Scientists claim that water molecules move faster and distances between them become greater when they are heated because of the energy which is transferred to them by heating. Thus, they 'escape' more easily from the water surface into the air, changing from liquid to vapour.

Pupils' interpretation
Most pupils hypothesize that the water in the saucepan on the cooking plate evaporates more quickly based on their experience gained from daily life. Many pupils form the opinion that sunshine or a heater also assists water to evaporate more quickly — and that this does not appear to happen in a

About the author
Dr Kavogui has been studying at Kings College, London for a research degree in science education. During her time in England, she taught primary science which heightened her interest in and awareness of interpreting science in children's terms. She developed this teaching strategy in response to pupils' apparent needs with success in terms of the pupils' participation in problem solving science activities.

Stepping into Science
An ICASE Primary/Elementary Science Project

AIMS
Stepping into Science is an ICASE project which aims to:

• Establish an international network for teachers to share ideas on the teaching of primary/elementary science and technology.
• Provide activities and support for teachers, thereby encouraging them to include more science in the primary/elementary curriculum.
• Promote the value of science experiences for young children throughout the world.
• Facilitate professional development opportunities for teachers by including sessions on primary science and technology in regional and international conferences.

ACTIVITIES
The Stepping into Science Team is actively involved in a number of projects and activities including:

• Publishing STEPS, the Stepping into Science Project Newsletter. This newsletter contains ideas for class activities at various levels in primary/elementary schools, activities for children to do at home, comments by network members on issues, examples of children's work, lists of helpful resources and contacts.
• Contributing articles and ideas for the Primary Science Section in Science Education International, the ICASE quarterly journal.
• Compiling ideas and activities for inclusion in a series of sourcebooks on the teaching of primary/elementary science and technology.
• Coordinating a scheme to encourage children to participate in science and technology activities. Certificates of Participation have been produced, and are available for schools to use in rewarding students as they complete a number of activities. Certificates are colour coded in seven different colours, so that they can be used to acknowledge progress in science from early to advanced levels within primary/elementary schools. ICASE is grateful to BP (Oman) for sponsoring this scheme.
• Organising Stepping into Science workshops and displays of children's work at national, regional and international conferences.

The Scientific Work Experience Program
A new and important model for science teacher development

by Sandra S Gottfried

Scientific work experience programs are those in which teachers work within businesses, industries, or universities in a variety of roles. By engaging in the scientific enterprise, teachers gain an understanding of the nature of the scientific process and infuse these understandings into their professional lives. In addition, involvement in scientific work experience programs increase teachers' feelings of self-confidence, self-esteem, and professionalism.

More than 80 scientific work experience programs are now in existence in the United States (Industry Initiatives for Science and Math Education, IISME, 1991). A few programs began in the late 1970s, but most were developed from the mid-1980s to the present. Although differences exist among scientific work experience programs, they have many commonalities.

Most programs take place over six to ten week periods in the summer with follow-up during the school year. Some programs have continuing work experiences spanning the school year and have academic experiences (such as courses or workshops) that extend beyond the summer. Many programs offer university credit for participation; some are a part of a master's degree program. All are considered internships because teachers work with mentors from the setting in which they are placed to do supervised work.

The goals of most scientific work experience programs include giving teachers 'real world' experience in business, industry, or academia. Project directors are interested in teachers improving their technical/scientific knowledge base. In addition, project directors and developers want teachers to use the internship experience to enhance their understanding of some of the kinds of skills scientists, engineers, and other types of technical workers need in the workplace. A related goal is for teachers to see the usefulness of scientific, mathematical, and technological knowledge and skills in a variety of 'non scientific' careers and occupations. These new understandings and insights enhance a teacher's ability to teach science and help students make academic and career decisions. Many programs also suggest additional goals of enhancing teachers' leadership skills, awareness and understanding of current science and technology, understanding of developing technologies, and understanding of the nature of scientific research.

Scientific work experience programs can be grouped into three categories according to the type of scientific work teachers do: project internships, research internships, and a combination of both research and project internships.

In project internships, teachers are placed within business or industry and complete a project for the company. Often these are projects that the business could not get to with its available workforce. For example, a teacher may be asked to set up and test new equipment, write manuals, teach within the company, or modify computer programs.

In research internships, teachers are placed in business, industry, or university settings and work with research scientists or engineers. Each teacher takes part in some aspect of the research work of his or her mentor. The research questions teachers explore vary tremendously and span both domains of basic and applied research. In project/research internships, some teachers are placed in business, industry, or university research settings, while others are placed in business or industry with a project focus.

The predominant method of classroom transfer in both research internships and research/project internships is a curriculum development project. Through the development of their projects (a process often facilitated by a science educator) the teachers translate their summer experiences into instructional materials. In research or research/project internships not using this mechanism, teachers are often asked to submit a personal action plan of classroom transfer. This plan allows teachers a wide latitude to develop classroom and extracurricular activities they will carry out during the school year and encompasses topics such as teamwork, problem solving, communication skills, updating of content, and career awareness. Some programs have no structured mechanism of classroom transfer.

An overwhelmingly consistent outcome reported by directors of all three types of scientific work experience programs is the increase in teachers' feelings of self-confidence, self-esteem, and professionalism. Scientific work experience programs are often catalysts, energizing teachers to aggressively pursue further professional development activities. These programs 'recharge' teachers. After their summer experiences, most teachers are anxious to return to their roles in their classrooms, having reaffirmed their reasons for entering the teaching profession. On sharing their experiences and new workplace perspectives with students, teachers sense that students view them as credible professionals in ways they
previously had not. Teachers describe their students as being genuinely interested in their experiences and eager to learn about happenings at the various corporations, universities, and research institutions.

Another consistent outcome reported by directors is the realisation on the part of teachers that communication skills as well as skills of cooperation and problem solving are essential in the scientific/technological workplace. Teachers report that this realisation occurs as they are put in learning-intensive roles that bring them into contact with new people, new viewpoints, and new ways of looking at problems. As learners, teachers have a unique opportunity to reflect on the learning process as they engage in experiences that challenge them to rethink their own thinking and their own abilities to solve problems as individuals and as members of teams. Following participation in scientific work experience programs, many teachers report that they now plan lessons to develop these skills in their students and work toward increasing the use of cooperative learning strategies in their classrooms.

The shift in teacher attitudes relative to teaching/learning, the workplace, and professionalism has great potential for altering teachers' decisions regarding curriculum practice, district policy, and professional standards. Most teachers believe that direct, personal interactions with colleagues are the most effective ways to serve as change agents in their schools and school districts. Much of this interaction occurs in day-to-day conversations. Broader means of interaction and influence occur through curriculum committees, strategic planning committees, staff development programs, and program assessment committees.

Many teachers reflect on the internship experience as having long-range effects on their careers as teachers. Post-internship discussions and follow-ups with many teachers reveal other aspects of professional development that are directly or indirectly associated with their involvement in the program. Some of these aspects include:

(a) attending more professional conferences,
(b) attending or providing after-school workshops,
(c) taking additional coursework,
(d) seeking other internships,
(e) volunteering as mentors in school programs, and
(f) establishing links with industry and research personnel.

Each teacher's additional professional development experiences ultimately feed back into the classroom, school, and school district to enhance and enrich science, technology, and mathematics education.

Author's note: A more complete discussion of research-related internships appears in:

Gottfried S S, Brown C W, Markovits P S, and Changar J B (February 1993) Scientific work experience programs for science teachers: A focus on research-related internships. Association for the Education of Teachers in Science (AETS) Yearbook

Policy, Practice and Professional Judgement: School-Based Assessment of Practical Science
by J F Donnelly, A S Buchan, E W Jenkins and A G Welford

Practical work has had an important place in British science education for many decades. However, it was only in 1988, with the advent of the GCSE, that assessment of pupils' practical abilities was required within all science examinations occurring at the end of compulsory schooling. The innovation was welcomed by many science teachers, but it was also seen as the most problematic part of the new examination in science. The study reported in this book involved an in-depth examination of the implementation of this policy. It took place between 1990 and 1992, and involved extensive interview with schools together with a national questionnaire. The findings raise important issues, both about how policy decisions in education are taken and implemented. Those issues are of increasing significance as science education practice becomes even more subject to centralised control in the context of the National Curriculum.

Teaching Science for Social Responsibility
by R T Cross and R F Price

This book explores the nature and place of science, using that word very generally, in the wider society. The authors try and show that the common assumption among science teachers, that the science they teach is a simple but faithfully reproduced model of science in the wider, R&D world, is, in important ways, not correct. The authors also set out to make clear why this is and what can be done about it. The authors believe that science teachers, like all teachers, and indeed all members of a democratic society, share a common responsibility for the future of humanity. The special responsibility of science teachers is to teach in a way that reveals the socially produced nature of scientific theory and to teach the scientific knowledge and skills required for an understanding of the social issues which the public is increasingly being faced with. This, the authors contend, requires a different attitude to science from that which has been traditionally held by classroom teachers. This book extends the discussion initiated in the STS movement and illustrates that, by concentrating on the examination of the scientific evidence required for evaluating social issues involving science and technology, science teachers will be fulfilling their special responsibility.

ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1993

September 6-16
Science, technology and society – appropriate science education for the twenty first century
Location: Department of Educational Studies, University of Oxford, UK
Contact: Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN, UK
Participants focus on the following issues: (1) the nature of STS as education; (2) objectives and the evaluation of courses; (3) information, knowledge and public understanding of science; (4) industry and STS; (5) STS in developing countries; (6) law, values and decisions about the environment; (7) new curriculum materials; and (8) teachers and in-service education. The seminar is intended for experienced science teachers, educationists, and government officials involved with curriculum planning and implementation and in-service work with teachers.

September 11-14
2nd European Conference on Research in Chemical Education
Location: Pisa, Italy
Contact: Dipartimento di Chimica e Chimica Industriale dell'Università di Pisa, Risorgimento, 35, 56126 Pisa, Italy
This conference aims to describe the state of chemical education research and to help chemists develop this research, and develop a European cooperation for the defence and promotion of didactics. Topics include presentations and discourses, evaluation, trends in didactics, problem solving, experimental teaching, computer assisted teaching, new technologies, and chemistry and the environment. Languages of the conference will be English and Italian.

November 22-27
Asian Workshop on Global Change Education
Location: Madras, India
Contact: Prof R R Daniel, Scientific Secretary, Committee on Science and Technology in Developing Countries (COSTED), 24 Gandhi Mandap Road, Madras 600 025, India
COSTED, because of its interest in the promotion of environmental education in developing countries, is considering an evaluation of the suitability of the materials on Global Change produced by ICSE-CETS to meet the needs of teachers and students of the developing world. Participation is by invitation only.

1994

January
ASE Annual Meeting
Location: UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
Full details of this large international event will be circulated in Education in Science, a journal of the Association for Science Education.

April 7-23
Sixth Edinburgh International Science Festival
Location: Edinburgh, Scotland
Contact: Marion-Jane Patie, Assistant Chief Executive, Edinburgh Science Festival Ltd, 1 Broughton Market, Edinburgh EH3 6NU, Scotland, UK
Following the success of the 1993 Festival which attracted over 200,000 people to 367 events, preparations for the 1994 Festival are now well in hand. Major themes include: (1) Being the right size; (2) Molecule of the day; (3) Science myths of our time. In addition, exhibitions, talks, debates, workshops (including Madlab, Computer Arcade, Funamental Physics, Science Dome), family events, performances, tours, and conferences will be featured in the program.

July 4-8
CONASTA 43
Location: Launceston, Tasmania, Australia
Contact: Donna McWilliam, CONASTA 43, PO Box 1922, Launceston Tas 7250, Australia, Fax (003) 34 2598
The theme for the 43rd annual conference of the Australian Science Teachers Association (CONASTA 43) is 'In from the cold'. The program brings contemporary developments and information to teachers within an atmosphere of support. Hear about new ideas and approaches in science and technology, keep abreast of latest developments, evaluate new resources, and meet teachers from all over Australia and beyond. Keynote addresses, workshops, displays, social events and a family program make Launceston an exciting place to be in July '94!

July 27 - August 10
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

August 8-12
13th International Conference on Chemical Education
Location: San Juan, Puerto Rico
Contact: Kam S Lumba, Chairman 13th ICCE, Inter American University of Puerto Rico, PO Box 191293, San Juan PR 00919-1293
This will be the first time that an ICCE meeting will have been held in the Caribbean Region. The objective of this conference is to bring together chemistry teachers from the pre-college and college levels to share ideas and learn from each other about innovations in the teaching and learning of chemistry. The theme is 'Chemistry: The Key to the Future'. The Conference will feature plenary lectures, symposia, lecture presentations, workshops, poster sessions and exhibitions. Scientists and science educators from around the world will report their work.

August 24-31
7th International Symposium on World Trends in Science and Technology Education
Location: De Koningshof, Veldhoven, The Netherlands
Contact: Secretariat 7th IOSTE symposium, PO Box 2041, 7500 CA Enschede, The Netherlands
Symposium presentations will be organised around at least three cross-curricular areas of interest: (1) science/technology related social issues including environment, health, peace, third world development, risk and safety; (2) further education and employment including career orientation, career preparation; (3) teaching methods include fieldwork, cross-curricular projects, computer simulations. Proposals for these and other topics are invited that report/reflect on research, practical experience or innovations relating to the main theme of 'Science and Technology Education in a Demanding Society'.

September 21-22
Third Symposium on Education Industry Partnerships
Location: Frankfurt, Germany
Contact: Drs Jan Hendriks, Koninpad 3, 7921 BM Zuidwalde (DR), The Netherlands
The 3rd Symposium on Education Industry Partnerships will be hosted by the Association for German Chemical Industry (VDI), and organised by Hoechst. The program will be a most relevant follow-up to the recent Project 2000+ International Forum, since Education-Industry Partnerships are an important strategy for improving scientific literacy.

December 6-10
9th ICASE Asian Symposium
Location: Bangkok, Thailand
Contact: Dr Janchai Yingprayoon, Science Society of Thailand, Physics Bldg, Faculty of Science, Chulalongkorn University, Bangkok 10330, Thailand, Fax +662 253 1150
ICASE Asian Symposia are always a significant event in the Asian region, attracting delegates across the region and further afield. Science Education International will announce details of the next symposium to be held in Bangkok in December 1994.

1995

June 5-12
XVIII Pacific Science Congress
Location: International Convention Center, Beijing, China
Contact: Secretariat, c/o Institute of Atmospheric Physics, Chinese Academy of Sciences, PO Box 2718, Beijing 100080, PR China, Fax +86-1-2562458
The Pacific Science Association invites delegates to this Pacific Science Congress which focuses on the theme 'Population, Resources and Environment: Prospects and Initiatives. Scientific sections include Science Communication and Education. For those who are interested in receiving a First Circular, write to the contact address above.

July 26 - August 9
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

August 25 - September 1
International Conference on Industry-Education Initiatives in Chemistry
Location: University of York, UK
Contact: Miranda Mapleton, Chemical Industry Education Centre, Department of Chemistry, University of York, York YO1 5DD, UK, Fax +44-904-432516
This international conference is co-sponsored by the International Union of Pure and Applied Chemistry (IUPAC) Committee on Teaching of Chemistry, and the Royal Society of Chemistry Education Division and Industrial Division.

