calendar, and explain how it is different from the calendars we use. Ask whether 365 is the best number of days to represent one year. Why or why not?

Example – Korea

Provide resources to enable students to explore these questions about the country:

• What is the climate of Korea? Is it different from the climate here? How so? What adaptations would be necessary to survive in a different climate?
• What types of crops are grown in Korea? How does the climate influence the food produced there? Are there any crops we can grow that Koreans can not? What crops do they produce that we can not?

In addition, allow students to make their own kites, using a Korean kite as a model. Develop hypotheses about which kites will fly the highest or the longest, and conduct experiments to test hypotheses.

Example – The Netherlands

Provide resources and materials for students to research lowlands, canals, dikes, windmills, and tulip farming.
THIRTY FIFTH
London International Youth Science Forum
28 JULY – 11 AUGUST, 1993

The world’s foremost annual meeting for top science students.

Young scientists from schools and universities in some 50 countries share a programme of Lectures, Seminars, Debates and Visits.

A choice is available of more than thirty visits to industrial and academic institutions, including the Universities of London, Oxford and Cambridge.

The programme features over thirty outstanding lecturers, speakers and seminar leaders from Britain and overseas. There are opportunities for participants to present their own research papers.

Participation fees include meals, accommodation in University Halls of Residence in Central London; a Travel Pass giving unlimited free travel on public transport in the city centre; all necessary transport relating to visits and a full social programme. Optional visits to theatres & concerts, and sightseeing visits are arranged at week-ends.

For additional information, applications etc contact
LIYSF, PO Box 159, London SW10 9QX
Tel: 071 373 4568 Fax: 071 835 1070

And in conclusion
By developing and using Culture Kits in the classroom, teachers of young children can provide valuable experiences for their students. The Kits allow exploration of cultures other than one’s own through hands-on involvement and, when properly planned encourage children to investigate related scientific concepts. Since Culture Kits are used independently or in pairs, they permit teachers to individualize instruction to a greater degree than is often possible. Creative teachers add to the materials and activities in their kits over time to keep them current and make the activities more stimulating. And extensive teacher testing shows that kids love them!

1992 ICASE YEARBOOK
Science Technology Society
Edited by Robert E Yager
Available now from
Jack Holbrook, Executive Secretary, ICASE
Science & Technology Education Unit, UNESCO 7 place de Fontenoy, 75700 Paris, France
Russian schools are preparing a new generation for active participation in the restructuring and democratization of society. We need well-developed and well-educated persons who are aware of the necessity for continuing self education. Biology, now taught according to new curriculum and programs developed in 1986, emphasizes learning the main biological concepts and leading scientific theories and ideas. Concepts and leading ideas determine course contents and structure and include:

- organic world evolution
- interconnected structure and function in wildlife
- interconnections of the biological systems with the environment
- connection of theory and practice

The biology course is preceded by a course in natural history in primary and early secondary school.

<table>
<thead>
<tr>

</tr>
<tr>
<td>I-IV grades (starts at age 6)</td>
</tr>
</tbody>
</table>

In the primary grades students study natural history, including seasons and weather, agriculture, plants and animals, and the general structure of the human body. Great attention is paid to personal and social hygiene. Natural history in the secondary school (beginning with grade five, one hour a week) is devoted to the study of physical science, interrelations of living organisms and environment, variety of living organisms and conditions, and necessities for their vital activity. The secondary biology course is divided into five parts:

- Plants (VI Grade - 68 hours; VII grade - 36 hours)
- Bacteria, mushrooms, lichens (VII grade - 8 hours)
- Animals (VII grade - 24 hours; VIII grade - 58 hours)
- Human health (IX grade - 68 hours)
- General biology (X grade - 34 hours, XI grade - 51 hours)

The biology course at some Russian schools isn't divided into traditional parts such as botany, zoology, human anatomy, physiology and hygiene, or general biology. In these schools, we created an integrated biology curriculum where the contents have been simplified. And, much more attention is paid to interrelations between specialized biological disciplines.

<tr>
<td>Grade</td>
</tr>
<tr>
<td>Hours a week</td>
</tr>
</tbody>
</table>

Course content varies according to the grade. VI grade includes information on morphology, vital activity, reproduction and development of flowers, and interactions between plants and their surroundings.

VII grade students study biodiversity and systematics of plants, bacteria, lichens and mushrooms and differences in their structure due to the evolutionary process.

In grades VII and VIII the 'Animals' unit gives information on the variety of animals from Protozoa to Mammals, their structure, functions, systematics, and relationships. Students of IX grade study 'Human body and health', which provides information on the peculiarities of the human body, its vitality, elementary first aid and also on sexual and hygiene problems.

The unit 'General biology', studied during X and XI grades, ends the course of biology at secondary school. This unit provides information on cell biology, genetics, evolutionary theory, biotechnology, ecology, and environmental protection.

After IX grade students may continue their education in secondary professional schools, (3 years) or secondary special technical schools (3 years). Study of general biology at this level is obligatory (73 and 70 hours respectively). Students can also deepen and extend their knowledge in special groups at various extra-school Pupils' Houses, Institutes, and Universities.

In addition, the State Committee on Peoples' Education worked out sixteen on biological and ecological elective courses. These elective courses start from the VII grade with students of VII - IX grades able to choose courses for two hours a week and grade X and XI for four hours per week.

Programs of advanced study on different subjects are being developed. In 1986 the new curriculum on biology was designed to provide an extended theoretical and practical study of the subject. The program is introduced from the VIII grade (VIII-IX grades - 4 hours a week; X-XI grades - 3 and 3/4 hours plus 2 extra hours on studying additional units, chosen by the teacher).

**Goals of biology studies**

The main goals of studying biology at school are to:

- ensure the mastering of main ideas of biology as a field of science (structure, vitality of organic world, structure and function of ecological systems, their changes due to human impact)
- form scientific world outlook and ensure the awareness of humankind's place and role in the biosphere
- understand the practical significance of biology as the basis of agriculture, food industry, biotechnology, and environmental protection
- use subject knowledge for professional and career orientation
- form ecologically educated people with responsible attitudes towards nature and readiness to protect it
- form skills and habits necessary for people to extend their knowledge, to develop logical thinking during education and future practice.

Current liberalization of education in Russia allows many schools and regions to work out their own school, city or national curriculums and programs on biology. Most of them are based on the state obligatory program and/or take into consideration the guidelines of biological education in the country. We are optimistic that these new programs of study will help insure that our students are as biologically and scientifically literate as they must be to succeed in the future.

Constructivism and Science Education Reform

by Robert E Yager

Constructivism is attracting increasing attention as the dominant learning model in educational reform efforts. Ernst von Glasersfeld, the leading constructivist today, has extensive research and writings which are very informative and useful to anyone interested in more effective teaching. His work and influence are central to the universally acclaimed reform movement in mathematics education elaborated in the National Council of Teachers of Mathematics Curriculum and Evaluation Standards for School Mathematics (1989).

Von Glasersfeld traces constructivism back to Vico who, in 1710, described his concept of human learning: "Epistemic agents can know nothing but the cognitive structures they themselves have put together." "To know" means "to know how to make." He substantiates this notion by arguing that one knows a thing only when one can explain it. Such explanations are for others to understand and to use (Vico, 1858). The extensive work of Jean Piaget also supports, elaborates, and exemplifies constructivist ideas. Unfortunately too many took Piaget's results and classification schemes and used them as doctrines to be taught and learned as other material in science is typically taught and learned; this prevented science educators from gaining the full impact of his work.

The crisis in science education of the 80s resulted in major attention and funding for "new" research concerning human learning. The emerging results of these massive efforts have been devastating to existing traditional curricula, instructional practices, and assessment programs in science education. This research on teaching and learning has verified the crisis while also identifying the folly of many correctives undertaken across the world. And, the results brought new attention and support for constructivism — what some now call the Constructivist Learning Model (CLM).

General results from cognitive science research permit the following generalizations:

1. Most persons have naive theories/ideas concerning the natural world (this includes the best students in the educational system, including undergraduate physics majors and engineering students);
2. Each person's explanation of the things around them comes from their own experiences (as opposed to what they are taught);
3. It is extremely difficult to alter a person's own mental constructs (certainly not by merely telling them they are wrong);
4. Altering misconceptions occurs best through personal challenges to the concept, thereby creating situations where the erroneous conception does not explain; and
5. Learning is a social activity; even when an individual constructs explanations for him/herself it must be communicated and validated.

All of these results can be used to support the Constructivist Learning Model. For learning to occur, students (and all persons) must be personally involved and in the end construct meaning for themselves. Meaning can not be "transmitted" from teacher or textbooks to student. What can be transmitted is meaningless terms and simple skills — neither of which can be used out of context. And this is the problem with school science — that which the best students seem to know and express on exams can not be used anywhere else.

The instructional reform called Science/Technology/Society (STS) is based upon the Constructivist Learning Model. The basic aim of the STS approach is engaging students in problem solving activities which they have identified and in which they have some personal stake. They often work individually, but are quickly parts of investigatory teams — sometimes the entire class. As other students provide challenges for given conceptualizations, outside experts are often sought out and used. The last confrontation/challenge is often the current conceptualization of the scientific community. Instead of telling students what these concepts are and using the so-called laboratory to verify what scientists have said, the ideas and the laboratory are used during the investigation as one further check and challenge. The attempt is always to use (and usually alter) the constructs students have when they enter our classrooms.

The Constructivist Learning Model demands new approaches to teaching. As reforms in science education are sought, constructivist ideas suggest such procedures as:

1. Allow student thinking to drive a lesson or entire unit;
2. Shift activities and content plans to fit student responses, interest, and ideas;
3. Encourage student initiation of ideas, display of leadership, and autonomy in planning and doing;
4. Encourage students to expand and follow-up on their ideas;
5. Allow adequate wait-time for students to think and to propose;
6. Encourage group work and encourage students to interact frequently with other students and others outside the particular class;
7. Use open-ended and thought provoking questions; encourage the same from students;
8. Encourage student reflection, analysis, and predictions;
9. Seek out existing student concepts; use these in teaching as opposed to ones from teachers or textbooks; and
10. Offer alternative suggestions and encourage them from other students; use these as challenges to misconceptions.

STS teachers who by definition utilize constructivist approaches use a self analysis scale to judge their successes with constructivist teaching practices for a given lesson or unit. Most are willing to concede that it is impossible to be perfect (right hand of the spectrum) in the thirteen features. The scale is offered for others interested in using the Constructivist Learning Model as a part of reform in their science teaching.

**Self-Analysis Scale**  
the Constructivist Learning Model

1. Who identifies the issue/topic:  
   - Teacher  |  |  |  |  |  | Student  

2. Issue seen as relevant by student:  
   - No  |  |  |  |  | Yes

3. Who is asking the questions:  
   - Teacher  |  |  |  |  | Student

4. Who identifies written and human resources:  
   - Teacher  |  |  |  |  | Student

5. Who locates written resources:  
   - Teacher  |  |  |  |  | Student

6. Who contacts human resources:  
   - Teacher  |  |  |  |  | Student

7. Who plans investigation and other activities:  
   - Teacher  |  |  |  |  | Student

8. Varied evaluation techniques used:  
   - No  |  |  |  |  | Yes

9. Students evaluate themselves:  
   - No  |  |  |  |  | Yes

10. Students apply concepts and skills to new situations:  
    - No  |  |  |  |  | Yes

11. Students take action following study:  
    - No  |  |  |  |  | Yes

12. Science concepts/skills emerge because they are needed:  
    - No  |  |  |  |  | Yes

13. Extensions of learning outside the school in evidence:  
    - No  |  |  |  |  | Yes

Second ICASE Symposium
Education Industry Partnerships
by Jan Hendriks
ICASE European Regional Representative

In September 1990, a very successful symposium was organised in Brussels by ICASE and the European Chemical Industry Council (CEFIC) about Education-Industry liaison. The outcome of the first symposium was the reason why it was decided to organise a symposium every two years.

AKZO, an international company active in the field of chemicals and pharmaceuticals, hosted the second symposium at the AKZO Centre in Arnhem, the Netherlands in November 1992.

The objective of the symposium was to strengthen the international network of people working in education or industry, especially those involved in education-industry partnerships in the area of science and technology.

The symposium provided opportunities for:
- the exchange of information and experiences with partnership programs
- improving and structuring of evaluation models of partnership projects
- stimulating the international involvement of other parties, such as educational media and science museums.

An Advisory Board was established with the following members: Dr J Andriessen, Minister for Economic Affairs, Netherlands; Prof Dr W Hilger, President, VCI, Germany; Mr R Lepischak, President ICASE; Dr F Pandolfi, Vice President, Commission of the European Communities; Mr J Peuchal, President CEFIC; and Dr Ir J Ritzén, Minister for Education and Science, Netherlands. The Symposium Chairman was Mr D Chisman, ICASE Honorary Treasurer. The Organising Committee comprised: Mrs J Pot-de Boer, AKZO; Dr D Bricknell, CEFIC; Drs E J Hendriks, ICASE European Regional Representative; and Ir J Hoekman.

Financial support was kindly provided by AKZO, CEFIC and the Dutch Ministry for Economic Affairs.

43 participants attended the program, representing education, industry, media, museums and publishers. Program highlights included:
- Welcome by Mr Loudon, Chairman, Board of Management, AKZO
- Official Opening by Mr van Oosterom on behalf of the Dutch Minister of Education and Science
- Reports from partnership projects of AKZO and BP
- Evaluation of partnership projects
- Experiences in projects for education and the community – CEPUP, University of Berkeley, USA
- Extension of the scope of education-industry links to science museums – Science Museums of Amsterdam and Paris
- Collaboration between science education and television in the UK
- Parallel workshops to define priority areas for further development during the next two years
- Social program, including a visit to the Wine Museum of Arnhem and a dinner in the Netherlands’ smallest town, Bronkhorst.

The outcomes of the Symposium are reported as follows:

Education-industry partnerships
1. Organisations such as CEFIC and ICASE have a role to play to encourage their members to form and action policies for education-industry partnerships and to prepare guidelines for the preparation of materials and activities for its members.

2. A part of the profits of a company have to be utilised for partnerships and community activities.

3. Partnership programs should include the community (adult education, museums and other out-of-school activities)

4. It is necessary to evaluate input, process and output of education-industry partnerships. The output consists of knowledge and acceptance of science and technology in the community.

5. A multi-media core database to register the partnership activities across Europe should be developed.

Other activities
1. Science museums started the formation of a network to broaden the scope of partnership programs.

2. CEFIC installed a permanent working party on education-industry partnerships, chaired by Dr Manfred Unger, Hoechst, Germany, with Dr David Bricknell (Science and Technology Director of CEFIC) as secretary.

3. Education-industry partnership programs will lead towards technological and scientific literacy, and are linked to the UNESCO ICASE Project 2000.

4. The third Symposium on Education-Industry Partnerships will be hosted by Hoechst, Germany in 1994.
Looking at science experiments through the students' eyes

by António Cachapuz & Isabel Martins

Introduction

A key feature of a constructivist approach to science teaching is that we must understand better the tasks which students are engaging and not just the tasks the teachers think they are giving (Posner, 1982). This requires a careful scrutiny and restructuring of course materials, in particular conventional examples and activities proposed to illustrate central concepts of the discipline. Such a critical analysis should be primarily based on research evidence. According to Driver and Oldham (1986) curriculum development from a constructivist perspective has to incorporate an 'empirical reflexive approach' (p 112).

For example, teachers should be aware of potential problems raised by experiments used to illustrate the concept of chemical change in which the salience of phenomenological aspects of the experiment may induce perceptual dominant reasoning rather than conceptual dominant reasoning. In other words they should be aware of experimental aspects which may or may not facilitate bridging the gap between empirical levels of knowledge and conceptual levels of knowledge.

This seems well to be the case of boiling an egg, often referred to in Portuguese middle school chemistry as a suitable example of chemical change (for details about egg chemistry see Grosser, 1983, 1984). This is because boiling an egg is simultaneously a familiar, cheap, safe and easy experiment to set up in the classroom.

As Arthur Grosser puts it, 'in our folklore, the newlywed who can't cook is exceeded in domestic incompetence only by the toast burner' (1984, p4).

Generally students are asked to identify when a chemical reaction has taken place by macroscopic changes such as the evolution of a gas, temperature or colour changes. In the present case, because of the very nature of the system (namely the existence of a shell) no such changes are directly identifiable and the most tangible feature accompanying the reaction raw egg — boiled egg is the increased hardness of the latter. Thus it may be hypothesized that some pupils perceive the transformation simply in terms of a change of state taking place inside the shell so the semifluid raw egg (egg white is almost all water, 88%) is transformed into 'solid' hard boiled egg, the nature of the initial system being conserved. It should be noted that (provided the egg doesn't crack) another perceptible feature occurring during the heating process, i.e air bubbles which escape through the shell, is compatible with a physical change (decrease of internal pressure).

The goal of this paper is to investigate whether the process of boiling an egg was understood as physical change by a sample of grade 9 (15 years old) and grade 11 (17 years old) Portuguese students and to analyse whether the nature of inadequate conceptions held by students in the elementary course differed from those in the advanced course. All students had been exposed to formal instruction in the topic of chemical reactions but in no case did the teachers explore the example under study.

Insights from the analysis may help science teachers to look at this experiment through the students' eyes and provide them with useful cues on how to explore alternative ways of teaching.

Research Procedures

The design adopted involved two closely related steps. In step 1, 30 students (15 of each grade level) were individually interviewed in order to build up conceptual inventories (Erickson, 1979) about the process involved when boiling an egg.

Interviews (40min) were based on an experimental task consisting of boiling an egg (without cracking) in a saucepan. Typical questions asked of the students were: 'What happens to the egg?' or 'Why does it become hard?'

In step 2, main conceptions identified in the interviews were used to design two true/false questions subsequently administered to a representative sample of 262 grade 9 students and 186 grade 11 students (drawn from mixed ability classes from schools located in urban areas of Portugal). The two items (see below) were false as no student in step 1 gave the acceptable answer previously defined by their chemistry teacher. Acceptable answers for grade 9 students considered that the process of boiling an egg involves separation/reorganization of atoms in the egg with new substances being formed in the boiled egg. Energy of the raw egg molecules and heat energy supplied during boiling are transformed so that energy of the molecules in the boiled egg is greater. For grade 11, teachers expected that students would be able to use a formal model of chemical reaction, i.e bond breaking...

Results
Roughly 60% of the students (step 2) agree with explanations not involving modifications in the nature of the substances composing the initial system (raw egg) and therefore were consistent with an understanding of the chemical reaction, raw egg — boiled egg, in terms of a physical change. The extent of the inadequate ideas held by students in step 2 is presented in Table 1. The data shows that the two mechanistic models tested, ie molecular packing as a function of either particle size (item A) or increase of 'bonding' forces (item B) were held by pupils from both grade levels hence suggesting the persistence of these alternative ideas. For each grade level there was a substantial percentage of DK responses, specially for item B. Only a few answers were obtained for 'Other', some of which rendering problematic the content analysis.

(a) Molecular packing and particle size
In this case (item A) the process would involve a change in the size of individual particles themselves. Pupils probably transferred to the microscopic level knowledge of properties usually perceived at the macroscopic level (eg metals expand when they are heated) a tendency which has been acknowledged by some authors (Driver, 1985; Ben Zvi et al, 1986). Interview transcripts obtained in step 1 suggest that pupils' attempts to use models of particulate nature of matter were probably guided by perceptually dominant arguments of the kind: hard boiled egg (solid egg) — particles tighter — volume of the egg is the same — size of particles increases. For example:

... when we heat the egg the particles become bigger ... the size (of the particles) increases and they become tighter (in the boiled egg) ... you see the egg is now harder; it is more solid (grade 9)

Such local reasoning is consistent with ideas of conservation of substance described in the literature (Anderson, 1986; Méheut et al, 1985).

(b) Molecular packing and 'bonding' forces
Some pupils (item B) explained the reaction as a direct result of the heat energy transferred to the system. This transfer would increase the intensity of the bonding forces between the molecules in the raw egg so they become more packed. It should be noted that the nature of the particles would remain unchanged in both the raw egg and the boiled egg. This could imply some sort of packing at the microscopic level. Typical responses given in step 1 are illustrated by the following transcript:

... we heat the egg and it becomes solid ... when it's boiled the molecules are stronger; you know, the bonds between the molecules are stronger (grade 11)

This mechanistic model was slightly more sophisticated than the previous one (item A) as students were somehow able to appreciate, the role of intermolecular (though inadequate) attributes to explain the 'physical change'. This probably explains the positive shift observed for grade 11 students. These students were not able to appreciate the difference between force and energy and its implications at the intermolecular level.

This confusion, which has been reported in other contexts (Brook et al, 1984) seems to be an important barrier to proper understanding of the chemical change under study. In this case solids
would have more energy than liquids (irrespective of temperature) simply because in the former particles are more packed, i.e. 'more packed' means 'more energy'. For example:

... this one (the boiled egg) takes in heat and it's harder ... you see the energy between the atoms of the solid is greater than the energy of the liquid (Grade 11)

Thus the change liquid — solid would be compatible with an endothermic process.

**Discussion**

Although experiments are indispensable tools in chemistry teaching, there is a need to be more critical about the sort of experiments we use and how they are used. We should perhaps re-examine the criteria used to choose some experiments we use and how they are used. We should perhaps re-examine the criteria used to choose some experiments proposed to pupils in our teaching, in particular the ones which have a perceptually obvious focus of attention. Familiarity with an event may not be the main criteria to select experiments in science lessons when perceptual aspects of the task may overrule conceptual dominant reasoning.

Clearly teachers should be more aware of the nature and role played by alternative ideas held by students about chemical change, both in structural and energetic terms (Martins & Cachapuz, 1990). In this investigation it became apparent how inadequate ideas about structural arrangements in solids and liquids which were earlier introduced in junior high school influenced further understanding of a chemical reaction. These inadequate ideas may often be used in a consistent and logical (though incorrect) way and are usually quite resistant to change as illustrated in this report for students from grades 9 and 11. Alternative ideas such as those identified in this study reflect how meaning was constructed by students and thus may be explored as inputs to help teachers to design appropriate diagnostic questions. For example, to challenge the idea referred to above that 'the energy of solids would be greater than the energy of liquids', teachers may find it useful to discuss this argument with pupils when the white (of a broken egg) is frozen. Furthermore they may also discuss whether the term egg used to name both the initial and the final systems implies the idea of conservation of substance.

Since for middle school students egg chemistry is beyond their level of comprehension, teachers should base alternative explanations exploring differences between directly perceived properties in both the initial and final systems, namely taste. For grade 11 students, teachers may go a bit further and explore elemental aspects of egg chemistry. For example, they may explain why cooked eggs present sometimes a dark green deposit (iron sulfide) as a result of a chemical reaction between iron (from the yolk) and hydrogen sulfide formed when proteins in the white are decomposed by heating (rinsing with cold water prevents the formation of iron sulfide). This will help students to adequately contextualize the process of boiling an egg in chemistry terms and to establish useful content bridges with the Biology course.

A Unique Indonesian Program for In-Service Education

by Euwe van den Berg

Introduction

Indonesia is a large archipelago of about 13,000 islands stretched for some 6000km along the equator. It has a population of about 180 million people spread over more than 1000 of these islands, which together cover a land area of about 2 million square kilometers (800,000 square miles).

At independence Indonesia inherited a very small and underdeveloped educational system and a literacy rate of only 20% (the Philippines' literacy rate at independence was 80%). Rapid growth in enrolments followed independence to accommodate an ever larger proportion of a rapidly growing population.

At present elementary education has participation rates of nearly 100% while junior secondary education enrollment rates are about 60% (up from less than 20% in the 1970s!). The average class size is about 45 students.

School facilities were much improved during the 1980s. Most state schools acquired some new classrooms and a laboratory with equipment. As in other countries quite a few schools rarely use the equipment. Private schools often have little equipment, no laboratory, and few books.

As in other countries, the explosion in enrolments has caused serious quality problems. Classroom teaching is still too much 'chalk and talk' resulting in too little student activity other than listening and writing (Beeby, 1979; van den Berg & Lunetta, 1984). Such practices still continue, amongst others because of the shortage of textbooks.

Many books were printed in the 1970s, but two curriculum changes in the 1980s have rendered earlier books out of date. In many private schools only 4 or 5 students per class of 45 might have physics books, thus forcing teachers to spend much time dictating.

The Intensive In/On Service Program, 1979 - present

Since the introduction of a new science curriculum in 1975 the Department of Education and Culture had been active in organizing in-service training. However, after some years it was felt that brief 2 or 3 week courses were useless. Thus in 1979 the Department embarked on a new ambitious program of in- and on- service training with support from some international organizations (Pietersz, 1982).

The major purpose of the program is to change the classroom learning from passive listening and writing to active experimenting and thinking. While this is a rather common goal for in-service training, the sheer scale of the program and the multivarious conditions under which it has to operate are unique.

The program started with the selection and training of outstanding teachers who were to become in-service instructors. Then the worksheets were written, based on the national science textbooks. As curriculum authority resides in another directorate-general-level unit of the Department of Education and Culture, one had to go with the existing textbooks and syllabi. The worksheets simply tried to teach the textbook concepts through active experimentation by students, hoping that along the way they would pick up process skills.

The instructors or 'master teachers' then started to train teachers with a very weak science background and almost zero lab experience, to use the worksheets properly. The training pattern followed at the start of the project was the following:

- At the beginning of a semester teachers participate in a two week, full-time, in-service training where they themselves work through the worksheet activities under the guidance of a master teacher and with occasional aid of a subject matter consultant.
- Then the teachers go back to their schools to try out the materials while the master teacher travels around to observe their teaching. During this so called 'on-service' part of the training teachers meet once a week (initially Saturdays) to discuss their experiences.
- After 5 weeks of on-service the participants come together again for a week to evaluate their experience and try out the worksheets to be used in the next 5 week period. Another 5 week cycle of on-the-job training follows.

Three such 6 week cycles constitute the program.

Evaluation

By about 1984 the organizers had established a national network with training centers and trainers (master teachers) in 18 out of the 27 provinces, and trained teachers in almost every county of those provinces. During 1985 and 1989 trips to some remote areas, I ran into participants of the
program in almost every town. This is a tremendous achievement in a developing country with so many islands and weaknesses in infrastructure, communications and bureaucracy. Many industrial nations would have great difficulty in establishing a similar network in spite of easier communications, more efficient bureaucracies and more funding.

The network seems to function surprisingly well and appears to be able to overcome all the logistic obstacles involved in inter-island communication. Commitment of both staff and participants is high.

Activities have expanded very rapidly. An evaluation study was carried out in 1984 (Eggleston, Kertiasa, Nasoeion, Sukarno, Wilardjo), using interaction analysis to assess teacher and student behavior and group practical tasks to assess students' ability to conduct simple investigations. The study was executed in two rural provinces and in the two largest urban areas of Indonesia.

Observation of teacher and student behavior was done using a slightly modified version of Eggleston's Science Teaching Observation Schedule (STOS). STOS was developed by Eggleston, Galton, and Jones (1975) and used in studies in the United Kingdom, Canada and Australia (Eggleston, 1983). Results indicated significant shifts in teacher and student behaviors, especially in the rural areas.

In three out of the four areas researched, project trained teachers showed a larger number and variety of intellectual transactions in science lessons than teachers who had not yet participated in the training. There was more 'teacher talk' and a greater proportion of that in the higher intellectual demand categories, with a substantial reduction in teacher's statements of facts. (In STOS 'teacher talk' is defined as intellectual transactions requiring student responses, lecturing is not counted as teacher talk.) There was also more

**Pasteur and Microbes**

**A Teacher Resource Book**

**Commemorating the 100th Year of the Pasteur Institute 1888-1988**

This valuable resource book (166 pages) provides information about the activities and facilities available at the Pasteur Institute. It contains a variety of science experiments relating to the action of soil microbes, yeast as a food-making microbe, micro-organisms in milk, making cheese, making vinegar, and making wine, to name just a few.

These activities are appropriate for secondary science teaching. Emphasis is on useful micro-organisms, food production and food preservation.

Order by sending a cheque (payable to "ICASE") US$8.00 or £5.00 (add 25% postage and packing) to:

20
pupil talk, about twice as much as in classrooms of non-participants, and a
substantial shift to higher intellectual demand categories in the rural areas. In
urban areas the project had produced less or even no change, presumably
because (amongst others) urban teachers are more likely to have second
and third jobs and thus are less likely to implement time consuming new
practical methods and some urban teachers and students already showed
the behaviors promoted in the in-service program.

The group practical tasks required
groups of students to solve novel
problems using experiments. Trained
observers attended and scored their
performance according to
pre-established criteria. The tasks were
administered to groups of
teacher-selected students from
classrooms of participants and
non-participants. Results showed
significant differences between students
of program participants and
non-participants (physics scores
doubled!), the former performing
considerably better.

Studies like this are subject to many
unavoidable methodological problems
in spite of careful planning. For
example sampling of schools and
students was not random. Most of the
observers used were trainers rather than
objective outsiders. Differences in
educational background and experience
of program participants and
non-participants (planned and
unplanned bias in the selection of
program participants) could account for
observed differences as well. However,
most accounts of outsiders visiting
classrooms of participants confirm the
changes observed in the study. It seems
that the program does have a major
impact on teacher and student behavior
and achievement, especially in the rural
areas (where 80% of the population
lives). Such positive outcomes are
unusual in research on outcomes of
in-service training. Major differences
with well known in-service studies in
industrial countries seem to be

- the 'on' service component
- the well focused character of the
training (clear and specific in its goals,
methods, and materials)

- the very low starting level of
participants (abundant room for
improvement)
- a less individualistic and more
cooperative attitude of Indonesian
teachers as compared to their
colleagues in western countries

Local Networks
As it was too expensive to train all
science teachers in Indonesia using the
above method, a cheaper version of the
project was developed and started
operating around 1983/4. Local
training groups were established under
the guidance of graduates of the
in/on-service described above. Such
groups meet one day a week to discuss
the science lessons and activities for
the following week. Initially the
meetings focused on the worksheets.
However, now meetings might also
include discussions of test items,
subject matter to be taught, and other
problems faced in schools and
classrooms. Participants are provided
with free materials. These local
training groups also showed gains on a
number of categories in the study
describe above. Teachers from private
schools participate in these groups
along with teachers of state schools.
Private school teachers have to pay a
fee (to cover cost of food but the
arrangement may differ depending on
the region).