September
CONASTA 44
Location: Brisbane, Australia
Contact: David Tulip, Convenor, CONASTA 44, Queensland University of Technology, Locked Bag No 2, Red Hill QLD 4059, Australia
The theme of the 44th annual conference of the Australian Science Teachers Association (CONASTA 44) will be 'The Science Teacher – An International Perspective'.
Extending and improving education in science for all children and youth by assisting member associations throughout the world

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Science Education International

A new editorial team for 1994

By Brenton Honeyman
President, ICASE

As you read this, a new editorial team will have commenced the task of producing the March 1994 issue of Science Education International. Ronald J Bonnstetter of the Center for Curriculum and Instruction at the University of Nebraska, USA will head the new team, comprising key science educators around the world. And just as the founding editorial team established new ground for ICASE four years ago, I am looking forward to seeing the ICASE Journal grow in its impact as it takes on new challenges and some revisions in format. I wish Ron and his team well as they undertake this important task on behalf of ICASE.

Just over four years ago, the ICASE Executive Committee endorsed the proposal that an ICASE Journal be published as a quarterly service to member associations, replacing the newsletter which had been produced until that time. This venture set out to provide a means for member associations, institutions, centres, foundations and companies, and for individuals concerned with science education, to share perspectives, concerns, ideas and information which would foster cooperative efforts to improve science education, and which would serve as a chronicle of the advancement of science education throughout the world.

Through the early establishment of editorial policy which sought to include a wide selection of articles representing input from as many different regions of the world as possible, the ICASE Journal has provided readers with a series of 'snapshots' of what is happening in science education around the world. For me, this has been a particularly rewarding aspect of my involvement with Science Education International.

For the past four years have put our team in a very privileged position to receive inputs from every corner of the globe. The diversity and, at the same time, the inter-relationship of ideas and issues around the world have meant that our task as an editorial team has been an enlightening experience. Thank you to all the many contributors for making our job an interesting one, and for being willing to share your insights and your experiences with the readers of Science Education International.

It is now four years since the journal content and format policy was developed. It is time, therefore, that we review the journal and prepare for changes which will strengthen both the content appeal to member associations and journal subscribers, and also the marketability of the journal leading to increased subscriptions.

There are many challenges ahead for the ICASE Journal. Jack Holbrook's recent participation in an International Meeting on Science Education Journals provided plenty of ideas for development. For some time now, we have been challenged by the task of providing journal articles in languages other than English. Resources permitting, this is an important development for ICASE to accomplish in the near future.

With the momentum of Project 2000 and its focus on six key areas of concern, there has been some initial discussion with the new editorial team in aligning the journal's columns with those six key areas.

I wish to record my thanks and appreciation to the many people who have supported the journal in various ways. In particular, my thanks go to the section editors and members of the advisory board — to Ron Bonnstetter, Lucille Gregorio, Jack Holbrook, John Penick, Mari Silis and Sue Dale Tunnicliffe. Their resolve to establish regular columns which share important ideas and statements in international science education has played a key part. My thanks also go to Jack Holbrook for his tireless technical support in supervising the journal printing and distribution. I am most appreciative of Dennis Chisman's diligence in managing subscription renewals. In addition Jack Holbrook, John Penick, Dennis Chisman, Bob Lepischak, Jan Hendriks, Ken Roy and others have worked hard to ensure that there is a constant flow of input to and articles for the journal — this has been critical in ensuring a balance of input across the globe, and I am very grateful for their efforts.

Through my previous role as Convener of the ICASE World Conference on Science Education and the Quality of Life which was held in Canberra, Australia in July 1988 and my roles as editor of Science Education International and Who's Who in Science Education Around the World, I have been in a key position to develop an extensive worldwide network of science educators. For this, I am very grateful, and I look forward to continuing the work of ICASE with friends and colleagues around the world in my new position as President.

Brenton Honeyman (Photo: left)
ICASE President
New Regional Representative for Latin American and Caribbean Region

ICASE welcomes Dr Jose A Chamizo to the ICASE Executive Committee, as the new Regional Representative for the Latin American-Caribbean Region. As the regional representative, he will be liaising with ICASE member associations and institutions in the area, and endeavouring to build up a strong network of science teacher associations in this important region. Dr Chamizo can be contacted at Colegio Madrid, A.C., Calle Puente 224, 14380 Mexico D.F., Mexico, Tel +52-5-673-1959, Fax +52-5-673-1826 for science education in the global community, working with its members to enhance the quality of science education for all.

• Strengthening the financial base of ICASE so that the Council is able to carry out its programs;
• Expanding existing services, and developing new services to meet the evolving needs of member associations, institutions, centres, foundations, companies and individuals with an interest in science education;
• Identifying and involving science educators and others in assisting the Council to carry out its initiatives.
• Developing policies and operational procedures to facilitate existing programs, and to more effectively address and respond to new challenges.

A new information folder entitled ICASE: The People and the Organisation is being compiled for use in increasing ICASE membership (currently 120 member associations, institutions, foundations and companies around the world), and in negotiating the involvement of organisations and companies in the support of ICASE programs.

For more information, contact Maris Silis, Policy & Development Officer.

ICASE Five Year Development Plan

The Executive Committee is currently considering a draft of the new five year development plan, which will be used to guide ICASE in terms of key areas of operation. Five major areas for development include:

• Establishing ICASE as an advocate

It's time to renew your subscription to

Science Education International

Renewals of individual and library subscriptions are due in December/January of each year

1994 subscription rates remain as follows:

Individual
£10.00
US$17.50
A$22.00
CAN$20.00

Library
£20.00
US$35.00
A$44.00
CAN$40.00

Subscriptions can be sent to: (cheques payable to "ICASE")

By Captain Jacques-Yves Cousteau
A Project 2000+ International Forum Address

This article is the text of a plenary address presented at the International Forum on Scientific and Technological Literacy for All held at UNESCO Headquarters in Paris on July 8, 1993.

When 106 heads of state and more than 135 national delegations closed the all-important Rio Conference on Environment and Development, simultaneously more than 800 Non-Governmental Organisations, originating from all over the world, closed their picturesque and vibrant meetings by a concert of hope and revolt. What had motivated such a momentous gathering? Certainly not just the desire to celebrate the twentieth anniversary of the historic Conference of Stockholm, but rather a growing, roaring consciousness that the future of our planet could be threatened and that the very survival of our species could be at stake. In spite of shocking differences between what was called the South and the North or between the East and the West, the people at large were realising that a global consciousness was born, and that neither the leaders nor the media were reacting accordingly to this universal need for closer solidarity.

What concrete results were adopted in Rio? A revolutionary program of badly needed reforms? Of course not! The two timid conventions signed, about biodiversity and global warming, as well as an inflated document, Agenda 21, were immediately criticised by a sarcastic press still under the influence of industrial lobbies. We must open our eyes, our ears, our hearts! The songs and dances at the Rio Forum, were irreversible hymns of hope and of faith in humankind, and the incomplete, laborious decisions of the 'Earth Summit' had made 'business as usual' impossible forever.

What is the future of the Rio spirit? A solution to the so-called economic crisis that affects only one fifth of humankind? Or to the unemployment tragedy that plagues a growing fraction of the wealthy nations? No, but now the whole world understands that in the third world unemployed are not counted in millions, but in billions, that the economic crisis is there – in Africa, South America and Asia – not as an artifact, but as an endemic plague.

And thanks to Rio, nobody on earth will tolerate any more that the rich would carry on getting richer, and the poor would become even poorer. This simple message was never as clearly heralded as in Rio and now, the leaders of countries as well as the international forces – UN, UNESCO, World Bank, IMF, EBRD, UNDP, WHO and UNEP – will be orchestrated by the UN Commission for Sustainable Development to implement the Rio Conventions and Agenda 21.

It is true that, in Rio, the paramount problem of population explosion was not identified as the major obstacle to our future. And the words 'sustainable development' were often branded as symbols of an upcoming miracle. The permissive use of that expression is typical of the generalised confusion we are living in. What is the goal of life? To die rich, or to live happily? Competition or cooperation? Most of the countries have changed their name of their 'Ministry of War' to 'Ministry of Defense' without modifying anything in their structure. In the wake of face lifting, the 'Ministries of Public Instruction' that taught education are replaced by 'Ministries of Education' only dealing with instruction and have become, under economic pressures, mere employment bureaux. The result is millions of jobless people who know how to safely pressurise acetylene or split atoms, but have never heard of Plato. Pleasure, a selfish satisfaction, can be bought. It has replaced joy in the heart of families, under the overwhelming influence of advertising. For the same reasons, science and technology are confused in the minds of adults as well as children; science anticipation is replaced by science fiction, as in electronic games. How can young men and young women of today, wishing to play a role in the construction of the future, hear with the absurdities of our social organisation? How can they tolerate that sophisticated weapons be officially sold as if they were harvesting machines, under the pretext of creating jobs or to fight international competition? How can they accept that this program results in enriching the rich and impoverishing the poor? Or even, in some countries, like France, accept that governments at the same time produce and advertise cigarettes and tobacco, while financing a campaign against tobacco?
When words have lost their original meaning, when simultaneous political decisions are often contradictory, when information becomes universal but unreliable, citizens lose their fixes, become temporarily intoxicated, but may wake up to violent protests. The public must be associated as an adult, responsible partner in all difficult decisions such as the acceptance of certain risks. All human enterprises may fail. Airplanes fall. Gas tanks explode. Nuclear plants themselves have proven not to be safe against mechanical or human failures. It may even be possible that with the fifty kilograms of enriched uranium missing in official world inventories, unidentified terrorists or an irresponsible national leader may use the ultimate atomic weapon. In the meantime, red and green mud are dumped into the sea, ships flounder with the loads of arsenic, nerve gases or defoliants; black tides multiply at a rhythm of almost one a week.

Scientific and technical progress have successfully fought sickness, increased the average lifespan and improved comfort, while inevitably generating some risks. But among these risks, we must decide to refuse those that have irreversible consequences, and to minimise the others. It is urgent to introduce in international politics, a new concept - the management of risks. This management of risks necessarily includes the evaluation of the consequences of possible accidents - not only in the short term but also in the long term.

This management thus begins by choices that must eliminate all the risks that have a chance, even minute, to threaten the essential survival of our species.

The tragedy is that technocrats believe that the public is not able to understand problems, that we have to be talked to like ignorant children, that the technicians are the only ones who know what to do. It is not true. They don't know what they are doing.

In spite of the arrogance of technocrats, we want to know the truth when an accident occurs. We want it to be the right of all people to decide what risks they will or will not take, to protect the quality of life for future generations. However serious problems are, such as pollution, desertification, depletion of the ozone layer, warming up of the planet, transportation of dangerous materials by sea or by air, or elimination of living species, we remain practically unaware of the main cause of all the threats that menace our planet and our future - the population explosion. The fact that this momentous danger is never mentioned by leaders demonstrates the seriousness of the confusion I mentioned earlier and in which we now struggle.

On the 30th September last year, I gave a speech on overpopulation at the United Nations. At the end, the head of UNFPA, Dr Nafis Sadik, gave me a computer that automatically counts the excess of births over deaths worldwide. It was only 281 days ago.

My display shows that during those nine and a half months, the population of the world increased more than 63 million - much more than the population of France! In my lifetime, the number of people tripled from 1.5 billion to 5.5 billion. In 40 years, it will reach 10 billion!

Almost all our social evils, famines, shocking differences between rich and poor communities, desertification, decrease of biodiversity, increase in the number of hereditary taints, and even the warming up of our planet, originate in the population explosion. And that explosion is due to the fact that our new set of antinatural values - generosity, solidarity, pride of our first medical victories on traditional evils - had been enthusiastically applied long before we developed their logical counterpart, birth control. Our lack of synchronism between part and counterpart shows that we have been very slow to understand that our revolutionary new course, replacing harsh natural rules by our own ideals of equality, fraternity, justice, implied new duties and perils. From victims of nature, we had to become relentless protectors of nature. By refusing for ourselves the Law of the Jungle, we committed ourselves to making sure that the natural vegetal and animal kingdoms around us would still benefit from that very Law of the Jungle they cannot survive without.

We have not yet fully realised that our recent divorce from Nature, is irreversible. Our ancestors have long ago burned the bridges and there is no possible return to nature. This implies for modern man the overwhelming burden to invent from scratch a behaviour at the same time acceptable

**Pétition pour les droits des générations futures**

La surpopulation et le débordement des activités humaines font peser une terrible menace sur notre descendance.

La Déclaration de droits de l'homme — qui proclame la liberté et l'égalité de tous — a deux siècles. Ce texte magnifique ne suffit plus. Nous exigeons que soient solennellement déclarés les droits des générations futures afin que tous les hommes héritent d'une planète non contaminée où toutes les formes de vie puissent s'épanouir.

En signant la pétition de l'équipe Cousteau, je demande aux chefs d'État du monde entier d'exercer toute leur influence pour que la Déclaration des droits des générations futures soit prise en compte par les Nations unies.

Equipe Cousteau
biologically, and satisfying for his moral ambitions. If we want our precarious endeavour to succeed, we must convince all human beings to participate in our Adventure, and we must urgently find solutions to curb the population explosion that has a direct influence on the impoverishment of the less favoured communities. Otherwise, generalised resentment will beget hatred and violence.

Our rejection of the Law of the Jungle came from our mind, not from our genes. Somehow, in the complex structure of our DNA is engraved our instinct to submit to the harsh laws and principles that have made the success and the diversity of life. The moral laws and principles that we have inherited, preferred and adopted will take a long time to conquer our genetic heritage.

We realise now that the subtle trail of our original wildcat nature has been saved, has grown and finally blossomed in the Free Market principle, the cornerstone of all our modern economy. The Free Market economy is by far the most efficient system. The collapse of the communist world is mainly due to the fact that in competition between East and West, the liberal economy of the West was much more efficient than the planned economy of the East.

However, once the East-West competition is over, a closer look leads to unanswered problems. Efficiency? What for? To boost the wealth of the rich fifth and sacrifice the poorer four fifths of human kind? Efficiency to favour the currency speculators? Efficiency to increase unemployment, to create millions of people in the richest countries? To waste resources here that are lacking elsewhere? Efficiency to provide youngsters with only one moral idea – get rich?

As long as the Free Market economy will not be far more severely controlled and submitted to our new set of Moral Values, it will be as cruel, as unjust, and will kill as often as the Law of the Jungle we have rejected.

Today, everybody agrees that Power – political, economic or industrial power – is only justified if it serves the people. And the people, finally emerging from ignorance, but drowned by a flood of incoherent information, are struggling in an ocean of confusion. They need clarification, they need to know the facts, even bad news; they have been lied to so often that they don't trust their leaders, their representatives not the media. And the relationship between Science and Media is at least as confused. The two communities do not speak the same language, and a few specialised interpreters are not sufficient to reassure the public. The new responsibility of scientists is to help change such a dangerous lack of faith, to dissipate confusion of the minds, to restore confidence in our destiny and individual pride in every human being.

Prince Albert of Monaco, a world renowned oceanographer, has been a major inspirational force in my life. He brought back from his expeditions information about marine life forms undreamed of before. But his commitment to understanding the world around us did not stop at merely answering a question to his satisfaction. He would personally ride a motorcycle from Monaco to factories in the suburbs of Paris in the late 1800's and talk to the workers, telling them of the importance of the ocean to the future of mankind. A prince mingling with the workers to tell them about science.

What an example for both scientists and newspeople! What a consideration for the average citizen!

The world can no longer survive without the help and total commitment of us all. Isolationism is unacceptable. Scientists themselves are absolutely vital to translate highly technical issues to all those who will elect or choose decision-makers. The public needs help. Citizens of the world must understand the consequences of – and the alternatives for – every course of action. But just the factual knowledge is insufficient by itself. There are moral and ethical issues which cannot be ignored.

The success of the Rio revolution is in our hands. We are millions of human beings, inspired by the Rio spirit and ready to serve as apostles to improve the habitability of our dear home, the Earth.