Participation of teachers in these
groups is voluntary, however due to
cultural and bureaucratic reasons
government invitations to participate
are rarely declined. That is certainly an
advantage, without that feeling of
compulsion, busy teachers might not

In almost every major town I have
visited on the main island of Java as
well as other islands including some
remote islands, thesecher groups are
meeting.

Reactions of participants vary.
Graduates of our teacher education
program who have participated in such
in-service groups usually found the
network support helpful in educational
matters and teaching methods but less
so on help with subject matter.
Participation in the group can greatly
help new teachers during their first
years of teaching. On the other hand,
subject matter mastery and laboratory
skills of many group leaders are
insufficient. The Ministry of Education
is working hard on improving the
quality of the national and local
in-service trainers and leaders. Many
leaders have been sent abroad for
further training in Graduate Diploma
and Masters programs in Australia and
UK. Annual national training courses
are organized for local group leaders.

Problems
The worksheets used in the projects
constitute the basis for an activity
oriented approach to science teaching
rather than a chalk-talk-textbook
approach. These worksheets show a lot
of creativity and they are interesting to
students. However, essential steps for
the acquisition of concepts are often
lacking and opportunities for providing
experiences to exercise process skills
are often not exploited. Lab manuals
and worksheets from many parts of the
world including the USA and college
level labs show similar weaknesses
(Hofstein and Lunetta, 1982).

Another problem concerns the structure
of educational incentives rather than
the program itself. Teaching activity
(lab) centered lessons in a proper way
requires a lot of extra preparation. At
present such extra efforts are not
rewarded, neither by extra benefits, nor
by a reduction in teaching load or
appointment of lab assistants.

Considering the low standard of living
in Indonesia and the fact that most
teachers are teaching at other schools
or private lessons in their free hours
(total loads of 40 periods a week are
not at all exceptional, occasionally I
have met teachers with loads of over
50 periods), the results of the
in-service program may quickly fade
away. Many (or most?) program
participants continue the laboratory
part of their courses after having
graduated from the in-service program.

Observers have noted clear differences
between schools with very supportive
principals and schools with 'neutral'
principals.

Yet another structural weakness
concerns the national curriculum. For
example, junior high school students
take about 15 different subjects (about
35 periods a week). At each grade level they get 2 hours of Physics and 2 hours of Biology. Using the activity oriented approach, teachers feel they cannot complete the ambitious syllabus. Until 1984 they could still use some hours reserved for skill education. With the introduction of yet another new subject this opportunity disappeared.

**Conclusion**

Indonesia has built a unique network for in-service training. The impact of the program on actual classroom teaching is difficult to assess and certainly not yet what was intended. However, the network could be a major asset in:

- induction of new teachers (assistance by peers)
- implementation of new policies (communication)
- sharing of equipment between schools
- educational change

The textbook is the principal foundation on which most courses of instruction are based. It is still by far the cheapest form in which to encapsulate large amounts of information in a way that makes it readily accessible to large numbers of individual students. French (1985) stated that “the printed word is one of the richest and most precious forms of human communication and if we can teach pupils to read intelligently then we are performing a valuable function.”

The objectives of teaching primary science are clearly stated in the core curriculum, together with the preamble: That provided appropriate equipment and materials which the child may manipulate and experiment with, in a suitable social interaction, science education at primary school should enable the Nigerian child to:

- observe and explore his environment
- develop basic science process skills
- develop functional knowledge of science concepts and principles
- explain simple natural phenomena
- develop scientific attitudes including curiosity, critical reflection and objectivity
- apply skills and knowledge gained through science to solving everyday problems in his environment
- develop functional awareness of and sensitivity to the orderliness and beauty of nature

It is noteworthy that cognizance is taken of the fact that the child must of necessity be provided with materials for science, which are suitable for social interaction and are specifically mentioned. The interplay between these and the acquisition of scientific knowledge by the primary school child must be explored for effective primary science instruction. Also the National Policy on Education identifies the laying of a sound basis for scientific and reflective thinking as one of its cardinal objectives.

The problem

Basically, national curricula are intended to achieve some measure of harmonisation among the states of Nigeria. In the primary science curriculum, provisions are made for materials for teaching specific topics or concepts. These guide teachers from varying localities as they adapt them to fit their local environments.

Seven different primary science programs formed the basis for the formulation of the national curriculum. It is therefore possible that certain factors peculiar to some states may have been incorporated into the document. Furthermore, at all levels of formal school education, science should be treated as a way of life... a way of thinking, of behaving, indeed a dimension of self and the lifestyle of the individual (Asun, 1987).

Since human variables in science instruction should be considered, it is important that experts in the teaching of science to children should be consulted for their views on identified instructional problems. It is against this background that answers were sought to several questions:

Method

A questionnaire was designed to elicit information about:

- qualifications and teaching experiences of respondents
- competences in textbook writing
- important cultural factors that could promote or inhibit adopting a text for use in a locality

- learning patterns among Nigerian children
- suggestions for improving books available in the market
- degree of support for teachers’ guide and pupils’ workbook
- suggestions for organising the content of the proposed book

The instrument was validated by science educators at Ahmadu Bello University. Using a test-retest technique, a reliability coefficient of 0.85 was obtained. Copies of the questionnaire were sent to science teachers, randomly selected from the list of members of the STAN primary science panel from 1984-88, which included teachers from all levels of the education system. 184 of the 200 teachers selected completed and returned the questionnaire (4 poorly completed returns were rejected).

Results

1. Qualifications of respondents

Grade II Teachers Certificate (55); NCE (45); BEd or BSc(Ed) (60); MEd (15); PhD (5). Years of teaching experience ranged from 8 to 25 years with an average of 12 years. All respondents had taught primary science at various levels. About 10% had written primary science instructional materials in one form or another.

2. What cultural factors should be considered when writing a primary science series for Nigerian children?

Use of local examples: this will vary from one locality to the other, given the size and other environmental conditions of the country.

Local alternatives for scientific terminology: names could be retained but pronounced and spelt in local language (eg rula for ruler).
Locally practised science and technology should be identified and included where applicable and where possible.

Use of local language: Books 1-3 should have English, Igbo, Hausa and Yoruba versions as suggested in the National Policy on Education.

Climatic factors and their effect as to the variability of plants and animals found in each geographic zone should be reflected in the book: different areas have different plants and animals inhabiting them.

Taboos and superstitious beliefs, where identified, could be explained so as to redirect the child's belief and ideas; this could be done by carefully structured lesson plans and effective teaching.

Local occupations, tools and agricultural products should be borne in mind as they vary from one locality to another; these are reflected in the curriculum under technology.

Variations in local buildings should be reflected in the texts: shapes and structures vary from one locality to another.

Co-operative attitude of communities in solving common problems should be reflected in the class activities: this could be used effectively in practical work by grouping the pupils.

3. What learning patterns are common in Nigerian children?

Although guided enquiry has been introduced in the teaching of primary science, together with process skills, most respondents observed that the Nigerian child learns mainly by memorisation. Most attributed this to our mode of evaluation which encourages recall. Hence children tend to memorise to pass examinations.

4. What specific changes or improvements are advocated for a new primary science series?

- More uses of common and local examples should be adopted.
- Guided enquiry and problem solving should dominate content and activities.
- The modular arrangement should be adopted.
- Pictorial illustrations should be self-explanatory. They may not necessarily be in colour to reduce cost.

- All evaluation should be incorporated in the textbook.
- All materials should be locally or readily available.
- The entry behaviour of pupils should set the level of learning experiences. Writers may like to carry out some studies on the readiness of pupils.
- Some activities should be open-ended involving designing, drawing and constructing materials.

5. What specific new ideas are recommended in science curriculum reforms?

- Evaluation of draft should be carried out before embarking on publication.
- There should be a set time limit for the review of the text.
- Emphases should be focused on the improvement of the quality of life.
- Use of games is lacking and should be included.
- Evaluation should involve the cognitive, affective and psychomotor domains, not cognitive only.

6. How should the instructional content of the book be organised?

- Workbooks should be avoided. They are expensive, pupils do not buy them and teachers rarely use them.
- There should be enough questions at the end of the book to replace workbooks.
- Units should adopt a modular approach, with the headings: (1) introduction; (2) objectives; (3) content; (4) summary; (5) exercises.

Each unit should be linked to others for readability and continuity. The teachers' guide should not be written because it discourages initiative.

Discussion

The objective of this study is to ensure that experts in the field supply information useful in guiding the writing of primary science textbooks so that they meet the needs of society. Although parents and the general public could make some input, expert science teachers are in a better position to provide vital information. In a multicultural, multilingual, plural society like Nigeria, instructional materials for early childhood education should be written with a lot of care – differences within society should be closely examined, and efforts should be made to incorporate the most profitable cultural attributes within the learning program.

The responses clearly show that science educators are concerned about primary science. Much has been said about primary education in general and primary science in particular. For example, Hollins (1985) recognised the need to consider cultural differences in a plural society; Bajah (1990) spoke about the documentation of superstitious beliefs with a view to correcting wrong impressions in young minds. In Kano (1990), members of the primary science committee called for a modular approach in the organisation and teaching of primary science.

SCIENCE EDUCATION International
Activities Book
The Stepping into Science Project is planning to produce an Activities Book as a resource for primary/elementary teachers of science. If you have activities to contribute for publication in such a book, or in the Stepping into Science Newsletter, please forward to:

Sue Dale Tunnicliffe  
18 Octavia  
Bracknell  
Berkshire RG12 7YZ  
UK

Recommendations
1. Efforts must be made to identify what are regarded as appropriate equipment and materials, as well as suitable learning environments with a view to recommending them for use.
2. Efforts should be made to have the books for the first three years in English, Igbo, Yoruba and Hausa versions.
3. Continuous assessment should be encouraged. Questions that could lead to discussions, design and production of materials should be given prominence.
4. A workbook should be discouraged, but a teachers' guide should be considered in view of the large number of unqualified teachers that teach primary science.
5. The life of a primary school textbook has been set at six years. Writers of primary science books must ensure that the books are so current that they may not need any review during this period.
6. The modular approach should be adopted. Each module should have a number of units. Different writers should decide on the format for their units.

The task of producing a standard set of primary science series is not an easy one in a plural society with pupils of varying educational backgrounds. The Nigerian child needs to be nurtured and exposed to the attributes and products of science so as to meet the demands of the technological age.

Stepping into Science
An ICASE Primary/Elementary Science Project

AIMS
Stepping into Science is an ICASE project which aims to:

- Establish an international network for teachers to share ideas on the teaching of primary/elementary science and technology.
- Provide activities and support for teachers, thereby encouraging them to include more science in the primary/elementary curriculum.
- Promote the value of science experiences for young children throughout the world.
- Facilitate professional development opportunities for teachers by including sessions on primary science and technology in regional and international conferences.

ACTIVITIES
The Stepping into Science Team is actively involved in a number of projects and activities including:

- Publishing STEPS, the Stepping into Science Project Newsletter. This newsletter contains ideas for class activities at various levels in primary/elementary schools, activities for children to do at home, comments by network members on issues, examples of children's work, lists of helpful resources and contacts. ICASE acknowledges the contribution of Philip Harris in sponsoring STEPS.

- Contributing articles and ideas for the Primary Science Section in Science Education International, the ICASE quarterly journal.

- Compiling ideas and activities for inclusion in a series of sourcebooks on the teaching of primary/elementary science and technology.

- Coordinating a scheme to encourage children to participate in science and technology activities. Certificates of Participation have been produced, and are available for schools to use in rewarding students as they complete a number of activities. Certificates are colour coded in seven different colours, so that they can be used to acknowledge progress in science from early to advanced levels within primary/elementary schools. ICASE is grateful to BP (Oman) for sponsoring this scheme.

- Organising Stepping into Science workshops and displays of children's work at national, regional and international conferences.

STS-Environment-Problem Solving

by William Soprovich

This article is reprinted from 'Sustainable Development for a New World Agenda: Proceedings of a Conference, October 17-20, 1990' edited by John E Penick & John R Stiles, and published by STAM/CASE/ICASE.

Background

Approximately four years ago, a Science Committee for years 5-9 was examining what emphases should be placed upon various goals for science education in grades 5-9. Emphases upon career development, using curriculum to increase the number of women in the physical sciences, problem solving, and scientific literacy (Roberts, 1983) (often undefined) were prevalent. In addition, a renewed emphasis has been placed by the National Science Teachers Association (NSTA) and the Science Council of Canada upon the inclusion of Science Technology Society (STS) in science programs. The Science Council of Canada report had recommended that a percentage of time be allotted to STS from K-12.

Unwilling to simply begin another crusade saying "stop doing Y and begin doing X" recommending a time allotment for STS without removing anything from the curriculum, the important question appeared to be that of defining the nature of STS and its potential relationship to the remaining part of the curriculum and emphases. Environmental literacy, indicated by many to be of critical concern to many, was represented at least partially by an ecosystem theme in K-9. Science processes, as part (or one kind) of problem solving was also a part of the science curriculum. Finally, the Science Committee did attempt to provide for a certain amount of time for STS, examining relationships to the total balance in curriculum with a resulting change in some of the topics and emphases.

STS: general concepts and some considerations

Including aspects of the nature of science-technology-societal interactions in the science curriculum is not novel. However, past efforts have been incomplete. During the 50's and 60's, for example, the principles of redox were applied to processes used in the iron ore industry by describing the Bessemer process. Similarly, the principle of heat exchange was described in the refrigerator as a scientific-technological interaction. As a result of the activities, Pella (1974), Aikenhead (1974), and many educators gave a more complete description of these interactions and their potential in science education became apparent. A brief overview of their major ideas included:

- Technological aspects of science are a link between the scientist and the non-scientist.
- The advancement of science and technology initiates social, economic and political changes.
- Science is an internally regulated social institution (includes knowledge of natural phenomena, processes, and a set of values).
- The changes in society resulting from advanced science and technology may produce social and political problems which must be managed, in a democracy, by appropriate social and political processes.

These ideas, which suggest at least some cooperation between disciplines such as science and social studies, were included in a series of concepts (objectives) developed by the New York State Education Department (1985).

The interdisciplinary nature of STS has a critical implication for decisions about the design of the science program (and possibly other programs). At one extreme, for example, does one design the science 5-8 program, using problems and major themes such as transportation to tie together the important science concepts and processes, while at the other extreme use a more science-oriented base and build interdisciplinary activities (short and long term) which could be related to use the latter approach as one with more familiarity to teachers and one which would still allow for the implementation of STS through inservice and pre-training work with specific case studies and other activities. Although a long term goal, it was considered important that many disciplines and teachers became a part of a new approach.

A second problem for the design of the curriculum lay in the definition of the nature of science and recent criticisms of the methods used by science programs to develop these understandings in children. For example, Hodson (1988) claims that "In relying heavily on inductive references, discovery learning methods present a distorted and inadequate view of scientific methodology ... For children to discover anything, they need a prior conceptual knowledge." Fleming, as a result of research with 16-18 year olds, concluded:

- All subjects used knowledge about science and scientists when reasoning about the issues. Most of the knowledge was incorrect. For example (a) science was seen as the creator of truth; scientists were the custodians of
this truth, (b) scientists were seen as concerned with progress but never were concerned with human issues, (c) subjects are thoroughly confused by the concept of a scientific fact.

- Socio-scientific issues were far more 'socio' than 'scientific' (Fleming, 1987). Again, the importance of 'integration or correlation' between science and social studies is implied. In addition, the questions of age levels and ways to develop a better understanding of the nature of science should be considered. Selley (1989), who examined this development in British science textbooks for ages 11-13, considered it to be premature because these students tend to be egocentric and up to the age of 12 seem not to be bothered by discrepancies between their own and other results. He suggested delay to the 13-16 age range and having students engage in scientific model-building (Nussbaum & Novick, 1981). Solomon suggested that attempts to deal with the philosophy of science be delayed to the 6th Form in order to be most useful and effective (Solomon, 1986). Some implications, then, for the design of STS within the curriculum include:

- At the elementary level, where the conceptual structure is simple, an integrated approach emphasising science processes would be valid. Simple hypothesis testing and even hypothesis generation could occur at the upper elementary and later levels (Pella, 1966; Quinn & George, 1975).

- Building of scientific models at the upper middle year levels with short term activities or discussions which develop such concepts as "chance" in scientific discovery.

- A course or program, for ages 17-18, which integrates knowledge and skills from a variety of disciplines (as suggested by Solomon's SISCON project). The difficulty with this approach would be its lack of availability to many students in an already overcrowded curriculum. A better approach, in terms of student availability, would be that of attempting to design a program for Grade 10 and to place STS oriented units in most other units.

- Laboratory activities are good for developing scientific knowledge and processes and laboratory skills. Additional active learning experiences will have to be available. For example, computer-assisted learning for work on hypothesis formation and testing, and project work which provides the learner with opportunities to choose an investigation and the investigation strategies, are possibilities.

**STS and problem solving/decision making**

Terms such as problem solving, decision making, critical thinking, and inquiry sometimes overlap in part of their definitions, may be narrow or wide according to the discipline or level, and can sometimes be confusing. At the elementary level, for example, Shaw (1977) defined problem solving skills to include the four integrated science processes of interpreting data, controlling variables, defining operationally, and formulating hypotheses (a somewhat limited operational definition). However, the science processes, including the simpler ones, are considered to be a good basis for contributing to the development of thinking skills. Although effectiveness of inquiry and activity oriented programs have been questioned in the past, recent analysis of studies have indicated success. Helgeson (1987), states "Clearly, inquiry experiences ... are effective in promoting problem solving and result in increased conceptual learning when content and science process instruction are integrated." In addition, problem solving behaviors are enhanced where students have some freedom of choice and control over events and can work in small groups. In addition to science oriented activities, consumer oriented testing such as comparing paper towels for absorbency and strength and the testing of simple paper or drinking straw bridges can be related to the nature of science and technology.

A more extensive model for problem solving/decision making was obtained from work by Zoller (1987) and Aikenhead (1974). Abilities to be developed in students include:

- Ability to look at a problem and its implications and recognise it as a problem.

**STS and environmental education**

Six out of ten Americans in 1982 believed that more good than harm has come from science and technology and that most of the economic and social problems that we face will eventually be solved by new technologies (Dissinger, 1986). Some would argue that this perception of science and technology is fortunate because of all the bad publicity found in the media. But, perhaps, even this perception has changed since the Chernobyl disaster. Although a negative impact upon students' perceptions of science and technology can be a concern, one of the issues is helping students to have a more balanced view of these interactions. Students should be helped to recognise that the use of an old technology or a change to a more
ecologically sound approach would be more appropriate, e.g. the experiences of the "green revolution" and its impact on rice growing in Indonesia.

Environmentally oriented topics provide major opportunities relating to STS. In Manitoba, approximately 20 percent of the program is oriented towards ecology and ecosystem concepts. In addition, such topics as soil and management, alternative forms of energy, and flight, from other disciplines increase the opportunity to provide an environmental-STS orientation.

A model for environmental education, which can provide a general framework for the Manitoba K-12 curriculum, is that proposed by Project Synthesis (Volk, 1984) and developed more fully in the UNESCO Environmental Series (Hungerford & Ramsey, 1989). The elements of the proposed model include:

Level 1: Ecological foundation knowledge
Permits the student to make ecologically sound decisions. Includes energy transfer and succession, limiting factors and ecosystems, population dynamics, and man as a variable.

Level 2: Conceptual awareness - issues and values
Develops an awareness of how actions may influence the relationship between quality of life and quality of the environment, and also how these actions result in environmental issues which must be resolved. An example of objectives in this area is "Describe the significant role that the individual and his/her family play in contributing directly and indirectly to the environmental quality."

Level 3: Investigation and evaluation
Provides for development of the knowledge and skills necessary to permit receivers to investigate environmental issues and evaluate alternative solutions.

Level 4: Environmental action skills
Development of the knowledge and skills to take positive environmental action.

Considerable overlap between the environmental model and goals of science education and STS occur. The development of science process and inquiry skills or the nature of science are obvious examples.

A recent report on the CBC program "Quirks and Quarks" stated that a northeastern US consortium had requested a quantity of electrical power from Quebec. When the powers that be started to discuss additional facilities however, the consortium indicated that all the power must be obtained through the method of conservation, an interesting, positive alternative or trade-off relative to sustainable development. The province of Manitoba has recently proposed some principles of sustainable development and has been receiving a great deal of public input into examining objectives and policies relative to water, soil and land use, and forestry. The response has again illustrated the vast differences in opinion and the difficulty of reconciling different value systems, particularly in the area of economics. Since an education component is one part of the strategy, it is hoped that new materials with some local slant will develop. This is beginning to occur with the development of case study materials in the Lake Dauphin watershed which look at some positive alternatives for resolving major salinity problems.

A brief summary
Curriculum models, more so than scientific models, have the general difficulty that they are only a representation of reality. Apart from the significant needs within this model to fit some parts into the "paper" curriculum, to identify support materials already available and/or to develop additional materials, an additional question relates to implementation within the classroom. This involves teachers and the school support system. Bybee and Bonnsteller (1987), recently looked at implementing STS with the following teacher rating of concerns:

- economical (materials, facilities)
- personnel (teacher education, background, abilities)
- pedagogical (lack of available teaching techniques, new strategies, etc)
- social (public support, social awareness)
- psychological (negative attitudes towards change, lack of encouragement and support)
- political (acceptance at local and/or national level, administrative support)

It is likely that a similar situation exists in Manitoba, and thus, a need for long term support through a cooperative effort among provincial departments and faculties of education for the local school system.

Science Across Europe: Key Issues for Society

Published by the Association for Science Education and supported by a grant from BP

Science across Europe is publishing a series of units on scientific issues and providing an associated database of participating schools.

Science across Europe provides a forum through which students may exchange facts and opinions with students in other countries.

Two books are now available - Acid rain over Europe and Using energy at home. Three are under development - Renewable energy, Drinking water, and What did you eat? , and more are planned for the future. Schools from Norway, Sweden, UK, Denmark, The Netherlands, Belgium, France, Luxembourg, Germany, Switzerland, Austria, Slovenia, Portugal, Spain, Gibraltar, Italy, Malta, Greece and Cyprus have already taken part in the project.

Each book includes an introduction to the project, maps, data and teachers' notes, as well as examples of the information exchanged between schools. The student pages are printed as copyright waived masters in ten language versions. Upon sending in a registration form, the project provides details of schools in other countries participating in the scheme. The teacher then selects schools who are listed as wishing to exchange information during the time specified, and whose age/ability is appropriate.

Books can be ordered for £19 each as follows. The price includes membership of the network, post and packing. Send order, specifying language edition required, with payment to:

NEW ICASE PUBLICATION

Education in Science and Technology for Development

Perspectives for the 21st Century

Proceedings of
ASETT/ICASE Conference 91

Edited by
Judith Reay & June George

This new ICASE publication contains the papers presented at the ASETT/ICASE Caribbean Conference '91 organised by the Association for Science Education of Trinidad and Tobago (ASETT), 27-30 August 1991, at the University of the West Indies, St Agustine, Trinidad & Tobago. Papers are grouped in three sections.

The first section 'Issues in Education' includes papers which take a broad view of policies and practice. One paper urges teachers to question all 'knowledge'; another identifies a need for universities to articulate better with schools and with industry; another argues for much more attention to technology in schools.

The second section 'Curriculum and Educational Strategies' is closer to the classroom and spans primary through secondary to tertiary teaching.

The third section 'Science and Technology and Education' has more emphasis on science/technology, including contributions on topics as diverse as biotechnology, solar dryers, and a steel drum. The publication concludes with a set of resolutions arising from Conference '91.

Copies can be ordered from:

ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

March 21 - April 2
Science Education in a National Curriculum: An International Symposium
Location: University of York, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
Topics include: building a national curriculum; new science curricula in secondary schools; styles of curriculum development; evaluation of science curricula; impact and research on developments in science curricula; student assessment; changing demands for staff development; links between industry and science education; the role of national and international agencies in science education.

March 25-30
Sixth International PATT Conference
Location: Motel Eindhoven, The Netherlands
Contact: dr Marc J de Vries, Pedagogical Technological College, PO Box 826, 5600 AV Eindhoven, The Netherlands, Fax 31-40-440045
The aim of this conference is to exchange ideas and information on theoretical and practical implications of the implementation of environmental issues in technology education according to the subthemes: (1) Pupils' attitudes towards technology and the environment; (2) Environmental issues in primary and secondary technology education; (3) Gender aspects of environmental issues in technology education; (4) Environmental issues in the education of technology teachers.

April 10-24
Edinburgh International Science Festival
Location: Edinburgh, UK
Contact: Edinburgh International Science Festival Ltd, 1 Broughton Market, Edinburgh EH3 6NU, UK
The program for the fifth Edinburgh Science Festival will span many themes ranging from the environment to space, and high technology to health but, perhaps most importantly, each of the 300 plus public events will explain -- in jargon free language -- how topical issues within each theme affect everyone. A major international conference focusing on initiatives taken by a wide variety of organisations, in many different countries, to improve communications between scientists, the media and the public will be one of the highlights.

April 12-16
Curriculum Reforms for the 21st Century Africa
Location: Mombasa Beach Hotel, Northern Main Island, Kenya
Contact: The Director, Centre for Curriculum Studies in Africa, PO Box 43844, Nairobi, Kenya
The Centre for Curriculum Studies in Africa announces an African Regional Conference on the topic 'Curriculum Reforms for the 21st Century Africa', sponsored by UNESCO. This conference will: (1) review current theories underlying curriculum development and their relevance to educational practices in the African region; (2) examine emerging models in curriculum design and development in the African region; (3) review innovations in curriculum activities in the African region; (4) examine new strategies in curriculum implementation in the African region; (5) examine the role of evaluation in curriculum design and development in the African region; and (6) identify research gaps in curriculum theories and practices with a view to establishing an African regional research capacity bank.

April 8-10
Building Bridges to Science
Location: King James Thistle Hotel, Edinburgh, UK
Contact: Sally Goodman or Brian Hamble, British Association, Fortress House, 23 Savile Row, London W1X 1AB, UK, Fax 071-734-1658
This British Association conference, sponsored by Glaxo, will bring together speakers from museums, science centres, science theatre, education and industry, to focus on ways of forging links between different areas of science communication which are consumer-led. Sessions will be devoted to international links in science awareness, the science-art divide in education, science 'advice centres', making links with industry, and bringing science to rural areas. The conference will give participants a chance to discuss new ways of bringing science to rural areas. The conference will give participants a chance to discuss new ways of bringing science to wider audiences across Europe and to see some of the projects in action.
April 21-25
International Conference on Geoscience Education and Training
Location: University of Southampton, UK
Contact: Mrs Esther Johnson, GEOED Conference Secretariat, Department of Geology, University of Southampton, Southampton S09 5NH, UK
The Association of Geoscientists for International Development (AGID) and the Commission on Geoscience Education and Training (COGEOED) of the International Union of Geological Sciences are convening this international conference with the support of ICASE. Themes include: geoscience education in schools; higher education; geoscience training for business, industry and public service; and public understanding of geoscience. The conference is open to all those with an interest in geoscience education and training - including practitioners and those involved in administration, course development, and the supply of resource materials.

June 27 - July 3
VII Pacific Science Inter-Congress
Location: Okinawa Convention Center, Okinawa, Japan
Contact: VII Pacific Science Inter-Congress, c/o Section of International Affairs, University of the Ryukyus, 1-Senbaru, Nishihara, Okinawa, 903-01, Japan
The Symposium will be organised around the theme The Pacific: Crossroads for Culture and Nature and subthemes (1) Cultural Interchange among Pacific Peoples; (2) Speciation, Dispersal and Conservation of Species in the Pacific; (3) Towards Appropriate Technologies and Policies for Development and for the Conservation of Natural Environments in the Pacific. Scientific sessions organised by the Scientific Committees of the Pacific Science Association focus on a range of science disciplines and issues, including Science Communication and Education.

July 5-9
CONASTA 42
Location: Sydney, Australia
Contact: Jenny Jones, Convener CONASTA 42, PO Box 787, Potts Point, NSW 2011, Australia
The Australian Science Teachers Association invites you to participate in the 42nd annual conference of the Association. The theme of 'Science – Teaching it Better!' aims to highlight the part that teachers can play in fostering in their students an interest in and understanding of science. Four subthemes will deal with both primary and secondary school issues: (1) Science updates - recent exciting developments and their impact; (2) Science education research - what it has to offer the classroom teacher; (3) Science teaching for effective learning - how do we engage minds in the classroom?; (4) National initiatives. The program includes theme lectures, interactive workshops, seminars, field workshops, 'wandertimes' and poster presentations. A comprehensive display of resources useful to science teachers will be presented by publishing, audiovisual, equipment and computing companies.

July 6-10
Project 2000+ International Forum
Location: Paris, France
Contact: Dr Jack Holbrook, ICASE Executive Secretary, Department of Curriculum Studies, University of Hong Kong, Hong Kong
This worldwide conference, organised by ICASE in conjunction with UNESCO and other international bodies is the second phase of the three phase Project 2000+. The theme of the forum addresses the issue of Scientific and Technological Literacy for All. Sessions will establish agendas for future action. Attendance will be by invitation only (500 participants). The forum plans to issue statements to affect political visibility for science and technology education for all as a requirement for national development, and provide a framework for major programs of action in science and technology education involving governments, IGOs and NGOs.

July 8-11
ASERA 93
Location: The University of New England, Lismore, NSW, Australia
Contact: Keith Skamp, Conference Convenor, ASERA 93, Centre for Education, UNE - Northern Rivers, PO Box 157, Lismore, NSW Australia, Fax 066-221-833
The Australasian Science Education Research Association (ASERA) invites all those with an interest in science education research, including primary and secondary teachers and teacher educators to participate in the 24th Annual Conference of ASERA.

July 28 - August 11
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

August 15-20
34th IUPAC Congress
Location: Beijing, China
Contact: Prof Xinqi Song, Secretary-General of 34th IUPAC Congress, c/o Chinese Chemical Society, POB 2709, Beijing 100080, China, Fax 86-1-256-8157
The Congress is being organised by the Chinese Chemical Society, sponsored by the International Union of Pure and Applied Chemistry (IUPAC) and supported by a number of scientific organisations in China. The program features plenary lectures and invited lectures from key scientists and educators around the world, addressing the following topics: (1) life science and organic chemistry; (2) chemistry for a better environment and analytical chemistry; (3) chemistry of advanced materials and inorganic chemistry; (4) new polymer materials and macromolecular science; (5) petrochemistry.
fossil fuels chemistry and catalysts; (6) physical chemistry; (7) chemical information and computers in chemistry; and (8) popularisation and education of modern chemistry.