But threatened as we are by the imminence of the disasters caused by the uncontrolled and accelerated population growth, we all agree that education has become our last recourse. Education of children, of students, of adults, with an emphasis on women and girls, education to restore the pride and the dignity of every human being, rich or poor. Do we have time, do we have the means to successfully win this formidable challenge? Is it feasible to train children from all breeds without severely harming the precious diversity of cultures all over the world? The global generalisation of food, beverages, instruction, communication, literature and art, all inspired and imposed by economic imperatives, jeopardise the generous intentions born in Rio.

The trivial obstacle of the cost barrier is always underestimated in all official projects. Today 600 million children lack adequate education, or even any kind of education! To provide one pencil to all those kids would cost 6 million dollars! To provide one very cheap schoolbook would cost 200 million dollars. And the schools themselves must be built, teachers don't exist in sufficient numbers. No electronic device can even be considered! If the affluent communities were to decide to make the enormous sacrifices necessary, we would also be obliged to face the fact that the population explosion would in thirty years bring the number of children needing help from 600 million to 1 billion 200 million!

Let us not forget that what is at stake is who will win the race between schools and cradles – between an orderly human community, or chaos. We can only win this challenge if we have the courage to face such realities without flinching.

Commandant Jacques-Yves Cousteau, a world renowned speaker and author, has kindly given permission for the text of his address at the Project 2000+ International Forum to be published in Science Education International.

Cdt Cousteau would like to draw to the attention of readers the Petition (for a version in French refer to the previous page) for the Rights of Future Generations which is reproduced on the next page.
PETITION
FOR THE RIGHTS
OF FUTURE GENERATIONS

Overpopulation and the excesses of human activities are posing a terrible threat to our descendants. The Bill of Rights, which proclaims freedom and equality for all, was written two centuries ago. This magnificent text no longer suffices. We solemnly demand that the rights of future generations be formally declared in order that all people may inherit an uncontaminated planet where life may flourish.

Jacques-Yves Cousteau

By signing this petition, I request the leaders of nations worldwide to exercise all their powers that the Bill of Rights for Future Generations be adopted by the United Nations and become part of their charter.

NAME (in capital letters)                        ADDRESS                        SIGNATURE

THE RIGHTS OF FUTURE GENERATIONS

Article 1. Future generations have a right to an uncontaminated and undamaged Earth and to its enjoyment as the ground of human history, of culture, and of social bonds that make each generation and individual a member of one human family.

Article 2. Each generation, sharing in the estate and heritage of the Earth, has a duty as trustee for future generations to prevent irreversible and irreparable harm to life on Earth and to human freedom and dignity.

Article 3. It is, therefore, the paramount responsibility of each generation to maintain a constantly vigilant and prudential assessment of technological disturbances and modifications adversely affecting life on Earth, the balance of nature, and the evolution of mankind in order to protect the rights of future generations.

Article 4. All appropriate measures, including education, research, and legislation, shall be taken to guarantee these rights and to ensure that they not be sacrificed for present expedients and conveniences.

Article 5. Governments, non-governmental organizations, and the individuals are urged, therefore, imaginatively to implement these principles, as if in the very presence of those future generations whose rights we seek to establish and perpetuate.

For Europe, Africa and Oceania, please return the petition to:

The Cousteau Society
Scientific and Technological Literacy for All
A Perspective Reality

by Thomas R Odhiambo

This article is a plenary keynote address delivered on 8th July 1993 at the International Forum for Project 2000+: Scientific and Technological Literacy for All, Paris, 5-10 July 1993.

While education is taken to comprise ‘organised and sustained communication designed to bring about learning’, literacy implies an ‘attainment of comprehension through a basic educational process’. In the world of today, a basic comprehension of scientific knowledge and technological skills has become an imperative for personal growth and national development. It is in that sense that the call made by the World Conference on Education for All (held in Jomtein, Thailand, March 1990), in directing attention to the urgent necessity for creating a world community of scientifically and technologically literate citizens, was so apposite and timely.

To achieve such a goal would require of the education, both formal and non-formal, of the entire spectrum of the population – all children, youth, adults, and old folk. Indeed, scientific and technological literacy among the old people in Africa is critical – for three main reasons. First, the continent is characterised by the extended family system, in which the grandparents assume a pivotal role in terms of family traditions, community lore, the transmission of experiential knowledge to the younger generation, and the upholding of yardsticks of excellence and societal expectations. Even though, by 1990, the old only comprised 6.0% of the total African population – in contrast to a larger proportion in the rest of the world (UNESCO, 1991) – they wield enormous influence on the eventual turnout of successive generations. Second, Africa possesses a rich diversity of languages that is found nowhere else in the world. Eschewing dialects and regional variations, Africa has more than 2050 indigenous languages – all demonstrating a varied tapestry of poetry, song, ballads and verbal repositories of natural histography, applied sciences and technology, and philosophical musings and political economy. Thus, Africa has been always intensely literate in oral tradition, and in reading verbal and body language, whereas the written literacy has been spotty throughout the 7000 years of African civilisation, from the Pharaonic times to the present. And third, the comprehension of science is not absolutely tied to the understanding of mathematics ‘of abstract and logically rigorous formulation’ (Medawar, 1967). The essence of understanding of science consists ‘in becoming aware of what is there, in nature’ (Medawar, 1967). This sagacious view is shared by Enrico Cantore (1977) in his book Scientific Man where he states that ‘science constitutes an essential factor of the historical development of man as a cultural being . . . I began to perceive that science is human not because it is produced by man, but also because it is in itself an agent fashioning man in culturally new ways’ (Cantore, 1977). To treat science as merely a tool, a handmaiden for development, or other variants of instrumentality, would be both shortsighted and short-handed; know-how alone would lead Africa nowhere. Africa’s sense of sagacity is vital.

Science is more than a tool

Such a paradigm is well expressed in an important area of Africa’s traditional knowledge base, which cannot be ignored in building a modern agricultural science and practice in the continent. This view was strongly expressed in a recent gathering of agricultural scientists and African farmers in Nigeria:

‘. . . the traditional knowledge base grows and develops through the accumulation of new experiences and the tested results of experimentation and repeated observations. It is evolutionary in character, but it is nonetheless solidly based even though it does not necessarily grow through the analytical methodology of science. The challenge for the African agricultural scientist is to be able to understand and rationalise this vast traditional knowledge base so as to have a systemic foundation on which to build a truly African-oriented science-based agricultural practice.’

Thus, agriculture in Africa should not only be conceived as instrumentality for earning a living. In the African context, where farming still commands the services of a very large agrarian population (from the least in Mauritius and Egypt, of 19.0% and 32.8% of the entire national population, respectively; to the normally high proportion as reflected in Senegal and Rwanda, at 80.6% and 92.8%, respectively) (UNDP, 1991), agriculture ‘must regain its capacity to provide a challenging and worthwhile way of life: an agrarian environment should not only be farmed, it should also be worked, perceived, known and lived. In short, we are looking at farming as a way of life rather than merely a source of employment’ (Odhiambo, 1992). In this milieu, the sagacious old people in the agrarian environment are able to impart a holistic sense of rural life that may well attract the youthful and the new literates to stay put and work at enjoying a fuller rural life.

The problem of the youth in Africa, that is those who are 15 years or below, who will have attained middle-level leadership roles by the year 2020, is extremely difficult in relation to the kind of education and training they should undergo in order to fulfill those roles. The scale of the problem itself is horrendous: in 1980, these under 15 year olds constituted a massive 90.3% of the population; in 1990, it escalated to 92.8%; moreover, there are only two working-age African adults for every school-age child, in contrast to a ratio of 1:5 in the industrialised North (UNESCO, 1991). The African population in 1990 was
approximately 648 million; at that time 240 million (or 37% of the population) constituted the labour force. The proportion of the labour force, those between 20 and 34 years old, in the year 2000 will rise to 42% of the total population. In the year 2025, the proportion of the African labour force will rise to about 45% or 650 million out of a total expected population of 1.6 billion. During that same year, the entire labour force in the industrialised North will comprise only 636 million (IMPACT, 1991). The current education system in Africa has achieved a great deal in the three decades since the great era of political independence, mostly in quantitative terms and in its phenomenal expansion from the secondary to tertiary levels. But these achievements have not kept pace with the quality expected from it, nor its relevance to Africa’s modern needs in a vastly competitive world which has left Africa, used to big-power protection and development aid, virtually alone and ignored. Africa needs to look afresh at the philosophical and operational bases of its education system – formal, informal and non-formal – and to deliberate on how to achieve the national and continental goals that the system is structured to attain.

Currently, the literacy rate in the continent is appalling. Adult literacy rate is a mere 45%, and even in countries with an old tradition of learning such as Senegal and Egypt, the literacy rate is only 32.1% and 44.6%, respectively (1985 estimates), with mean years of schooling a paltry 0.7 and 1.7 years, respectively (1980 figures) (UNDP, 1991). This relatively low rate, closely associated with the high density of material poverty in the continent, probably explains the comparatively low life expectancy of 51.8 years. What is most troubling, with a long-term impact level, is the paucity of scientific and technological capacity in the continent. Most countries in Africa, including Egypt, have less than 3 scientists and engineers per 1000 population (1980-1988 figures); and there are, on average, only 7.7% of the workforce employed in the industrial sector (UNDP, 1991). It is clear that the various national programs of universal primary education have achieved, or are approaching to achieve, quantitative goals that have been set; but they have left a yawning gap in scientific and technological literacy at the very top – with less than 26% university graduates qualifying in science-related subjects (UNDP, 1991) – and have shown abject failure in developing a quality content for this basic level of education. The World Bank perspective study, Sub-Saharan Africa: From Crisis to Sustainable Development (1989) has not minced words (World Bank, 1989). Quality has yet to be assured in primary education. Content is of low quality and relevance: indeed, ‘tests on reading comprehension, general science and mathematics suggest that many African students are learning very little’. Very little is spent on educational materials; on average, US$0.60 per student a year in Africa, in contrast to a basic requirement of US$5.00. And there is very little capacity to develop and fabricate low-cost teaching materials conforming to the requisite learning expectations (World Bank, 1989). Yet, education, particularly science and technology education, is intrinsic to modern social and economic development.

A profound change in this scenario can only manifest itself if the geopolitical leadership, the policy community, the scholarly and scientific community, and the business-industrial sector jointly and deliberately take a long-range strategic decision to break with the past, and adopt a vision of what the continent needs of its leadership.

---

**ICASE AWARD SCHEME**

for outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.

**ICASE Distinguished Service Award**

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

**ICASE Regional Service Award**

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels.

**ICASE Association Award**

This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association.

Contact Dr Jack Holbrook, Executive Secretary ICASE
72B Blue Sea House, 28th October Street, Limassol, Cyprus
by the year 2020. If the continent is to achieve a universal literacy in science and technology by that time, then it has to begin to deliberate along the lines that the Africa Leadership Forum, in its declaration formulated in The Kampala Document has highlighted. The declaration begins by stating that 'people are both the means and the desired end of the benefits of development. Africa's development is principally hampered by inadequate human capabilities' (Africa Leadership Forum, 1991). It then goes on to prescribe what to do:

- Illiteracy should be eliminated across the continent by the year 2000.
- Africa should adopt national systems of meritocracy; and should therefore adopt attractive levels of incentives and compensation for professionals and public servants, so as to curb the growing brain-drain, while ensuring that African talents in Africa are used in preference to foreign experts. In this respect, Africa should establish a bank for Africa's human resources and skills.
- Science and technology should be introduced at an early age into the national education systems.

Such thinking, as illustrated by The Kampala Document, needs to grow into a general public debate throughout Africa. Programmatic proposals which do not comprehensively examine both the process and the objectives are unlikely to make a deep impact. For instance, the electronic media have been touted as a possible option for mass education in Africa. Yet, as K'Omodho states in a recent paper to environmental journalists in Kenya, despite the current communication explosion, 'do we effectively communicate with our people? the huge investments by governments in the mass-media have not yet yielded real expected benefits, those of a people eager and willing to work for development' (K'Omodho, 1990).

Indeed, political will and purposeful leadership in matters of science and technology education, in furtherance of the empowerment of the entire population to engage in science-informed development, is what had distinguished Africa from its Asian co-developing countries, who are far outstripping it in this sphere. Forty years ago, the two continents had comparable living standards. How has Asia moved ahead, out-distancing Africa in the process? The InterAction Council, in its report of a high-level meeting it convened in Cape Town, South Africa, in January 1993, has reached a most revealing conclusion (InterAction Council, 1993). Apart from implementing a green revolution-type of agriculture, which gave the South-East Asian countries food security as well as permitting them to diversify their agriculture, and apart from adopting an aggressive and highly competitive export-oriented economy which diversified into light and advanced industries, and in addition to having stable governments, these countries have a high-quality education system for all, which produced an adequately educated and skilled labour force as well as a managerial class capable of absorbing technology and investment. This modernisation experience could be a model for Africa — without the continent de-banking its traditional values and experiences, as the Council states convincingly (InterAction Council, 1993):

"To release people's energies, Africa needs to bring back its own values, culture, identity and structures, to be confident in itself, to build on the people's sense of themselves . . . and to develop their capacity to think and act for themselves.

Development cannot be and should not be seen as something handed down from outside, but something emanating from within."

This lesson is hammered home by a South Korean political scientist very much involved in the Korean industrial resurgence, Dr Mark Suh, in his guest lecture to the Annual Research Conference of the International Centre of Insect Physiology and Ecology (ICIPE) in Nairobi, Kenya in May 1993, on 'Science and Technology Policy of Japan and Korea: From copy to self-reliance', when he concluded (Suh, 1993):

"The experiences of Japan and Korea indicate that the adaptation and utilisation of Science and Technology were essential for economic as well as social advancement. This required central planning and effective management of human as well as natural resources. Education played a very important role in producing needed scientists and in adapting and advancing foreign technology. Japan and Korea internationalised their economies rapidly without losing their own culture and social structure. The examples of these two countries' path to development through technological advancement and independence can serve as a guide to countries now faced with the great task of determining the most appropriate means of development."

There is no doubt that building an independent national and regional capacity in science and technology, able to create, adapt and utilise new results from scientific research and technological development (R&D), together with the entrepreneurial and managerial capacity to transform this knowledge and know-how into technological products and social services, is a prime requirement for the rapid economic and social advancement of the continent. Foreign aid — and even multilateral assistance — can only catalyse this process; it cannot be the sole prop for this very societal responsibility of the continent itself. United States Congressman George Brown has put it succinctly in characterising United States' aid for science and technology to developing countries (Brown & Sarewitz, 1991):

"In spite of such examples [of previous S&T aid to South Korea and other South-East Asian countries], efforts by the United States to promote economic development abroad have never included a comprehensive approach to science and technology. Although 'technical assistance' has been an integral part of US development aid since the late 1940s, it has not served to foster an independent S&T capability in developing nations. Moreover, the S&T budget for the Agency for International Development (AID) is almost entirely devoted to research carried out by US scientists on specific, and often urgent, developmental problems, not to institution-building. Of the $300 million operating budget for AID's S&T bureau in 1991, a mere $150 000 was slated for joint research with scientists from less-developed countries."

Thus, United States policy continues to focus on supplying
technology and US expertise to developing countries, rather than contributing to indigenous science and technology capacity.

The published word
The public debate on science and technology for national and regional economic and social development is only starting in Africa. The decision-makers, the opinion-makers, the money-makers; the geopolitical leaders, the geoeconomic leaders, the scientific and technological leaders; the civic communities, the agrarian communities and the workers communities — all need to be engrossed in this debate. This requires a comprehension and perspective view of science and technology of an entirely different order from what we have now.

Apart from the oral literacy in which Africa excels, it must also now embrace the written-and-reading literacy. The book, especially the science and technology book, must become a life-long friend and a fountain of knowledge and inspiration — rather than a route to success in school and college examinations. Yet the publishing world in Africa is a very poor world indeed.