**September 6-16**

Science, technology and society – appropriate science education for the twenty first century

Location: Department of Educational Studies, University of Oxford, UK

Contact: Your local British Council office, or Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK, Fax +44-71-389-4154

There are vacancies for 30 participants to focus on the following issues: (1) the nature of STS as education; (2) objectives and the evaluation of courses; (3) information knowledge and public understanding of science; (4) industry and STS; (5) STS in developing countries; (6) law, values and decisions about the environment; (7) new curriculum materials; and (8) teachers and in-service education. The seminar is intended for experienced science teachers, educationists, and government officials involved with curriculum planning and implementation and in-service work with teachers. The seminar fee, including accommodation, is £1440.

**September 11-14**

2nd European Conference on Research in Chemical Education

Location: Pisa, Italy

Contact: Dipartimento di Chimica e Chimica Industriale dell'Università di Pisa, via Risorgimento, 35, 56126 - Pisa, Italia, Fax 050-918-260

This conference aims to describe the state of chemical education research and to help chemists develop this research, and develop a European cooperation for the defense and promotion of didactics. Topics include representations and conceptions, evaluation, trends in didactics, problem solving, experimental teaching, computer assisted teaching, new technologies, and chemistry and the environment.

1994

**January**

ASE Annual Meeting

Location: UK

Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK

Full details of this large international event will be circulated in *Education in Science*, a journal of the Association for Science Education.

1995

**July 27 - August 10**

London International Youth Science Forum

Location: London, UK

Contact: LIYSF, PO Box 159, London SW10 9QX, UK

The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

**August 8-12**

13th International Conference on Chemical Education

Location: San Juan, Puerto Rico

Contact: Ram S Lamba, Chairman 13th ICCE, Inter American University of Puerto Rico, PO Box 191293, San Juan PR 00919-1293

This will be the first time that an ICCE meeting will have been held in the Caribbean Region. The objective of this conference is to bring together chemistry teachers from the pre-college and college levels to share ideas and learn from each other about innovations in the teaching and learning of chemistry. The theme is 'Chemistry: The Key to the Future'. The Conference will feature plenary lectures, symposia, lecture presentations, workshops, poster sessions and exhibitions. Scientists and science educators from around the world will report their work.

1994

**January**

ASE Annual Meeting

Location: UK

Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK

London International Youth Science Forum

Location: London, UK

Contact: LIYSF, PO Box 159, London SW10 9QX, UK

The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

**August 25 - September 1**

International Conference on Industry-Education Initiatives in Chemistry

Location: University of York, UK

Contact: Miranda Mapleton, Chemical Industry Education Centre, Department of Chemistry, University of York, York YO1 5DD, UK, Fax +44-904-432516

This international conference is co-sponsored by the International Union of Pure and Applied Chemistry (IUPAC) Committee on Teaching of Chemistry, and the Royal Society of Chemistry Education Division and Industrial Division.
International Forum

Scientific and Technological Literacy for All

Phase 2 of Project 2000+

Paris, France
6-10 July 1993

This International Forum is the Second Phase of Project 2000+, an international project on scientific and technological literacy for all, which addresses the following 6 focus areas:

1. The nature of, and the need for scientific and technological literacy
2. Scientific and technological literacy for development
3. The teaching and learning environment for scientific and technological literacy
4. Teacher education and leadership for scientific and technological literacy
5. Assessment and evaluation for scientific and technological literacy
6. Non formal and informal development of scientific and technological literacy

Attendance will be by invitation only and limited to 500 participants representing:

- National EFA (Education For All) Groups
- National policy makers overseeing science and technology education
- INISTE centres
- Project coordinators and field workers for organisations
- Science and technology teacher associations
- Institutions, centres, universities and colleges involved in science and technology curricula, examinations and teacher education
- Science and technology out-of-school centres and organisations
- Non formal science and technology educational organisations
- Industrialists
- Persons from the mass media interested in Project 2000+

There will be a US$100 Registration Fee for each participant to help defray material costs. This will be payable to the Project 2000+ Secretariat on receiving the invitation. For further information, contact:

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Paris in summer ...

Sounds an ideal place to spend a few days for a holiday — but there won't be much spare time for ICASE delegates as they meet in Paris for the International Forum which marks the second phase of Project 2000+.

After many months of intensive planning and preparation, this key meeting is about to take place. Delegates from all over the world will converge on Paris to contribute, share and consider follow-up programs which will carry forward the challenge of scientific and technological literacy into the 21st century. The article by Dr Jack Holbrook in this issue provides readers with an overview of Project 2000+.

On Sunday 4th July, ICASE Executive Committee Members will meet. On Monday 5th July, ICASE will hold its 6th General Assembly (Part 1) in which all ICASE member associations, institutions and companies are invited to participate.

Part 1 will feature reports by ICASE officers and representatives as well as by ICASE member organisations. Part 2 of the General Assembly will be held on Sunday 11th July. During this time, the new ICASE Executive Committee will be elected, and Project 2000+ proposals will be considered.

Elections will be held for President, President Elect, and Regional Representatives for the following regions — Africa, Asia, Australasia & Pacific, Caribbean & South America, Europe, North America. Other appointments will be determined by the newly elected Executive Committee.

ICASE will be developing plans for projects and activities in the years ahead — no doubt these will be closely aligned with the need to move ahead supporting Phase 3 of Project 2000+.

Brenton Honeyman, Editor

This section provides news for the information of member associations, institutions, centres, foundations and companies. The Executive Committee encourages members to reproduce this section in journals and newsletters to communicate this information to as many as possible.

Technology Teaching Systems Ltd joins ICASE as a Company Member

ICASE welcomes Technology Teaching Systems Ltd as a Company Member.

TTS was formed eight years ago to supply materials for the rapidly expanding subject of technology in elementary schools but in the ensuing years their range of products was expanded to include science materials and equipment.

The company has always produced effective books and manuals to help teachers get the best from the equipment in terms of use and safety.

Recent export contracts emphasise that the company's experience is valued internationally as well as in the United Kingdom.

TTS can be contacted at the following address:

New Subscription Rates for Science Education International

Since the first issue of the ICASE Journal in March 1990, individuals and libraries have been subscribing to Science Education International.

Due to increasing production and postage costs, 1993 subscription rates have been increased to:

Individual
£10.00
US$17.50
A$22.00
CAN$20.00

Library
£20.00
US$35.00
A$44.00
CAN$40.00

Subscriptions can be sent to:
(cheques payable to "ICASE")

Basic and Applied Science Education in Developing Countries

Trends and Needs of the 21st Century

by Dr J B Holbrook
Executive Secretary, ICASE

'Science and technology will, according to forecasts, play a significant and dominant role in the 21st century. It is for this reason that this committee stressed the need to give science and technology a significant place within the Education for All program in Africa.'

(Extract from the advisory committee report on the renewal of science and technology education in Africa, 1992 Dakar)

'The World is at the threshold of a new century, with all its promise and possibilities. Today there is genuine progress toward peaceful detente and greater cooperation among nations. Today there are many useful scientific and cultural developments.

Therefore we participants in the World Conference on Education for All recognise that sound basic education is fundamental to the strengthening of higher levels of education and of scientific and technological literacy and capacity and thus to self-reliant development.

'BASIC education is the foundation for lifelong learning and human development on which countries may build systematically, further levels and types of education and training. In an increasingly scientific and technological world, scientific and technological literacy must form part of this foundation.'

(Short extracts from the World Declaration on Education for All, adopted at an international conference in Jomtien, Thailand, 1990)

'Never before in the history of the world has the quality of peoples' lives been tied so directly to science and technology . . . . Although there is no doubt about the linkage between overall economic well-being and scientific and technological development, the global impact on countries is often uneven and can result in negative consequences . . . . The problems need to be analysed globally and locally; they need to be dealt with internationally and at the national and local levels . . . . To accomplish this it is imperative that we have a world community of scientifically and technologically literate citizens.'

(Comments taken from a special UNESCO study by Bower, 1990, undertaken for the World Conference on Education for All)

But how is the world doing?

Coping with issues such as health, nutrition, environment, energy sources, finite resources, risk assessment, population control, global change and sustainable development at the local national and international levels is surely part of basic learning needs. These social issues need an increasing degree of scientific and technological literacy on the part of the populace for both the understanding and the decision-making involved to stimulate the necessary action. Yet it would appear that, in many countries, basic education in schools includes little that will help students achieve such literacy, or feel confident, either in applying their knowledge, or in dealing with societal issues and the need for a responsibility for action. It is also a sad fact that the ultimate decision makers, the politicians do not always have the background needed to receive and absorb the required scientific and technological advice necessary for them to function as efficient decision makers and administrators.

Scientific and technological 'illiteracy' is thus not only confined to the uneducated. There is much illiteracy even among scientists and science and technology educators, partly as a consequence of the high degree of specialisation encouraged in educational systems. A growing realisation is that 'science for the scientist' is not the only goal of science education. Furthermore, technology education is more than a craft course and involves processes as well as products.

Science and technology are part of the culture of societies and not to be conceived as purely mental and manipulative pursuits, isolated from issues pervading the society.

The need

Education faces a major challenge in learning how to help citizens cope with the 21st century and its increased use of technology. Technological development has been vast and swift and continues to increase at a rate that seems to be a never ending spiral. While the industrial revolution developed over an approximate fifty year period, the latter part of the 20th century has seen a rapid rush through the age of plastics, electronics, space, and into the computer age in about the same period of time. Our technological world is in a period of extensive change. Change for the future can be expected to be equally vast and today we no longer regard science fiction ideas as purely a matter of unattainable dreaming.

There is an urgent need to accept that science education and technology education are important for us all and that there are also differences between science and technology education which need to be recognised and understood. There is a need to rethink the objectives of science and technology teaching to give more serious consideration to the nature of science, science - technology links and the importance of technological skills in science courses. There is a further need to recognise that capability through technology
education is more than applied science and certainly far removed from the mere acquisition of technical skills.

Whilst a knowledge of science plays an important role in scientific and technological literacy, societal concerns rarely lend themselves to solely scientific or technological solutions. It is thus important that science and technology are taught in a societal context and students learn to cope with a decision making process in which a variety of factors (e.g., economic, environmental, ethical) may be more influential.

While conferences like the Education for All (WCEFA, 1990) grappled with the major concerns of worldwide education, the crucial role of scientific and technological education has been given far too little attention. Curriculum development often requires five to ten years preparation time and thus today, we begin to work on the pattern of education for the 21st century. If education in the schools is to have any hope of meeting such anticipated challenges for scientific and technological literacy, it is necessary, now, to establish goals, definitions, and strategies which will lead us into appropriate strategies for science and technology education suitable for societal needs in the next century.

**The issues**

In preparation for the 21st century, citizens need increased scientific and technological literacy. Not entirely clear is the exact nature of such literacy, how to achieve it, and what assessment mechanisms are most valid. Any discussion and the subsequent development of possible models for achieving scientific and technological literacy depend on research and development in this area around the world.

It would appear another issue is the degree to which science education should be directly relevant to the concerns and demands of the society and how far it should establish a groundwork for further learning, should a student wish to pursue a scientific career. A report commissioned by the World Bank in 1989 (The British Council, 1989) suggests that these approaches are somewhat in conflict and that presently far greater attention is given to science for continuation even at the primary level of education.

A further issue is the extent to which technology education should be an integral part of the formal school curriculum and taught separately from science. Whilst the two subject areas have unique components, there are also areas of great overlap and literacy issues between these subject areas, in which science tends to take on a societal slant, are often heavily interrelated. For developing countries, hard pressed to provide specialised facilities (such as that demanded by pure science), the attractiveness of a technology-science mix for all, may not only be desirable, but could prove doubly attractive when consideration is given to the less expensive, more flexible, facilities that would be required.

Appreciating, managing and having a sense of responsibility for the environment is another pressing issue in society and yet the natural world cannot be considered in isolation. This leads to education for sustainable development and how it can be achieved, given that the world is united in concerns such as global change, ozone layer depletion, the finiteness of energy reserves and the impact of deforestation. The environment has traditionally been taught within social science studies, but there is a growing recognition that a deeper understanding of the scientific and technological aspects are important and that science and technology education themes should take on an environmental outlook e.g., air, water, pollution, transport, energy sources, our health.

Education is important for all members of society and there is a growing need for the 21st century that there should be equal opportunity for all within education. Traditionally science education has attracted boys, either by offering choice at an age when boys are more easily motivated toward science, or by orientating the science topics for study so that they draw upon the experiences that favour boys. Yet where girls have studied science and technology, the research shows that they achieve equally as well as boys. Equity in science and technology education means recognising the importance of science and technology education for all citizens and then providing a wide range of experiences so that its appeal is appreciated by all.

**Project 2000**

Project 2000+ has been initiated by UNESCO and the International Council of Associations for Science Education (ICASE) to promote and to guide the implementation of a scientific and technological dimension of basic education in the context of education for all.

Project 2000+ recognizes the growing need for a greater scientifically and technologically literate society and seeks to:

- identify ways of promoting the development of scientific and technological literacy for all;
- put forward educational programs (both formal and non-formal) in such a way as to empower all to satisfy their basic needs and be productive in an increasingly technological society;
- provide guidelines for the continuous professional development of science and technology educators and leaders;
- encourage the formation of national task forces involving personnel from Government, Inter-Governmental Organizations (IGOs), and from Non-Governmental Organizations (NGOs) such as associations for science education – to initiate programs for greater scientific and technological literacy;
- support the development of a wide range of projects that aim to improve quality of life and productivity in society and that lead to promoting solidarity and cooperation in achieving scientific and technological literacy for all;
- support the evaluation of existing and projected programs to ensure scientific and technological literacy goals are being met.

**The educational directions to be clarified**

The project is designed to emphasise the growing need for a scientific and technologically literate public; to draw attention to the failure of societies to meet this need in their current educational programs, to examine ways of promoting the development of scientific and technological literacy for
all and to provide a foundation for the professional development of educators and leaders in the area of scientific and technological literacy. To meet these concerns, project 2000+ draws attention to more research development and dissemination studies in the following 6 focus areas:

1. The nature of, and the need for, scientific and technological literacy
   - **The meaning of scientific literacy, technological literacy and their interrelationship**
     This focuses on the need to examine the nature of scientific and technological literacy, the interdependence of science education and technology education, and the nature of technology education and the misconceptions held about it.
   - **A rationale for acquiring scientific and technological literacy**
     Scientific and technological literacy are essential for all to meet the challenge of:
     (i) the increasing impact of science and technology on people's lives, individually and in relation to society, as well as to their careers and quality of life
     (ii) the need for scientists, politicians and other key personnel to be scientifically and technologically literate as a basis for decision making, and for citizens to be able to participate meaningfully in science-related political issues
     (iii) the need for people to be functional in an increasingly technological environment; 'operacy' in relation to machines; appropriate societal behaviour for the benefit of the individual and society as a whole
     (iv) the need for a flexible work force which can be more effective if scientifically and technologically literate.
   - **Demystifying science and technology**
     To demystify science and technology, they must become accessible to all. Fears that this subject area is hard and remote must be overcome, preferably by initiating children, in appropriate ways, into science and technology concepts and processes at an early age.

2. Scientific and technological literacy for development

Areas for consideration here include national, social and economic development with particular reference to personal development, including human ethical values; science and technology education for women and girls; and quality of life issues such as sustainable development strategies and economic development opportunities for employment at local, regional and national levels.
In particular, this applies to

**Life-long scientific and technological literacy**
As science and technology develop, efforts have to be made to update the knowledge base needed to sustain scientific and technological literacy throughout life. Formal education systems must be complemented by efforts to promote public understanding, developing well thought out values and skills in decision making, based on science and technology. For this, use should be made of the media and other local community provisions.

**Research into scientific and technological literacy**
Serious research efforts must be directed to investigation of needed basic concepts; the knowledge base; processes necessary for scientific and technological literacy, including

---

**ICASE AWARD SCHEME**

for outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.

**ICASE Distinguished Service Award**
This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations

**ICASE Regional Service Award**
This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

**ICASE Association Award**
This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Contact Dr Jack Holbrook, Executive Secretary ICASE, Science & Technology Education Unit UNESCO, 7 place de Fontenoy, 75352 Paris, France

---

5
problem solving, decision making, communication and risk assessment skills. Also, research should consider teacher education, learning environments, and career-related issues, all of which contribute to enhancing sustainable development. Further research should consider the place of population, health, energy and environmental issues in relation to scientific and technological literacy.

Case studies and examples of scientific and technological literacy in various settings

Descriptions of existing literacy programs are necessary to stimulate discussion, research, and action. Such examples are essential for preparing models for educational development.

3. The teaching and learning environment for scientific and technological literacy

The ultimate goal of scientific and technological literacy is to produce individuals who feel comfortable with, and who are capable of, learning and using science and technology and who are able to deal with change which accompanies developments in the field of technology. In developing this literacy, learning must focus on the individual. Such focus requires a carefully planned and creative learning environment. This includes taking account of:

- the role of the learner
- the role of the teacher
- the curriculum
- the physical environment where the learning takes place.

The desired role of the learner must be compatible with the nature of science and scientific and technological literacy and what is known about how people learn. To be useful, this role must be carefully described and documented.

Once the role of the learners is specified, a careful search of the literature should reveal appropriate teacher behaviour and actions which should lead to good learner performance. The object should be to develop appropriate teaching strategies for enhancing scientific and technological literacy. Since learners interact with the teacher in a context and physical locale, these too must be designed for compatibility with the ultimate goal — scientific and technological literacy.

4. Teacher Education and Leadership for Scientific and Technological Literacy

The teacher (or tutor/educator) is a key figure in the learning environment. Hence the teacher’s own education must be carefully planned to optimise the learning environment. Teachers (and others directing an environment for developing scientific and technological literacy) must consider and control the learning environment and their own behaviours. The following need consideration:

- necessary background knowledge
- knowledge about teaching and learning
- appropriate attitudes and commitment
- competence with appropriate teaching strategies
- ability to select, modify, and design curricula
- ability to communicate effectively.

To achieve these, programs for educating those in guidance and leadership roles that influence the education of teachers must have specific components which lead to the capabilities desired.

5. Assessment and evaluation for scientific and technological literacy

Whereas assessment is most commonly used in formal school classrooms, there is need to use evaluation as a tool for accountability in all scientific and technological literacy programs. Educators need to assess regularly and meaningfully the academic achievement of their students in scientific and technological literacy. Both valid and reliable assessment strategies need to be developed. Equally important, teachers must devise methods for monitoring their own teaching of the programs they operate and the system in which they carry out their profession. There are many issues on which to focus, but research data and exemplary details are needed for:

- the role of assessment and evaluation
- assessment and evaluation for all desired goals (attitudes, creativity, the nature of science, application of knowledge), not just knowledge of concepts, vocabulary, and processes
- public acceptability of appropriate assessment and evaluation
- how such assessments/evaluations can be identified and monitored in formal and non-formal situations
- use of formative as well as summative evaluation strategies
- self evaluation for users of technology
- the role of evaluation agencies.

Assessment and evaluation should be directed to providing usable information for improving the quality of life.

6. Non-formal and informal development of scientific and technological literacy

While formal schooling provides a major mechanism for the enhancement of scientific and technological literacy, non-formal education (museums, science centres, zoos) and informal education (the media, social events) also provide significant avenues for development, either linked with or independent of formal schooling. In fact, for adults and out-of-school youth, these forms of education play the major role in gaining or enhancing scientific and technological literacy. Knowing this, serious proposals must consider:

- identifying, supporting and publicising exemplary non-formal and informal mechanisms
- educating personnel for undertaking non-formal and informal efforts
- linking schools with non-formal and informal efforts
- evaluating the effectiveness of various non-formal and informal approaches.

Expected results of Project 2000+

The expected result from implementing Project 2000+ is enhanced scientific and technological literacy for all students as part of basic education and for all adults. Specifically the results expected are:

- Closer links between goals of basic education in general and the teaching of science and technology in schools at the basic education level
• New curricula for compulsory school science and technology that have a greater degree of relevance for all students and which promote scientific and technological literacy above 'science for scientists' strategies.

• New resource materials together with detailed guidelines for use that relate to the society outside the school or the learning centre and emphasise relevance.

• New pre-service teacher education programs that promote scientific and technological literacy as the goals of science and technology education programs.

• New in-service teacher education programs that emphasise scientific and technological literacy philosophies and put forward ways in which such literacies can be encouraged.

• New assessment mechanisms appropriate for the emphasis on science and technological literacy.

• New formal/non-formal education links that promote basic science and technology education and enhance adult literacy.

• Greater involvement of NGOs in project design and promotion.

• Greater emphasis on evaluation of research, on programs, and on training of personnel in evaluation techniques.

Project considerations at an operational level

1. Re-examination of curricula strategies

A common science curricula strategy today can be described as 'fundamentals first'. It is based on the idea that appreciating the uses of science and understanding the issues where scientific research is being undertaken needs a grasp of fundamental concepts. The concepts are introduced in a 'science' framework usually using scientific conceptual headings eg force, work, properties of matter, heat, light. The approach is logical and orderly from a scientist's point of view and allows the introduction of experimentation, investigation and the build up of scientific learning in a hands-on and orderly manner. Teachers like it, often because it was the way in which they were taught and furthermore it seemed logical and appropriate for them when they themselves were learning science in school.

But this approach is now being perceived as turning students away from science studies. Whilst logical to the scientist, it seems largely irrelevant to life within society. The problems and issues in society are complex, technology related and are very different from the conceptual build up being developed within the school.

As scientific knowledge increases, so does the basic learning. Much of university study of previous decades is now taught in schools. By emphasising fundamentals, there is less and less time to relate to the societal implications of science, or to look at some of the applications except as an afterthought. Science as a subject, useful outside the school, becomes sterile and irrelevant.

Whilst it is undoubtedly important for future scientists to have a fundamental grasp of scientific concepts, few students enter such a career. Yet scientific and technological literacy is a need of all students, irrespective of their future vocation. It is important for all students to have a grasp of a wide range of scientific skills and be in a better position to cope with change in technology, assess risk associated with technology, make decisions with respect to the technology they encounter or which affects their society and to appreciate their role in the 'global village' that technology affects.

Science education in schools has failed to provide students with the attributes and skills to meet the challenges and issues in society that impinge upon science and technology. Worst, the science and technology curricula in schools have not even been able to keep pace with the rapid changes in science and technology within the society.

Basic education in the field of science and technology does not therefore mean that a fundamentals-first approach is mandatory. A new strategy is needed. A relevant-to-the-needs-of-society approach needs to be given greater consideration. Such an approach has been attempted in some projects under the names of STS, SADIS, or an industry-oriented approach. The approach stems from:

• our interests in our environment/industry

• our needs (skills both personal and societal)

• the concerns in society

• betterment of the society leading to

• sustainable development ideas.

2. Technology-led science curricula

The made world around us is technological therefore confining science education to nature study is no longer appropriate. This made world is a series of technological products and it is thus no longer applicable to study science in a technological vacuum. Humankind has striven for a better quality of life and the trials and tribulations along this path provide the setting for science and technology education in a relevant setting. The setting emphasises issues, recognises aesthetic beauty, realises the nature of science and relegates factual knowledge to a need-to-know basis. Basic science courses cannot ignore the processes of technology, which need to be made an integral part of science teaching. A technology-led science curriculum seems to be more appropriate. The science begins from that which is visible in the society and, where complex, breaks it down to the inherent concepts. The science is systematic, from an environmental or experiential point of view. Previous fundamentals, such as the periodic table, are inappropriate. A systematic study of the elements is no long appropriate.

Chlorine, for example, is not a topic of study - its relevance is likely to be included from a study of bleach, because that is experiential reality.

3. Emphasis on process skills in science and technology teaching

Personal skills need a greater promotion in science and technology teaching. Manipulative skills gained from experimentation are not all that is required of science and technology teaching. The experiments must be meaningful and lead to greater involvement in the design, method of operation and the objectives to be achieved. Design and planning skills need greater attention. And to illustrate that reality is a compromise, greater attention needs to be placed on alternative solutions to problems where economic, political or societal considerations may play important roles. Activities such as role
playing, brainstorming, project work and dramatisations need to be given greater consideration.

4. Role of the textbook in science and technology teaching

Whilst a reference book containing data has a useful place in teaching, a 'guidebook' which one might consider to be the role of the textbook needs to be imaginative, stimulating and relevant to the objectives of the teaching. The textbook is, however, all too easily the 'spoiler' of lessons as it supplies 'the answer', removes investigatory spirit, puts undue emphasis on conceptual understanding and ignores process and communicative skills.

5. Summative assessment of students

With the removal of the textbook, the challenge to more appropriately undertake assessment of student achievement can become a reality. External examinations have tended to take the textbook as the curriculum, emphasise conceptual understanding and give scant attention to process skills and, certainly, to any non-written skills such as debating, acting or even manipulating. A great challenge is therefore to change the external examination system and to find ways to involve teachers in the summative assessment of student ability. This is certainly challenging, as it will ask much of the teacher who is more familiar with formative assessment and recognises the conflicts that can arise if formative and summative assessments are combined. The place of criterion referenced assessment and student progress development profiles need serious planning, research and development.

6. The place of the school within the society

A major challenge is defining the role of the school in the learning of science and technology. It is well recognised that students learn much from their surroundings, the society, the radio or television, the science and technology museum, science centre, or from involvement in indigenous technology. For a school to isolate itself from such places of learning is obviously undesirable, especially when ideas are presented so much better than in the school. Look how much better a science centre or a museum is able to present facts, data, historical ideas and cater for experiences with technology. Why should a school contemplate competing with such institutions? The links between the formal and the non-formal need to be greatly strengthened so that the school can devote far greater attention to societal skills, even within science teaching, and less to acquisition of facts. It might be going too far to side with a vision of science learning in the 21st century as being of a student sitting at home with a computer, connected to information centres and able to communicate with the teacher, then coming to school to learn how to interact with other students. But certainly putting students together in a concentration such as that within a classroom calls for careful attention to be paid to the type of learning opportunities this best creates for the student.

7. School-community links

The school-community link can work both ways and the role of the school as a learning centre can play a great role in the community, involving the community in the student learning and also allowing the community to benefit from being a centre which meets their own learning needs. Adult education in scientific and technological literacy can be seriously attacked by the school being more open to the community even to the extent of members of the community being involved within the lessons being offered to students. Students would also present, guide and otherwise relate to the community in work related, or other programs.

Designing schemes and implementing scientific and technological literacy

It has long been recognised that formal, non-formal and informal education play specific, yet important and often interrelated roles in guiding the development of a country. It is illustrative how the UNESCO/ICASE project initiative, planned on a worldwide scale, can be translated into meaningful developments within a country. In so doing it must be emphasised that developments and their implementation will be, and are planned to be, at an individual country level. External agencies are planned to be involved only at a supportive, rather than a leading role.

The outcomes from an international forum (to be held in July at UNESCO headquarters) are expected to be disseminated to governments for consideration. At the same time, guidelines are needed, to evaluate current programs for suitability in achieving the degree of scientific and technological literacy desired, and a national task force created to oversee developments. Project 2000+ calls for external agents, such as UNESCO and ICASE to provide training and evaluative support for developments.

Whilst developing scientific and technological literacy is a many faceted task that takes place over a considerable period of time, it is anticipated that one area of major development is curriculum within the formal school setting. Outcomes from the international forum are expected to give specific proposals for reforming primary and secondary school science and technology curricula so that they address problems for the school population as a whole. This is not an easy task as it has now been recognised that providing a degree of scientific and technological literacy in society at large is not the same as, and may not even complement, science and technology education in further education. It is expected that much time and energy will now be needed if countries wish to seriously address the literacy side of science and technology that affects all members of their community, irrespective of their interest, aptitude, or need of academically oriented science learning.

One curriculum area which needs special attention, as much research has pointed to large discrepancies, is that between the 'intended' and the 'implemented' curriculum. This often comes about by the curriculum being specified nationally by a group of 'experts' and this is then disseminated to schools in a trivial manner. The usual source of guidance for teachers becomes the external examination, but this is limited in its ability to recognise literacy objectives and also the expert role of the teacher who includes local relevance, especially where this centres around societal issues.

Curriculum development, initiated by curriculum developers, can be described as a 'top-down' model and no matter how refined, the developed syllabus, or curriculum, represents an intention that may face implementational difficulties. Curriculum development initiated by teachers has often been described as the 'bottom-up' approach. Such development is
difficult to achieve. The involvement of science and technology teacher associations, putting forward the needs with respect to a 'bottom-up' development, can help to provide the balance between innovative ideas from the developers and implementation possibilities (particularly teaching time allocations) from the practitioners.

Science and technology teacher associations represent a group of enthusiastic teachers committed to narrowing the gap between the intended and the implemented curriculum. Their involvement in the curriculum development process enables operational ideas to be incorporated at an early stage and assists the important dissemination mechanism i.e. allowing teachers to comprehend the philosophy of any curriculum renewal. Their members are teachers who can try out curriculum ideas and by interacting within a science or technology teacher association, play a big role in the evaluation process. It is anticipated that science and technology teacher associations would play a major role in the development and implementation of curriculum. For this the teachers would obviously need strong support as they will be volunteering, in effect, for a second, and probably unpaid, time consuming task.

Developments within a country is thus envisaged as a team effort where the overseer would be a task force, made up of Government and non-governmental organisation representatives. Details are purposely left vague at this stage as developments would be dependent on the wishes of the various countries that are involved. However an important component on which UNESCO and ICASE would place emphasis is the training of personnel within a country both in developing intended guidelines and in implementational or evaluative strategies.

**Implementational Strategies**

'Give a man fish and he can eat for today. Teach the man to fish and he can eat for a lifetime.'

Intention is not enough. Implementation is also crucial. Implementation is dependent on skill, resources and perhaps most crucial of all, attitudes. Intentions need implementational support. Success needs to be nurtured and monitored through evaluation programs which relate to attitudes as well as achievement. For this, the practitioners (teachers an fieldworkers) need to be actively involved. Partners in Project 2000+ are international NGOs linked to the practitioners. They have an important role to play in assisting teacher associations and the international NGOs themselves also need strong support.

**Overseers of projects**

This is intended to be national task forces, linked to a regional network organised by the project 2000+ steering committee partners. The national taskforces are intended to consist of governmental and non-governmental organisation representation. The intention is that representatives would have organisational support and would thus not be acting in an individual capacity.

The taskforces would be expected to oversee the whole project from the development of strategies, to trialling of curricula/materials, teacher education programs, assessment strategies, formal-nonformal links, etc. to evaluation of the project. They would be expected to be able to call upon expertise from the regional network if needed. The task forces would also be expected to obtain information from databases in support of national developments.