There is, undoubtedly, a book famine in Africa. There are very few indigenous publishers of any significance in the continent. During the period 1985-1989, only four publishers in Kenya produced children’s books; in 1989, a mere total of 22 titles were published in the entire country. During the same period, a total of 1045 titles of all categories of books (textbooks, religious books, leisure books, etc) were published. Of these, only 25% were written in Swahili and other African languages. With about 300 languages spoken in Kenya, it is certain that the great majority of the people are not literate in their own languages — which are the carriers of their culture, mores and traditions, and on which a modern science culture should be grafted.

Although there have been many attempts by international organisations and aid agencies to foster an indigenous publishing enterprise in Nigeria, Ghana, Zimbabwe, Kenya and many other countries in Africa, a robust, confident, indigenous publishing world has still to make its entrance felt in Africa. In this situation, a concerned publishing consultant based in London, Hans Zell, was impelled to state the obvious line of needed action (Zell, 1992):

"The scarcity of books has meant that neither the needs of educational institutions nor of the general public can be met. Devastating and quite possibly lasting damage is being inflicted across a whole generation going through primary, secondary and university education in Africa today."

The problem is compounded by the fact that the African famine related to science literature is even more profound than that afflicting the general book availability in the continent. In a survey published in 1990 by the recently established Council for the Promotion of Children's Science Publications in Africa (CHISCI), of science publications available for children below 14 years in bookshops in Nairobi, just over half of the titles were published in East Africa, and of those only 1.69% publications were written in African languages. The paucity of mother-tongue science publications for African children is extremely serious, as it confirms the prevalent view that science is not part of the African culture. The principal motivation of CHISCI is to re-integrate science into African culture, since the current educational system does not relate science to everyday life, to household community life and to future livelihood. The Preface to the Survey concludes (Odhiambo, 1990):

INARTICULATE SCIENCE?
Perspectives on the Public Understanding of Science and Some Implications for Science Education

by David Layton, Edgar Jenkins, Sally MacGill & Angela Davey

The public understanding of science is a matter of concern in most countries. This is not simply because educators or scientists wish to promote a wider understanding of scientific ideas as worthy of the attention of all thinking citizens. Such understanding is commonly regarded as essential for the effective implementation of a wide range of social, economic, technological, medical, employment or other policies which have a scientific dimension. This book explores the ambiguities and limitations of the concept of 'public understanding of science' and, by means of case studies, addresses the meanings and social uses which science has for members of the adult public who are not themselves professional scientists. Drawing upon a substantial literature to place the case studies in a broader context, the final chapter examines the implications of the research for science education.

ISBN 0 905484 55 X, 159 pp, Price £9.95
"There may be many factors that could have led to this situation which could be attributed to economic situations in third world countries. However, CHISCI tends to be of the opinion that developing African countries have given this excuse for too long and this persistent shrouding of the problem has inhibited a lot of possible growth and development in many aspects including education. Science, in the context it has been put to the African Society, does not attract much attention... The best way to reverse this situation would be to inoculate science education at an early age."

Prospect

If science and technology is, indeed, to form an integral component of an African culture and to imbue it with its own genius and vitality, African educational systems — whether formal or informal, whether non-formal and on-the-job — must be able to speak, write and think science and technology in the language of the household, as a process of re-integrating science and technology into everyday living and lifelong cultural interaction, at the same time that the international language of science and technology — in its international dialogue and trade — continues the international tradition started in mid-nineteenth century, of communicating in English, French and German.

In this way, Africa will find a new harmony in their being at peace within themselves, while facing — at the same time — the competitive world of modern science and technology-dominated livelihood.

In the words of Sabra, in the Preface to his book on 'Theories of Light' (Sabra, 1967): "I came to see in the history of science the history of man's most imaginative and most rational enterprise." Africa needs to share in this exciting and rational adventure.

Science Education in Developing Countries
What's the Point?

by C J Stoll
Centre for Development Cooperation Services
Amsterdam, The Netherlands

Introduction
There is no doubt that the situation of mathematics and science education in many countries is in urgent need of improvement. Likewise, there is no doubt that a considerable amount of research has been done worldwide on basic issues of teaching and learning mathematics and science. Yet, the increasing level of our understanding of conceptual development so far has not been paralleled by an equal increase in the quality of science teaching. Problems of implementation persist worldwide and are perhaps most noticeable in the majority of the developing countries. In industrial countries there also is a huge gap between the desired state of math/science teaching and actual classroom practice.

At a recent conference on 'Science education in developing countries: from theory to practice' (Jerusalem, January 1993) the case was put forward by some that more attention should be given to the problems of science education specific to developing countries. In contrast, others argued that science education is an academic subject in its own right, and that the laws of Newton do not differ from country to country and neither do the difficulties which learners may have in understanding them. This dispute calls for an attempt to consider the question of 'what - if anything - is special about science education in developing countries'. In the following paragraphs some thoughts are given to this question, especially with respect to matters of teacher training and curriculum development.

The nature of the problem
The wave of post second world war decolonisation has led to many independent nations which had to develop their own educational systems on the basis of the pre-independence foundations. A common feature which is almost invariably connected with the post-independence educational efforts of these countries is the dramatic increase in enrolment figures in the educational system. Universal Primary Education is high on the political agenda of most countries (and rightly so!); this has led to an unprecedented expansion of many education systems in periods of time hardly exceeding one or two decades. The expansion of the primary education system has, with some delay, put an even stronger numerical pressure on secondary education. Figures from the World Bank Study on Education in Sub-Saharan Africa (1988) show that between 1960 and 1983 the educational systems at the primary level on average expanded by a factor of 4, and at the secondary level expanded by a factor of 14 ! The dramatic shortages of teachers which resulted from the steep increase in school enrolments have compromised the quality of the system often beyond the level of acceptability. In addition to teacher education not being able to retain quality with rapid expansion, the appeal of the teacher profession also declined, resulting in weaker students entering teacher education programs.

Among the numerous consequences of this educational policy, quite a few factors have a bearing on the situation of mathematics and science education at the secondary level. It should be noted in this respect, that in most countries the teaching force at primary level predominantly consists of generalists (one teacher per class, teaching virtually all subjects) whereas the teaching force at secondary level predominantly consists of subject specialists (many teachers per class, each teaching his/her own subject). At primary level, the vacancies are often pushed in a downward direction, the more competent teachers teaching the higher grades, leaving the lower grades for underqualified teachers and temporary stand-ins. At secondary level, however, the shortages of teachers may vary per subject, but are always largest in the mathematics and science subjects. Not only the numbers of students are low who opt for a career in science and maths because of the relative difficulty of these subjects, but also the economies in many countries are in strong need of science-based manpower in the government and private sector. As a result, the individuals who would qualify to teach science and maths in the secondary school system tend to 'evaporate' to greener pastures. Indeed, many of the less industrialised countries are struggling with the problem of an unstable and underqualified teaching force for the science and maths subjects, which are most crucial with regard to agricultural and industrial development. This situation profoundly affects any attempts to boost human resource development in the field of science and technology. For example, the scientific and technical manpower potential per million population was estimated (1985) to be 130 000 in North America as compared to 1300 in Sub-Saharan Africa (UNESCO, 1989).

The teaching of science and mathematics subjects by teachers who are insufficiently qualified to teach these subjects at the level they are required to do, often leads to a rather rigid teaching style with a minimum of interaction between teacher and learners: the less confident a teacher is in a particular topic, the more he or she is inclined to 'chalk and talk', sticking closely to prepared notes at best, and avoiding to deal with questions which might reveal the marginal level of understanding the teacher himself has of that topic. The response of learners in such cases usually is to rely on rote learning of the topic at hand. Many learners are finding their
way towards the final examinations on the basis of learning by head standard answers to standard questions, without a clear notion of why these answers are correct.

Furthermore, the curricula and accompanying textbooks inherited upon independence by many countries are of western origin. They often were adopted in full — for all practical purposes. Yet, not all syllabi which have a strong relevance for the average school in, say, Germany, are necessarily of equal importance to the average school in Zaire or Bangladesh. Moreover, even standard topics which feature in virtually all curricula should be presented in a local context. However, in many cases they are not. How then should teachers be encouraged to link their teaching to the daily experience of the learners, if there is such a wide gap between this experience and the educational materials they are provided with?

On top of that, here also the language issue comes in. In order for learners to build new concepts into the existing framework of reference it is of crucial importance that the learners should be able to discuss in their mother’s tongue all features and examples familiar to them which could contribute to attaining a full understanding of these new concepts. I think it is hardly possible to overestimate the importance of the role of the language and the selection of books in the teaching and learning of mathematics and science, the more so when the language of instruction is a second (or even a third!) language for both teachers and learners, as is the case in many of the developing countries. Last but not least, it should be realised that the budget available for science education is a factor which is extremely variable throughout the world. It will be no surprise to find that rich countries can spend more money on education than poor countries can (UNESCO, 1991), but it may be useful to bear in mind the fact that the poorest countries can spend less than 3% per pupil per year of what the rich countries do (i.e. approximately US$100 on average in 70 ‘developing’ countries, versus approximately US$3000 on average in 30 ‘developed’ countries). This not only has its negative effect on the remuneration of the teaching force, it is also reflected in the material conditions in the schools. Material conditions can be the mere availability of such basic things as classrooms, laboratories and furniture, but also the educational materials such as books, laboratory tools and demonstration apparatus.

Related to this are important considerations such as the organisation and management of schools and the effective use of teaching time, provision of facilities for making homework, etc. Moreover, the material conditions which affect the success of science education are not only the conditions prevailing in the schools, but also include material aspects of the learners’ lives such as nutrition condition, distance to be travelled (walking) from home to school and the conditions at home for studying and making homework.

Summarising then, the type and the magnitude of the problems which many of the developing countries are facing are unheard of in most industrialised countries, where the bulk of the research into cognitive problems and process
skills related to science education is taking place. It seems to me that we are missing the point if we try to contribute to strengthening science education in developing countries without addressing with some priority the issues raised in the previous paragraphs. Notwithstanding the high standards and the professional relevance of the bulk of the research in the field of science education, which are fully acknowledged and which should be given full credit, the issues studied are not always necessarily the most urgent ones as seen from the perspective of many developing countries.

Options for interventions
Some may well argue that it is not difficult to identify the solution to the majority of the problems described in the previous paragraphs: it is money. In this sense there is little the academic community of science educators can professionally contribute to solving the problem. However, in my opinion this issue cannot be dismissed as a non-issue. Quite to the contrary, it is only realistic to recognise the fact that this overriding problem in many countries will not be solved in the foreseeable future. It is necessary, therefore, to direct more efforts to the question of how to improve the quality of the teaching-learning process in situations where the social and material conditions constitute an extremely limiting factor. In the following paragraphs I will make an attempt to identify some areas in which the use of professional expertise in the field of mathematics and science education could play an essential role in addressing the problems in these fields in developing countries.

Interventions aimed at strengthening the teaching force
First and foremost, strategies should be designed which in the long run will lead to an increase of the numbers of mathematics and science teachers. In some southern African countries a number of donor-supported projects have been specifically targeted towards a steady increase in the numbers of students at the tertiary level with a math/science background (Dulfer & Thijs, 1993). Special bridging programs have been developed for disadvantaged students who failed to meet the requirements for regular entry into science based studies at tertiary level. These programs are of a remedial nature and offer an alternative route to potentially able students to pursue a science based career. In this way a process has been set in motion that tackles the vicious circle of a shortage of science students at tertiary level perpetuating the shortage of science teachers at secondary level, etc.

Second, proper attention should be given to the professional quality of the teaching force in terms of mastery of subject content. The very trivial observation that self-confidence in (school science) subject matter is a pre-requisite for good teaching more than any other factor (v.d.Berg, 1993) should have a bearing on teacher training curricula. Too often the curricula for training of mathematics and science teachers consist of a loosely designed package of university courses from a BSc degree program and elements of educational foundations, which does not specifically prepare the students for the teaching of secondary school mathematics and science. In many countries there is an urgent need for more targeted curricula for science teacher training (Ware, 1992). This statement also applies to teacher education in industrial countries (McDermott, 1990).

Third, ways should be found to improve the teaching-learning process, both in terms of educational effectiveness and in terms of local relevance (which are, of course, two sides of the same coin) (Knamiller, 1984; Lunetta & van den Berg, 1993). Regular in-service programs for maths and science teachers have been mounted in various countries in Asia and Africa which aim at supporting the teachers in acquiring a more solid professional background and a more challenging teaching style. Strengthening the morale of teachers, developing leadership in curriculum innovations and supporting the initiatives of professional associations of mathematics and science teachers are further tools which may be effective in promoting the case for science education.

With respect to these three crucial issues, the focus of 'science education in developing countries' should be on studying the effectiveness of a variety of possible interventions (or a combination of these, de Feiter, 1993) aiming at a greater stability and a stronger professional quality of the teaching force. It has been widely recognised (Knamiller 1984, 1992; Lewin 1992, 1993; Walberg, 1991) that all of these points offer a wide range of professional questions to be addressed in more detail, most of which are country specific, or at least show marked differences from region to region. Here is a role which science educators could take up with more vigour than hitherto has been the case.

Interventions aimed at developing a relevant curriculum and accompanying educational materials in a local language and local context
In each country it is important that the curriculum selected should be viewed in the context of the national educational system as a whole. What purposes is it supposed to serve? Is the curriculum predominantly meant to prepare the learners for taking up further academic studies for which mathematics and science are a prerequisite, or should it prepare school leavers who do not intend to pursue an academic career for life in the social and economic context pertaining to the country concerned? What types of science education curricula are best meeting the educational demands of a particular nation, and how large a diversity of curricular options is desired for a country so as to derive the maximum benefit from its investments in the educational system? In the last decade, indeed, many countries have embarked on a process of curriculum reform, both in the highly industrialised countries and in the less developed countries (for a survey, see Ware, 1992).

Not only the design and/or the selection of the curriculum presupposes a thorough analysis of the parameters defining the local situation. The process of implementation, too, can only be the result of an intricate interaction between curriculum developers, pre-service and in-service teacher trainers, textbook writers and examination boards. The development of locally designed trial materials, along with the evaluation of the use teachers can make of these materials, and an assessment of the effects on the performance of the learner, offer a vast field for much needed investigations which should yield the data on which implementation strategies can be based.
Problem of poor material conditions

It is essential to acknowledge the fact that material constraints — within certain limits — can only be overcome by well qualified teachers who are well motivated and resourceful. A weak teacher cannot achieve much, even if the material conditions are relatively satisfactory; a strong teacher can achieve a lot, even in relatively poor conditions. The teacher training process, therefore, is of crucial importance, but the teacher training curriculum should always take into account the limitations of the sometimes harsh reality the teachers will face once they are at post. This is not only a matter of developing low cost equipment, although simple home made teaching aids may turn out to be very powerful demonstration tools in teaching science in a local context (Van den Berg, 1988). It also requires school curricula and teacher training curricula which are designed with the explicit aim to make an optimal and creative use of the limited opportunities the locally prevailing circumstances still offer (Walberg, 1991).

Here, then, is another area to focus upon for science educators: how to develop and improve methods for teaching certain science and mathematics topics in countries lacking the financial resources to adequately equip the schools.