**A possible mechanism for the operation of a project nationally**

- Evaluate the current situation by conducting a needs assessment
- Carry out planning work to develop projects in the area of scientific and technological literacy in areas of national interest e.g. curriculum development, materials development, teacher education, assessment strategies, linking formal and non-formal education, enhancing S&T literacy for women, establishing a relationship between science education and environmental education, health education, sustainable development.
- Develop models to promote scientific and technological literacy in these areas.
• Create strategies for curriculum/materials development and/or training programs to follow up with target groups on the models developed.
• Create strategies for teacher education, teacher acceptance and, above all, teacher motivation towards the project.
• Develop strategies for evaluation of project at its various stages.
• Develop strategies for assessment programs for students linked to scientific and technological literacy in the 21st century.
• Initiate pilot studies, evaluate, re-trial and re-evaluate.

Main goals expected from the project
• Teaching of science and technology in schools at the basic education level and in non-formal centres more closely linked with and relevant to society
• Positive attitudes towards science and technology in the schools and the community
• Greater skills in decision making, problem solving communication achieved through science and technology teaching
• More relevant curricula in science and technology for scientific and technological literacy for all
• Development of teaching resource packages
• Use of interactive teaching methods as the mainstream of science and technology education
• Enhanced teacher education programs
• Greater involvement of teachers and NGOs in the development, dissemination and evaluation of programs
• More relevant assessment programs more closely linked with the goals of science and technology education
• Development of effective evaluation and assessment packages

Conclusion
It seems clear that in a world of ever expanding knowledge where new technologies are introduced at a faster and faster pace, there is an urgent need to examine seriously education related to scientific and technological literacy for all. The following are areas which need attention:
• Development, dissemination and evaluation of curricula and curricular materials that link formal and non-formal education, encourage teachers to use innovative classroom practices and to make use of the expertise of the non-formal sector, including village crafts and technologies. Curricula to be designed which integrate science and technology with societal concerns and promote objectives emphasising skills in problem solving, decision making and communication.
• Effective teaching and learning strategies in a given situation. Cost effective, innovative 21st century experimental rooms, mobile science and technology rooms, electronic visual aids and innovative teaching strategies which make good use of all community resources (institutional skilled personnel, etc).
• Pre-service and in-service education programs, particularly with follow up and evaluation; the training of educators of teachers and field workers
• Assessment strategies for use with students that can form acceptable alternatives to the summative emphasis now being practised in many countries. Research into examination validity, guidance to examination boards and the conducting of employer evaluations
• Formal or non-formal programs portraying a positive image of science and technology and covering aspects such as determining risk assessment, education for a changing society, how to cope with new technologies, the place of alternative technologies in sustainable development and the recognition of the world as an environmental 'global village'.
• Education of women, minorities, disadvantaged persons in seeing science and technology as improving their quality of life and, used wisely, of benefit to humanity in the future.
• Promotion of education emphasising a balanced picture of the place of industry in society, the decisions that need to be made for sustainable development and in providing the expertise for industry in the future.

Project 2000+ is an ambitious program. Yet governments in many countries wish to place an emphasis on science and technology education for all. Project 2000+ sets out to give science and technology education renewed attention so that formal and non-formal programs can adequately be restructured in time to keep pace with the needs of the 21st century.

Pre-College Science Education in Thailand

by Naruemon Yutakom & John E Penick

For centuries, the Buddhist monasteries played an important role in the education of the Thai people as centers for local and regional tradition. Modern education, brought by traders, foreign ambassadors, and missionaries, came to Thailand in the mid-nineteenth century. Following contacts with foreign visitors, the royal Thai family established and supported the first modern school in Thailand for royal pages in 1870. Later, in 1855, education was expanded for the civil service. However, major expansion of public education did not take place until 1913 culminating in 1921 with compulsory education.

Since 1961, Thailand has been engaged in systematic educational planning as an integral part of its National Economic and Social Development Plan. National Education Development Plans have followed the same five-year pattern as the National Economic Plans. By the end of 1991, six plans had been completed. In the first three plans (1961-1976) emphasis was on developing secondary education to provide medium and high level manpower requirements for a rapidly growing economy. The third plan improved rural access to an education. In the subsequent plans (1977-1991), there was a shift towards increasing educational access improving the administrative system, reforming the curriculum and encouraging equality of educational opportunity throughout the country. The seventh five-year plan, begun in 1992, emphasizes acceleration of educational opportunity for all, especially the rural at pre-primary levels. The lower secondary school will become more accessible to primary graduates and career development will be enhanced.

The Thai educational system is currently under the National Education Scheme of 1977 which conceived education as a continuing life-long process to promote the development of the citizen. In 1978, educational administration was unified under the Ministry of Education, and the previous educational system of 7:3:3 was replaced by the 6:3:3 system. Each level of the 6:3:3 system comprises a diversified curriculum in both general and vocational education. Primary education is compulsory and special education and non-formal education are available for every level of education.

With rapid changes in the social, economic, political, cultural and ecological agendas, Thailand again needs educational reform. Acceleration of such reform in Thailand has been influenced by the United Nations adoption of 1990-1999 as the 'Education for All' decade. The United Nations hopes that this will spur Third World Nations to make greater efforts in encouraging their citizens to acquire basic education as well as scientific and technological literacy.

Thailand's National Policy on Education for All, under the scope and guidelines of the World Declaration and the Framework for Action to Meet Basic Learning Needs, recognizes that basic education is the right and responsibility of all people and should be supported by the government regardless of age, gender, socio-economic status, place or residence, religious belief or other constraints. The policy which will serve the educational endeavor in the coming decade comprises:

- Universalization of primary education; expanding basic compulsory education from six to nine years; providing special education for the handicapped; establishing a network of information learning centers to foster community learning
- Eradication of illiteracy (literacy rate in 1985 was 86%)
- Promotion of continuing education
- Participation of non-government organizations in Education for All activities

The program strategies stressed in the National Education Policy include:

- Learning networks
- Administration and mobilisation of resources
- Staff development
- Lifelong learning opportunities

These policies have worked well. By 1991, 38% of eligible Thai children were attending private or public pre-elementary schools, many in three year programs.

In 1991, 94% of children who belong in first grade were attending and their net survival rate at the end of primary schooling was 89%. The enrolment rate for continuing in secondary school was 48%. That same year, 20% graduated from high schools, 75% of whom went on to universities. Under the Seventh National Education Development Plan (1992-1996), the government's Education for All plan is to see that all school age children are enrolled and complete six years of primary education and aims to increase basic compulsory education to nine years so that nearly all primary school graduates will attend secondary school.

There are still some problems in Thailand that need to be addressed through educational efforts. About 3% of children of primary school age in Thailand never attend school. They consist primarily of minority groups of children from the hill tribe population, children of migrant workers, those living in remote areas, disabled children, slum children and other socially and economically disadvantaged children. For those in school major problems are high rates of repeaters and drop-outs, low achievement levels, lack of necessary facilities, personnel and budget, health problems of children due to malnutrition and disease which have affected their
THIRTY FIFTH
London International Youth Science Forum
28 JULY – 11 AUGUST, 1993

The world’s foremost annual meeting for top science students.
Young scientists from schools and universities in some 50 countries share a programme of Lectures, Seminars, Debates and Visits.
A choice is available of more than thirty visits to industrial and academic institutions, including the Universities of London, Oxford and Cambridge.
The programme features over thirty outstanding lecturers, speakers and seminar leaders from Britain and overseas. There are opportunities for participants to present their own research papers.
Participation fees include meals, accommodation in University Halls of Residence in Central London; a Travel Pass giving unlimited free travel on public transport in the city centre; all necessary transport relating to visits and a full social programme. Optional visits to theatres & concerts, and sightseeing visits are arranged at week-ends.

For additional information, applications etc contact
LIYSF, PO Box 159, London SW10 9QX
Tel: 071 373 4568 Fax: 071 835 1070

overall intellectual development.
To help alleviate these problems, on-going innovative projects include:
• establishment of a school cluster system to share resources
• developing schools in rural areas into community development centers
• the Teacher-on-Horseback Project with self study materials for schools in remote areas
• the Self-Reliant School Project
• the School Health Care Program
• the Pre-service and In-service Teacher Training Program

Entrance Examination at various levels
Those who finish their compulsory education at grade 6 may go on to secondary education by passing an examination at the school of their choice. Students in 38 designated provinces who pass the exam for secondary education receive government support in terms of free tuition and learning materials. In the Bangkok Metropolitan area, where there is school zoning, a special quota is allocated to students whose residence is within the school zone.
To continue beyond the secondary level, students must pass an entrance examination, except for the open universities Ramkamhaeng and Sukhothai-Thanamathat. A special

program, the Thai Institute for the Promotion of Teaching Science and Technology (IPST), allows selected gifted students to study an innovative curriculum without fear of the somewhat restrictive entrance exams. On being selected for the IPST program, students are guaranteed admission to university of their choice.

Science education reform in Thailand

In Thailand, as in other developing countries, there are many problems related to insufficient and inappropriate education, especially in the area of science and technology. Nonetheless, Thailand has made some progress in providing science education in order to educate its people to use science in improving their lives and the economy of the country. As Sippanondha Ketudat (1981) stated, 'the general expectation of science education in developing countries is 'science for development' with the purpose of inculcating scientific knowledge and the inquiry approach to people so as to gain a proper response to the basic human and societal needs in harmony with social, cultural and natural environments.'

The Sputnik event of 1957 had a catalytic effect on science education reform in developing countries as well as the developed countries. Since then, many international and regional organizations have participated in forums to discuss the issue of science education in countries in Asia and the Pacific. These forums have had a significant effect on science education reform in several countries as well as in Thailand. In 1971, Thailand, with assistance from UNESCO, established the Institute for the Promotion of Teaching Science and Technology (IPST) in recognition of needs in science curriculum development. The institute played an important role in science and mathematics education reform in the country. From the beginning, its work was concerned with science and mathematics curricula development at both the primary and secondary levels. Later efforts expanded the reform to many areas of specialization and included some aspects of post-secondary vocational education. Examples of course offerings comprised Electronics and Computer Education, Basic Science and Mathematics in Agriculture, Industrial Arts, Home Economics, Arts and Crafts, and Mathematics for Commerce.

IPST is responsible for developing science, mathematics, and technology curricula. Its objectives are

• to develop and improve science, mathematics and technology curricula.
• to promote teaching and learning methods in sciences, mathematics, and technology
• to promote the study and research of curriculum development, teaching techniques and evaluation in science, mathematics and technology
• to promote networking among the institutes of science and technology in the country and with those of other countries.

Curriculum and its development

IPST has been concerned with the development, testing, implementation and follow-up of various courses in science, mathematics and technology for primary, lower secondary, upper secondary and vocational schools. It adopted a systems approach from the beginning to synchronize and provide adequate preparation for the acceptance of the major outputs and provide a clear insight of needed inputs and their timing and to see developmental tasks as an intricate part of the total operation.

In each curriculum, four areas are developed concurrently: writing of students' texts and teachers' guides; evaluation; teacher training; and acquisition of science equipment. All materials are tried out in selected schools and feedback collected for the final revision for full implementation throughout the country. IPST put in great effort designing equipment at low cost. It then commissioned mass production of this equipment using locally available material and manpower. Moreover, the science curriculum content links with real life situations relevant to Thailand by utilizing data and information on Thailand to illustrate scientific concepts, and to present specimens and materials available in local areas for laboratory activities.

The science curriculum

Primary Level

With the educational reform in 1978, science is no longer taught as a subject but is integrated with health and social studies within the life experience area. Comprising 15% of grades 1 and 2, the aims for life experience are to emphasize the problem solving process and the various aspects of human societal needs and problems, for the purposes of survival and leading a healthy and productive life. Life experience time increases to 20% in grades 3 and 4 to 25% of the total curriculum in grades 5 and 6.

Secondary Level

The general objectives in teaching science at the secondary level are:

• to develop an understanding of the basic principles and theories of science
• to develop an understanding of the nature, scope, and limitation of science
• to acquire skills important for scientific investigations
• to develop a scientific attitude
• to recognize the relationship between science, technology, human beings and the environment in terms of mutual interaction
• to be able to apply knowledge of science and technology to society and living.

At the secondary level, where the credit system is in operation, science is required during all 3 years of lower secondary education. There are six 1.5 credit courses, each taught for 3 periods a week. With 40 weeks per academic year, this is about 16% of the curriculum. Science during these 3 years is integrated and includes soil science, conservation, and environmental education. The curriculum also provides many elective science courses for students who are especially interested in science.

At the upper secondary level, all students are required to take 6 credits in science. There are two programs of science curriculum at this level. Program 1 is provided for students who do not intend to study further in science related fields or those who terminate their studies at this level. The students
may select a variety of subjects (each a separate booklet) from physical and biological science courses. They must complete booklets in the ratio of 5 physical science for every 3 biological science topics. Each course meets 3 periods a week.

The science oriented students in Program 2 are required to study 3 core courses in Physics, Biology and Chemistry for 6 credits (2 credits each). And there are elective courses in Physics, Biology, Chemistry and Biological Technology from which students can select according to how they fit into their future plans for higher education.

In all cases, students are learning to adapt technology, use mathematics, and link theory and practice. Much of this through applications of science knowledge.

The curricula for science are developed by the The Ministry of Education (often working with the Science Teachers Section). These curricula emphasize inquiry, laboratories, and applications of science. Some are adaptations of popular and successful books such as CHEMstudy, BSCS, and others. Many in-service efforts are also conducted by the science teachers section.

While most science classrooms are still teacher-centered and university oriented, more and more teachers are heeding the cry of 'Education for All' and are stressing issues, applications, and student-centredness. Even with a severe shortage of school laboratories, teachers are introducing more hands-on activities. As in most countries, this is a time of serious and rapid educational thinking and reform. The Ministry of Education is well aware of the need to enhance science and technology education and is working to improve teacher education, materials, facilities, and opportunities for students. This reform is encouraged by enhanced communication as well as the perceived need as compulsory education is extended into the secondary school.

**Teacher training**

In order to continue improvement in science curriculum development, the quality of teachers is crucial. The IPST plays an important role in training the staff of instructors and in organizing all the in-service training programs, providing teachers' guides, class equipment, audio-visual equipment, video-tapes and filmstrips, as well as supplementary materials for teachers. The IPST uses an integrated approach for inservice programs, the content being integrated with methodology and with evaluation. Concurrently, the IPST with the cooperation of the Thai Teacher Training Department have established Science Teacher Service Centers (STSC) to facilitate the decentralization of certain aspects of IPST's work, including the school follow-up program, continuing in-service education and evaluation of new courses. The 36 STSCs now established are within the existing teacher training colleges throughout the country.

Although the in-service teacher training improved the quality of teachers to some degree, the pre-service program seemed to be a better way for preparing science teachers. In 1977, after considerable experience and feedback had been gained from the in-service teacher training programs of IPST, the Ministry of University Affairs initiated the 'Thai-STEP Project' by appointing project personnel representatives from the faculties of science, mathematics, from every university in Thailand and from the Teacher Training Department to serve as the project team.

The Thai-STEP group accepted responsibility for identifying the competencies needed for successful implementation of the new secondary school science and mathematics curricula and for developing instructional materials to be used in pre-service programs. The working team conducted research for analyzing the pre-post secondary curricula and the teacher training curricula in Thai institutions of higher education. It also researched the competencies of science and mathematics teachers, collected data to set the hierarchy, content and proportion of various courses in the teacher training curriculum, developed guidelines for the preparation of teachers at the pre-service level for submission to the Ministry of University Affairs, and worked on the follow-up of in-service teacher training and the implementation of the new science and mathematics curricula. Fifteen instructional packages or modules to be used in the pre-service education of teachers were produced from the research information related to science teacher competencies. In 1980-1981, these instructional packages were tested and revised. The revised versions have been accepted by the Ministry of University Affairs and the teacher training staff for implementation in the pre-service teacher training program throughout Thailand since 1983.

**The science talent project**

Besides its major role in development of science and mathematics teaching in schools, IPST is also taking part in conducting other important projects in science and technology education development. The most interesting one is the Science Talent Project. Since 1984 the Ministry of Science, Technology, and Energy, the Ministry of Education, the Ministry of University Affairs, with the cooperation of IPST, have been conducting the Science Talent Project with the aim of identifying and nurturing young children who possess a high level of learning ability and show consistently high academic achievement in science. The first period of the project took 7 years from 1984-1990. The project was implemented by the government and extended to a second period of 6 years.

The Science Talent Project will select lower secondary school students with high level academic achievements in science to study in the upper secondary school where the special science and mathematics study programs are provided. After graduating from school, they will be able to further their study in the Faculty of Science at a designated university without taking an entrance examination. They are also encouraged to continue their studies to their highest potential at Thai and foreign universities.

These students receive scholarships which include tuition and fees, personal expenses and books. After graduating at least with a master's degree, they are offered employment with government institutions of science and technology in Thailand. From 1984 to 1992, there were 3 PhD graduates and 18 graduates with master's degrees in science and technology who were sponsored through the project. There are presently 100 graduates students; 30 are working for PhD degrees and 70 are working for the master's degree. In
addition there are 182 undergraduate students and 65 upper secondary school students in the program.

With a renewed emphasis on education, strong reform efforts, and a growing economy, this is, indeed, an exciting time in Thailand.

NEW ICASE PUBLICATION

Education in Science and Technology for Development

Perspectives for the 21st Century

Proceedings of ASEET/ICASE Conference '91

Edited by Judith Reay & June George

This new ICASE publication contains the papers presented at the ASEET/ICASE Caribbean Conference '91 organised by the Association for Science Education of Trinidad and Tobago (ASEET) on 27-30 August 1991 at the University of the West Indies, St Augustine, Trinidad & Tobago.

Papers are grouped in three sections. The first section 'Issues in Education' includes papers which take a broad view of policies and practice. One paper urges teachers to question all 'knowledge'; another identifies the need for universities to articulate better with schools and with industry; another argues for much more attention to technology in schools.

The second section 'Curriculum and Educational Strategies' is closer to the classroom and spans primary through secondary to tertiary teaching.

The third section 'Science and Technology and Education' has more emphasis on science/technology, including contributions on topics as diverse as biotechnology, solar dryers, and a steel drum.

The publication concludes with a set of resolutions arising from Conference '91.

Copies can be ordered from:

Dennis Chisman
Honorary Treasurer, ICASE
Knapp Hill, South Harting
Petersfield GU31 5LR
UK

Price: £6.00 or US$10.00 plus 25% postage and packaging
Member associations and individuals are invited to contribute to this section. Suitable items include brief accounts of specific projects of international significance, science education in a particular country, or international and regional seminars and conferences.

COSTED ICSU

Asian Workshop On
Global Change Education

November 22-27, 1993
Madras, India

Introduction

The ICSU Committee on Science and Technology in Developing Countries (COSTED) has identified Science Education as one of its priority areas for its activities. Over the years, COSTED has developed several teaching materials in the form of slide packages, trainer kits, experimental models, etc. Some of these kits are being used in educational institutions in developing countries. Similar projects are under progress even now. The ICSU Committee on Teaching Science (CTS) has as its main objective the promotion of innovative methods of science teaching all over the world and at all levels. It cooperates with other ICSU bodies and other like minded organisations to further the cause of teaching of science. Among its various activities several good quality teaching materials have been produced in the past. One of its recent projects is on 'Education in Global Change' through which it plans to create in students of the 16-18 age group an awareness in the environment around them, how it works and how it is influenced by natural processes and human induced activities.

CTS has already developed several innovative units of teaching material on Education in Global Change in the form of booklets for teachers with portions for students incorporated in them. These booklets also contain authoritative information about the topics and related issues to extend the knowledge of teachers, and suggestions on teaching strategies.

Booklets on the following seven topics have been developed:

• The Global Carbon Cycle
• Remote Sensing – Window on Global Change
• The Changing Atmosphere
• Clues from the Past – Glimpses of our Future
• Energy Systems
• Population and Land Use
• Oceans

The above CTS study material has been prepared for the teacher - student community at large. Some of these units have been field tested with teachers and students in some European countries.

Objective and Rationale

COSTED, because of its interest in the promotion of environmental education in developing countries, is considering an evaluation of the suitability of the material produced by CTS to meet the needs of teachers and students of the developing world. Therefore the main purpose of the present workshop will be to subject these materials to a critical study by selected teachers from developing countries of Asia and examine changes, if any, to be introduced to make them more relevant and meaningful to the concerned students.

As a first step COSTED and CTS are jointly planning to have a six day workshop in Madras to familiarise participants on Global Change Education and to test the material prepared by CTS. The likely participants in this workshop will be senior secondary and pre-university teachers of science, and science educators from Asia. The teachers where possible, would have some experience in curriculum development and their interest would preferably cover education in scientific disciplines or interdisciplinary subjects related to environment.

It is proposed to send the CTS teaching materials to selected teachers in advance so that they can test them with their classes before the workshop and send back their views and suggestions. Some of these teachers will be invited to attend the workshop and participate in it.

COSTED will also identify a group of teachers/teacher educators from the developing countries of Asia who will be interested in writing additional chapters; they will also be invited to the workshop.

Participation

Participation will be by invitation. The number of participants will be restricted to about 40 including participants from India. To enable the participation of as many countries as possible it is proposed to limit in general the number of participants from each country to two. These will have to be nominated and sponsored formally by the parent institution or country with their recommendation.

Workshop Program

The program will comprise three parts: (1) familiarisation of the CTS project on Global Change; (2) review of lessons prepared by CTS; and (3) attempts to write a few new units.

Report on
International Conference on Geoscience Education
by Dennis Chisman

This conference, held in the University of Southampton, England from 22-24 April, was attended by about 200 participants from 55 countries. It is believed to be the first international conference of its kind.

Among the participants were representatives from developing countries including Africa, Asia, Latin America and the Caribbean. There were also several representatives from Russia, Poland, the Czech Republic, Lithuania and Croatia.

The main themes of the conference were:

- geoscience education in schools
- higher education
- geoscience training for business, industry and services
- public understanding of geoscience

There was also a special session on women in geoscience.

The conference was organised by the Association of Geoscientists for International Development (AGID) and the Commission on Geoscience Education and Training (COGEOED) of the International Union of Geological Sciences (IUGS), in association with ICASE, ICSU and the Earth Science Teachers Association in Britain. The British Geological Survey and the Geological Society in the UK provided some local support. Further support was provided by the ODA, The British Council, The Royal Society, The Commonwealth Foundation and UNESCO, as well as by a number of commercial organisations involved with geological sciences.

The conference began with a number of geological field trips to local places of geological interest. These were followed by a program of lectures, workshops, poster sessions and discussions. Abstracts of papers and posters are given in an Abstracts book, which will form part of a final report to be published later.

The AGID and COGEOED committees are to consider recommendations from the conference for a second international conference on geoscience education.

SOS: Save Our Spaceship Earth
by Mary Lou Biel
Indian Hill School, Illinois USA

The Lake County Business Industry Education Consortium, affiliated with the ISSS (International Student Space Simulation) is located in the USA in the state of Illinois. We are a group of elementary, junior high and high school teachers and pupils who are participating in a Global Environmental, Co-operative Research Project.

We are interested in contacting other countries around the world, as well as our own United States, in an effort to obtain first hand information vital for the success of our project. We are beginning a year long study on the problems affecting the environment of our Earth. We will begin by doing extensive research on targeted global locations and their environmental problems.

After our initial research of particular continents, countries or states is done, we will build simulated biospheres. Within the confines of the biospheres, we will perform experiments relative to the particular global area under study and also gather data from other representative biospheres. We will make comparisons and do problem solving activities.

We are doing this to enhance global awareness among our students and to reach out to others in an effort of sharing our awareness, concerns, and maybe a possible solution or two to the myriad of global environmental problems that concern us all.

Write below for a copy of a data sheet. We would appreciate you completing this sheet, as well as any pictures, maps, articles that would help with our Environmental Project. We will share with you the findings of our research.

Contact Mary Lou Biel, Teacher, Indian Hill School, c/o Lake County Business Industry Education Consortium, 19525 W. Washington Street, Grayslake, IL 60030-1194, USA.
Young people throughout the world are invited to complete this opinion survey and to return it to the address of IASC above.

Teachers and other adults are asked to photocopy this page in order to help this Opinion Forum.

1. There are now more people alive in the world today than have ever lived in total before: (a) Is this idea new to you? (b) Do you believe it?

2. There are more than 5,000,000,000 people alive today, and the population explosion curve shown on this page shows no sign of levelling off:

(a) Do you see this as a serious matter?
(b) Should nature be allowed to take its course, or should measures be taken to help the curve towards a steady level? (Underline the option you support)
(c) List the main consequences you think go with overcrowding.
(d) What population control measures do you think are acceptable?
(e) What population control measures do you think are not acceptable?

3. (a) Do you agree that the greater the number of people, the less the room for wildlife? (b) Does this concern you?

4. (a) Would you like to have children of your own in time? Or (b) how many children do you already have?

5. How many children would you like to have?

6. In view of world overcrowding, how many children do you think you should have?

7. Assuming that it is desirable for all people to have a fair quality of life, and that this does not go with overpollution and exhaustion of resources, what do you consider to be the optimum level for the world's human population?

8. (a) With respect to the possibilities which curve do you think is the most likely to happen? Number......

(b) Which curve would you prefer to happen? Number......

(or draw your own versions on the reverse of your answer page, stating which is 8a and which is 8b.)

9. Please state your:
(a) age
(b) sex
(c) locality (town, county or state, country)
(d) country of birth
The Tellus Syndrome
A Norwegian Project for Environmental Studies

by M Anna Garner
President, The Icelandic Science Teachers Association

The Tellus Syndrome or Earth Syndrome is a multimedia project in environmental studies for educators at all levels, for people working in environmentally related fields including agriculture, industry, public administration, etc., and for adult education organisations and other groups interested in environmental concerns. Colleges and schools could also benefit by selecting materials and ideas from the project.

The project was established to help create a new way of thinking about the environment and about sustainable growth. Based on a report of the World Commission on Environment and Development (Brundtland Commission), the project aims at creating a body of leaders and teachers with competence and understanding in global, national and local environmental issues.

The Tellus Syndrome project is cited in the recommendations of the Third INISTE/UNESCO Nordic Conference on Science and Technology Education as an example of existing or new teaching materials to be developed for wider use.

The project is also relevant to the policy statement on Environmental Education issued last December by the Association for Science Education (ASE) UK.

Developed by the University of Bergen in collaboration with the Norwegian State Institution for Distance Education, the Norwegian State Broadcasting Corporation, the National Film Board and the Gyllestad Publishing Company, the project was launched in Norway in September 1991. The project is now running in its second year and the number of study participants has totalled over a thousand.

Structurally, the study projects are based on extra-mural private study and can be followed on at least four levels of progressive depth. The materials can also be used in the general classroom. The first level can be covered by the general public following the 16 video programs and the 8 radio cassette programs. The second level for non-examination study groups can add basic and supplementary texts along with study guides. The third and fourth levels can lead to accredited courses at various educational establishments, such as universities, colleges of further education and schools. These introductory and advanced courses add more specialised texts, additional video programs, term papers, PC-based test banks, weekend seminars, a week field course and final examinations. In Norway these courses give 2 and 10 university credits respectively.

The cross-curricular themes of environmental education are not always easy to collate. The Tellus Syndrome gives a good base which science teachers interested in developing environmental education programs could use.

The project materials will be on display during the Project 2000 international forum at UNESCO headquarters, Paris in July 1993. It is hoped to make Tellus more widely available in other languages and work is currently in progress on an English version.

NVON Annual Meeting

A report by Jan Hendriks, ICASE European Representative

NVON, the Dutch Association for Education in Science, organised very successful annual meeting on the last weekend of March 26-27 at the University of Amsterdam.

About 300 Dutch teachers participated in the different parts of the program which included workshops (eg about Weather and Climate), lectures (eg about Light Food), and many excursions to local industries, university laboratories and the new Amsterdam Science Centre.

The plenary lecture featured the story of 'The big bang' – an inappropriate name for the origin of the universe. This excellent lecture was all too short for the interested participants!

These annual meetings achieve an important aim of providing an opportunity for colleagues from across the country to meet each other.

The reception was again sponsored by the Dutch Association for Chemical Industry, and the buffet provided an excellent opportunity for informal discussions.

Next August, the first years of secondary education will undergo a curriculum reform. There will be one core curriculum for physics and chemistry, one for biology, one for technology as well as one for each of the other school disciplines (Dutch, English, French and German language; History; Geography; Mathematics; Economics; Domestic Economics; Music; Drawing; Handcraft; and Physical Education).

Some students also study Latin or Greek languages. No wonder Dutch children do not have much time to watch television!

Discussions about the new curriculum will resume again after the first year of operation under the new program.
Seeking New Links
An Open Letter from NSTA's International Activities Committee Chair

by Florence Juillerat
Indiana University/Purdue University, Indianapolis
Indiana USA

Each year the United States National Science Teachers Association sets a theme for the organization's programs. "Science for All Cultures", the agenda for 1993-94, expresses the organization's concern with all groups in the process of improving science literacy. "The Teacher is the Key" (to better science education) was another recent theme. Both of these important ideas are now incorporated in a position statement on International Science Education recently adopted by the organization's Board of Directors. The statement will guide NSTA's international projects in coming years. (See the complete text at the end of this article.)

The position statement's declarations are important to you and to the more than fifty thousand members of NSTA because they are a commitment for change in all of our classrooms. NSTA is interested in promoting formal partnerships and exchanges with science teachers and their associations worldwide and promoting conferences on science education. Within the past ten years, the organization has, for example, initiated seminars for educators in Latin American countries, the United Kingdom, and Japan. NSTA and the Association for Science Education [UK] have a continuing teacher exchange lecture exchange for their respective annual meetings. Recent Moscow and Vancouver teacher conferences are to be followed by one in the summer of 1993 in Oaxtepec, Mexico. These conventions feature formats similar to regular NSTA national and area conventions -- hands-on workshops, featured speakers, and opportunities for one-on-one teacher discussions. And, individual state teacher organizations within NSTA have promoted joint meetings with neighbors across the US borders such as the recent annual meeting of the Michigan Science Teachers Association (US) and the Science Teachers of Ontario (Canada). While some of these outreach projects took place near the continental US to encourage full participation by our members, NSTA is now ready to extend its links to locations much farther afield.

As the incoming Chair of NSTA's Committee on International Activities, I invite you to write me with proposals of locations, themes, and formats for possible teacher conferences in your region of the world. We are interested in traditional as well as more focused conferences such as the "Harare (Zimbabwe) Generator" that drew international innovators, young African science teachers using or developing innovative techniques, and teachers in schools who offered their student classes as activity participants. (For more information on the Generator, see the September 1991 issue of Education in Science, Journal of the Association for Science Education.) Perhaps we should encourage more small gatherings such as the 1986 ASE/NSTA joint seminar where a group of US and UK teachers met together, got to know each other, and planned collaborative projects. The seminar resulted in projects in schools of both countries, a continuing series of follow-up programs, and friendships that continue today!

Science Education International contains advertisements for a variety of conferences sponsored by both broadband and focused organizations -- ICASE, UNESCO, ICPE (International Commission on Physics Education), IOSTE (International Organization for Science and Technology Education), GASAT (Gender and Science and Technology). What international activities can NSTA best organize and provide that will enrich and support current projects by other international organizations or that make the best use of the variety of curriculum resources and classroom experiences of our thousands of US teachers working in a variety of disciplines, levels, and school environments?

The NSTA position statement on international science education also charges the organization, and our committee, with the work of encouraging global transfer of information related to science teaching and learning. Should our work focus more on this objective than the others? How can we reach you more effectively? How can we all best tap into the global network of energetic classroom teachers? Here are a few of the many suggestions that emerged in our committee discussions. They are not meant to limit your vision but to encourage your thoughts. Send your recommendations to help us formulate projects of mutual global classroom benefit.

- Should we, for example, devote future journal article space to highlights of recent NSTA convention sessions of international interest? The summaries would be accompanied by names and addresses of presenters to encourage readers to establish networks of teachers interested in particular curricular or conceptual issues. Is this a more efficient way to promote linkages and information transfer for you than more formal published books of abstracts?
- Should we start a videocassette mailing circuit of convention highlights and "hands-on" workshops? Would videotape programs be used at your local teacher meetings?
- What is the appropriate technology to reach isolated teachers worldwide? Are electronic computer networks and satellite conferences that we might organize to share ideas still too far in the future for you? Is it possible to form alliances with local businesses, industries, governmental agencies, or universities to aid in this endeavor? Access to such computer networks for US teachers, by the way, varies greatly from school district to district and from state to state.
- What classroom exchanges or joint
collaborations are possible between school children in different countries?
Very successful ventures, for example, have occurred in the US between
classes collecting acid rain data, monitoring weather, or studying sand
gains from various geological areas. Students have also enjoyed exchanging
small boxes of mysterious artifacts that illustrate principles of
mathematics, science, or technology operating in distant geographical
regions.
• Or, should we use this article space to advertise the unique projects of
individual teachers looking for global collaborators or to seek solutions to
particular problems teachers are having developing science concepts?
With these ideas in mind, I invite you, on behalf of my committee members,
to suggest what activities we might undertake for mutual benefit. Please
share your ideas with us.

MNU Annual
Meeting
A report by
Jan Hendriks
ICASE European Representative

About 1500 teachers of mathematics
and science attended the 84th annual
meeting of MNU, the German
Association for Education in
Mathematics and Sciences, 4-8 April
1993, at the Technical University
of the united capital of Germany, Berlin.
The opening ceremony at the Congress
Centre for Education featured a lecture
by Prof Dr Stock, Schering AG, about
genetic technology (and a recital by
the school orchestra of Carl Philipp
Emanuel Bach Gymnasium).
On the first afternoon, about 60
participants joined the ICASE
Symposium. Chemistry
demonstrations were presented by Ludo
Brandt, Jean Jansen and ElisaPauwens
of the University of Leuven, Belgium.
Fred Archenhold, University of Leeds,
UK presented an evaluation of science
teacher education. Onno de Jong,
University of Utrecht, The
Netherlands summarised research
about difficulties in translating
scientific concepts to the learning
abilities of secondary students.
This successful ICASE Symposium
was organised by Prof Dr Hans-Jürgen
Schmidt, University of Dortmund,
who has long been involved in
international activities in science
education. Lectures were presented in
German and this contributed to the
large delegation of German teachers
attending the discussions.
The program featured lectures,
demonstrations, workshops and
excursions relating to mathematics,
physics, chemistry, computer science
and astronomy.
Participants came from Germany (both
East and West), Austria, Switzerland,
France, Belgium, Luxembourg, The
Netherlands, Italy and the United
Kingdom.
The next MNU meeting will be held
from 28th to 31st March, 1994 in
Karlsruhe.
Evaluation of the educational benefit of a special exhibition at an interactive science centre

by R A Schibeci

The role of non-school sources of science learning, including interactive science centres, continues to be a source of interest. Such centres are one of the many sources of what is generally termed informal sources of science learning. The interest in such out-of-school sources of science education continues (Lucas, 1991).

The role of interactive science centres has been questioned by some (see, for example, Shortland, 1987). In order to arrive at a fair judgement, however, it is necessary to examine what evidence there is to support the educational role of these centres. This report is a contribution to the growing literature on the educational impact of interactive science centres.

Interactive science centres

As Bhattacharyya (1988) noted, the word 'museum' has associations with 'musty, dusty, dingy places'; they are often filled with 'rows upon rows of static technical devices of a bygone age or jars full of pickled animals or plant specimens or stuffed animals'; visitors are encouraged to gaze silently on these exhibits. The newer kind of museums are characterised, according to Bhattacharyya, by a number of features which include: an emphasis on contemporary science and its technological applications; encouragement of visitors to 'interact by pushing buttons, turning cranks, lifting levers'; and, an emphasis on scientific principles and processes, not just static display. These centres also offer educational programs usually oriented towards local schools.

Scitech Discovery Centre in Perth, Western Australia, is one of the new breed of interactive science centres. 'Sports Works' was a major exhibition planned and built by Scitech. There were sixteen exhibits, complemented by a program of special events. The focus of the exhibition was on health, sports, fitness and exercise. It was designed to help people appreciate how their bodies can benefit from exercise and the particular skills that are involved in a variety of sports.

Aim

The aim of the evaluation study reported here was to assess the impact

Valuable insights on teaching and learning may be gained from research and it is the aim of this section to bring significant research information to the attention of science teachers, with a view to helping them in their important work.

of a Scitech visit on the knowledge of a group of school students and a group of adults. More specifically, students and adults were asked to work through a pre-determined pathway, which constituted a subset of the Sports Works Exhibition. The focus of the evaluation was on the knowledge of these adults and students of some general health issues, and what their perceptions were about the link between exercise and health.

Sample

School students

It was decided to include some primary and some secondary students in the sample. Year 6 and Year 9 students were chosen, as these would cause minimal disruptions to the schools concerned.

Students from six schools were involved. A year 6 class from each of three primary schools and a Year 9 class from each of three secondary schools participated in the evaluation.

The schools were chosen to draw from populations from quite different areas of the metropolitan area of Perth, Western Australia. All were government schools.

The three secondary schools were selected because the Head of Science was known personally by the secondary education officer at Scitech Discovery Centre and it was anticipated that each would be willing to involve a Year 9 class in the evaluation study.

The three primary schools were selected at random from a list of schools in their respective suburbs. At each school, the principal was asked to nominate a Year 6 class. As for the secondary school classes, a requirement was that the class had not previously visited the Sports Works exhibition at Scitech as part of a school excursion. Also, classes were chosen so that they consisted largely of students of average ability for that year group.

A total of 171 students participated; from these, there were 151 useable responses. Of these 151 students, 52 per cent were female.

Adults

Initially, the intention was to approach existing adult groups (such as hobby or other special interest groups) to participate in the evaluation study. Such intact groups would facilitate any necessary follow up. However, despite numerous approaches, one intact group only participated, the members of a bowling club. The remainder comprised a sample of adults who visited Scitech without any approach from an evaluation team member.

A total of 137 adults were approached, from whom 107 useable responses were obtained. Of these 107
respondents, 63 per cent were female.

Procedures

Students

All students sat for a pre-visit and a post-visit test in their normal classroom. The tests were administered within two to three days of the visit. At SciTech, students worked through an especially designed Sports Works ‘Pathway’, which was indicated on a map provided to them. This was followed by the viewing of a Sports Works demonstration. This visit lasted between 90 and 120 minutes. The students, teachers and other adult supervisors were admitted into SciTech free of charge in exchange for taking part in the study.

The first part of the student questionnaire consisted of 15 multiple choice questions related specifically to the set of the Sports Works exhibits in the pathway. Sample questions were as follows:

A healthy heart, compared with an unhealthy one,
(a) will pump more blood with each heart beat
(b) pumps redder blood (blood with more oxygen)
(c) does not pump as much blood with each heart beat
(d) is identical in appearance

In a short running race, a fast start is very important. To start the race quickly, it is best to use
(a) a standing start
(b) a standing start and starting blocks
(c) a crouched start
(d) a crouched start and starting blocks

The second part of the questionnaire contained a series of questions that asked them to nominate whether they participated in a range of activities, as well as asking them whether they thought these activities might be related in any way to health.

Adults

In addition to the members of the bowling club, a sample of adults who visited SciTech were approached to take part in the study; this occurred on four different days. They were invited to participate in the survey in exchange for free entry. They were asked to fill in a pre-test, follow the (student)

pathway through the exhibition on a map provided to them, and finally to complete a post-test.

The first part of the adult questionnaire consisted of 10 multiple choice questions. The second part included a series of questions on activities and sports they participated in, and possible links between these activities and health. Common to both the student and adult multiple choice questions were four that dealt with general health issues, and three that dealt with exhibits in the pathway; these seven questions were designed to allow a direct comparison between student and adult responses.

Ten of the adults who participated were contacted two weeks later by telephone to check on the responses provided in the questionnaires.

Results: multiple choice questions

Students

Summary statistics for the 15 multiple choice questions are given in Table 1. Of the 15 questions, four were related to general health; a score was computed for this scale (HEALTH). The remaining items related to specific exhibits; a separate score was computed for this scale (EXHIBIT).

Finally, a total score (TOTAL) for the 15 questions was computed.

T-test comparisons revealed that the difference between each of these three pairs of means (pre- and post-test) was statistically significant. Analysis of these data by gender showed two statistically significant differences only, on the mean scores for pre- and post-test values for EXHIBIT, respectively. As expected, the mean scores for the Year 9 students were uniformly greater than the corresponding values for the Year 6 students.

Adults

The first part of the adult questionnaire comprised ten multiple choice questions. Of the 10 questions, four related to general health; a score was computed for this scale (HEA). The remaining six items related to specific exhibits; a separate score was computed for this scale (EX). Finally, a total score (TOT) for the 10
questions was computed. Summary statistics for each of these three scales are given in Table 1.

Comparison of adult and student results

In the multiple choice section, there were seven items common to the student and adult questionnaires. A score was computed for the four items related to health issues (HEAL), and a separate score computed for the three items related specifically to the exhibits (EXH).

T-test analyses revealed that the mean values for both the health (HEAL) and exhibit (EXH) scales on the pre-tests were higher for the adults than for the students, and that these differences were statistically significant. However, there was no statistically significant differences in mean values for these scales in the post-tests.

Summary statistics for these two scales (HEAL and EXH) are given in Table 2.

Results: remaining questionnaire items

Students and adults: health and regular exercise

Both students and adults were asked to give reasons why they thought there was a connection between regular exercise and health. The responses were grouped into five categories. The reasons (with per cent in parentheses) given by 151 students who gave useable responses were: Keeps one fit/healthy (34.6); Burns cholesterol (17.3); Burns fat (9.6); Works muscles in the heart (7.7); Keeps heart rate/blood flowing (4.5); No response (26.3).

Of the 107 adults, 70 gave some responses to these questions. These responses were categorised. The reasons (with per cent in parentheses) given by these adults were: Keeps one fit/healthy (61.4); Keeps heart rate/blood flowing (12.9); Burns fat (8.6); Increases oxygen in the blood (7.1); Works muscles in the heart (7.1); Increases self esteem (2.9).

Adults

In response to the question, 'Where would you go, or whom would you contact, if you wanted more information on health issues?', 54.7 per cent nominated a 'doctor' and 28.0 per cent government departments. Other sources nominated were: fitness centres/gyms (6.7 per cent); library/books/TV (5.3 per cent); hospital (2.7 per cent); heart foundation (1.3 per cent); and, universities (1.3 per cent).

When asked to nominate sports they were currently active in, 41.6 per cent nominated 'none'. Apart from lawn bowls (nominated by 27 per cent), no individual sport was nominated by more than six per cent of the sample. Those who nominated lawn bowls would have been members of the only intact adult group to take part in the survey.

Discussion

Student mean scores on both general health questions and exhibit-specific questions showed a statistically significant increase over the two test occasions. However, the pre-test scores were relatively high, which indicated that students were generally well educated in the area of health covered by the Sports Works exhibition. The Scitech visit appeared to reinforce this knowledge, as well as produce a modest increase in mean scores.

Adults showed no such increase. They, too, appeared to have a good general health knowledge, but this did not increase as a result of the Scitech visit. This may be explained in part by the methodology employed with the adults. As indicated earlier, the original intention had been to approach existing adult groups to participate in the evaluation study. However this turned out not to be possible, and so the evaluation team resorted to approaches to adults as they visited Scitech. This procedure was not satisfactory, as respondents filled in the pre-test at the entrance to Scitech, and filled in the

post-test inside the Centre, where it was noisy and distracting. Further, many who completed the pre-test did not complete a post-test, despite the free entry provided in exchange for participation. For example, on one of the four occasions when data was collected, 70 adults completed pre-tests, but 50 only of these completed the post-test. Clearly, this is an inefficient procedure. Future evaluations will need to consider other ways of attracting adult groups.

Investigation of adults' knowledge and perceptions is important, as there is a need to add to the existing data in this area (for example, Schibeci, 1990). However, alternative methodologies need to be explored with adults in future evaluation studies. It may be that adults do not see the science as it is presented in exhibits as relevant to them, and that they need opportunities to 'reconstruct' the knowledge in ways that makes it useful to them (Layton, 1991).

In general, then, this evaluation study supports the view that there is an educational benefit to school students of a directed visit to Scitech. This adds support to the findings of the earlier evaluation study at Scitech (Dymond, 1991).

An additional finding is that students appear to be well educated in the general health area covered by the Sports Works exhibition; for this, it is likely that schools and their teachers can take the credit.

With adults, the study reveals that no increase in knowledge resulted from the visit, although adults appeared also to be well educated in the general health area covered by the Sports Works exhibition; this was confirmed through the telephone interviews.

Further, these interviews indicated that adults go to Scitech either to take their children or to take visitors. That is, these adults do not go to Scitech with the intention to be educated.

It is important to continue evaluations of the impact of learning of interactive science centres. We need to know how interactive science centres can be effective when they are used as an adjunct to the science classroom with school students. The centre becomes, in effect, a giant classroom.

Are there other ways in which these centres can contribute to science and technology education? Does Shortland's (1987) claim, that they are places of entertainment, have any validity?

The Iowa Chautauqua Program
A Model for In-service Science Education

by Robert E Yager

If real reforms in science education are to occur, teachers must change. They must change their ideas about the meaning of science and their views of effective teaching. Most educational reforms undertaken during the past two centuries have resulted in little real change even though the goals and ideas of the reformers were articulated well. We have never been successful with educational reform. We have never identified programs that have been effective in stimulating change in teachers who ultimately determine if changes in the classroom are to occur.

Too often anticipated change is defined by new curriculum frameworks. Across the world curriculum committees – often established by government ministries of education – are at work producing new courses and course sequences that teachers are expected to follow. The contention is that if teachers use the new and improved materials that reform will have been accomplished. A long history suggests the fallacy of this logic.

Yager (1988) found in studying in-service educational models that the most effective ones were elective ones that teachers sought out and ones that lasted more than a few days. The study also identified the importance of having some of the most innovative teachers as vital parts of the instructional team. Such teachers provide the perspective of teachers who are faced with daily problems and direct experience with dealing with them. They can provide concrete examples rather than theoretical suggestions. They can provide enthusiasm and living examples of the changes needed in terms of setting goals, perfecting new instructional strategies, analyzing new materials, and devising more authentic assessment tools.

This section focuses on the pre-service and in-service education of science teachers, and aims to communicate ideas and strategies which will assist science teacher educators to enhance and enrich their pre-service and in-service programs.

This was the setting when the Iowa Chautauqua Program was conceived. An in-service model was sought that could help K-12 teachers move to Science/Technology/Society (STS) teaching and programs. Three STS teachers were found and prepared for Lead Teacher roles in the project. Outside STS leaders were identified to assist center staff in establishing the model. The Iowa Chautauqua Program was initiated in 1983 and has enrolled over 2,000 K-12 teachers during the nine year period.

Today the Iowa Chautauqua Program is an in-service model that spends a full year of time with several specific features. Basically the model includes the following:

- a two week leadership conference for the most successful teachers who will become a part of future staff teams
- a three week summer institute where 30-50 teachers will experience STS as students (while also learning about the use of educational technology, human resources, and new assessment strategies)
- a week long experience with STS instruction in the school headed by each teacher enrolled
- a three-day short course in the fall after teachers have completed their five-day STS experience as they plan for a month long STS module
- the four to nine week STS experience in schools with pre/post assessment data, including video records
- a three-day short course in the spring to share results and to assess the general successes with STS in schools.

The Iowa Chautauqua Program operates in the State of Iowa (Central USA) which is divided into 15 Area Education Agencies (AEAs). These AEAs are regional centers responsible for providing special education and administrative services to all schools in their regions. These school districts number from 18 to 57. The Chautauqua instructional sequence is undertaken in each area of the state every three years. During the year after an active Chautauqua Program, the Lead Teachers remain in contact with the ten new teachers for whom they served as mentor. The following year the leaders are helping prepare other leaders from the last Chautauqua ranks and planning for the next program. There is a continuing dialogue about the program and some grass roots promotion seeking out new volunteers/participants in the next Chautauqua sequence.

In a very real sense it is the collaboration and team approach responsible for the change. Teachers are helped by the most successful student-centered teachers in the year long sequence. Teacher enrollees help define the real issues preventing reform and change; they also help develop correctives which they try and evaluate. The structure of the Chautauqua Model is less important than the processes which are modeled by the entire staff team.

The Chautauqua program seeks to accomplish certain specific objectives.
These include:

- increased confidence in K-12 teachers to teach science
- a greater understanding on the part of teachers and their students of the basic ingredients of science (i.e., questioning, explaining, testing ideas)
- more focus on career awareness relative to science and technology
- more concern for positive student changes in six domains of science education.

The domains identified as outcome goals for science courses include:

- Concept domain (mastering basic content constructs);
- Process domain (learning the skills scientists use in science);
- Creativity domain (improving quantity and quality of questions, explanations, and test for the validity of personally generated explanations);
- Attitudinal domain (developing more positive feelings concerning the usefulness of science, science study, science teachers, and science careers);
- Applications and connections domain (using concepts and processes in new situations); and
- Worldview domain (formulating an accurate picture of the nature of science and technology).

Significant improvements are attained in all STS classes in these six domains when compared to situations where science is approached in more traditional ways.

The Iowa Chautauqua Program is viewed as a model worth emulating for the following reasons:

- over 95% of the 30-50 teachers enrolled at each site complete the entire sequence
- all who complete the sequence report significant changes regarding their perceptions of their own teaching
- in excess of 90% of all participants report (with actual assessment scores) positive changes in their students who experience STS and the new mode of teaching it requires.
- nearly 20% from each in-service group excel and aspire to leadership for further projects in their AEA
- Administrative, parent, and business/industrial leaders become active collaborators in the reform.

Student changes include:

- demonstrated mastery of basic concepts
- ability to define and to use basic process skills
- ability to use basic science concepts and processes in new situations
- growth in creativity skills, including greater questioning, ability to explain, and ability to devise tests for explanations generated
- more positive attitudes about science study, careers, and science teachers.

In summary, the Iowa Chautauqua Program utilizes the following features which are suggested as important as improved models for enhancing K-12 science teaching are contemplated

- introduction of new materials and teaching strategies by example (i.e., teachers being taught in ways we would like them to teach) during summer workshops
- a chance to try new materials and procedures for a short period of time early in the fall (five days)
- a full short course where a longer (30 days or more) innovation is planned which also includes assessment planning
- a 30+ day module structured and taught while in touch with a mentor teacher (one mentor for ten new teachers)

- a spring short course where materials, experiences, and formal assessment results can be shared
- a chance to participate in leadership training for a future Chautauqua Program

The evidence is striking that such a program makes a tremendous difference. Chautauqua-type in-service programs can provide the vehicle for real reform. Could professional societies (as represented in ICASE) be the vehicle for promoting Chautauqua programs that assist with reforms?

27
Developing Primary Science in Pakistan
by Hafiz Muhammad Iqbal

Introduction
During the last decade or so, we have witnessed a growing concern for science teaching at primary level. In the past either science was missing from primary school curricula or it was left to the choice of individual teachers. Where it was included in the primary school curriculum, it was taught as a passive activity. With the approach of the 21st century, national governments as well as teachers and teacher educators are committing themselves to improving primary science by putting more emphasis on the process rather than the product. The work of organizations and individuals like UNESCO (1983), DES (1985), ASE (1983), Hodgson and Scanlon (1985), Harlen (1980) and Garson (1988) provide evidence of efforts to improve primary science.

In Pakistan since the mid-seventies, science has become a compulsory component of the national curriculum from grade one through to grade eight. From grade nine onwards, students opt for the science stream because of its role in securing jobs. Science after grade eight is more rigorous and abstract compared to lower level science. Students at secondary level cannot demonstrate the desired level of performance in science because of its weakened component at primary and lower secondary level. Due to a multitude of financial and professional constraints, science at this level was not activity oriented.

Primary Education Project
The need to improve primary science was realized in the mid-eighties. In a needs assessment study, the following factors were identified:
- poorly trained teachers
- poor teaching environment
- inadequate resources
- little or no supplementary reading material in schools or in the home environments of both teachers and students
- no use of teachers' guides or handbooks
- lack of research data on the socio-economic and classroom conditions or behaviour
- inadequate and ineffective INSET programs
- teaching based on rote learning
- assessment geared to testing memorization

With the help of the World Bank, the Primary Education Project was launched in 1987. This project encompasses the development of new curricula, providing building for shelterless schools, training of teachers for new curricula and developing improving primary school kits to incorporate new activities provided in the newly developed curricula. Under this project, for the first time in the country, efforts are being made to strengthen primary education taking into consideration local and national contexts. A number of research studies related to teachers' performance, students' achievement, socio-economic conditions and incentives for primary school teachers are being conducted to give a research base to these developmental efforts. Three separate text-books are to be produced for classes 1-3 following an integrated approach to curriculum. Language, SS and RE are to be included in one subject/textbook and Maths and Science in two different books.

Approach to Science
For developing new science curricula for classes 1-3, the following objectives have been formulated:
- understanding of scientific method and development of a range of basic skills, and relevant content
- awareness of natural resources, their use and conservation
- an understanding of environment and the interactions among human population, plants and animals and the physical conditions.
- understanding the need for communication and transportation as essential elements in development
- understanding and participating in physical activities.

Efforts are being made to weave together appropriate knowledge, concepts, and process skills. The new TLR provides a sufficient body of knowledge and requires candidates to demonstrate a sufficient range of scientific skills, including inquiry, observation, curiosity, simple classification, communication, recording information and problem-solving. Activities suggested are based on the student's prior knowledge of things in their immediate environment, mostly from the rural context.

Evaluation of TLR
Following the development of new curricula, Teaching Learning Resources were developed which are under trial in selected schools. These TLRs include a workbook for pupils and an accompanying teacher's guide which acquaints primary teachers with the rationale and strategies for arranging activities for pupils involving locally available material or the material supplied in the school kit. In developing new TLRs, local experts, foreign consultants and practising primary teachers have been involved. The material will be revised in the
light of feedback received. The flow chart shows steps undertaken to develop new TLRs.

This arrangement is a new experience for Pakistan and it is yet to be seen to what extent these efforts will be successful. One thing which is very clear, however, is that there is a communication gap between local personnel and foreign consultants. Whilst being competent and experienced educators, their lack of knowledge of the Pakistani context limits the effectiveness of their contributions to the development of a sound science program for Pakistan.

Stepping into Science
An ICASE Primary/Elementary Science Project

AIMS
Stepping into Science is an ICASE project which aims to:

• Establish an international network for teachers to share ideas on the teaching of primary/elementary science and technology.

• Provide activities and support for teachers, thereby encouraging them to include more science in the primary/elementary curriculum.

• Promote the value of science experiences for young children throughout the world.

• Facilitate professional development opportunities for teachers by including sessions on primary science and technology in regional and international conferences.

ACTIVITIES
The Stepping into Science Team is actively involved in a number of projects and activities including:

• Publishing STEPS, the Stepping into Science Project Newsletter. This newsletter contains ideas for class activities at various levels in primary/elementary schools, activities for children to do at home, comments by network members on issues, examples of children’s work, lists of helpful resources and contacts. ICASE acknowledges the contribution of Philip Harris in sponsoring STEPS.

• Contributing articles and ideas for the Primary Science Section in Science Education International, the ICASE quarterly journal.

• Compiling ideas and activities for inclusion in a series of sourcebooks on the teaching of primary/elementary science and technology.

• Coordinating a scheme to encourage children to participate in science and technology activities. Certificates of Participation have been produced, and are available for schools to use in rewarding students as they complete a number of activities. Certificates are colour coded in seven different colours, so that they can be used to acknowledge progress in science from early to advanced levels within primary/elementary schools. ICASE is grateful to BP (Oman) for sponsoring this scheme.

• Organising Stepping into Science workshops and displays of children’s work at national, regional and international conferences.

Young reporters for the environment
Observing science while it happens

by Philippe Saugier,
Foundation for Environmental Education in Europe

The Foundation for environmental education in Europe (Fee) conducted a pilot experience called the 'Ozone Project' from 1990-1992. Its promising results have led to the creation of a permanent network of secondary schools under the title 'Young reporters for the environment'.

The Ozone Project: a thousand European students take an inside look at research on polar ozone

What's happening with ozone over the North Pole? Some unusual visitors went to the heart of the research campaign of the European Arctic Stratospheric Ozone Experiment (EASOE) to find out. About fifteen young people - gathered from as many secondary schools across Denmark, Finland, France, Germany, Latvia, Norway, Poland, Sweden and Switzerland - visited the polar laboratories of the EASOE in the very north of Scandinavia to observe the process of data collection from the balloon probes, aircraft labs and ground based instruments which sounded the upper atmosphere during the winter of 1991-92.

A total of three missions provided them the opportunity to observe closely the development of this information and the availability of the scientists who assisted these enthusiastic young people enabled the students to produce living articles about complicated scientific issues.

The inquiries of those visiting the polar laboratories were guided by those they represented through a computer network which was made available by the University of Copenhagen. Despatches, articles and reactions were exchanged there everyday and then gathered into a multilingual newspaper which was published by the students every two months. Each team had carefully prepared the missions by undertaking inquiries in their own school, town and country. The young journalists interviewed leading scientists, members of the government and industrial managers about environmental issues. In this way, they developed an increasingly deeper insight into the causes of the problem and thus formulated appropriate questions.

Financed by several French Ministries (Research, Environment, Education, Youth Foreign Affairs), the 'Ozone Project' showed the willingness of youth and teachers to obtain a deeper insight into the activities of scientific research. It provided an opportunity for these people to inform the public through an original enquiry linking several key fields across Europe - education, environment, science, journalism, new technologies. The success of the first project has resulted in the Council of Europe commissioning Fee to publish a 50 page booklet recording the project as an example of a successful integration of environmental education with the European dimension. This booklet is to be distributed to teachers and institutions in thirty-five different countries.

Towards a permanent network of young reporters

The ozone project provides a new concept in research experiments. Its efficiency proven, Fee defined the main features of a new, broad, long term international program. 'Young reporters for the environment' encourages young Europeans in secondary schools to act for a better understanding of global environmental issues, by committing themselves together with their teachers to the following innovative educational program:

- Facing the real world through studying human interactions with their environment, through means of journalistic enquiries which go beyond usual documentary sources, and through field missions.
- Bringing the scientific community closer to their support base - the general public - and to the teaching of science by taking up their willingness to share their field work.
- Involving oneself in strengthening Europe through exchanges utilising the most advanced technologies of communication to enhance intercultural dimensions.
- Promoting environmental studies in schools, by revealing its pedagogical potential to teachers, and working with teachers to help them implement such programs.
- Contributing to the development of community attitudes through quality programs.

Topics

Encouraged by the success of the 'Ozone Project', the 1993/94 project will focus on the general theme of the influences of human activities on the global environment. Each topic will include a focus on local investigations and field missions based on major scientific investigations. Topics under consideration include:

- simulating an accident involving the release of a radioactive cloud over Europe (air pollution, nuclear energy, nuclear safety)
- stratospheric ozone experiments
- oceanographic projects (greenhouse effect, global change, oceans, pollution in seas)
• fusion energy
• renewable energies
• environment and development

Organisation

The program is organised at the national level by official member bodies of Feee. A coordinating secretariat is funded at the international level. Denmark, France, Greece, Italy, Norway, Portugal, Spain and Turkey are planning to participate during 1993-94. Teachers from these countries are welcome to contact Feee.

Schools in other countries are also welcome to join as informal associate participants or as correspondents. Feee is looking for new operators to join the program at the organisational level and to implement programs in other regions of Europe.

Future developments

Since Feee has a strong vision for promoting its program to schools as well as the general public, it welcomes the development of links with ICASE. The ICSU-CTS project 'Education in Global Change' provides an opportunity for Feee to establish valuable links with CTS.

Feee looks forward to its participation in the International Forum for Project 2000+ to be held during July 93 in Paris. This will provide an opportunity for us to extend our activities beyond Europe.

For further information

A 50 page report on the ozone project 'synthèse du projet ozone' is available in French at the above address.

About the author

Philippe Saugeir is the Chargé de mission Feee and can be contacted at address above.

Measuring ozone in the atmosphere

100 km from Kiruna is a little town called Abisko – the site of a Swedish scientific research centre. This centre is connected to the EASOE campaign – the European Arctic Stratospheric Ozone Experiment. The use of a 1 metre telescope (photo above) is helping to measure, among other things, the amount of ozone in the atmosphere.