Conclusion

The point I want to make is, that the relatively poor performance in the areas of mathematics and science in many countries in the world is not primarily stemming from an insufficient access to the findings of science educators. The roots of the problems lie in the socio-economic conditions these countries find themselves in. This does not mean, however, that science educators have little to contribute professionally to improving the situation. There is a lot that can be done and must be done for which professional expertise in the field of science education is required. Studies should be directed towards the most effective strategies leading to an increase in the number of science and maths teachers. Within the context of each national educational system, teacher training curricula (both pre-service and in-service) need to be continuously evaluated and readjusted in accordance with the needs of the local society in any given point of time. School curricula in science and mathematics need to be localised and examinations design should parallel this development. Implementation of the intended curriculum innovation requires a thorough analysis of the teaching-learning process on daily classroom practice. Strategies for change need to be developed in consultation with the change agents themselves — the mathematics and science teachers. Building up more expertise in the areas mentioned above as areas of priority is the task of science educators. There is a valid point in 'science education in developing countries', and it deserves proper attention.

On the basis of the thoughts presented above I would like to address the question put forward in the introduction in an open mind. Science education as an academic field of study is a worldwide discipline. It studies the nature of the science subjects and the nature of the problems learners may have in understanding the basic concepts in the various subjects, and it develops teaching strategies for optimising the teaching-learning process. On the basis of this definition there is no need to discriminate between science education in the industrialised world and science education in developing countries.

INTERNATIONAL MEETING
Science Education Journals
Gaeta, Italy, August 1993

Report compiled by Jack Holbrook, ICASE Executive Secretary

Introduction
This international meeting brought together editors of international as well as national science education journals. Several national journals are, due to their distribution, available internationally.

Some journals carry abstracts in three languages. This could be important for any journal purporting to be international. However, it is far more desirable to have the whole article in the language of the reader if the journal is to be of benefit to the reader.

These, and many other issues of interest were discussed. The meeting was divided into four discussion groups. I have summarised the major discussion points, outcomes and recommendations from each group:

1. Discussion, outcomes and proposals: Supporting the author

   Awareness
   • Be clear about the purpose of the journal (eg Is it to improve science teaching in classrooms? Is it to support networks of academic researchers? Is it to give recognition to science education research?).
   • Provide clear guidelines, plus examples of good practice, both in general and specific to content.
   • A database on what journals are available and their emphases would help potential authors to become aware.

   Incentives
   • Have specific subject issues, and invite papers on these.
   • Use national conferences and contacts with schools to encourage teachers to contribute articles.
   • Make provision for authors to 'start small' by establishing special sections for short articles, reviews, notes and comments.
   • Editorial board members should actively encourage contributions and be prepared to give specific advice when required.
   • Make use of tertiary course assignments as a means to obtain articles (ie from pre-service courses, in-service courses, higher degree programs).
   • Consider the use of 'rewards' such as a free annual subscription, or a free copy of a special issue, or even payment for the article (although this is not usual practice).

   Support
   • Help for teachers modifying their manuscripts could be provided by supervisors, researchers, editorial board members, etc.
   • Rewrite a potentially good article completely.
   • The editor to communicate positively and constructively with authors concerning articles which have been rejected or articles which need modifying.
   • Referee's comments to authors should also be positive. This can be achieved by having comments in two parts, one part for the editor only, and the other part for the author.

   Personal follow-up in order to encourage potential authors is useful.
   • Keep authors informed of review procedures and the stage the article has reached.
   • Encourage (even insist) on quick reviews and decisions on whether to publish or not.
   • Establish guidelines which lead to quick publishing of articles once received, eg the time from submission of an article to decision on whether to publish could be set at a maximum of three months; the time from acceptance of an article to actual publication could be set at a maximum of 18 months. This course would depend on the nature of the article or contribution.

   • The language of international journals needs careful consideration. Should it be English only? Should it be English, Spanish and French? Should it be English but with abstracts in other languages? Internationally, English is the most widely used second language and, unless costs permit multiple language versions, it is realistic to expect that English will continue to be used as the language for international journals.

   • To help authors, steps should be taken to review articles in the language of the author and to have the articles translated after acceptance. This may necessitate an international network of referees.

Dissemination
• Articles need to be comprehensible, useable, interesting, relevant, and rigorous.
• Better dissemination to teachers will result if international journals can be linked to national journals.
• Abstracts should be in the language of the author and the journal.
• A circulation centre should be established for abstracts/contents pages
of science education journals, preferably as a national/international database. The centre should receive the titles/abstracts as soon as the manuscript is accepted, rather than waiting until published.

Group 2 Discussion, Outcomes & Proposals: The Nature of Research

Responsibility of authors

- Authors should consider the following process for developing an article for submission to a journal: (1) circulate to peers; (2) present at conferences at a local, regional or international level; (3) communicate the idea of the article to the editor, or discuss with a member of the editorial board; (4) construct a personal review process; (5) collaborate as needed in areas of weakness.

- Authors should locate the study within the expectation of the community of researchers and/or teachers to whom the article is primarily addressed. This includes use of key concepts about which the community has shared knowledge.

Responsibilities of Editors – General

- These include providing feedback to authors; providing feedback to referees; providing information to contributors; accepting citations used by authors who are not known to the editor or the reviewer (eg due to the use of another language); dealing with conflicting judgements from different referees in ways which take into account known strengths/weaknesses/biases of referees; providing advice on format and academic qualities required by the journal (including publishing of exemplary papers, publishing of comments on the quality of such papers alongside the papers themselves, publishing papers on research methodologies, etc).

Responsibilities of editors – Specific to influencing authors’ thinking about and practice of research

- Publish reviews or research in areas to increase the clarity and relevance to teaching and to focus on practical involvements.

- Invite papers that encourage voices from new researchers (eg teachers, culture, nationality, across professions)

- Encourage different voices on new topics and policies.

- Publicise events which bring teachers together with researchers.

- Editors can ask for a review paper to help new authors (teachers, non-speakers of English) understand new research strategies.

- Editors can encourage authors to focus on educational issues and not just research issues.

- Editors can communicate to teachers, the journal’s policy regarding the purpose of research and the style of research.

- Editors can consider whether dissemination of research to teachers be by national or international journals.

- Editors can encourage authors to improve their papers’ ability to communicate to practitioners and professional concerns by considering: inclusion of vivid descriptions of the critical events in classrooms; linkages between principles of education and expression in practice; the personal and social contexts which can cause plural understandings and thus the need for expression of alternative or rival theories that explain practice; the use of simple and direct language avoiding jargon.

- Editors can consider articles which might be used in monographs or special issues.

- Editors can consider including a section for reports written by or in collaboration with classroom teachers, and establish a board of teachers as reviewers for such sections.

- Editors can request the inclusion of implications for practice in articles, or the inclusion of evidence for problems being solved in reports of research.

- An annual review could be written by a teacher or group of teachers or representatives of a national community of researchers directed towards teachers’ concerns and problems about practice.

- A common framework for dissemination of review type articles could be employed across journals.

- Solicit readers’ and teachers’ evaluation of research reported, including discussions of the impact specific articles have on teaching and on thinking about teaching.

- Attend conferences to solicit research papers and elicit the teacher’s perspective on the impact of these papers on their practice.

- Editors’ support of one another in increasing the impact of research articles upon teachers’ thinking and practice

- Share exemplary papers (ie those showing high quality communication

If you belong to an association which is an ICASE member the card entitles you to benefits from the member association of the country you visit

Contact your local association

or Dennis Chisman, ICASE Honorary Treasurer

Knapp Hill, South Harting, Petersfield GU31 5LR, UK
and/or high quality of the paradigm of research) for discussion among editors, boards and reviewers.

- Collaborate in an action research enquiry into editorial practices, with the aim of improving editors' judgement of quality with special reference to the impact upon teachers.

The evidence may include: anonymised cases of submitted papers which have generated controversy in refereeing and editorial decision-making (eg dilemma between judgements of high teacher relevance vs low academic rigour); personal records by referees to the editor on the thoughts and feelings evoked by the paper (their subjective experience of wrestling with the dilemma); brief account of the reasons leading to the decision made; evidence elicited from teachers who read the anonymised article and report on its impact on their thinking and practice.

The analysis may involve the editor theorising about how the dilemma was solved in each case and what principles are justified to guide the judgement of future cases, and collaborative cross case analysis and testing of principles in action as against criticism of other editors.

Roles and responsibilities of researchers wishing for increased impact of their research upon teachers' thinking and practice

- Consider an appropriate type of involvement with teachers within the spectrum of cooperation and collaboration.
- Establish the relevant agreed power, control and ethical relationships, giving as much as possible to the teacher.
- Assist teachers to create conditions within their own teaching for the conduct of data gathering.
- Encourage the adoption of teachers' own questions, problems and concerns as the research foci.
- Take sensitive account of the culture of the classroom in the task of interpretation of evidence.
- Consider very carefully how to decide what evidence to report and which interpretations to pursue when the complexity of classrooms make so many available.

- Remain open to the many factors which may be relevant in complex classroom situations, and yet work towards a sharp focus.
- Accept that such research will be very difficult, very time consuming, but very important.

Group 3 Discussion, Outcomes & Recommendations: Audience Needs

Audience

- Can any one journal cater for all the needs of university teachers; high school & primary school teachers; researchers; university and school students; educational advisers and policy makers; subject specialists; generalists?
- Are the readers also writers?
- In catching the reader, it is necessary to consider the nature of the captive audience as well as market forces.
- There is a need to balance the needs of readers, writers and editors as follows.
- Specialist needs (in physics, chemistry, biology, university, etc.) vs broad range of interests (all researchers, science teachers, etc.)
- Emphasis and personality of small number of editors (shape and design of journal's direction) vs responsiveness to a large group or organisation (demands of organisation of readers)
- Research and academic articles (what teachers should be reading) vs professional, practical and classroom material (what readers want for their work)
- Service to readers (abstract service, translation to other languages, thematic issues, separate sections) vs service to writers (editorial assistance, offprints, copyright protection, quick response)
- Pro-active (anticipating themes, generating controversy, soliciting articles) vs reactive (presenting members' views, responding to needs, association journal)
- Cost/profit support (subscriptions, fees, government grants, budgets) vs quality and value for money (colour, technical support, more pages, more issues, good paper)

- Voluntary workload (unpaid editors, secretaries, no technical support) vs publishers' provision (fees, time, computers, full time staff)
- Choose key contributors as mediators between science of classrooms and research/practice.
- Other discussion points included more teacher material, consideration of other languages and cultures, review policy to expand and expose ideas, change structures to meet new demands, plan early for themes and debates and new ideas, review quality and presentation, and monitor readers' opinions.

Group 4 Discussion, Outcomes & Recommendations: The Make-up of a Journal

- A summary of journals (teacher-oriented, student-oriented, research) was presented.
- While recognising the popularity of informal/popular science magazines, it was decided not to discuss the role of such commercial publications.
- It was decided to focus discussion on possible modes of collaboration (eg develop a system to share journal title/abstract database; brainstorm ways to provide science educators and teachers with greater access to knowledge; establish communication to facilitate international discourse and collaboration on projects.
- It is ideal situation to have the capacity to freely translate and publish any article at any time; to have the capacity to have multiple/concurrent submission of a manuscript; and to be able to distribute any or all reprints in multiple quantities upon request. The constraints are clearly the copyright laws and the copyright issue depending upon use.
- It was resolved that both organisations and individuals should identify articles of interest, and that the editor corresponds directly with the author when requesting that the author adapt the article to meet his/her rationale/purpose.
- In the area of special issues or thematic editions, there is an identified need for synthesis articles to be orientated toward to international community, to be issue oriented, and
to summarise what we know, the contexts and to target future action. While the journal could commission papers, most will still need to adhere to editorial review policy. This appears to be possible within existing organisational structures and does not infringe upon issues of editorial board responsibility, compared to a proposal which would require periodic reviews of literature, format/section requirements.

- Possible first themes and sample ideas include (1) international dialogue on the science curriculum – goals, purposes, curriculum orientation; aims/forms of use of experimental work, purposes, new technologies, evaluation/assessment; link to teaching/learning literature; relationship among disciplines/ways to establish interdisciplinary bridges; (2) issues of teacher education; (3) teacher oriented synthesises of research on specialised topics within science education that could enhance the teaching and learning of science.

First International Conference on Geoscience Education and Training

A conference report

The UK’s first ever international conference on geoscience education and training was held at the University of Southampton from 20-24th April, and turned out to be a resounding success. Some 250 participants from 50 different countries worldwide attended – everywhere from Croatia to Vietnam, Lithuania to Columbia, Senegal to The Phillipines.

But equal to the spectrum of nationalities represented was the range of questions addressed:

- How should we teach geoscience at school and where is it provided for in different national curricula?
- How are we coping with the challenges that face higher education today and are we keeping pace with the dramatic changes in educational technology?
- Why do so many girls choose to study geology at university and how can we redress the pyramidal decline of women geoscientists moving up the career ladder?
- Does the quality of geoscience degrees worldwide match the needs of society and how do we further meet the training needs of business and industry?
- Is geoscience education responding adequately to the very real and live issues of global environment and development?
- How do we as geoscientists translate our knowledge and concerns to the language of politicians and planners?
- What are the ways in which we can raise the general profile of geology in our society? What is the role for geotourism, ecotourism, etc?

"At first we thought that this was far too much for a single event" said the Conference Convenor, Dr Dorrrik Stow of the University's Geology Department, "but we divided the issues into five separate themes, each with its own set of workshop sessions, and ran with it. The information exchanged, ideas generated and enthusiasm promoted was quite astounding."

Several keynote speakers were invited to address the plenary sessions. Sir Ronald Oxburgh, Science Adviser to the UK Ministry of Defence, gave a lively and graphic illustration of how geology has changed from a sterile to a sexy subject. Jerry Leggett, Scientific Director of Greenpeace, spoke passionately of our overriding responsibility to the environment, to document the long-term changes in global climate and to warn our politicians the consequences of our actions. Diane Warwick of The Westminster Foundation for Democracy emphasised the importance of a stable social, economic and political foundation as the template on which to build any meaningful educational service.

The ideas flowed! A geo-walk around the city demonstrated how effectively building stones can be used to teach geology. Good practice in field excursions was further examined during the wet evening in a local gravel pit and through a sunny day on some classical geological sections along the south coast. Workshop sessions were devoted to the use of self-instructional computer programs for teaching, the making of geo-movies, the greening of geoscience, adult education and much more.

An evening workshop on Women in Geoscience was brimming with anecdotes and statistics. Jane Plant, Assistant Director of the British Geological Survey, profiled this largest employer of geologists in the UK, clearly illustrating the slow change towards equality between the sexes. Rosemary Enie recounted the struggles of being the only girl geology student in her class in Nigeria, whereas Zac Amante-Roberts portrayed the higher profile of women geoscientists in The Phillipines.

At the close, the convenor said "Geosciences play a vital role in underpinning the social and industrial infrastructure of nations, and the training of geologists is therefore crucially important for the future. We had hoped that this meeting would provide a valuable forum for the international exchange of ideas, methods and data, and that it would stimulate a continuing dialogue between participants. On both counts we are delighted with the outcome."

The conference was organised by AGID and COGEOED (IUGS) in association with ICSU, the Earth Science Teachers Association (UK), The Geological Society, The Geographical Association, The British Geological Survey, the Geology Department of Southampton University, as well as ICASE.

Science, Technology and Communication: Utilisation depends on access

by Mitch O'Toole

This paper considers the relationship between science and technology and explores the role of communication in student access to either. Some indications of communicative difficulty are touched upon and the issue of teacher expectations is raised. The author proposes that science teachers take an active role in helping students to meet those language expectations which are often implicit in science curricula.

Science and technology are not necessarily a 'horn of plenty' from which national development will flow. Science involves a search for more powerful explanations while technology involves the refinement of 'knowhow' (Cross and Price 1992 p27). The relationship between the two is more complex than it may sometimes seem. Optimal development involves repeated interaction between both scientific and technological workers. Inappropriate technology will divert, if not waste, both finances and energy as surely in Hamburg (Germany) as it will in Hermannsburg (central Australia). Choices between technologies rest on explanations of their uses and functions as well as on knowledge of how to use them. Unthinking transfer of technology from one context to another can cause a host of unintended effects, many of which undercut the very reasons for which the technology was transferred.