When light enters the telescope it hits some large mirrors, which reflect the light onto a smaller mirror, which again reflects the light into a little hole at the end of the large mirror. Behind this hole there is a spectrometer, which divides the light into its different wavelengths which subsequently get measured. On the side of the telescope, there is a hole through which scientists can look through to find the star whose light they wish to measure. In a building nearby, 2 computers follow the measurements – one to control the telescope's direction to track the star, the other to collect the data from the telescope. Using known information about the star's spectrum outside the atmosphere, and known information about the different levels of light absorption for the elements in the atmosphere, scientists can calculate the content of ozone and other gases in the atmosphere. Two types of stars are used in their measurements – hot stars (12000 kelvin) and cold stars (6000 kelvin) because hot stars have most of their light in the blue part of the spectrum, and cold stars have most of their light in the red part of the spectrum. In this campaign, hot stars are usually observed because UV light is in the blue part of the spectrum.

This information is an extract from an article by Anders Poulsen, provided by Philippe Saugeir, Chargé de mission, Feee.

The cartoon comic in French on the next page was developed by one of the students participating in the Foundation for environmental education in Europe (Feee) program 'Young reporters for the environment'.
LA COUCHE D'OZONE
par le professeur Eugène Mortibus

En effet, sous leurs actions, les molécules de CFC sont AMPUTÉES d'une molécule de chlore !

Aussitôt les molécules de chlore sont EMPRISONNÉES, par une molécule de NOx.

Mars les nuages STRATOSPÉRIQUES les libèrent rapidement.

le chlore va aussitôt attaquer les molécules d'ozone...

... qui explosera en deux parties...

... et le chlore rentrera à la base...

... le CFC a retrouvé son pouvoir destructeur...

... et va détruire ainsi plusieurs autres molécules d'ozone, ZNK! ZNK!!
**What is the Secret of Life?**

WGBH-TV will present *The Secret of Life*, an eight-part series premiering on public television stations nationwide in the United States in fall 1993. (Check with your local PBS station for exact airdates and times). The series, known as *Life: Cracking the Code* in the United Kingdom, will also be broadcast on BBC-TV.

Hosted by geneticist and television personality David Suzuki, this series explores the "new biology" for both scientists and non-scientists and defines the moral, financial and political implications of this new technology.

To extend the educational impact of the series, WGBH is offering free print materials for science and social studies teachers. A 32-page secondary school teacher's guide, with activities and discussion questions, will help teachers tackle the very important issues and ethical questions that the 'new biology' raises. A full-color classroom poster with reproducible hands-on activities and a special elementary school teacher's contest will help teachers introduce simple genetics concepts to elementary school students.

**NEW ICASE PUBLICATION**

**Empirical Research in Chemistry and Physics Education**

**Proceedings of the International Seminar**  
**10-12 June 1992**  
**University of Dortmund, Germany**

Edited by  
Hans-Jürgen Schmidt

This new ICASE publication contains the papers presented at the International Seminar on Empirical Research in Chemistry and Physics Education held at the University of Dortmund, Germany, June 10-12, 1992. The papers reflect very different research methods. Titles include:

*Dale R Baker*  
Learning science; insights from research on teaching and assessment

*Robert W Fairbrother*  
Criterion-referenced assessment: a case study of the English National Curriculum

*Myra L Halpin*  
Strategies students use to solve chemistry problems

*Hanno van Kuehen*  
The educational structure of organic synthesis

*Gerhard Meyendorf*  
Students' abilities in working with chemistry textbooks

*Michael D Pihurn*  
Meta-analytic and multivariate procedures for the study of attitude and achievement in science

*Iris Pigeot*  
Correlation and causality

*Peter van Roon*  
'Work' and 'Heat' in teaching thermodynamics

*Elisabeth Schach*  
Methodological aspects of University of Dortmund studies of students' conceptions of chemistry

*Amos A M Shaibu*  
A study of the relationship between conceptual knowledge and problem-solving proficiency

*Rodney B Thiele & David F Treagust*  
Analogies in senior high school chemistry textbooks: a critical analysis

Copies can be ordered from:

Dennis Chisman, Honorary Treasurer, ICASE  
Knapp Hill, South Harting  
Petersfield GU31 5LR, UK

**Order from:** ICASE Publications  
Knapp Hill, South Harting, Petersfield GU31 5LR, UK
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

**1993**

**June 27 - July 3**

**VII Pacific Science Inter-Congress**  
Location: Okinawa Convention Center, Okinawa, Japan  
Contact: VII Pacific Science Inter-Congress, c/o Section of International Affairs, University of the Ryukyus, 1-Senbaru, Nishihara, Okinawa, 903-01, Japan  
The Symposia will be organised around the theme *The Pacific: Crossroads for Culture and Nature* and subthemes (1) Cultural Interchange among Pacific Peoples; (2) Speciation, Dispersal and Conservation of Species in the Pacific; (3) Towards Appropriate Technologies and Policies for Development and for the Conservation of Natural Environments in the Pacific. Scientific sessions organised by the Scientific Committees of the Pacific Science Association focus on a range of science disciplines and issues, including Science Communication and Education.

**July 6-10**

**Project 2000+ International Forum**  
Location: Paris, France  
Contact: Dr Jack Holbrook, Project 2000+, Science and Technology Education Unit, UNESCO, 7 place de Fontenoy, 75352 Paris 07SP, France  
This worldwide conference, organised by ICASE in conjunction with Unesco and other international bodies is the second phase of the three phase Project 2000+. The theme of the forum addresses the issue of Scientific and Technological Literacy for All. Sessions will establish agendas for future action. Attendance will be by invitation only. The forum plans to issue statements to affect political visibility for science and technology education for all as a requirement for national development, and provide a framework for major programs of action in science and technology education involving governments, IGOs and NGOs.

**July 8-11**

**ASERA 93**  
Location: The University of New England, Lismore, NSW, Australia  
Contact: Keith Skamp, Conference Convenor, ASERA 93, Centre for Education, UNE - Northern Rivers, PO Box 157, Lismore, NSW Australia, Fax 066-221-833  
The Australasian Science Education Research Association (ASERA) invites all those with an interest in science education research, including primary and secondary teachers and teacher educators to participate in the 24th Annual Conference of ASERA.

**July 28 - August 11**

**London International Youth Science Forum**  
Location: London, UK  
Contact: LIYSF, PO Box 159, London SW10 9QX, UK  
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.
July 19-24
International Conference of Physics Education on Light and Information
Location: Braga, Portugal
Contact: GIREF 1993 Conference Local Committee, Universidade de Minho, 4719 Braga Codex, Portugal
The conference is sponsored by the International Union of Pure and Applied Sciences (IUPAC), the International Group for the Advancement of Physics Teaching (GIREF), the European Physical Society (EPS) and Sociedade Portuguesa de Fisica.

July 31 - August 5
Gender and Science and Technology Conference: GASAT 7
Location: Waterloo, Ontario, Canada
Contact: Ann Holmes, GASAT 7, Ontario Women's Directorate, 480 University Avenue, 2nd Floor, Toronto, Ontario M5G 1V2, Canada
GASAT's seventh conference is entitled 'Transforming science and technology: our future depends on it'. GASAT provides a forum for individuals and organisations concerned about the inclusion of girls and women in the world of science and technology, from early childhood to work environments. Four areas focus on: (1) recruitment and retention of girls and women in science, engineering and technology; (2) developing a feminist perspective on science that recognises the diversity of experiences of women, girls and indigenous peoples; (3) creating a more inviting climate for work and study, and developing strategies for change; (4) gender sensitive science, engineering and technology curricula.

August 15-20
34th IUPAC Congress
Location: Beijing, China
Contact: Prof Xinqi Song, Secretary-General of 34th IUPAC Congress, c/o Chinese Chemical Society, POB 2709, Beijing 100080, China, Fax 86-1-256-8157
The Congress is being organised by the Chinese Chemical Society, sponsored by the International Union of Pure and Applied Chemistry (IUPAC) and supported by a number of scientific organisations in China. The program features plenary lectures and invited lectures from key scientists and educators around the world, addressing the following topics: (1) life science and organic chemistry; (2) chemistry for a better environment and analytical chemistry; (3) chemistry of advanced materials and inorganic chemistry; (4) new polymer materials and macromolecular science; (5) petrochemistry, fossil fuels chemistry and catalysts; (6) physical chemistry; (7) chemical information and computers in chemistry; and (8) popularisation and education of modern chemistry.

August 26-31
WOCATE 93 International Conference
Location: Northern College, Aberdeen, Scotland
Contact: Carole Thomson, Conference Director, Science & Technology Department, Northern College, Aberdeen Campus, Hilton Place, Aberdeen, Scotland AB9 1FA
The World Council of Associations for Technology Education will hold WOCATE 93, the Festival of Technology Education for Elementary Stages (ages 5-14). This conference will focus on: Technology education as an indicator of humanistic education; Innovation in curriculum developments and teaching materials; Technology education in the process of developing attitudes, values and social relations; Technology education and its potential for developing children's thinking; Developments in the initial and continuing education of teachers for technology education.

September 6-16
Science, technology and society - appropriate science education for the twenty first century
Location: Department of Educational Studies, University of Oxford, UK
Contact: Your local British Council office, or Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK, Fax +44-71-389-4154
There are vacancies for 30 participants to focus on the following issues: (1) the nature of STS as education; (2) objectives and the evaluation of courses; (3) information knowledge and public understanding of science; (4) industry and STS; (5) STS in developing countries; (6) law, values and decisions about the environment; (7) new curriculum materials; and (8) teachers and in-service education. The seminar is intended for experienced science teachers, educationists, and government officials involved with curriculum planning and implementation and inservice work with teachers. The seminar fee, including accommodation, is £1440.

September 11-14
2nd European Conference on Research in Chemical Education
Location: Pisa, Italy
Contact: Dipartimento di Chimica e Chimica Industriale dell'Università di Pisa, via Risorgimento, 35, 56126 - Pisa, Italy, Fax 050-918-260
This conference aims to describe the state of chemical education research and to help chemists develop this research, and develop a European cooperation for the defence and promotion of didactics. Topics include representations and conceptions, evaluation, trends in didactics, problem solving, experimental teaching, computer assisted teaching, new technologies, and chemistry and the environment. Languages of the conference will be English and Italian.

November 22-27
Asian Workshop on Global Change Education
Location: Madras, India
Contact: Prof R R Daniel, Scientific Secretary, Committee on Science and Technology in Developing Countries (COSTED), 24 Gandhi Mandap Road, Madras 600 025, India
COSTED, because of its interest in the promotion of environmental education in developing countries, is considering an evaluation of the suitability of the materials on Global Change produced by ICSU-CTS to meet the needs
of teachers and students of the developing world. Participation is by invitation only (refer to article in the section Science Education Around the World).

1994

January
ASE Annual Meeting
Location: UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated in Education in Science, a journal of the Association for Science Education.

July 27 - August 10
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

August 8-12
13th International Conference on Chemical Education
Location: San Juan, Puerto Rico
Contact: Ram S Lamba, Chairman 13th ICCE, Inter American University of Puerto Rico, PO Box 191293, San Juan PR 00919-1293
This will be the first time that an ICCE meeting will have been held in the Caribbean Region. The objective of this conference is to bring together chemistry teachers from the pre-college and college levels to share ideas and learn from each other about innovations in the teaching and learning of chemistry. The theme is 'Chemistry: The Key to the Future'. The Conference will feature plenary lectures, symposia, lecture presentations, workshops, poster sessions and exhibitions. Scientists and science educators from around the world will report their work.

1995

July 26 - August 9
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

August 24-31
7th International Symposium on World Trends in Science and Technology Education
Location: De Koningshof, Veldhoven, The Netherlands
Contact: Secretariat 7th IOSTE symposium, PO Box 2041, 7500 CA Enschede, The Netherlands
Symposium presentations will be organised around at least three cross-curricular areas of interest: (1) science/technology related social issues including environment, health, peace, third world development, risk and safety; (2) further education and employment including career orientation, career preparation; (3) teaching methods include fieldwork, cross-curricular projects, computer simulations. Proposals for these and other topics are invited that report/reflect on research, practical experience or innovations relating to the main theme of 'Science and Technology Education in a Demanding Society'.

August 25 - September 1
International Conference on Industry-Education Initiatives in Chemistry
Location: University of York, UK
Contact: Miranda Mapleton, Chemical Industry Education Centre, Department of Chemistry, University of York, York YO1 5DD, UK, Fax +44-904-432516
This international conference is co-sponsored by the International Union of Pure and Applied Chemistry (IUPAC) Committee on Teaching of Chemistry, and the Royal Society of Chemistry Education Division and Industrial Division.
International Forum

Scientific and Technological Literacy for All

Phase 2 of Project 2000+

Paris, France
6-10 July 1993

This International Forum is the Second Phase of Project 2000+, an international project on scientific and technological literacy for all, which addresses the following 6 focus areas:

1. The nature of, and the need for scientific and technological literacy
2. Scientific and technological literacy for development
3. The teaching and learning environment for scientific and technological literacy
4. Teacher education and leadership for scientific and technological literacy
5. Assessment and evaluation for scientific and technological literacy
6. Non formal and informal development of scientific and technological literacy

Attendance will be by invitation only and limited to participants representing:

- National EFA (Education For All) Groups
- National policy makers overseeing science and technology education
- INISTE centres
- Project coordinators and field workers for organisations
- Science and technology teacher associations
- Institutions, centres, universities and colleges involved in science and technology curricula, examinations and teacher education
- Science and technology out-of-school centres and organisations
- Non formal science and technology educational organisations
- Industrialists
- Persons from the mass media interested in Project 2000+

There will be a US$100 Registration Fee for each participant to help defray material costs. This will be payable to the Project 2000+ Secretariat on receiving the invitation. For further information, contact:

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

International Forum on Scientific and Technological Literacy for All
A Report on Phase 2 of Project 2000+

The Project 2000+ International Forum was formally opened on Tuesday 6 July 1993 by Mr Frederico Mayor, Director-General of UNESCO. Mr Mayor welcomed more than 450 participants who had come from more than 90 countries. They included representatives of other United Nations agencies and international governmental bodies and a large number of non-governmental organisations.

In his opening remarks Mr Mayor emphasized the fact that the Forum provided a unique opportunity to reflect on the many issues related to scientific and technological literacy and to put forward suggestions for action to be taken at the regional, subregional and national levels.

The Forum was also addressed by Mr Georges Laforet, Doyen of the Inspection Général of the Ministry of Education who welcomed participants on behalf of the Government and people of France. He recalled the special importance attached by the government and ministry to the need for education to provide for all citizens to be enabled to participate in and share the benefits of a culture which embraced not only its rich heritage but also extremely important scientific and technological components.

The International Forum was co-chaired by Mr Colin Power, Assistant Director-General for Education at UNESCO, and Mr Bob Lepischak, President of ICASE. In his introduction to the work of the Forum, Mr Power drew attention to the declared objective of Project 2000+ to mobilise support worldwide in concerted efforts to bring scientific and technological literacy within the reach of all, particularly the young, and women and girls.

Following the opening plenary sessions the work of the Forum continued in six Focus Areas Groups:
1. The nature of and the need for scientific and technological literacy;
2. Scientific and technological literacy for development;
3. The teaching and learning environment for scientific and technological literacy;
4. Teacher education and leadership for scientific and technological literacy;
5. Assessment and evaluation for scientific and technological literacy;
6. Non-formal and informal development of scientific and technological literacy.

The conclusions reached by these groups, which are contained in the following reports, were presented in plenary session to the Forum on the morning of Thursday 8 July. This session was also addressed by Professor T Odiambo, Director of the International Centre of Insect Physiology and Ecology in Nairobi, Kenya.

A public lecture, entitled 'The race between the school and the cradle' was given by Commandant Jacques Cousteau on the evening of 8th July.

Six regional groups (Africa, Arab States, Asia, Europe, Latin America, and Small Island States) convened on the afternoons of 7th and 8th July and on the morning of 9th July. They were invited to prepare suggestions for Phase 3 of Project 2000+ and to present their conclusions at the closing plenary session of the Forum. The Chairpersons of the Focus Area Groups formed a drafting committee to receive amendments and prepare the final text of the Declaration. Delegates accepted the Declaration (refer to this section for a full report of the text of the Declaration) at the closing plenary session on Saturday 10th July.

ICASE will continue to play a key role, together with UNESCO and other international organisations on the Steering Committee of Project 2000+, in facilitating the establishment of National Task Forces and their development of plans for projects and activities in the years ahead.

In initiating this major international event, ICASE has clearly established its capacity to carry out the charter for which it was conceived — to extend and improve education in science for all children and youth by assisting member associations throughout the world.

Several members of the ICASE Executive Committee made substantial contributions to the planning and development of Project 2000+ and the International Forum. In particular, I would like to acknowledge the superb effort by Dr Jack Holbrook, Executive Secretary of ICASE. As one of the several volunteer staff who worked with UNESCO to plan the International Forum, Jack's contribution was a particularly outstanding one.

New Subscription Rates for Science Education International

Since the first issue of the ICASE Journal in March 1990, individuals and libraries have been subscribing to Science Education International.

Due to increasing production and postage costs, 1993 subscription rates have been increased to:

**Individual**
- £10.00
- US$17.50
- A$22.00
- CAN$20.00

**Library**
- £20.00
- US$35.00
- A$44.00
- CAN$40.00

Subscriptions can be sent to:
(cheques payable to "ICASE")
In US$ — Prof John Penick Centre for Science Education University of Iowa, Iowa City IA 52242, USA
In £ sterling — Dennis Chisman Knapp Hill, South Harting Petersfield GU31 5LR, UK
In A$ — Brenton Honeyman ICASE Journal Editor 10 Hawken Street, Monash ACT 2904, Australia

ICASE General Assembly Elects New Executive Committee

The 6th ICASE General Assembly was held in two parts. Prior to the International Forum, representatives of member associations presented reports on their activities. These are reported in this issue in 'Science Education Around the World'.

At the second part of the General Assembly, held following the International Forum, a new Executive Committee was elected.

Officers elected at this meeting were:

**President:** Brenton N Honeyman (Manager, Education & School Programs, The National Science and Technology Centre, King Edward Terrace, Canberra ACT 2600, Australia)

**President Elect:** M Anna Garner (President, Félag Raunagreiksnar, Lagunafi 7, 108 Reykjavik, Iceland)

**African Regional Representative:** I O Ileobi (Federal Ministry of Education, Science Education Division, PMB 12573, Victoria Island, Lagos, Nigeria)

**Asian Regional Representative:** Dr Janchai Yingrayoon (Thai Institute of Physics, Physics Bldg, Faculty of Science, Chulalongkorn University, Bangkok 10330, Thailand)

**Australasian-Pacific Representative:** John Anderton (Vice Principal, Tuart Senior College, Banksia Street, Tuart Hill WA 6060, Australia)

**European Regional Representative:** Alicja Wojtyna-Jodko (President SNPPIT, Skrytki Pocztowa 62, 85791 Bydgoszcz 32, Poland)

**Latin American-Caribbean Regional Representative:** To be appointed

**North American Regional Representative:** Dr Kenneth R Roy (Director of Science, Glastonbury Public Schools, 330 Hubbard Street, Glastonbury CT 06033, USA)

The position of Past President was assumed by R (Bob) Lepischak (Neepawa Area Collegiate, PO Box 430, Neepawa MB, Canada R0J 1HO) following his four year term as President of ICASE from 1989-93.

At the first meeting of the new Executive Committee, the constitution requires that the above members appoint a number of officers. Those appointed are as follows:

**Executive Secretary:** Dr Jack B Holbrook (72B Blue Sea House, 28th October Street, Limassol, Cyprus)

**Honorary Treasurer:** Dennis G Chisman (Knapp Hill, South Harting, Petersfield GU31 5LR, UK)

**Journal Editor:** Ronald J Bonn Steiter (Center for Curriculum and Instruction, University of Nebraska, Lincoln, Nebraska 68588, USA)

**Policy & Development:** Maris Silis (University of South Australia, Smith Road, Salisbury East SA 5109, Australia)

**Special Projects:** John E Penick (Professor, Science Education, Science Education Center, University of Iowa, Iowa City IA 52242, USA)

**Primary Science:** Sue Dale Tunnicliffe (18 Octavia, Bracknell, Berkshire RG12 7YZ, UK)

**French/Spanish Liaison:** Claude Gadois (CEGEP du Vieux-Montreal, 255 est. rue Ontario, BP 1444, Succ. N, Montreal QC, Canada H2X 3M8)

In addition to these appointments, ICASE welcomes the nominations of key international bodies to membership of the ICASE Executive Committee, as follows:

**UNESCO Representative:** Mr Emmanuel Apec, France

**ICU-CTS Representative:** Prof David Waddington, UK

Special thanks to retiring members of the Executive Committee

At the General Assembly, Dr Winston King of Barbados concluded his term as Past President (he was President during the years 1985-89). The incoming President, Brenton Honeyman acknowledged the valuable role and contributions that Dr King had made during his long association with ICASE, during which many new ventures and programs had become established.

Dr Jan Hendriks retired as European Regional Representative following a most active four years during which the European region had grown not only in membership numbers but, as a significant development, in establishing closer links with industry. Jan Hendriks has been instrumental in establishing a series of Industry-Education Seminars in the region — adding to the other very important meetings and seminars promoted through ICASE in the region. The President, Brenton Honeyman, commended Jan Hendriks on his initiative, energy and skill which had led to substantial developments in the European region.

Dr A M Shariuddin of Bangladesh, who had been the Asian Regional Representative, stepped down at the General Assembly. The Asian Region is a particularly active region, and the President acknowledged Dr Shariuddin's contributions to ICASE during his term of office.

Ms Althea Maud of Trinidad, has completed her two terms as Caribbean-South American Regional Representative. As a very keen supporter of ICASE and science teacher associations in the region, she has made a fine contribution over the past 8 years in this capacity. The President paid tribute to her very valuable contribution to ICASE in the region.
Distinguished Service to Science Education
Award presented to Dennis Chisman

This citation was read by the ICASE President, Mr Bob Lepischak, in recognising the contribution of Dennis Chisman, Honorary Treasurer of ICASE, to science education. The Award was made on the occasion of the ICASE General Assembly held at UNESCO Headquarters in July 1993.

"Dennis Chisman was born in Leeds, Yorkshire, an only child of a teacher father... these roots have directed him to a life of dedication to improving and enhancing education.

"A family move to London at an early age afforded Dennis the opportunity to attend a blue ribbon grammar school where he continued his academic career and was flattered by a young lady who commented that his moves on the ballroom floor were as smooth as his manner and conversation... the young lady, Sheila, was to become his bride and wife of many years.

"At Kings College, Dennis studied Chemistry, then taught Chemistry as Head of Science at a grammar school in Richmond. Along with excellence in instruction, Dennis organised science exhibitions which motivated students and served as professional development activities for fellow educators.

"He loved teaching and fully intended on continuing with instruction as a life long career until his curiosity was aroused by a newspaper advertisement inviting applications for a new post of Education Officer at the Royal Institute of Chemistry. This opportunity gave Dennis a new career in the 'wider world' of education. A second international career opportunity came to Dennis when he was appointed Chief Education Officer of The British Council. This enabled Dennis to stamp his personality on another new challenge. Work with The British Council afforded opportunities to network with educators throughout the Commonwealth.

"In 1973 Dennis took an active role in the establishment of ICASE at the University of Maryland which hosted an International Integrated Science Conference. ICASE was to begin the work of facilitating information exchange among science teacher associations worldwide.

"Dennis was appointed Executive Secretary Treasurer of ICASE and arrangements were made to launch an ICASE Newsletter. He guided the Association through a ten year period which saw a global membership base develop, many publications printed for science educators, regional conferences planned worldwide, the human resource base of ICASE expand... due in most part to the efforts of the man who seemed to know people all over the global community, always remembering their faces, affiliations, names and spellings of their names — even if they were as challenging as Uzwynshyn.

"From 1985 to the present, Dennis has continued to support the work of ICASE as Honorary Treasurer... a challenge in these years of the lightening pound, the faltering franc, and the dwindling dollar.

"One would never guess that Dennis has been 'retired' for nearly 12 years. He continues to act as an international science consultant who has worked extensively in Africa, the Near East, the Far East, and most recently in the new Eastern Europe.

Part of a less than relaxed retirement sees Dennis watching sports like soccer and cricket which he avidly pursued for years, listening to piano music (which he could be playing if he had not been so busy as to keep him away from the piano bench), and supervising Sheila's work of enhancing and beautifying their country estate — truly an English country garden.

"Dennis, it is today a singular pleasure to speak on behalf of science educators worldwide and, on behalf of this global network, to honour you with this award of Outstanding Service to International Science Education 1973-1993. I join colleagues and friends who stand in your shadow and applaud your contributions to the global science community.

Photo (below): Dennis Chisman receiving his award from Bob Lepischak in Paris during July
PROJECT 2000+

International Forum
Scientific and Technological Literacy for All

DECLARATION

At the conclusion of the International Forum on Scientific and Technological Literacy for All held at UNESCO Headquarters, Paris, 5-10 July 1993 (refer to the report on page 2-3), more than 400 participants from more than 90 countries endorsed the following declaration.

We, participants in the Project 2000+ Forum meeting at UNESCO, Paris, France from 5-10 July 1993:

1. Recalling the World Declaration on Education for All, in particular its recognition that ‘sound basic education is fundamental to the strengthening of higher levels of education and of scientific and technological literacy and capacity and thus to self-reliant development’ and, further recalling recent worldwide expressions of concern for the environment and for the quality of human life, especially those contained in Agenda 21, the output of the United Nations Conference on Environment and Development, Rio de Janeiro, 3-14 June 1992,

2. Believing that scientific literacy and technological literacy are essential for achieving responsible and sustainable development,

3. Declare our full commitment to the promotion of science and technology education for all in keeping with the World Declaration on Education for All, and our readiness to contribute through Project 2000+ to the concerted action set out in the Framework for Action to Meet Basic Learning Needs;

4. Call on governments, industry, public and private sector interests, and education and other authorities in all countries to:

(a) review critically existing provisions for science and technology education at all levels and in all settings with the aim of giving appropriate attention to development and maintenance of learning programs responsive to the needs of individuals and communities;

(b) assign priority to the development and introduction of programs leading to scientific literacy and technological literacy for all with the aim of achieving responsible and sustainable development;

(c) take such steps as may be necessary to ensure equity of access for everybody to science and technology education, notably for women and girls, young children and other under-represented groups;

(d) develop appropriate in-school and out-of-school opportunities, programs, curricula and assessment procedures for science and technology education responding to the human needs of a scientific and technological society;

(e) ensure and support appropriate pre-service and continuing in-service provisions for those responsible for all forms of science and technology education;

(f) encourage and support evaluation, research and development in science and technology education in both formal and non-formal sectors;

and to this end:

(g) establish and support task forces involving partnership with public and private educational bodies and councils; these might include universities and other institutions of higher and further education, research institutions, libraries, interactive science centres, environmental areas and nature reserves as well as public and private bodies active in the fields of agriculture, natural resources, environment, health, industry, commerce and the media, and also organisations and individuals especially concerned with science and technology education;

(h) recognise the central role of teachers in achieving scientific literacy and technological literacy for everybody, and enhance the status of careers in science and technology education at all levels;

(i) recognise the capital role of institutions of non-formal education, such as museums and scientific centres, of the media (radio, television and the press) and of all other out-of-school channels for communicating knowledge of science and technology, in fostering scientific and technological literacy for all; and

develop activities designed to set science and its applications in a wider social and cultural environment;

(j) ensure that adequate resources are available to achieve these aims;

5. Urge United Nations Agencies and other inter-governmental organisations to work together to initiate and support programs which will advance the ability of countries and of populations to shape their own future in a scientific and technological society and which will increase the capacity of countries for designing, planning and implementing scientific literacy and technological literacy programs;

6. Urge non-governmental organisations active in fields of science and technology education, as well as the social sciences, and professional associations of teachers and educators and educational organisations at all levels to:

enter into partnership with, and make their knowledge and experience available to, United Nations and other inter-governmental bodies as well as establish innovative programs in a common effort to achieve the goal of scientific literacy and technological literacy for all; and
participate in national, regional and international programs for the enhancement of scientific literacy and technological literacy for the improvement of the quality of life in all societies and for the achievement of sustainable development;

7. **Recommend** that UNESCO makes provision, within its Medium Term Plan (1996-2001) in the field of education, and in the context of Project 2000+, for an international program to develop co-operation among all countries in the field of science and technology education, with particular reference to the promotion of scientific literacy and technological literacy for all:

- **(a)** understanding of the nature of, and the need for, scientific literacy and technological literacy in relation to local culture and values and to the social and economic needs and aspirations of each country and its peoples, and also in accord both with the general aims of education for the all-round development of human personality and with human rights and basic freedoms;

- **(b)** identification of those issues concerning the applications of science and technology which are of special importance for personal, local and national development and their embodiment in educational programs;

- **(c)** establishment of teaching and learning environments as well as supporting structures conducive to the achievement of scientific literacy and technological literacy for all;

- **(d)** formulation of guidelines for the preparation and continuous professional development of science and technology educators and leadership coupled with assistance to countries in giving effect to them;

- **(e)** development of effective communication, both verbal and visual, assessment strategies and evaluation programs designed to enhance general levels of scientific literacy and technological literacy;

- **(f)** support for the non-formal and informal sector in its own right and support for development strategies which will help to stimulate and maintain lifelong scientific literacy and technological literacy;

8. **Recommend** that by the year 2001 there be in place appropriate structures and activities to foster scientific literacy and technological literacy for all, in all countries.

---

*Photo (above): Madame Sheila Haggis, Chief Rapporteur for the Project 2000+ International Forum, addresses the final plenary session.*

*Photo (above right): Presiding over the final plenary session are (L to R) Prof. Samuel Bajah of the Commonwealth Secretariat; Mr Emmanuel Apea of UNESCO; Mr Colin Power, UNESCO Assistant Director General for Education; and Mr Bob Lepischak, ICASE President. Mr Power and Mr Lepischak co-chaired the Forum.*

*Photo (right): Delegates at the final session endorsing the Declaration.*
The following is a brief survey of some of the most common features of scientific language, the recognition of which will enable the teacher to design exercises to assist learners better develop their understanding and learning of science.

Scientific language usually avoids personal styles and common words and has a formality of register which school pupils may not encounter in their study of narrative prose – so often the only diet of English language classes. In recent years the relatively new science of linguistics has been analysing the nature of scientific language and has shown it has a specific structure with its own characteristics. Learners may experience difficulties with conceptual problems or the use of technical words, but linguistic studies have revealed that technical words make up only a small percentage of scientific texts (Hoffman 1981, Inman 1978) while the linguistic features of scientific English create a much more significant barrier to learning.