A fundamental example

Remote Aboriginal communities in central Australia exist in very arid environments. The people do not move around as much as did their grandparents. So the disposal of human waste becomes very important to the health of the community. Traditional Australian pit-style bush latrines are smelly and unhygienic. They also support large numbers of bush flies, and these are a major cause of eye disease in remote communities. One response to this has been the provision of urban type ablation blocks with toilets attached. These require considerable water and some expertise if they break down. Urban style facilities tend to be used until they stop working and are then ignored or destroyed. The technology is not understood, and is only valued so long as it is useful. When it ceases to work, the community leaders see no reason to continue caring for it. A concrete ablation block squatting in 40 degree Celsius heat is only a smelly inefficient oven when the water stops flowing!

The Centre for Appropriate Technology (1990) developed a low maintenance alternative in 1982 (see Figure 1). The Ventilated Improved Pit (VIP) latrine is a safe, hygienic and comfortable place to sit which has outlasted more sophisticated systems in many remote communities. It is still very much in demand and the VIP latrines often remain in use even after flush toilets can be maintained by the community. The contrast between appropriate and inappropriate technology is fairly clear. Appropriate technology persists while inappropriate technology falls into disuse. In this case the appropriate alternative involved the application of some fairly basic science. The VIP latrine depends on understanding the behaviour of bush flies (they do not like dark places), heat absorption (a dark pipe will get hot), heat flow (heated air will rise) and the interaction between the three. The vent pipe produces a draught which draws the smelly air out of the pit, keeping the latrine in good odour and the flies out.

A balance between knowing how to do something and having enough understanding to decide whether the action is wise is very important for both local and national development. It is an essential part of literacy in science and technology. Science contributes that understanding.

The language of science

However, science is a communal activity. It is carried out by communities of scholars who are united by a common interest in the features of the material world around them and grouped according to the parts of that world in which they are interested. One of the marks of the scientific community is the specialist style of language which it has developed for internal communication. The scientific style is a characteristic mix of features drawn from the standard dialect of English. It is much more than merely a matter of jargon. The details of the scientific style have been investigated by many workers including Widdowson (1974), Evans (1974), Gardner (1974, 1977, 1980), Lynch et al (1979), Taylor (1979), Triamble (1985), and Veel (1992). Halliday (1990) indicates that the processes which led to the development of this style may not be restricted to the English language. Scientific registers seem to be emerging in other
languages as well.

Consequent problems for learners

Over the past decade, more and more science teachers have become aware of the difficulties which the scientific style can cause for secondary students. Vecl (1992) is part of an entire edition of the Australian Science Teachers Journal devoted to language and science. Student language difficulties have been most obvious to teachers working in richly multilingual contexts, but they are by no means restricted to such contexts. Gardner's work on non-technical words shows remarkable consistency, whether the students are in Papua New Guinea, Australia, the Philippines or the United Kingdom. There is also evidence of a similar consistency in the difficulty caused by features of the style at other levels (O'Toole 1985).

Many students are having some difficulty with the language through which secondary science is communicated.

These difficulties are being documented in reports on the final school exams in New South Wales, Australia. The examiners who compile these reports are science teachers and academics. They are neither language trained nor often able to clearly articulate their language expectations. However, they are able to recognise text which does not meet those expectations. They drew attention to student difficulty with technical words (such as 'geomorphology'), non-technical words (such as 'describe', 'name' and 'code'), sentence structure, expression and spelling. Some of the problems which the examiners isolated are well known. Students are notorious for not reading questions and then answering only part of what is asked. However some of the comments refer to specific communication difficulties, and there is sometimes a very fine distinction between a communication difficulty and a problem in conceptual grasp.

When students favour Lamarckian explanations of biological adaptation, it can be very difficult to disentangle conceptual confusion from imprecise expression. However, the very difficulty of separating conceptual and communicative issues makes student control of the conventions of the expected style all the more important. The recent examiners' reports indicate that there is a clear problem with communication within science for the senior school candidate group at large. The problems are not restricted to a small group of students for whom separate remediation may be appropriate. It is also unlikely that the phenomenon is restricted to Australia. If these problems exist among students who both choose science and complete their secondary education, it is little wonder that there are difficulties with scientific literacy in the general population.

Teacher expectations

Science teachers share a fairly broad constellation of expectations regarding students. They expect students to be able to understand when instructions or explanations are given. Teachers expect students to be able to extract meaning from text. They expect students to be able to demonstrate their understanding by answering questions or giving explanations. Teachers expect students to be able to write practical reports, notes, summaries and answers to examination questions. They expect students to understand instructions which deal with the particular processes and concepts of science.

It may be that some of the things teachers expect are unreasonable. It is true that a lot of needless verbiage could be cut out of science. Science text should not require 'the ability to comprehend inordinately circumlocuous prose all set about with fractured syntax' (Macinnis 1979 p5). However, there are some things which teachers will still want students to be able to do. Syllabus documents form expectations regarding students' communicating by reading, writing, speaking, listening, graphing, tabulating and so on. Teachers will continue to expect students to access stored knowledge to solve problems and this access is gained by extracting, organising, interpreting and evaluating information. Public statements by scientists, or about science, are often made using the specialist language style of science. Students need to be able to understand these statements before they can meaningfully evaluate them. Such evaluation is a necessary part of any notion of scientific literacy.

As science teachers, we need to be conscious of our language expectations because we do have reasonable expectations about what our students should be able to do in science. If our students do not meet these expectations then we should help them. If we want our students to function within the scientific style, then we need to actively teach it. Many students are not able to absorb the scientific style by intellectual osmosis. Lack of control of the style will greatly impede their access to the products of the scientific community.

Figure 1 The C.A.T. Ventilated Improved Pit Latrine

![Diagram of C.A.T. Ventilated Improved Pit Latrine]

22
We want our students to gain this access, so that they can use those products to improve their lives. The language through which that community interacts is a barrier to our students gaining such access and their attempts at that language can be a barrier to students demonstrating their degree of access in formal assessment tasks. If we expect them to write clear, concise and accurate practical reports, then we need to spend time teaching the conventions which define that particular format. If we expect them to describe complex processes and explain how they come about, then we need to help them to write paragraphs. No one else is going to teach our specialist style for us. We need to teach the things we expect our students to be able to do.

**Little use without access**

We want our students to have access to the intellectual products of the scientific community so that they can make proper use of the technological products which are proliferating so widely. This desire does not seem to be realised. Many of our students are not acquiring the concepts and skills which are the focus of much of our activity. This has wide social implications as schools are potentially the most efficient, if not always the most successful, agent for disseminating knowledge through the community. Once students leave school, they are no longer nearly so available, and attempts to help them come to clearly understand and wisely use are much more difficult.

Science is communicated through a particular style of language, and if students do not have some degree of control over this style, their access to the products of the communities which use it will be necessarily restricted. People who teach science, prepare science resources and write science textbooks all use versions of scientific English. Science teachers often expect students to operate within the style. Students need to be able to read material written in versions of the scientific style if they are to acquire the information contained in that material. If operation within the scientific style is seen as a reasonable expectation on the part of science teachers, then they need to be prepared to teach the requirements of that style directly. That is not as large a task as it sounds, as there is a variety of published material which they can use to help them do this. Supplementary language exercises (O'Toole 1992) can be selected or prepared to isolate and expose the features of the scientific style which cause problems for students. These can

---
be sequenced into conceptually coherent sets which form a more active alternative to the more usual practice of note copying. Language development tasks can be used to realise the positive potential of group based practical work (Freer and O’Toole 1990).

There will be little wise use of technology if people do not have access to the tools for understanding provided by the scientific community. However, science teachers can make a positive contribution by directly teaching the style through which scientists communicate. Science teachers use a version of the style themselves and often expect students to operate within it. Therefore, directly teaching the style which forms part of their own expectations will certainly improve the performance of students for whom they are responsible.

Professional Development for Science Teachers: A School Based Approach

by John Loughran

Introduction

In the latter part of 1990 and for the first three months of 1991, 75 science teachers from varying schools across Australia were interviewed as part of the Science Education Professional Development Project (SEPD). This was a Department of Employment, Education and Training (DEET) funded Project of National Significance and its brief was to develop a strategy to enhance the professional development of science teachers.

The SEPD project aimed to provide data (Loughran & Ingvarson 1991a, Ingvarson et al 1992) that would eventually help teachers. Such data is helpful in better validating science teachers' views of professional development and thus strengthening the need for enhancing science teachers' professional development.

This paper attempts to outline one recent attempt at responding to some of these findings.

Factors affecting teachers' views of professional development

During the interviews, a number of issues were raised by science teachers as they discussed their experiences of professional development activities. There was no disagreement with the notion that if a science teacher is to develop and grow in a career, teaching and professional development should be closely linked. But for varying reasons, science teachers perceive that this is not as common as it should be.

1. Low level expectations for the value and usefulness of professional development

Teachers' expectations of professional development were affected by their previous experiences. They had come to expect little from professional development activities because they had received little from them in the past. For many their expectations were often related to the level of boredom they had experienced. The activities they attended did not seem to have a positive impact on their professional development and tended to encourage them to be wary of their choices in the future. Consequently, valuing the professional development activities currently offered was not common.

The main point in many of these interviews was the frustration from not getting enough in-service education focused on science content, and the teaching of science content — what Shulman (1987) calls 'pedagogical content knowledge'.

As many formal professional development activities for science teachers do not appear to address satisfactorily their pedagogical needs, they tend to look elsewhere for advice and ideas to enhance their pedagogical content knowledge. This may be one reason why science teachers tend to attach more importance to talking informally with colleagues than to externally organised and run professional development activities. They continually spoke of 'learning from colleagues' and 'sharing ideas' as major influences on their professional development.

2. Low level requirements for their own professional development needs

The striking feature of teachers' responses to questions about their professional development needs was the modesty of their claims. By any objective measure, or in comparison with other occupations, science teachers have limited opportunities to keep up with their field (Loughran & Ingvarson 1991b). But, an extra half-day or so for a course, a chance to visit another school or a factory — these were the limits of most teachers' claims. Their responses were couched in global terms related to such things as resources, equipment (amount and use of), content, 'catchy' new experiments, teaching strategies, technology and, in Victoria, the VCE (Victorian Certificate of Education).

It seems as though science teachers were not used to being consulted about their professional development needs. When speaking with science teachers, it was readily apparent that if professional development incorporated a process of determining needs then the outcomes would be much more positive.

3. A lack of participation in professional development activities

Of all the science teachers interviewed, 77% had attended no more that one day of professional development in science in the previous two years. Only 4% had attended more than three days of professional development in science during the same time period.

It is difficult to imagine how it is possible to stay in touch with one's area of science with so little time for professional development. It also seems quite unfair to expect science teachers to be up to date with recent
innovations with so little support. It seems an unreasonable expectation that science teachers keep up to date with their specialist field when they are not given a real opportunity to be involved in professional development activities.

4. A lack of time available to attend professional development activities

Many science teachers’ reason for limited involvement in professional development was a lack of time. Science teachers continuously spoke of an inability to ‘fit’ professional development into their schedule. For many teachers professional development was not a major school priority, or something their school could afford. This meant time to attend professional development became increasingly difficult for individuals. This is not to suggest that science teachers used ‘time’ as an excuse for non-attendance. Most of the science professional development activities that teachers attended were in their own time after school and on weekends. This was due to the limited opportunity they had to attend during school hours and partly because the organisers were teachers themselves and could not be released to offer the programs during the day.

5. Feelings of guilt associated with ‘abandoning’ classes and ‘forcing’ colleagues to cover their absence

A disincentive for involvement in professional development activities was the feeling of guilt that many teachers experienced as a result of being away from school and their classes. It was difficult for science teachers to reconcile the benefits of professional development with the consequences of the absence from the classroom and from school generally. Another disincentive to attend in-services is the extra work their absence creates for them. When teachers are working away from school, they have to prepare appropriate work plans for replacement/substitute teachers to follow. They also feel that the students are missing out if they are not there to teach their own class.

Minimal relationship between professional development activities and shifts in their pedagogy

Unfortunately, it was not common that science teachers noted much, if any, change in their teaching as a result of professional development activities. Significant changes in attitude and skill take considerable time. Programs that lead to changes in pedagogy are time consuming, expensive and require ongoing commitment. But the opportunities for such involvement have been limited.

A response to the SEPD findings: school-based professional development

It is interesting that in Britain similar concerns about science teachers’ professional development are also emerging. Nott, Watts & Oakes (1992) describe how a recent survey of science teachers illustrates how uninformed science teachers are about the opportunities of in-service education. Also, how little control they have over their own professional development. They highlight the need for career development to be matched by appropriate professional development and that this be a right and a duty, not “as it is at present—snatched opportunities”.

One way of responding to these findings is currently being explored at a large independent co-educational school in Melbourne. The Science Coordinator has organised to bring professional development to the teachers. More importantly, the nature of the professional development varies with the teachers’ needs. The program is organised so that each member of the science faculty is given the chance to work with a science educator from a nearby university. However, the collaboration between the two revolves around the school setting, not the university. In this case, the science educator must be able to attend the school when the teachers are free, rather than the teachers having to fit in with the university’s timetable or program. This effectively gives the teachers control of when they will be involved in professional development, considerably easing the constraints on their time. The issue of time is also minimised as the activities occur at the school, removing the burden of travel often associated with getting to professional development activities.

The success of the collaboration hinges on the relationship each individual teacher has with the science educator. A major requirement of good professional development is trust. Because this project is for a minimum of twelve months, interpersonal trust between participants is developed over time enhancing learning opportunities for all those involved.

Program organisation is dynamic rather than static. Teachers ‘contract’ with the science educator to discuss their issues/concerns and to decide how they might like to tackle them. A variety of approaches has been developed in the first six months of this project. One approach has been for the teacher to invite the science educator into his/her class to observe ‘normal’ classroom practice. As was pointed out by one of the science teachers, “I haven’t had anyone actually watch me teach since I did my DipEd.” An important aspect to this approach is that the teacher is using a third person to act as an observer or recorder of the classroom events. This means that reflection on activities may be enhanced as the observer can concentrate on the events without having to also be responsible for directing them. Debriefing focuses on students’ approaches to learning, giving the teacher the chance to construct appropriate pedagogical responses for future lessons.

Debriefing is not an expert’s critique of a teacher’s lesson. It is (and must be) a genuine sharing of ideas and construction of responses to the complexities of learning in the particular class being observed.

Variations of this activity have included the teacher seeking help with particular teaching strategies. In this case, different ways of teaching content may be tried (eg Jig-saw group work method, interpretive discussions, Prediction-observation-explanation techniques) so that the teacher’s understanding of these skills may be increased; the focus always being the impact of the strategy on student learning. Another is the teacher directing the observer to note how particular teaching skills (eg questioning, wait-time, encouraging student responses) are performed. This leads to debriefing that focuses on a teacher’s skills, but is not personally
threatening as it is at the individual's instigation so tends to be a very positive learning experience.

Because the project has no formal organisational structure which must be adhered to, a great degree of flexibility in the mode of professional development activities is developing. One of the most interesting has been by a small group of chemistry teachers. They have organised to meet at the same time each week and to discuss how they have taught particular content and how it influenced their students' understanding. Through this approach, they are able to 'experiment' with different teaching strategies in the same content area all at the same time. Therefore, their discussions allow them to better compare and contrast approaches and to seriously reflect on both the advantages and disadvantages from their own perspective. That way, no-one is 'forced' to take pedagogical risks that they are uncomfortable with, but are able to 'ease' themselves into areas which they may once have lacked the confidence to pursue. Also it allows them to have a more coordinated approach to curriculum development and to use the science educator in different ways at different times. This varies from a resource for ideas on teaching strategies, to a researcher, or additional classroom teacher depending on the need at the time or as the teachers see fit.

Implicit in this project is the need for the professional development to be responsive to the teachers' needs. After six months of 'experimenting' it appears as though real inroads are starting to be made. The teachers are dictating the direction of the project and are apparently bridging the theory-practice gap as they seek to better understand their own teaching and their students' learning. This has been possible because barriers to professional development for science teachers noted in the SEPD project are being addressed. Their expectations of professional development are raised because they are able to set the agenda, therefore placing more value on the process and the outcomes. Their requirements of professional development increase as their individual needs are able to be addressed. They also get more from the activities because they put more into them. Their participation rates have increased because access is easier and does not require extended absence from the classroom, resulting in time being better used so that professional development is moulded around the classroom instead of out of the classroom. Finally, there is a positive relationship between professional development and pedagogy because student learning has become the focus. Therefore, shifts in pedagogy are inevitable if teachers genuinely wish to enhance their students' learning.

**Conclusion**

There has been a considerable advance over the past fifteen years or so in what we know about effective models of professional development. This research is well summarised in a number of publications (eg Commonwealth Schools Commission 1988). Effective professional development is best if it is long-term and carefully planned with follow-up support. There are no short cuts to change in teaching methods but science teachers should at least be in a position that affords them a reasonable opportunity to be involved in professional development. It is important that the professional development offered to science teachers is appropriate and relevant as well as being presented in a meaningful way.

The Commonwealth Schools Commission (1988) report 'Teachers Learning' defines the purpose of professional development as improving the 'educational enterprise' through improved teaching quality and better student outcomes. Professional development is a useful medium for focusing teachers' attention on research and practical classroom activities designed to improve the quality of science teaching and learning. It should be an integral component of work, not an occasional additive. The school-based program briefly described in this paper is one attempt at doing this.

A more extensive research report will be written at the completion of the first twelve months of this project. It will be documented from the teachers' perspective so that learnings may be built on in the future in a similar way to the PEEL project (Baird & Mitchell 1986, Baird & Northfield 1992). Through this mechanism of reporting research findings, it is hoped that teachers' knowledge might be better documented and become more accessible to other teachers. That way professional development might be better able to help science teachers bridge the theory-practice gap.

Exsciter Paks
A classroom resource playing a role in the professional development of primary teachers

by Brenton Honeyman

At first sight, it looks like a spelling mistake! But 'Exsciter Pak' is an acronym for 'Exciting Science & Technology Resource Pak'. A number of 'paks' have now been developed by Questacon – The National Science and Technology Centre in Canberra, Australia. Titles currently available include Bubbles, Environment, Music, Balloons, Candles and Energy. Each pak includes an activity booklet which includes core activities, explanations of science principles, links to everyday situations, and suggestions for further exploration. The paks contain the necessary materials for each of the core activities. Materials are usually readily available from supermarkets, etc.

The paks are being used in a variety of contexts. They are popular purchases by families visiting Questacon, a large interactive hands-on science centre with a national charter to facilitate the understanding of science and technology by Australians of all ages. As such, the paks are helping children and adults in family settings to understand simple science concepts and how they relate to their everyday lives.

The paks have also been used in School of the Air programs. This involves sending paks in advance to children living in isolated regions of Australia, and their teacher communicating with them by two-way radio. The teacher 'coaches' the children as they learn through the many open-ended hands-on activities.

But, by far the biggest demand for Exsciter Paks has been by classroom teachers in primary schools across Australia — and one of the reasons for their popularity is that Questacon's workshop program for primary teachers has been using the paks to illustrate how they can bridge the gap that is so often missing in other primary science resources.

The professional development program entitled Hands-on Minds-on: Strategies for Primary Science and Technology consists of a series of workshop sessions during which primary teachers experience a variety of strategies which focus on the quality of interactions between teacher and students. The very first activity that participants experience involves them in a fun exercise which, at first sight, seems to be a great idea for a science activity. But participants come to realise that it is not enough to simply do activities, no matter how much fun or excitement they may generate. It is important for primary teachers to provide hands-on activities so that they are minds-on as well.

The workshop program goes on to emphasise the importance of (1)
providing a context which is real for children; (2) providing opportunities for open-ended investigating and exploring; and (3) helping children to develop an understanding of the science underlying activities. The workshop program explores these points via strategies based on a constructivist model of learning, while building up teachers' understanding of -- and, just as importantly, confidence in -- a number of science topic areas. Exciter Paks help greatly in this because:

(1) they are structured so that teachers can use strategies to monitor children's learning growth as children explore the science activities;

(2) they provide simple explanations and storylines of the science principles involved; and

(3) they avoid the 'recipe' approach to doing science by encouraging children to carry out further investigations; solve problems; design, make and appraise a device or procedure; etc.

As such, they are proving to be a useful resource for schools implementing a primary science curriculum. Because they contain the materials required to do the activities, busy teachers are more likely to try the activities and therefore become confident in engaging their students in the activities.

Australia, as are many other countries, is engaged in a period of national curriculum development in primary science. The Centre's professional development program together with its Exciter Paks are providing primary teachers with support to tackle what is for many of them a formidable challenge because of their relative unfamiliarity with science.

Early in 1994, Exciter Paks will be available in a new 'export' pak form, and indications are that they will provide a useful resource for primary teachers in other countries. Some early planning has commenced to work with local teachers in other countries to adapt and translate the paks so that they relate to the contexts of children in those countries.

Each pak focuses on a theme which encompassing several science concepts:

**Bubbles**

Float a paperclip, make a soap powered boat, create bubbles of different shapes and explore the science of surface tension. Learn about animals that walk on water, how detergents clean away dirt, and lots more!

**Environment**

Explore the science of our environment -- investigate air pollution, make your own recycled paper and study the effects of sewage. Learn about soil erosion, acid rain, biodegradable materials, the effect of salt on the growth of plants, and more!

**Balloons**

Discover how rockets work, make a balloon powered boat and stick a pin into a balloon without bursting it! Investigate how hovercraft glide and satellites orbit the earth. Learn about air pressure, static electricity and more!

**Candles**

Explore the science of candles, create shadows of candle flames and make candles you can eat! Investigate the fascinating world of heat, design a hot air spinner and interpret invisible messages using a candle. Learn how water can be boiled in a paper cup, and much more!

**Other titles**

Other pak titles include: *Music*, which explores the science of sound and music; and *Energy*, which focuses on sources of energy and energy changes.

New titles in production for release during 1994 include: *Circuits*, which features basic electric circuit principles and problem solving; and *Magnets*, which explores the behaviour and applications of magnets.

Stepping into Science
An ICASE Primary/Elementary Science Project

AIMS
Stepping into Science is an ICASE project which aims to:

• Establish an international network for teachers to share ideas on the teaching of primary/elementary science and technology.
• Provide activities and support for teachers, thereby encouraging them to include more science in the primary/elementary curriculum.
• Promote the value of science experiences for young children throughout the world.
• Facilitate professional development opportunities for teachers by including sessions on primary science and technology in regional and international conferences.

ACTIVITIES
The Stepping into Science Team is actively involved in a number of projects and activities including:

• Publishing STEPS, the Stepping into Science Project Newsletter. This newsletter contains ideas for class activities at various levels in primary/elementary schools, activities for children to do at home, comments by network members on issues, examples of children’s work, lists of helpful resources and contacts.
• Contributing articles and ideas for the Primary Science Section in Science Education International, the ICASE quarterly journal.
• Compiling ideas and activities for inclusion in a series of sourcebooks on the teaching of primary/elementary science and technology.
• Coordinating a scheme to encourage children to participate in science and technology activities. Certificates of Participation have been produced, and are available for schools to use in rewarding students as they complete a number of activities. Certificates are colour coded in seven different colours, so that they can be used to acknowledge progress in science from early to advanced levels within primary/elementary schools. ICASE is grateful to BP (Oman) for sponsoring this scheme.
• Organising Stepping into Science workshops and displays of children’s work at national, regional and international conferences.

1993 International Model Solar Car Challenge
Adelaide, South Australia

On Sunday, November 14th, students from around Australia and New Zealand converged on Adelaide for the first International Model Solar Car Challenge—a unique event to design and race one-tenth scale cars powered only by solar energy. 24 teams brought their innovative vehicles to Prince Alfred College to compete on the 100 metre track. The teams, with members ranging in age from 12 to 18, had qualified for the event in state-based events.

The Chairman of the Organising Committee, Jeff McIntyre reported that the event had been a unique opportunity for students, teachers and parents to become involved in an event that links scientific, environmental and technical themes. "Students understand predictions of global warming and other environmental problems and realise that we must change the way we do things if we are to preserve our environment" commented Jeff McIntyre.

"As Thomas Edison once said, the best way to predict the future is to invent it" he added.

The first section of the event involved a time trial under artificial lights along a 15 metre single lane track. These time trials were used to provide the seedings for the outdoor event.

The outdoor event realised very fast times due to optimal sunlight conditions on a warm, cloudless day. Students raced their vehicles in pairs on a dual lane 100 metre S-shaped track and, considering that the track was not perfectly flat, the 20 km/h average speeds achieved by the faster cars were impressive accomplishments.

Cars progressed through early round-robin competitions through to semi-final and final rounds.

Winning teams were as follows:
- 1st place: Eastern Hills Senior High School Team 2, Western Australia
- 2nd place: Lynall Hall Community School, Victoria
- 3rd place: Eastern Hills Senior High School Team 1, Western Australia
- 4th place: Shalom Catholic College, Queensland

The next International Model Solar Car Challenge will be held in 1996 to coincide with the finish of the 1996 World Solar Challenge, which is a 3200 km race between full size solar powered vehicles from Darwin to Adelaide. The 1993 World Solar Challenge was the biggest event ever, attracting 46 entries from many nations including the USA, Canada, Germany, New Zealand, Japan, Switzerland and Australia.

One of the special features of the IMSCC event in November was the opportunity to see the vehicles and meet the teams which won top placings in the 1993 World Solar Challenge. The winning vehicle, the Honda Dream had just won the long race from Darwin to Adelaide in record time, travelling at average speeds between 90 and 95 km/h.

Utilising a teaching resource kit developed in Australia by Keymac Educational which includes an 8 watt array of Australian-made solar cells, students have used the event to explore ways to apply their increased knowledge of solar energy to improving transportation options of the future.

The 1993 International Model Solar Car Challenge was based on a challenge first held in Victoria and now held throughout Australia. In those events, students have advanced the design of model vehicles and, in the process, developed important teamwork and engineering skills.

It is hoped that IMSCC 1996 will attract teams from several countries. There is already a growing interest in Japan and the USA in joining this event. Model solar cars can be designed and developed on a small budget and therefore offers schools a viable way to participate in a program which has the

Photo: Brenton Honeyman (left) presenting the IMSCC Trophy to the winning team members of Eastern Hills Senior High School, Western Australia.
potential to link students of science, technology, environmental studies and enterprise programs in a team effort to design state-of-the-art model vehicles powered only by solar energy.

The 1993 IMSCC was generously supported by a number of sponsors including the Department of the Environment, Sport and Territories; Electricity Trust of South Australia; Energy Credit Union of Western Australia; General Motors Holden Automotive; Questacon – The National Science and Technology Centre; the Australian and New Zealand Solar Energy Society and the Society of Automotive Engineers.

For information about the 1993 event, or how to enter future national and international events, please contact:

Mark Needham, Project Coordinator
22 Harding Street
Glengowrie SA 5044
Australia
Fax (International) +61-8-296-5912

Photo (left): As the starter gate is open, the solar panels of two model vehicles begin their work of converting solar energy into electrical energy. The performance of these cars will depend on combined factors such as vehicle weight, suspension system, capacity to negotiate a curved track, gearing and motor specifications.

Photo (right): Two contestants wait to catch their model vehicles as they approach the finish line after negotiating a 100 metre S-shaped dual lane track made of corflute with PVC channel which, in combination with the guide pin mechanisms of the model cars, keeps the vehicles in their lanes.
Bridging School and University

The Pre-Entry Science Course at the University of Botswana

Edited by Mike Cantrell, Wim Kouwenhoven, Thabo Mokoena, Gerard Thijs

The book provides a comprehensive account of the development of the Pre-Entry Science Course at the University of Botswana from its inception in 1977 until the present. The Vrije Universiteit in Amsterdam has assisted the University of Botswana in implementing the Pre-Entry Science Course. This cooperation was the start of a broader program of so-called 'basic science projects' of inter-university cooperation of the Vrije Universiteit in Amsterdam with other universities in the region of southern Africa.

The topics and issues presented in this volume will be of interest to educational planners and policy makers and institutes in developing countries.

The book is not intended to be a detailed history of the course, but rather an analysis of the current program and the various strategies and refinements which have proved effective in the fifteen years since it began. It is divided into four parts:

The first part sets the scene describing the educational background and how the course was started with donor assistance. The second part considers the current Pre-Entry Science Course after sixteen years of development. The third part looks at the impact of the course from various points of view. The fourth and last part examines trends in this and other bridging courses in the region.

The seven month long course is not an A-level crash course for aspiring scientists. Rather, it attempts to remedy gaps in students' knowledge and skills, particularly the practical skills which are often underdeveloped at school, and provides upgrading from an O-level base to meet the requirements of the existing BSc year 1 program.

Language and study skills training is linked to the sciences so that students are better able to learn and succeed in the tertiary environment.

Within the Southern African region there is increasing concern about better access to tertiary education for disadvantaged students and ways to improve their chances of survival after admittance. This book is one contribution to the debate on this complex issue.

ICASE

The First 20 Years

1973-1993

A brief history

This new publication is a brief history of the International Council of Associations for Science Education.

It is not intended to be a comprehensive account, but rather an overview of the key happenings and milestones in the development of the organisation and the policies and strategies that have enabled it to reach its present position in the international community of science education.

It also looks forward to the future, especially to the turn of the century, and examines possible options for the continual development of ICASE as an umbrella organisation for science education associations and similar bodies.

Copies can be ordered from:

Charles Sturt University - Mitchell
Bathurst NSW 2795, Australia
ICASE is keen to arrange regional or world events for the benefit of member associations. If your association or organisation is interested in hosting an international seminar, workshop or conference, contact the Executive Secretary or your Regional Representative. To gain ICASE endorsement, the meeting must be international in nature, open to member associations, and, while all sectors of the science education community should be encouraged to participate, must be relevant to classroom teachers.

1994

January
ASE Annual Meeting
Location: Birmingham, UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
This large international event is the annual meeting of the Association for Science Education and features a wide ranging program of sessions led by speakers from many parts of the world.

January 27-30
SAARMSE Second Annual Meeting
Location: University of Durban-Westville, South Africa
Contact: SAARMSE Secretariat, PO Box 17112, Congella 4013, South Africa
The meeting, open to anyone interested in research in science or mathematics education, is being organised by the Southern African Association for Research in Mathematics and Science Education (SAARMSE). There is no specific theme for the conference, but there will be a major thrust in the areas of policy research and action research. The meeting will consist of plenary lectures, symposia, workshops, poster sessions and presentations.

April 7-23
Sixth Edinburgh International Science Festival
Location: Edinburgh, Scotland
Contact: Marion-Jane Pate, Assistant Chief Executive, Edinburgh Science Festival Ltd, 1 Broughton Market, Edinburgh EH3 6NU, Scotland, UK
Following the success of the 1993 Festival which attracted over 200,000 people to 367 events, preparations for the 1994 Festival are now well in hand. Major themes include: (1) Being the right size; (2) Molecule of the day; (3) Science myths of out time. In addition, exhibitions, talks, debates, workshops (including Madlab, Computer Arcade, FUNdamental Physics, Science Dome), family events, performances, tours, and conferences will be featured in the program.