The Language of Science

The language of science will usually show more frequent use of the following features:

• Academic Vocabulary: Words such as tangible, simultaneous, potential, establish, fundamental, function, verified. Many of these words are unlikely to be part of the learner’s everyday language.

• Passive forms of the verb may cause more difficulty than active forms: The litmus paper is placed (passive verb) in the liquid is more difficult than Place (active) the litmus paper in the liquid (Carroll 1986, 41-42 et al).

• Complex nominal compounds: The day and night weather observation station. A low cost diesel engine transmission unit. Complex nouns of this sort feature strongly in science texts.

• Compound Words: Another aspect which might be considered is the need to be able to interpret new words by breaking them into component parts, for example; poly many quadrilateral side epi on the upper surface meso middle of structure. A poly gon of four sides is called a quadrilateral. A leaf is covered by a single layer of cells called the epidermis which forms the skin. Between the upper and lower epidermis is the mesophyll. Direct teaching of word parts such as these will give clues to meaning of a variety of words in context.

• Modals: ie may, could, should, would, etc. Correct and exact use of these words need practice.

• Tenses: There may be confusion over the precise implications of the tenses used, viz The material burns. The material is burning. The material has burnt.

• Sentence length: Complex sentences will require the reader to scan backwards and forwards to pick out subjects and verbs.

Fluoridation is the addition of chemical a chemical called fluoride to a town’s water supplies to reduce tooth decay. Fluoride occurs naturally in the drinking water of some towns and for many years scientists have been aware that people living in such areas suffered from less dental curies than those whose water supplies did not contain any.

• Comparison and contrast: X and Y are similar/different. X is virtually/precisely/approximately the same as ...

• Cause and effect: If X then Y ... If a match is inverted the flame becomes larger.

• Definition and generalization:

Definition:

An ammeter is an instrument which measures electrical current

term class special features

Generalization: Ammeters measure electrical current

• Classification: Preparing classification diagrams (as shown below) will help to make the structure of a text clear.

Human teeth are of several types, each adapted to a different function. In front are the chisel-shaped incisors, four in the upper jaws and four in the lower. There are canine teeth on each side of the jaw. Behind these are three molars (in adults) and two pre-molars: these are ridged, flattened surfaces and function in grinding and pounding and crushing food. A child’s first teeth do not include those mentioned above. The first teeth are...

• Another aspect which can be considered for classroom practice is for the teacher to use what Buzan (1974) called hooks or burrs on which to hang meaning. The more connections which can be found the more improvement may
The idea here is to use language communicatively to discuss meaning which may reveal a learner's personal interpretations and misconceptions. Inviting learners to express themselves in their own words and experiences has been mentioned by others. (Carre 1981, Sutton 1992)

Learners come to understand language based on what they already know: it is necessary to encourage reflective thinking through talking and writing about experimental work.

I have presented here just a few ideas in which recent knowledge of the linguistic structure of scientific English can be used in the science classroom. The development of language support work can be done in conjunction with English department staff who, with encouragement, will recognise the importance of this language across the curriculum approach.

ICASE AWARD SCHEME

for outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.

ICASE Distinguished Service Award

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

ICASE Regional Service Award

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels.

ICASE Association Award

This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association.

Linking Science Education and Research

by John R Percy

Until about a century ago, any intelligent person with sufficient resources could contribute to scientific research. Then science became big, complex, technical and specialized, at least in the industrialized countries. Intelligent lay people were reduced to the role of bystanders, able to watch but unable to participate actively in the excitement of research and discovery. Perhaps this is why science is no longer part of culture in countries like mine. (There is, of course, a second kind of 'research and discovery' in which an individual personally experiences the thrill of observing or understanding a phenomenon for the first time. This is an extremely important process, but not the subject of this article.)

There are exceptions. In my field of astronomy, skilled amateurs still play an important role, for instance by discovering comets, and measuring the changing brightness of variable stars in a systematic way. This work is co-ordinated internationally by the American Association of Variable Star Observers (25 Birch Street, Cambridge MA 02138-1205, USA). Could this model be applied in other branches of science as well? Certainly in the industrialized countries, there are millions of intelligent, enthusiastic people looking for stimulating ways to fill leisure time or retirement years. Involving them in original scientific research would increase direct support for science, and increase public understanding of science by bringing science and the public closer together.

The most suitable projects might be those involving surveys, interviews, routine sample collection, or measurement with simple, calibrated instruments. Volunteers could also create and maintain databases on a microcomputer, and perform simple statistical analyses. Long-term studies, or comparative studies between geographical regions or populations would be possible and worthwhile. These would be useful approaches in fields such as pollution and other environmental studies, health and nutrition, consumer studies, conservation and recycling, gardening and agriculture. These fields are not only smaller and simpler than experimental particle physics, for instance; they are also more practical, at least in the short run!

For this reason, the 'volunteer' approach might be relevant to the developing countries. There are always some bright young students in schools and universities, looking for active involvement in science. They could provide their teachers and professors with enthusiastic help in practical research projects, while learning the basic methods of science. Perhaps this would be an effective way of attracting more young people to careers in science and engineering in those countries.

Students, of course, can participate in research through science fairs, and some science fair projects are significant contributions to scientific knowledge. This tends to occur 'by accident', since science fairs are usually disconnected from the scientific community.

The University of Toronto Mentorship Program (Faculty of Arts and Science, University of Toronto, Toronto, Canada M5S 1A1) enables outstanding senior high school students to work on real research projects with university faculty members. To the student, the program offers involvement, challenge, skills development and experience. To the mentor, it offers an enthusiastic, capable assistant, and a useful contact with the school system. A disadvantage of the program is that it can only accommodate about 150 students (though if every faculty member supervised a student, it could accommodate ten times more). An alternate model would have the mentor meet with a group of students (and their teacher) two or three times a year, to guide them in a group project with sub-components for each student.

A university, science centre or museum could provide the infrastructure through which students (or the general public) could participate in research, matching up mentors, projects and volunteers. An alternative (or adjunct) possibility would be a local 'academy of science', such as are found in many parts of the USA. These could disseminate the results of volunteers' research through conferences and journals, giving the volunteers experience in making oral or written reports, and feedback from other researchers. The most important results could be abstracted and circulated internationally. This social and educational component of the research process is very important; volunteers should not simply be used as cheap labour.

By linking formal and informal science education with research in this way, the gap between science and society would close a bit; science would gain an army of enthusiastic supporters; and the public could experience the excitement of science – which is, after all, a human endeavour. If you are interested in linking science education and research, either in a school or public setting, I would be glad to share my experience with you.

Sixth Edinburgh International Science Festival

Edinburgh, Scotland
7-23 April 1994

Following the success of the 1993 Festival which attracted over 200,000 people to 367 events, preparations for the 1994 Festival are now well in hand.

Major themes include
Being the right size
Molecule of the day
Science myths of out time
In addition, there are
exhibitions, talks, debates, performances
family events, tours, conferences
and workshops including
Madlab
Computer Arcade
FUNdamental Physics
Science Dome

Photo (below): Three of the leaders of Focus Area Group 6 in session with 40 participants developing proposals relating to the non-formal and informal development of scientific and technological literacy, at UNESCO Headquarters, Paris, July 1993. From left to right: Jayshree Mehia (India), Cheng Donghong (China) and James Bradburne (France). The reports of the six focus area groups will be published along with recommendations arising from the six regional groups.
Teaching Science in an Artistic Way

by James E Nesbitt

From a very early age, young children have experiences with art. Although children may not be able to articulate a definition for this activity, they do have an understanding of what it means to do art. These children have already utilized artistic tools, such as scissors, construction paper, paste, and crayons. Most young children enjoy doing art and approach this activity freely and creatively.

Doing art is perceived as an activity worthy of pursuit for its own sake. Art is perceived as an expressive and creative activity that children do freely outside of the school curriculum. That is, children do art and do it well, without appealing to its association in a school context. It is even normal for children to think of art in this way.

On the other hand, few children do not perceive science in this way because science is viewed as 'practice' for what occurs later in their lives. The activity becomes disassociated from a child's everyday life. Science is seen as a disciplined activity and therefore the expressive and creative element gets lost as children sit in textbook-centred classrooms and sift through memorizable facts.

Young children are curious. They explore the world around them. They ask questions about science very early in their lives and make many attempts to understand how things work. Yet, we often wait to provide children with the 'tools of science'. Science apparatus is usually found locked behind glass cabinets in our schools. Many students, as well as adults, perceive these 'tools' as nothing more than the tools of a scientist.

Children who have an early interest in doing science have very limited access to the equipment necessary for experimentation; even experimentation on an elementary level. Therefore, any expression of science activity or idea gets reduced to improvisation, or at the other extreme, the activity does not get carried out. In a sense, this lack of access to science resources contributes to the perception of science as 'just something that we do in schools'.

If we establish a philosophy about science that de-emphasizes its 'classroom image' and its image as 'something only scientists do' and emphasize its potential as an activity engaged in for its own sake, then young children will have another context for establishing the role of science in their lives. As children experience formal science education in school, science for some of them will be perceived as a subject that is designed for the most highly skilled student. When children reach high school, this image of science becomes even more believable. The low numbers of children in upper level science courses (chemistry and physics) supports this image. According to some, only the brightest children can compete in such courses. Of course, this is not always the case. Yet, we go on believing this to be true by upholding the position that if you take chemistry and physics and 'succeed', then you are among the most talented and gifted students. As a result of these perceptions, images, and beliefs, many students decide against including science in their studies. These students avoid science. Why can't science be more like art?

Even the term 'science' may impede access, because this term, for some, denotes a field of study concerned primarily with objectivity, rigor, precision, and exactness. This connotation divorces science from its meaning for our everyday lives. It is this meaning that helps provide the validity of, or that explains the useful role of science for us.

When children perceive science as an experience detached or isolated from their everyday experiences, then the role or the usefulness of science becomes more obscure. By establishing a type of science in the minds of young children that consistently promotes relevance, we can redirect our thinking about the role of science in our lives. This relevant science should cause us to redefine the nature of science and make it consistent with our needs. The result of this type of thinking hopefully will cause individuals to perceive and experience science as a natural activity, much like art.

The appreciation expressed for art, the value placed on it, and its cultural and historical significance has implications for the sciences. Science is more than practice; it has a cultural and historical component. Like art, it is an expression of one's creativity.

In art class, one does not rely on a textbook for instruction. Art does not attract only the most skillful, thereby limiting the number of individuals who will do art. Art has met the needs of most cultures. Art has representation in most cultures; therefore, a marginalization or lack of access by certain groups does not exist. Our philosophies about and the way we teach art have implications for the sciences.

Science can be taught by utilizing the tools of art and by adopting the instructional techniques employed in the art classroom. The freedom to express one's ideas or to be creative in art class is very important for young children. The hands-on, creativity approach of the art class could be utilized in science class to provide similar instruction.

Students do art within procedural guidelines that will not compromise their imagination, creativity, or resourcefulness. Art students are encouraged to conceive their ideas and mental images and then transform these concepts into real and tangible objects through media such as paper, watercolour or clay. The expression of oneself or one's ideas is a basic philosophy of art. Yet in science, we employ pre-established procedures or methodologies that sometimes leave very little
room for creativity; thus decreasing the opportunity for serendipitous discoveries.

Science is more than just a method. Yet many students are guided through their science experiences having little chance to express themselves. The very nature of children suggests that they love hands-on activities, they love to explore, and even more, they love to create.

Although children may be exposed to a philosophy that exploration, discovery, imagination, and creativity are acceptable in the science class, they may actually be the recipients of science which minimizes these attributes. Limitations imposed by the instructor, by the use of the textbook, or even the laboratory manual can undermine a child’s curiosity and minimize the potential that a science experience can offer. We provide students, many times, with well-intended prescriptive science activities, thus sending forth a message that there is a proper or exact procedure to be followed which will provide us with exact results.

In reality, practicing scientists employ different procedures and methods to arrive at intended, as well as unintended, results (Knorr-Cetina, 1981). Yet, we teach science as if it were pure and objective with prescribed, orderly steps to be followed. Granted, structure must exist within the discipline, but it should not hinder curiosity or creativity in the classroom.

Before becoming engaged in a science activity, students should be encouraged to conceive and articulate their understanding of an activity; they should verbalize their procedure or method, as well as their expected results. This visualization could be compared to an artist who creates his or her mental images of a painting or sculpture before beginning to work. A science activity will offer more understanding and will bring to bear misconceptions about science when students formulate and articulate their own way of thinking or understanding about the activity, process, problem, or principle. Their understanding of the activity allows for an expression of themselves. They become a part of the activity, much as an artist becomes a part of his or her painting and the painting becomes a part of the artist. This opportunity creates an essence, making the experience more meaningful.

The intensity, energy, and concentration observed in artist at work is a result of the artist being occupied or absorbed in something that symbolizes a part of the artist. A similar commitment can be made by the science student, when he or she participates in a science class that provides the opportunity for self-expression. If this occurs then there is a greater likelihood that students will become adults still interested in science.

About the author

Dr James E Nesbitt is a Visiting Assistant Professor in the School Mathematics and Science Center at Purdue University, West Lafayette, Indiana 47907-1442, USA.
Member associations and individuals are invited to contribute to this section. Suitable items include brief accounts of specific projects of international significance, science education in a particular country, or international and regional seminars and conferences.

SCIENCE TEACHER ASSOCIATION REPORTS
ICASE General Assembly
Paris, July 1993
Compiled by John E Penick, ICASE Special Project Officer

Asian Region
Delores Hernandez of the Philippines presented a brief overview of activities in the Asian region, and introduced representatives of regional science teacher associations.
Anna Poedjiadi of Indonesia reported that there is a new Indonesian Association for Science Education (IASE) which involves science teachers and teacher educators. They have sponsored two symposia on science and mathematics research in 1990 and 1992, and have commenced a journal. IASE is an affiliate of the Indonesian Education Association.
Choi Kuen Or of the Hong Kong Association for Science and Mathematics Education (HKASME) reported that association membership is about 700. Many in Hong Kong are leaving teaching for the private sector. HKASME has recently revised and re-started their journal. They now also conduct monthly programs relating to various disciplines and grade levels. They have also organised programs and competitions for children.
Merle Tan presented the report of the Philippine Association of RECSAM Grantees. They have sponsored a number of workshops for teacher education as well as seminars for educators.
Delores Hernandez reported that the Philippine Association for Biology Education has an annual meeting and seminars. The most recent meeting focused on oceanography and marine biology – two critical concerns in the Philippines.

Christina Padolina of the Philippine Association of Chemistry Teachers reported that each year they organise a chemistry conference, and they produce an occasional newsletter.
Janchai Yingprayoon of the Science Society of Thailand, noted that the Society includes scientists and science teachers. They publish a quarterly journal in English and a magazine in Thai. Of the Society's 2000 members, about 500 are teachers. Activities include summer programs, workshops, field trips and science camps. They will be organisers of the 9th ICASE Asian Symposium to be held 6-10 December 1994 on the topic 'Equipment and Computer Applications in Science and Technology Education'.
Sujitha Dharmaratne of the Sri Lanka Association for Science and Mathematics Education, reported that SLASME now has 600 members from all levels and disciplines. They strive to promote curriculum development and teaching methods. There are annual and regional meetings as well as monthly committee meetings.
Sukanda Rajanasoothon reported for the Institute for the Promotion of Science Teaching and Technology (IPST). This governmental organisation is charged with developing and promoting science, technology and mathematics education at the school level. They are also concerned with environmental education.
Dr Abbas Alikhan representing the Kuwait Foundation for Science Education reported that the Foundation, established in 1976, is supported by a proportion of revenues from publicly held corporations in Kuwait. One of the Foundation’s goals is to popularise science through publications, clubs, translation of journals such as Scientific American, and various other programs. The Foundation also provides support for other societies related to science or technology.

European Region
Jan Hendriks, the ICASE Representative for the European Region, indicated that there are now 30 ICASE members in the region, almost half of which are company members. The region has hosted a number of symposia and conferences. Jan then introduced the representatives of member associations in the region.
David Moore, General Secretary of the Association for Science Education (ASE), reported that the ASE supports an international committee. The ASE provides a variety of journals, meetings and programs for its members. A new journal will be entitled 'Science Across Europe'. In the UK, national assessment has been a priority for several years. ASE hopes to introduce more practical investigations and meaningful practical exercises. In the UK, there is considerable interest focusing on science teaching.
Bert van Beek reported that NVON of the Netherlands now has 2000 members, almost all of whom are secondary teachers. New government regulations are mandating a number of changes, such as combining chemistry and physics instruction. They are expecting shortages of teachers in some areas, especially in the physical sciences.
Hans-Juergen Schmidt reported that MNU in Germany now has 6000 members. He would like to see even
more teachers involved. A recent inclusion of primary teachers will increase membership. Reunification has also caused many problems as the two educational systems were quite different. The regular series of educational research conferences at Dortmund has been very popular. The next conference will be held during 1994.

Alicja Wojtyna-Jodko reported on the activities of SNPPIT of Poland. SNPPIT produces a bulletin (produced in English and Polish), and organises conferences and other projects. The first annual conference focused on the environment. The second dealt with environmental protection. The third, to be held in September 1993, will focus on Microcomputers in Education. Projects involve cooperation with other organisations. Several publications are planned, including one on physics demonstrations.

Anna Garner, President of the Icelandic Science Teacher Association, reported that the association consists mostly of upper secondary teachers. The 300 members include every secondary science teacher in Iceland. Their journal is the prime means of communication, and they hold several meetings every year, each one on a theme. Meetings are organised as both a professional and social event. ISTA has also sponsored several sub-regional conferences.

Jacqui Clee, Royal Society of Chemistry in the UK, reported that the Society supports several competitions for students. In addition, they sponsor 'Chemistry at Work', exhibitions, and many career lectures and programs. Teachers can attend four-day residential industry-tours and summer school programs. They also provide summer fellowships for teachers, hands-on symposia, and written materials.

Brian Tricker of the International Association of Science Clubs reported that the IASC sponsors conferences and discussions as well as activities for students. They produce occasional publications, including a journal which has been published three times during the last ten years. Publications include descriptions of model science clubs as well as discussions of issues such as environmental protection.

Birgitta Lindh of the Swedish Association reported that the name of the association is about to be changed. The Swedish educational system is changing to provide more flexibility for pupils and teachers. Sweden has a shortage of professionals in science, mathematics and engineering. There is some concern that the new regulations will not alleviate this problem.

### African Region

Isaiah O Iokebi, ICASE Representative for the African Region, after commenting on the difficulties of communication in Africa, introduced the delegates to report on the activities of their science teacher associations.

Jophus Anamuah-Mensah of the Ghana Association for Science Teachers (GAST) reported that the association has 500 members, including primary teachers, secondary teachers and teacher educators. They hold an annual meeting and a science fair for students. They have published several books, and are involved with national testing programs. Fewer students are studying science, feeling that it is too difficult. GAST is planning on developing a special curriculum and to set up regional technology education centres in all regions; TV programs will also help by popularising science.

Gerard Mathot of the Lesotho Science Teachers Association reported that they conduct an annual competition and science fair for all levels. They are seeking to involve other southern African nations in science education activities. Many teachers are leaving for jobs in the private sector where salaries are higher.

Sikhonhla Sumbi of the Swaziland Science Teachers Association reported that SSTA is now 25 years old and currently has 200 members. The slight reduction in numbers is due to schools joining, rather than individual teachers, in order to reduce costs. SSTA sponsors science fairs with other regions and produces a newsletter. Swaziland is also experiencing an exodus of science teachers to industry. SSTA hopes to expand their horizons and be involved with other countries, gaining ideas and friends.

Emile Lisk, representing the Sierra Leone Association of Science Teachers, reported that SLAST has several projects underway. A major project is exploring the relationship of science and technology.

Dr U M O Ivowi, President of the Science Teachers Association of Nigeria (STAN), reported that STAN, formed in 1957, has grown to a membership of 1000. This includes primary and secondary teachers as well as teacher educators and others interested in science education. STAN has sponsored a variety of projects.

If you belong to an association which is an ICASE member the card entitles you to benefits from the member association of the country you visit.

**Contact your local association**

or Dennis Chisman, ICASE Honorary Treasurer

Knapp Hill, South Harting, Petersfield GU31 5LR, UK
Jan Hendriks (Left), ICASE Representative for the European Region, introduces European delegates who presented reports at the ICASE General Assembly in Paris, July 1993.

Isaiah O Ikeobi (Right), ICASE Representative for the African Region, introduces African delegates who presented reports at the General Assembly.

Anna Garner (left), President of the Icelandic Science Teachers Association, presents her report on the activities of the association.

Kenneth Roy (right), ICASE North American Representative, introduces North American delegates who presented reports on their activities.

John Penick (left) presents his report on the activities of AEIS at the ICASE General Assembly.
including workshops in 9 different subject areas, and symposia (including a joint one with ICASE). STAN has developed an exchange at annual meetings with ASE and NSTA. The STAN executive officer is also obtaining additional training at ASE and NSTA. In addition to their journal, STAN is sponsoring several position papers on current topics such as STS.

Isaiah O Ikeobi presented a brief report on the Science Teachers Association of Malawi (STAM). Efforts are being made to revive the association.

Caribbean Region

Winston King, Past President of ICASE, reported that the Caribbean has seven science teacher associations. However, only Trinidad & Tobago and Jamaica have active organisations. Others are dormant as they are experiencing a lack of finances.

Recent events in the region include the ASSETT-ICASE Conference in 1991, and several science fairs and exhibitions.

There will be such a fair in the British Virgin Islands in August 1993. The region plans to be involved in Phase 3 follow-up to Project 2000+ during 1994-95.

Australasian-Pacific Region

Maris Sils, the ICASE Representative for this region, reported that there are now four member associations.

Since the last General Assembly, the Fiji Association of Science Teachers (FAST) has become a member following its formation in 1991. Their plans include organizing a conference, competitions and a journal.

Maris reported that the New Zealand Science Teachers Association now has an executive secretary courtesy of the Royal Society. NZSTA is developing policy statements related to publicity, commercial activity, and education. They also distribute materials and are conducting research about teachers and teaching.

The Australian Science Education Research Association is now the Australasian Science Education Research Association, a move designed to reflect their membership and mission. Primarily, they conduct research and produce papers. The ASERA Conference is a major annual event for the association.

The Australian Science Teachers Association, through expanding its full time secretariat, is becoming more visible and is helping teachers to develop a national, as distinct from a state focus. ASTA sponsors a variety of activities, competitions and meetings, including an annual conference (CONASTA) which attracts a number of overseas delegates. The UK-Australia Exchange program provides an opportunity for 10 ASTA science teachers to study in the UK, and for 10 ASE science teachers to study in Australia.

The Solomon Islands Science Teachers Association, not yet an ICASE member, is developing a resource centre and holds meetings twice a month.

North American Region

Kenneth Roy, ICASE Representative for the North American Region, introduced the representatives of North American science teacher associations.

Sylvia Ware, representing the American Chemical Society, reported that the ACS now has 148,000 members of whom 3000 are high school chemistry teachers. ACS is active in all levels of chemistry education and has an education division staff of 35. ACS offers short courses, two educational journals, and programs for all levels. School programs include curriculum work such as CHEMCOM, a very successful chemistry text designed for the college-bound but not science oriented student. CHEMCOM now has 17% of the US market. A new program FACETS is being developed for release next year. ACS also sponsors competitions and scholarships and is working to attract parents to work with their children. One aspect of this is a bi-weekly column in USA Today which includes science questions and activities for children and parents. ACS also publishes WONDER SCIENCE, a comic book for students.

John Penick reported that the Association for Education of Teachers in Science (AETS) is holding steady at 750 teacher educator members. In addition to their four regional meetings, AETS had its first annual meeting which was separate from the NSTA meeting; 400 attended that first meeting. A second meeting is scheduled for January 1994 in El Paso, Texas. AETS publishes two journals – Science Education, a general research journal, and The Journal of Science Teacher Education, which focuses more on teacher education. AETS is active in working with the National Board for Professional Standards, setting criteria for teacher licensure. AETS also reviews all proposals for accreditation of science teacher preparation programs throughout the US.

Bob Lepischak, President of ICASE, reported that the Canadian Association for Science Education (CASE) is working to overcome the problems associated with coordinating science education efforts in such a large and diverse country with a small population. CASE has recently commenced a series of national, rather than provincial meetings. CASE is now seeking to establish a permanent secretariat.

Jeane Dughi of the National Science Supervisors Association (NSSA) reported that NSSA provides leadership through a journal, newsletter, conferences and symposia. NSSA has completed a strategic plan to reflect the changing needs of members. The plan will enhance communication, collaboration and continuation of a strong science education for all.

Wendell Mohling of the National Science Teachers Association (NSTA) reported that NSTA publishes 5 journals, including one for high school students. NSTA has a membership of 49,000 and offers 3 regional conventions and a national convention each year. 30,000 teachers attended these four meetings last year. NSTA has a strong commitment to international science education, including a committee on international activities. In 1991, NSTA sponsored a meeting in Moscow where 340 Americans met with 650 Soviet science educators. In July 1993, 300 Americans are meeting with 650 Mexicans in Mexico City for another joint international conference. NSTA sponsors numerous awards (up to
As the countries of Asia Pacific draw closer together both economically and politically, it is important to raise awareness in students for one another's societies. Many of the issues faced in the environment, such as energy supply, water quality and pollution are of common concern and related to scientific problems, yet perspectives as to their causes and resolution may differ.

The Science Across Asia Pacific Project aims to:

- introduce an Asian Pacific dimension into science education by raising awareness of different perspectives, ways of life and national traditions of students in other Asia Pacific countries
- raise the awareness of the ways in which science and technology interact with society, industry and the environment
- provide opportunities to develop communication skills in the widest sense, including in languages other than their own
- provide opportunities for schools in different countries to collaborate.

Science Across Asia Pacific is publishing a series of units (packaged in two separate books) on scientific issues and providing an associated database of participating schools. The project provides a forum through which students may exchange facts and opinions with students in other countries. Australia, Brunei Darussalam, Canada, Indonesia, Malaysia, New Zealand, Philippines, Singapore, Thailand and Vietnam have already joined the project.

Book 1 includes the units: Drinking water; What do you eat?; and Using energy at home. Book 1 is available from July 1993.

Book 2 will include four units: The impact of global warming; Renewable energy; Tropical forests; and Domestic waste. These are currently undergoing trials and will be made available as Book 2 in mid 1994.

Each unit includes an introduction to the project, with maps, data, teachers' notes, student pages, and an exchange form. Each unit involves the collection of information, data and opinions. The results are combined for the whole class in order to exchange with schools in other countries. The information is usually sent by mail or fax, although the work also provides for an opportunity for linking schools by E-mail.

A unit usually takes one or two hours in the classroom and possibly a homework session to complete the preparatory work and send off the exchange forms. Another lesson is required later to discuss the information received from other schools. In addition to English, materials will be available at a later date in the national languages of Malaysia, Indonesia, Brunei, Thailand and Vietnam.

The subject matter in each unit has been carefully selected to link with, but not interfere with, existing school curricula. The level of knowledge and skills required in the units make them generally suitable for students between 14 and 17 years of age, although some teachers have also expressed interest in using them with younger students.

Experience in trials has shown that making links with students in other Asia Pacific countries is highly motivating.

INFORMATION SHEET

Commonwealth Association of Science, Technology and Mathematics Educators (CASTME):
Awards for science, technology and mathematics teachers 1993/94

1. Introduction

The CASTME Award Scheme was started in 1974 when CASTME (then CASME) undertook to develop the former Guiness Award Scheme. Many entries have been received over the years since it started. It is certain that some schools and individual teachers have received major professional stimulus through its activities.

The awards are intended to encourage teaching of the social aspects of science, technology and mathematics, with particular reference to developing countries of the Commonwealth. The scope of the awards is interpreted broadly, and 'social aspects' includes the relevance of science, technology and mathematics curricula to

☐ local needs and conditions
☐ the impact of technology, industry and agriculture on the local community.

2. Eligibility

Teachers and officials (advisers, inspectors, etc.) working in primary, secondary and tertiary education in Commonwealth countries are eligible to enter. Individuals or syndicates may enter.

3. Topics

There are no set topics for the competition. Reports of work carried out by the teacher or official should be based on personal experience and should include a substantial account of teaching and/or other educational work, such as curriculum development or programmes of teacher training. Entries based on ideas, proposals or general arguments which have not been tried out in practice are not acceptable.

An example of a recent prize-winning entry was entitled 'Using reed - a no-cost material - for science experiments in a rural middle school'. The author teaches in a rural school with no laboratory or commercial apparatus. The project describes how the author and students developed a wide range of experiments and investigations using reeds gathered from a nearby swamp. Examples of activity-sheets are included, links with both the environment and the prescribed science syllabus explained, and the effects of the approach described and evaluated.

Each entry must be the original work of the entrant and must not have been published previously.

4. Awards

In addition to a small money prize donated by CASTME, a few traveling fellowships are sometimes awarded at the discretion of the judges. These fellowships, a gift of the Commonwealth Foundation, enable the prize-winners to follow a short programme of professional visits in a Commonwealth country. Edited versions of all winning entries may be published in the CASTME Journal and short abstracts of winning entries are printed in The British Council's Science Education Newsletter. All prize winners will receive twelve months free subscription of the CASTME Journal. The judges are appointed by the Council of CASTME and their decisions will be final.
Judging is based on the following criteria

☐ evidence of originality and creativity

☐ evidence of use in practice and cost effectiveness (entries based on ideas, proposals or general arguments which have not been tried out are unacceptable)

☐ evidence of evaluation of the idea or material in use

☐ evidence of the social relevance of the project

☐ standards of presentation, organization and structure of the report

☐ overall impression of the report

5. Presentation of the entry

Only one entry can be accepted from any one individual or syndicate.

Entries previously submitted to CASTME may not be re-submitted.

The entry must be written or typed on A4 or quarto sheets of paper, and should not exceed 10,000 words in length. Reports in the past have mostly been between 2,000 and 5,000 words long.

Photographs and other illustrative material should be included wherever relevant, together with any other evidence that shows the ideas have been effective in practice. Pupil's work may be included when possible.

Reference should be made to the source of information or of original experiments wherever this is necessary to a proper assessment of proposed modifications.

If a substantial part of an entry is being published or submitted as a thesis, this should be mentioned on the top sheet of the entry.

6. Registration and submission

Registration must be made before 30 November 1993.

Entries from registered candidates must arrive in the Education Department, Education and Science Division of The British Council before 1 March 1994.