April 10-13
International Symposium: When Science Becomes Culture
Location: Montréal, Québec, Canada
Contact: Quand la science se fait culture, Université du Québec à Montréal, CP 8888, succursale A, Montréal, Québec, Canada H3C 3P8
Symposium themes include: (1) Realities of today’s scientific and technological culture – how far have we come? National reports on accomplishments; (2) Methods and practices of scientific and technological culture; (3) Practitioners of scientific and technological culture; (4) Sharing of knowledge and democratic accountability; (5) Taking up the challenge of sustainable economic development. The deadline for receiving full papers (conditions apply) for consideration by the scientific committee is 1st February 1994.

June
Schola Ludus: Science and the Public
Location: Bratislava, Slovak Republic
Contact: Schola Ludus, Faculty of Mathematics and Physics, Comenius University, Mlynská dolina F2, 2 15 Bratislava, Slovakia
This international conference will feature four themes: (1) Building up a hands-on science centre; (2) Supporting lifelong education; (3) Building up an open and consistent learning about the universe and life on Earth; (4) Finding the essence of real scientific, human, technical and environmental problems. The conference sessions will be conducted in English and Slovak/Czech.

July 4-8
CONASTA 43
Location: Launceston, Tasmania, Australia
Contact: Donna McWilliam, CONASTA 43, PO Box 1922, Launceston Tas 7250, Australia, Fax (003) 34 2598
The theme for the 43rd annual conference of the Australian Science Teachers Association (CONASTA 43) is ‘In from the cold’. The program brings contemporary developments and information to teachers within an atmosphere of support. Hear about new ideas and approaches in science and technology, keep abreast of latest developments, evaluate new resources, and meet teachers from all over Australia and beyond. Keynote addresses, workshops, displays, social events and a family program make Launceston an exciting place to be in July 94!

July 17-22
Fifth InterAmerican Conference on Physics Education
Location: Texas, USA
Contact: Robert Beck Clark, Texas A&M University,
College Station, Texas 77843-4242, USA, Fax +1-409-845-2590.
The theme of 'Building bridges for cooperation in physics education' will feature sessions in English and Spanish.

**July 27 - August 10**
**London International Youth Science Forum**
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

**August 8-12**
**13th International Conference on Chemical Education**
Location: San Juan, Puerto Rico
Contact: Ram S Lamba, Chairman 13th ICCE, Inter-American University of Puerto Rico, PO Box 191293, San Juan PR 00919-1293
This will be the first time that an ICCE meeting will have been held in the Caribbean Region. The objective of this conference is to bring together chemistry teachers from the pre-college and college levels to share ideas and learn from each other about innovations in the teaching and learning of chemistry. The theme is 'Chemistry: The Key to the Future'. The Conference will feature plenary lectures, symposia, lecture presentations, workshops, poster sessions and exhibitions. Scientists and science educators from around the world will report their work.

**August 24-31**
**7th International Symposium on World Trends in Science and Technology Education**
Location: De Koningshof, Veldhoven, The Netherlands
Contact: Secretariat 7th IOSTE symposium, PO Box 2041, 7500 CA Enschede, The Netherlands
Symposium presentations will be organised around at least three cross-curricular areas of interest: (1) science/technology related social issues including environment, health, peace, third world development, risk and safety; (2) further education and employment including career orientation, career preparation; (3) teaching methods include fieldwork, cross-curricular projects, computer simulations. Proposals for these and other topics are invited that report/reflect on research, practical experience or innovations relating to the main theme of 'Science and Technology Education in a Demanding Society'.

**August 28 - September 2**
**Scicon 94**
Location: Wellington, New Zealand
Contact: The Convenor, Scicon 94, PO Box 523.
(VCI), and organised by Hoechst. The program will be a most relevant follow-up to the recent Project 2000+ International Forum, since Education-Industry Partnerships are an important strategy for improving scientific literacy.

December 6-10
9th ICASE Asian Symposium
Location: Bangkok, Thailand
Contact: Dr Janchai Yingprayoon, IPST, 924 Sukhumvit Road, Bangkok 10110, Thailand, Fax +662 381 0750
ICASE Asian Symposia are always significant events in the Asian region, attracting delegates across the region and further afield. The theme of this symposium, organised by the Institute for the Promotion of Teaching Science and Technology (IPST) and The Science Society of Thailand, will be the use of computers in science education and the need for low cost, locally produced equipment.

1995

January
ASE Annual Meeting
Location: UK
Contact: Annual Meeting Secretary, ASE Headquarters, College Lane, Hatfield AL10 9AA, UK
This large international event is the annual meeting of the Association for Science Education and features a wide ranging program of sessions led by speakers from many parts of the world.

June 5-12
XVIII Pacific Science Congress
Location: International Convention Center, Beijing, China
Contact: Secretariat, c/o Institute of Atmospheric Physics, Chinese Academy of Sciences, PO Box 2718, Beijing 100080, PR China, Fax +86-1-2562458
The Pacific Science Association invites delegates to this Pacific Science Congress which focuses on the theme 'Population, Resources and Environment: Prospects and Initiatives. Scientific sections include Science Communication and Education. For those who are interested in receiving a First Circular, write to the contact address above.

July 26 - August 9
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

August 25 - September 1
International Conference on Industry-Education Initiatives in Chemistry
Location: University of York, UK
Contact: Miranda Mapleton, Chemical Industry Education Centre, Department of Chemistry, University of York, York Y01 5DD, UK, Fax +44-904-432516
This international conference is co-sponsored by the International Union of Pure and Applied Chemistry (IUPAC) Committee on Teaching of Chemistry, and the Royal Society of Chemistry Education Division and Industrial Division.

September
CONASTA 44
Location: Brisbane, Australia
Contact: David Tulip, Convenor, CONASTA 44, Queensland University of Technology, Locked Bag No 2, Red Hill Qld 4059, Australia
The theme of the 44th annual conference of the Australian Science Teachers Association (CONASTA 44) will be 'The Science Teacher – An International Perspective'.

October 27 – November 1
Third Conference on History, Philosophy and Science Teaching
Location: University of Minnesota, Minneapolis, USA
Contact: Prof Fred Finley, Dept of Curriculum & Instruction, University of Minnesota, Minneapolis, MN 55455 0208, USA, Fax +1-612-624-8277.
The organisers are keen to encourage the production of units of work and lessons in science and mathematics which incorporate historical and philosophical themes.

Science Education International
Guidelines for Contributors
Updated: January 1994

Science Education International is the quarterly journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science by assisting member associations and institutions throughout the world to examine ways of promoting scientific and technological literacy for all and to provide a foundation for the professional development of our science and technology educators and leaders.

This Journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science and technology education throughout the world.

Section Contributions
When sending material to section editors, it is preferable that it reaches the section editor well in advance of the deadline for submission to allow for review and first round editing. Each section will offer a balance between an elementary and secondary focus, with half of the annual contributions being directed at each level.

Copyright
Unless otherwise stated, material published in Science Education International may be reproduced without prior permission by association, institutions, centres, foundations and companies who are members of ICASE. Acknowledgment of both ICASE and Science Education International is requested. The opinions expressed in this publication are those of the authors and do not necessarily represent the official position of ICASE or ICASE members. In general, articles submitted for publication should not have been previously published, and the author is responsible for securing permission to use any material under copyright.

Language
Articles and other materials are accepted in English, French, and Spanish. French or Spanish articles should be sent to Ronald J. Bonnstetter, Editor, 211 Hennizk Hall, University of Nebraska, Lincoln, Nebraska 68588-0355, USA.

Feature Articles
Feature articles should be relevant to an international readership. Feature articles are normally solicited by invitation. Authors submitting feature articles for publication must restrict the length of article to 3000 words, including references. Authors are encouraged to include relevant diagrams, graphs, tables, and photos to illustrate their articles (see guidelines for supply of artwork and photos below). In addition, the author should supply a portrait photo and brief summary (50 words) of position and responsibilities, institution, etc.

Feature articles should be sent to Ronald J. Bonnstetter, Editor, 211 Hennizk Hall, University of Nebraska, Lincoln, Nebraska 68588-0355, USA. In the case of unsolicited articles, the Editor will advise each author whether the submitted article has been forwarded to a Section Editor or accepted as a Feature Article after an examination by referees.

ICASE News, Science Education Around the World, Resources, Calendar
Contributions for these sections should be brief and relevant to an international readership. It may be acceptable to submit excerpts from other publications and periodicals. For the sections ICASE News and Science Education Around the World the author may send a portrait photo and/or a fully captioned photo relevant to the event or project, together with brief details of author’s position, institution, etc. For the section Resources, a photo or line artwork pertaining to the resource may be sent with the contribution (see guidelines for the supply of artwork and photos below). These contributions should be sent to the journal editor.

Research on Curriculum, Teaching, and Learning
Articles about science education curriculum development and research should be relevant to an international readership. The number of articles published in this section will normally be limited to one per issue. The length of article should be limited to 1500 words, including references. Authors are encouraged to include relevant diagrams, graphs, tables, and photos to illustrate their articles (see guidelines for the supply of artwork and photos below). In addition, the author should supply a portrait photo and brief summary of position, institution, etc.

For more detail as to the nature of this section please review Focus Area Two of Project 2000+, Scientific and Technological Literacy for All found in the September, 1992 issue of SEI, Vol. 3, No. 3, page 5-6. Articles should be sent to the Section Editor, Jon Pedersen, 314 Graduate Ed., University of Arkansas, Fayetteville, Arkansas 72701 USA

Teaching Materials and Strategies
This section includes classroom ideas, student activity sheets, and articles which are relevant to an international readership. Each contribution should be short. Authors are encouraged to include relevant diagrams, graphs, tables, and photos to illustrate their articles (see guidelines for the supply of artwork and photos below). In addition, the author should supply a portrait photo, and brief summary of position, institution, etc.
For more detail as to the nature of this section please review Focus Area Three of Project 2000+, Scientific and Technological Literacy for All found in the September, 1992 issue of SEI, Vol. 3, No. 3, page 5-6. Teaching Materials contributions should be sent to the Section Editor, Sue Dale Tunnicleffe, 18 Octavia, Bracknell, Berkshire RG12 7YZ, UK

Science Teacher Education and Leadership
Articles about science teacher education (both pre-service and in-service) should be relevant to an international readership. The number of articles published in this section will normally be limited to one per issue. The length of article should be limited to 1500 words, including references. Authors are encouraged to include relevant diagrams, graphs, tables, and photos to illustrate their articles (see guidelines for the supply of artwork and photos below). In addition, the author should supply a portrait photo, and brief summary of position, institution, etc.

For more detail as to the nature of this section please review Focus Area Four of Project 2000+, Scientific and Technological Literacy for All found in the September, 1992 issue of SEI, Vol. 3, No. 3, page 5-6. Science teacher education articles should be sent to Section Editor, Ewve Van Den Berg, De Achikant 25, 1851 BV Heiloo, Netherlands.

Assessment and Evaluation Trends
Articles about assessment and evaluation should be relevant to an international readership. The number of articles published in this section will normally be limited to one per issue. The length of article should be limited to 1500 words, including references. Authors are encouraged to include relevant diagrams, graphs, tables, and photos to illustrate their articles (see guidelines for the supply of artwork and photos below). In addition, the author should supply a portrait photo and brief summary of position, institution, etc.

For more detail as to the nature of this section please review Focus Area Five of Project 2000+, Scientific and Technological Literacy for All found in the September, 1992 issue of SEI, Vol. 3, No. 3, page 5-6. Teaching Materials contributions should be sent to the Section Editor, Peter Spargo, School of Education, University of Cape Town, Randeboosh 7700, South Africa

Non-formal and Informal Science Education
Articles concerning non-formal and informal science development (such as out of school or public science experiences) should be relevant to an international readership. The number of articles published in this section will normally be limited to one per issue. The length of article should be limited to 1500 words, including references. Authors are encouraged to include relevant diagrams, graphs, tables, and photos to illustrate their articles (see guidelines for the supply of artwork and photos below). In addition, the author should supply a portrait photo and brief summary of position, institution, etc.

For more detail as to the nature of this section please review Focus Area Six of Project 2000+, Scientific and Technological Literacy for All found in the September, 1992 issue of SEI, Vol. 3, No. 3, page 5-6. Teaching Materials contributions should be sent to the Section Editor, Andrea Anderson, ASTC, 1025 Vermont Ave. N.W., Washington, DC 20005, USA.

Research in Brief
This section contains several brief, 300-400 word, summaries of published research related to the teaching and learning of science. The summaries may be drawn from journals world-wide but must be relevant to an international readership. The section may offer several summaries on varying topics or describe findings related to a central theme. Guest editors will be assigned. Contact the journal editor for additional information.

Profile
This occasional section features profiles of prominent science educators who have made a significant impact (e.g., ICASE Award Winners), and profiles of ICASE member association, institutions, centres, etc. Profiles should be limited to 400-600 words. A portrait photo must be sent with an individual profile; the logo of an organization and captioned photo of, for example, key officers, headquarters building, a project in action, delegates at a meeting, may be used to illustrate the profile of an organization.

Editorials
This occasional contributed or invited section represents an open forum to discuss science education concerns and perceptions. Editorials should be limited to 400-600 words. Profiles and editorials should be sent to the journal editor.

Supply of artwork, photos, etc.
Diagrams and graphs should be provided as finished line artwork, preferably bromide quality - note that the editor does not at this time have an artwork or graphics service. It is preferable that Tables be provided as finished artwork, however the editor has facilities to format tables. Photos should be supplied un-screened in original form. All illustration (diagrams, graphs, tables, photos) must be fully captioned. When there are a number of illustration, the author should endeavor to reduce the amount of text to accommodate the illustrations in the limited space available for any one article.
ICASE WELCOMES NEW MEMBERS

Centre for Educational Technology (CET) Israel

The Centre for Educational Technology (CET) is an independent non-profit organization dedicated to improving Israel's educational system. Its main task is to develop effective methods of instruction by generating and applying innovative educational ideas. CET programmes utilize modern technologies and original instructional materials.

Attuned to the needs and problems of Israel's educational and training systems, CET professionals offer educators and school principals comprehensive solutions which incorporate organizational improvement, in-service training, going professional guidance, innovative study methods and a variety of study materials (textbooks, workbooks, games and computer courseware) CET's projects and products serve a wide range of students in Israel, from pre-school and school pupils to soldiers and adults.

Established in 1971 and initially endowed by the Rothschild Foundation (Yad Hanadiv), CET finances its activities through distribution of its programmes and publications, and receives financial assistance from various foundations. The majority of CET's 250 member staff consists of professionals in the fields of education, psychology, computers, engineering, production and management.

CET programmes and multi-media materials (print, audio, video, computer) cover much of the basic school curriculum: mathematics, grammar and reading comprehension, literature, Bible, English, geography, and the sciences.

CET has also developed a few computer programmes for teaching scientific subjects at elementary and middle school levels. These computer programmes integrate innovative tools, such as a computerized laboratory, simulation, and visual data bases, with supportive pedagogical instruments.

CET has also developed learning materials (pupils workbooks, teacher's guides and kits) for Technological Literacy at the elementary school level in cooperation with the Curriculum Division of the Ministry of Education of Israel and is also developing materials for a general Technology course introduced at the high school level.

A great number of study books, exercise books, experiment books, etc. in technological subjects like electricity, control, communication for grades 10-12 have also been published by CET in the last few years.

The widespread acceptance and use of these programmes and learning materials, has led CET to become one of the largest publishers of textbooks and learning materials in Israel, producing some seven hundred titles.

Coming Events

THE 9TH ICASE-