Intending applicants should fill in a registration form. These can be obtained from

☐ Their local British Council Office

Chemistry in the Community
CHEMCOM: Description and Evaluation

by Frank X Sutman & Matthew H Bruce

Chemistry in the Community (ChemCom) is a year long chemistry course designed for high school students who may or may not be college bound. It is intended for that group of students who enter high school chemistry with little interest in the quantitative aspects of the subject and who have little experience in developing or applying higher order thinking skills, and who for the most part read below grade level. ChemCom was developed against a backdrop of general concern that the existing high school level chemistry texts and courses give little or no consideration to the relationships among science, technology, and societal issues. The need for school level science courses with this emphasis has been expressed in a number of national reports such as those by the National Assessment of Educational Progress (Science Report, 1975) and the American Association for the Advancement of Science (AAAS, 1988). It was developed also out of concern that existing school level chemistry texts too often merely mimic those developed for use in beginning level college chemistry courses.

ChemCom was designed to motivate students to learn chemistry by considering its applications to the resolution of societal issues. For the most part these issues are environmental in nature. An example, below, will distinguish the thrust of ChemCom from that of other high school level chemistry courses.

The chapter of the ChemCom text titled 'Petroleum: To Build or To Burn?' is introduced with a detailed presentation of the significant role of petroleum in our society. Students are challenged to assess items in their homes that are related chemically to petroleum or that are derived from petroleum. Consideration of the role of petroleum in economics through simple graphic representations is followed by a series of investigations emphasizing the 'mixture' nature of petroleum, how the components of the mixture are separated, and how certain properties of the components are related to their chemical structures. Study of the structures of 'petroleum molecules' includes a brief look at chemical bonding and isomers. An introduction to reaction mechanisms is followed by qualitative and quantitative considerations of how petroleum is used in the production of electrical energy. Heat of combustion is presented in the form of a simple investigation, including the use of basic mathematical calculations designed to support a better understanding of the mole concept. An opportunity is offered for students to read tables of data and graphs, and to interpolate and extrapolate from the graphs. The chapter concludes with a section, 'Putting It All Together', designed to involve students as a team of 'experts' who are given a set of assumptions to be applied in preparing for a public debate on the future of petroleum in our economy.

Readability Level
During the developmental stages of ChemCom the evaluators monitored the project's readability level using the Dale-Chall Readability Formula (Dale & Chall, 1948). With input from the evaluators, the final version has a readability level of grade 9, which is unique for school level chemistry texts, most of which are written at a 12th or even 13th grade level.

The Nature of the Evaluation
The formal evaluation of ChemCom was conducted by a team of independent researchers. Specific instruments were developed and validated for use in each of the four phases of the evaluation process. These four phases included:

- Phase I development and analysis of an opinionnaire related to the validity of the ChemCom objectives;
- Phase II development and analysis of the cognitive tests;
- Phase III assessment of the nature of the student and teacher populations for the field test;
- Phase IV assessment of teachers' reactions to ChemCom through an ethnographic survey.

Phase I: Initial Development and Analysis
The objectives, as shown in Table 1, are presented as questions on an opinionnaire designed to answer these two questions:

- Are the objectives developed for ChemCom valid?
- To what extent would/did this course and its use in instruction meet these stated objectives?

Note that the objectives include some that are typical of more traditional high school chemistry courses (for example, '... to learn basic chemical facts and knowledge.') and others that less
### TABLE I

</thead>
</table>
| 6. Better understand the importance of acquiring appropriate scientific information before making a decision about related societal issues. | Chapter I  
0.45   | Chapter II  
0.74 |
| 7. Recognize that each solution to a complex societal problem may produce new problems. | 0.54   | 0.75 |
| 8. Identify alternative courses of action in dealing with societal issues. | 0.54   | 0.88 |
| 9. Better appreciate the scope and the limitations of science. | 0.67   | 1.08 |
| 10. Better appreciate the scope and the limitations of technology. | 0.66   | 0.92 |
| 11. Gives students opportunity to become familiar with some important issues involving interactions among science, technology and society. | 0.41   | 0.76 |

Typical, reflecting a departure from tradition (for example, "... to better understand the importance of acquiring appropriate scientific information before making decisions about related societal issues.")

### Validity of Objectives

The determination of the validity of the objectives was accomplished by comparing reactions to the stated objectives by the five groups involved in ChemCom's development. This comparison used a five point response scale and analysis of the response data utilizing the Provus Discrepancy model, a procedure that has found extensive use in social science research for similar purposes. This model assesses discrepancies among opinions held by the various participant groups regarding the appropriateness of the objectives. Results of the analysis, using the Provus model, indicate a high degree of acceptance of the objectives, with a high level of agreement across the five groups involved in the project's development, as evidenced by the fact that all group mean responses were between 4.0 and 5.0 on a 5-high scale. Based upon these results, the objectives were accepted as standards to be met by the ChemCom program.

### Meeting the Objectives

According to Provus, a discrepancy of 1.0 or less, out of a possible four, indicates a very high level of agreement regarding the acceptance of any item under question. As shown by the values in Table I, only one of 22 discrepancy values was greater than 1.0, and that only 1.08, indicating a very high degree of correspondence of the performance to the ChemCom standards. The groups that participated in the study of both the validity of the objectives and the degree to which they were met included the ChemCom Steering Committee, project administrators, authors, pilot test teachers and students.

More telling even than the above are the calculated Kendall Coefficients of Concordance and the associated probability values (p) for the agreement of performance with standards, as presented in Table II. In three of the four instances the value for p is <.001, and for the fourth, the value is <.01. These values reflect an
extremely low likelihood that the extent of agreement noted could have occurred by chance. The comparatively high p values for the two columns headed 'Discrepancy' (<.20 and <.10) support the contention of close agreement among the groups on both the validity of the objectives and the expectations for program performance.

The largest group involved in the above process was the students. Table III indicates that most of the pilot test population were enrolled in chemistry courses at the tenth and eleventh grade levels.

**Phase II: Development and Analysis of the Cognitive Tests**

**Pilot Testing**

An early decision was made to utilize a multiple choice format for the testing. This decision was based on recommendations from studies appearing in the literature at the time of ChemCom's development (Wall, 1972; Doran, 1980; Tuckman, 1975). The writing teams constructed rough drafts of 50 test items for each of the first two chapters or modules. Thirty-three were modeled after items appearing on the American Chemical Society's high school level standardized chemistry test and emphasized chemical content. Fifteen items emphasized applications of this content to societal issues. These draft items were reviewed and revised against the following six criteria:

- clarity of presentation
- content accuracy (validity)
- reasonable sampling of content from each chapter
- consistent format for all questions
- minimizing of redundancy and cueing
- maximum reading level of ninth grade.

Reliability was also a consideration; it is dealt with later. Each item was validated by a panel of specialists, three chemists and two educators, to assure (a) that they responded adequately to the ChemCom objectives and (b) their correct categorization as either chemical knowledge or application questions.

The assumption was made that a rigorous pilot student assessment following the teaching of the first two chapters would set an effective stage for the development of the remaining six end-of-unit tests and the final examination; all of which would be used in the field testing. The correctness of this assumption was borne out, as will be seen, by the results of the field testing.

** Chi-squared values associated with "W".
*** Chance probability values for Chi-squared, indicating confidence to be placed upon the values for "W". For Standards and Performances, low "p" values indicate higher confidence. For discrepancies, the higher probabilities indicate that the calculated values are not below the accepted chance level of 0.05, and thus can be considered to be chance variations.
The tests to be piloted were administered to both an experimental and a comparison group. The experimental group had just completed a traditional chemistry course in an inner-city high school, while the comparison group had had no formal chemistry instruction. Each group was asked to comment on any difficulties they encountered in understanding any test item. Both groups indicated that the items were understandable and eighty per cent of the chemistry students indicated that they wished the chemistry course they had just completed had included information about how chemistry is applied to resolving environmental issues. The non-chemistry comparison group contributed almost no comments and, as expected, were not able to answer the questions above the chance level. Following minor revision of four items, these tests were then administered to over 1,000 students in the formal piloting process.

A shortened form of the Longeot Test for Cognitive Development Level was administered to the students who piloted Chapter II to determine if a relationship existed between the students’ level of cognitive development and their ability to answer correctly the pilot test items (Sheehan, 1970). Correlation of the Longeot and ChemCom scores revealed the involvement of the students in using the processes identified by Lawson and Wollman as requiring skills needed to apply knowledge to problem resolution (Lawson & Wollman, 1976). The results of this are described below.

Test and item analysis following the pilot testing of the two model tests included the following factors.

Inarticulate Science?

Perspectives on the Public Understanding of Science and Some Implications for Science Education

*by David Layton, Edgar Jenkins, Sally MacGill & Angela Davey*

The public understanding of science is a matter of concern in most countries. This is not simply because educators or scientists wish to promote a wider understanding of scientific ideas as worthy of the attention of all thinking citizens. Such understanding is commonly regarded as essential for the effective implementation of a wide range of social, economic, technological, medical, employment or other policies which have a scientific dimension. This book explores the ambiguities and limitations of the concept of ‘public understanding of science’ and, by means of case studies, addresses the meanings and social uses which science has for members of the adult public who are not themselves professional scientists. Drawing upon a substantial literature to place the case studies in a broader context, the final chapter examines the implications of the research for science education.

25
Test Reliabilities

Reliability for each of the unit tests was 0.80 or better, indicating that revision on this basis was unnecessary.

Item Reliability and Discrimination

All but two of the test items were found to discriminate acceptably between the more academically able and the less able students. Revisions were made on two items having low reliability coefficients.

Cognitive Level

There was modest significant positive correlation, 0.40, between test scores and students' cognitive development levels, as indexed by the Shortened Longoet Test. This supported the contention that the tests contained a reasonable number of items functioning to assess understanding, application and other higher order thinking skills.

Time

Students' reactions during the piloting indicated that they required about 1.5 class periods to complete the items. For the field testing, each test was reduced in length from 50 to an average of 33 items to ensure that they could be reasonably completed in a 45 minute class period.

Level of difficulty

The index of difficulty for all but three of the pilot items fell within an acceptable range (0.3 to 0.8). Although these included the higher level items, the mean index of difficulty was calculated to be 0.45 for each test, indicating that, as planned, the overall tests fell close to 5 (Wood, 1966).

Relevance to the ChemCom Objectives

The five chemistry and science education specialists on the validation panel indicated unanimously that each test item was valid. That is, each item related to the students' attainment of the ChemCom objectives and that the total adequately reflected the content of each of the units.

Readability

Subjecting the items to the Dale-Chall Readability Formula indicated that the test items were, as planned, readable at the ninth + 0.5 grade level.

Applying Chemical Knowledge to Problem Solving

No significant differences in test scores between the experimental and control groups were found for those items designed to assess students' ability to apply chemical knowledge to the solution of societal problems. This unpredicted finding was interpreted to be the result of one or more of five possible causes. Of these possibilities, the evaluators and the ChemCom Steering Committee agreed that the most likely cause was that the time period (one to two months) was too short to have produced significant change in favor of the ChemCom students as expected.

The overall results of the pilot test evaluations indicated the correctness of the earlier assumption of no need to pilot each of the remaining seven tests. Thus the nine tests (eight chapter tests and the final examination) underwent only revision based on the experience of the pilot of the first two and final editing before their use in the field testing.

Field Testing

During the field testing, the cognitive tests were administered to nearly 2,700 students in seven centers across the United States: California, Washington, Maryland/DC, Colorado, Louisiana, New Jersey/New York City, Texas and Virginia. The 64 field test teachers taught each unit of ChemCom and administered each end-of-unit test and the final examination. A questionnaire, designed to reveal the characteristics of the teachers involved in the field testing was completed, and an ethnographic interview of a sampling of the field test teachers was done to confirm the questionnaire results and to determine their assessment of the future role for ChemCom and other courses with similar objectives.

The results of the field testing are reported in a detailed monograph on file in the Education Division Office of the American Chemical Society (ACS) in Washington, DC (Sutman, et al, 1989). This report and the originally published ChemCom Teachers Guide include the nine field-tested tests, with minor revisions to only five of the total 291 items, based on the field experience.

The field test students were then compared to two classes of students who had completed a conventional college preparatory chemistry course and with two classes that had no formal chemistry instruction. These

** Statistically significant at better than the customary confidence level of a 0.05 probability of a chance occurrence

---

Traditional and comparison groups were both from urban schools, the traditional group from a high school from which a high percentage of graduates enter college, many into programs emphasizing science, and the naive group from a school from which most students did not enter college. Beyond the data obtained by the evaluation team, the field testing provided valuable information to the editors of ChemCom for use in the final manuscript of ChemCom for commercial publication. This information, for example, helped to overcome some inconsistencies and problems related to the presentation of laboratory investigations found in earlier drafts.

**The Final Examination and the Effectiveness of ChemCom**

For the final examination, comparisons were made among the ChemCom field test group and the traditional and comparison groups noted earlier. The ChemCom field test group out-performed the other two groups in the area of applying chemical knowledge to societal problems.

In the area of chemistry content knowledge, final examination questions were written to be equivalent to a sample of items from the ACS examination, with the reading level adjusted to ninth grade (somewhat below that of the ACS test). The traditional group was predicted to out-perform the ChemCom group, and both the traditional and ChemCom groups to out-perform the comparison group. However, the ChemCom group significantly out-performed both the traditional and comparison groups! (See Table V). The results reported in this table clearly support the integrity of the ChemCom approach to instruction.

Part reliabilities for the two subtests of the ChemCom final examination were: for content, $R = 0.80$; and for Applications, $R + 0.58$. The reliability of the test as a whole was 0.76, a figure that meets accepted psychometric standards for such tests. Based upon the above data analysis, the conclusion is made that ChemCom is a highly functional high school chemistry course for secondary school level students for whom it is intended. Further, the program has the potential to be substituted for the more traditional high school chemistry course since it does not deter students from learning significant chemistry content.

**Phase III: Field Test Teachers and their Students**

The formal education of 67 per cent of the teachers included 30 or more academic credits in chemistry, and that 81 per cent of these teachers had taught more than six years, yet 42 percent of them had taught chemistry five years or less. Sixty two percent of the teachers indicated that their students were in a college preparatory program (not necessarily science-oriented), while 36 per cent of the students were enrolled in non-college oriented, while 36 per cent of the students were enrolled in non-college oriented, while 36 per cent of the students were enrolled in non-college bound curricula. Ninety percent of both groups of students were enrolled in the 11th and 12th grades. Not shown in the table is the distribution of teachers: nearly even between urban and non-urban schools, with a small percentage from rural schools.

**Phase IV: Teachers' Opinions Regarding ChemCom**

Most of the field test teachers perceived experience in the more traditional high
school chemistry course to be important for success as a science major in college. By contrast, the data from the field testing reveal that these teachers also believe that high school chemistry should meet the 'societal objective'. This dual role for high school was further analyzed in the ethnographic survey reported below.

This survey was administered to a carefully constructed sample of the field test teachers in order to provide in-depth information from the ChemCom teacher population that would be helpful in interpreting the results of the other aspects of the study. As an example, the ethnographic survey results reflected a perceived conflict between the need to prepare all high school level chemistry students to be successful in beginning college chemistry and an understanding of the role chemistry plays in the 'real world'. This possibly irresolvable contradiction occurs in the face of the results of historical science education studies that indicate that college chemistry faculty place relatively little value on the level and amount of formal chemistry taught in the high schools; instead only valuing adequate preparation in mathematics.

Summary
The results from the field evaluation of ChemCom indicate that while ChemCom was designed for a non science major-bound high school population it may also serve as appropriate background for science-oriented, college bound students! ChemCom experiences could, for example, motivate students to enrol in advanced high school chemistry courses and/or motivate them to enrol in college chemistry courses. The critical issue for college bound students continues to be where and how they will develop the necessary mathematics in the context of its use in the sciences. It would appear that serious rethinking of the school level approach to teaching mathematics, with perhaps a more utilitarian approach, as indicated in the National Council of Teachers of Mathematics' publication, Curriculum and Evaluation Standards for School Mathematics is in order.

The results of this research give some indication that ChemCom itself, or a ChemCom type high school chemistry program can better prepare students either to enter the work force directly from high school or to enter collegiate level science courses. While ChemCom may not be an effective curriculum 'for all Americans', the evidence is that the approach utilized by ChemCom better serves the needs of high school students than does the traditional approach to chemistry instruction. In light of this research, and in light of recent dissemination data, ChemCom has begun to play a significant role in molding the shape of high school chemistry in the years ahead.

The Bolivia Instructional Enrichment Partnership

by Jon E Pedersen

Introduction

Teaching science in a third world country such as Bolivia is difficult since many science teachers operate with little or no equipment and very few supplies. Few Bolivian schools have funds for staff development or professional enrichment. Hence, instruction in most Bolivian classrooms depends heavily on copying text material word-for-word along with rote memorization drills.

The lack of supplies, equipment and diversity of methods is a concern for many Bolivian educators. Because of this concern, a cooperative venture was initiated between the University of Arkansas at Fayetteville (U.S.A.), the Cochabamba Cooperative School, the Universidad Privado Boliviano, and the Minister of Education for Bolivia through its Servicio de Apoyo Educativo Departamental (S.A.E.D.). The cooperative venture, the Bolivian Enrichment Partnership, will provide Bolivian teachers with the opportunity to enrich their own classroom instruction with new ideas in teaching and learning.

The model used in the development and implementation of this project can provide guidance for other institutions as they develop international partnerships which promote the sharing of information and knowledge about pedagogical strategies and curricula.

The Planning

The planning team was comprised of a representative from the University of Arkansas, a Bolivian educator, a representative of S.A.E.D., the principal of the Cochabamba Cooperative School, and a representative of U.P.B. Not unlike any other planning team, this one wanted to ensure that their project would be successful both in the short and long term. For that reason, consideration was given to what it would take to make this project long term with appropriate short term impact rather than a workshop, that at best, is here today and gone tomorrow.

Based on the concern for long term impact, the focus of the planning team turned to an examination of the changes that teachers and others in the project would be experiencing from participating in this project.

In light of the above, a model of change was used as a guide for the development of the project. Although there are many effective models of change, most all of these models contain basic steps and considerations to use any time one attempts to restructure or reorganize. In the current project, the following basic change principles were used as guides in the development and implementation process. (Liberman & Miller, 1990; Timar, 1989; and Sizer, 1991).

- Agree on a new vision and from this develop the goals.
- Get conflict in the open.
- Understand that you cannot accomplish all your changes at one time. Change takes time.
- Go beyond surface issues in order to promote quality and equality for all students.

- Recognize the importance of building partnerships and networks with all involved and involve them early on.

In addition, there was also a need to consider cultural differences. This is especially true in light of the fact that individuals from the United States would be presenting, to Bolivian teachers, methods and curricula that they would use in their own classrooms with Bolivian students.

Vital to the understanding of the cultural differences was the input from Bolivian educators in regards to the impact that certain teaching methods and curricula might have on Bolivian teachers and their students. It was important to establish the "cultural correctness" of the methods and curricula that would be taught.

Through their involvement, Bolivian teachers and officials for S.A.E.D. were successful in shaping the proposed instructional strategies and materials to the culture of Bolivian teachers.

The Project

Change is never easy and as Cushman (1993) laments, "the first steps to change - agreeing that a problem exists, and setting goals to solve it - sound deceptively simple." (p. 4)

Knowing that all must have their say and raise concerns about the visions projected for the project, we spent a full year in discussions developing four main goals:

1. To improve the quality of teaching in Bolivian public and private schools which includes:

   A. To aid in the development of a philosophy of teaching that is consistent with current research on
science teaching and with the culture of the participants.

B. To broaden and deepen the understanding of Bolivian teachers knowledge of the current trends and research on science teaching.

C. To develop and implement appropriate teaching strategies for teaching science in Bolivia.

D. To develop curriculum which is consistent with the teachers' philosophy and compatible with current trends in science teaching.

2. To provide courses (during the winter break) for Bolivian teachers which will earn them credit towards their masters degree in education at the Universidad Privado Boliviano.

3. To prepare a cadre of Bolivian educators who can act as consultants in their own country.

4. To aid in the development of a masters degree program for education at the Universidad Privado Boliviano.

5. To develop long term and permanent opportunities for continued study and growth in education.

The new vision portrayed by these goals was one that was uniquely different from current trends in teacher education in Bolivia. In lieu of this extreme difference and understanding that change cannot occur rapidly, a four year plan was developed, as an organizational guideline, in order to implement the goals. Each year, a single change activity, which may address one or more of the project goals, would occur. In each successive year, the project would implement an additional change activity to address remaining goals. The important component of the plan was to go slowly, to be flexible and not demand that all of the project goals be completed in four years. We also developed consensus that if changes occurring were not positive, or if changes were being made too fast and were not meaningful, then the action plan could be altered.

The Action Plan

Year One: Establish an Instructional Enrichment Institute

The partners in the project will establish an annual summertime (northern hemisphere) Instructional Enrichment Institute to be held on the Cochabamba Cooperative School Campus. This will be comprised of a series of professional workshops on classroom instructional theory and methodology to be presented by faculty and/or associates of the University of Arkansas. Those teachers who go through this program will act as trainers in the process of facilitating current methods and theories of sound educational practices for other Bolivian teachers. It is important to note that the methods and theories presented will be based on current knowledge of teaching that reflect the reality of Bolivian culture and values.

Year Two: Establish a Post-Graduate Degree Program

A Master’s Degree program will be established at the new Bolivian Private University (Universidad Privado Boliviano, UPB) for the purpose of encouraging Bolivian teachers to seek and secure a post-graduate degree in the field of education. The establishment of the program will be a cooperative effort between the parties involved in the partnership. Courses for this Master’s Degree will be taught at UPB by UPB faculty. Cochabamba Cooperative School faculty (Americans trained in the United States), and faculty from the College of Education at the University of Arkansas.

Additionally, teachers who participate in the Instructional Enrichment Institutes will receive university credit toward their Master’s Degree at UPB.

Only Bolivian university graduates with degrees from a Normal and who possess Título Provisional National (Bolivian teaching certification) will be eligible for admission to the Masters program. Issuance of the Masters Degree in Education will be determined by the satisfactory completion of an approved course of study consisting of 30 graduate semester units of credit and satisfactory submission of a Project Thesis (describing the student’s approved educational research project).

Year Three: Establish the Universidad Privado Boliviano Shadow Program

Through its relationship with the College of Education at the University of Arkansas, UPB hopes to establish a closer relationship between other colleges at the University of Arkansas (including engineering and business) for the purpose of assisting UPB in the development of programs that would allow its students to apply and be considered for post graduate work at the University of Arkansas.

In addition, UPB will establish a “shadow program” at the University of Arkansas in order for the faculty at UPB to learn the latest methods in administration. This program would entail a faculty member from UPB being assigned to an administrator at the University of Arkansas for the purpose of becoming more conversant with current administrative management techniques.

Year Four: Establish the Continuing Education Center (C.E.C.)

Cochabamba Cooperative School in Bolivia will provide land for the construction of a resource facility providing research, training, and development opportunities for Bolivian teachers who are members of the Institute, Cochabamba Cooperative School faculty, faculty from the College of Education at the University of Arkansas, and student teachers from the College of Education at the University of Arkansas.

The Continuing Education Center will be a complete instructional resource facility. It will offer the facilities and resources necessary to provide technical and professional assistance to Institute members for improving the quality of instruction in their individual classrooms.

The Center will provide a resource facility for teachers in Bolivia to visit and from which to learn. This is a dire necessity as teachers in the Bolivian public school system lack the monetary resources to pursue their own professional growth. The Continuing Education Center would provide them with the opportunity to (1) study and/or pursue research at the professional/classroom library; (2) to observe proven instructional techniques in the demonstration classrooms or auditorium on educational trends and instructional methodology; (3) to create their own teaching models and instructional materials in the resource workroom; and (4) to learn from the most advanced technologically equipped educational computer facility.
in Bolivia.

The Center will also provide housing for out-of-area staff, visiting educators, and student teachers from the College of Education at the University of Arkansas. It will provide daily pick-up and return transportation for teachers who live outside the Cochabamba transportation system.

Conclusions

The project has completed its first year, and is leading into the second summer institute. Over 40 Bolivian teachers participated in the initial two week institute which covered basic science methods. After the two week workshop, 35 of the 40 teachers agreed to continue to meet every Friday evening to further discuss science methods and share their own experiences using the new methods of instruction. This was all initiated, coordinated and carried out by the participating teachers.

The Bolivian teachers have all indicated that the first year experience has been positive. The increased knowledge of methods has provided for them an increased flexibility and diversity vis-a-vis science teaching. The teachers have also indicated a desire to continue their professional development through additional workshops and institutes which focus on curriculum development to further enhance their effectiveness as science teachers.

The second summer institute will occur June of 1993. Rough estimates are that 100 Bolivian teachers will participate in an introductory methods workshop and an advanced workshop (the advanced workshop will be for those who participated in the first summer institute). The goal of the advanced workshop is three fold:

1. to provide teachers with a broader and deeper understanding of science methods through experiences
2. to provide the teachers with an understanding of curriculum development by application, and
3. to provide the teachers with an understanding of the change process so that they can begin to formulate a plan of action to train other Bolivian teachers.

In addition, work has begun on establishing the first masters degree program in Bolivia for teacher education.

The success or failure of a project such as this rests with the individuals who have a stake in the effects of the change. Many of us have good ideas and good intentions of sharing our ideas with others. Yet, we must ask ourselves if our vision is shared by all of those individuals that it will impact.

Can we be sure that those who are most effected by change see a need to change? Or, do they have the attitude, if we don't think it is broke, don't fix it? Without the commitment of all involved in the project, the vision of one becomes little more than an imposition on others.

Subtitle: Anthropomorphizing: Another Teacher’s Methodology for Better Pupil’s Learning in Science

According to Solomon (1986) anthropomorphizing is helpful in teaching children and is used frequently in different ways in our culture. It is a kind of analogical reasoning. Consequently it is a precious tool for expanding human knowledge (Dupin & Joshua 1989, Duit 1991).

The teacher introduces the idea of water molecules as human beings in motion (Figures 1 and 2). This metaphor is based on developing animate attributes of water molecules and ideas on their kinetic behaviour. These ideas permeate discussions on the explanations of their observations. A method which runs through all teachers’ remarks to children (9-10 years old) is that we are ‘explaining a physical phenomenon, such as the water molecules’ motion, on the basis of human being moving behaviour.’ The learner builds a set of useful water molecule activities out of some already existing set from his/her experience on human activities. According to Fisher (1987) this learning state is called the personal analogy where pupils place themselves directly in the same situation with water molecules, as it happens in the above mentioned event.

As mentioned below, water evaporation is something mysterious; no acting mechanisms can be seen, only effects. So, children reason by means of anthropomorphized water molecules on the basis of their daily life experience. Under this approach, the teacher sets the new idea of water evaporation in a concrete form. It is essentially a picture. The teacher’s purpose is not to perform new empirical experiments, but to encourage ‘thought experiments’. Pupils must think about the new system (evaporation of water = water’s disappearance and/or quicker water’s disappearance), go deeply into it and propose some relevant hypothesis. By confrontation with other pupils and with the teacher, it is possible to reach a reasonable physical model.

Water molecules in motion!

Water is not only a material that you can drink or swim in or wash yourself with. Studying its properties can be an engaging hobby because you can find out the answers to some of water’s ‘why?’ and other interesting things that you can do with water.

Can you present that water molecules move?

STEP ACTIVITY 1: WATER’S DISAPPEARANCE

Challenge

How can you explain water’s disappearance?

What you need

A water glass, a bottle, a measuring cup and water.

Do

Drop the same quantity of water in (a) a water glass, (b) a plate, and (c) a bottle. Put them in a certain place where they receive the same quantity of sun radiation and heat (Figure 1).

Further investigations (expected outcomes)

(a) What happens to the water in each case? In all three cases the water ‘disappears’ or evaporates.

(b) Is there any difference? The quickest ‘disappearance’ (evaporation) is of the water in the plate. The water in the glass evaporates more quickly than the water in the bottle.

(c) What ideas have pupils to explain the difference?

Teacher’s notes

A great number of water molecules (eg in a lake, a river or the sea) escape into the atmosphere. In this case water ‘disappears’ or evaporates (the more accurate physics term). The teacher can introduce a model of water molecules as in Figure 1, for a better pupils’ understanding of the phenomenon of evaporation. That is, pupils understand that the water in the plate evaporates most quickly, because the largest free surface permits water molecules to move into the air without any obstacle. What seems to be the case with the bottle is that the smaller opening makes it more difficult for molecules to escape into the atmosphere.

Pupils’ interpretation

Most pupils hypothesize that in all three cases the same quantity of water disappears because the conditions are the same. They set fair tests by taking measurements of the heights of or depths below the level of the water surface in all cases after a predetermined period of time (eg 3-5 minutes) in order to verify their hypothesis. Pupils write down their measurements and observations as to in which case water disappears the fastest. They ask questions such as ‘why?’ or ‘how can we explain this water’s behaviour?’ and other similar ones. They express various ideas on it. The teacher’s proposed model sharpens their ability to explain this kind of water behaviour because anthropomorphizing water molecules helps pupils to draw a parallel between human behaviour and the behaviour of water molecules, as a result to understand the latter by analogy to their personal experience.
Figure 1 (left)

Place a measuring cup of water into each container.

An imaginary picture of evaporating water molecules.

Figure 2 (right)

Faster water disappearance due to heat.
STEP ACTIVITY 2: QUICKER WATER DISAPPEARANCE

Challenge
Can you explain why water molecules disappear more quickly by heating?

What you need
Three saucepans of the same size, a measuring cup and water.

Do
Using the measuring cup, pour the same quantity of water into each saucepan. Put the first saucepan in a cool place, the second one in a warm place (e.g., in sunshine or near a heater) and the third one on a cooking plate (e.g., an element of an electric cooker) and leave it boiling (Figure 2).

Further investigations (expected outcomes)
(a) What happens with the saucepan in the cool place? Water evaporates (at a slow rate) even in a cool place.
(b) What happens with the saucepan in a warm place? Water evaporates at a faster rate than in the previous case.
(c) What happens with the saucepan on the cooking ring of an electric cooker? Water evaporates at the fastest rate.
(d) How do pupils explain these differences? They claim that heat facilitates the water's evaporation.
(e) What ideas do pupils have about water evaporation? The water molecules' anthropomorphized model helps pupils to understand that the higher the temperature, the faster water evaporates.

Teachers' notes
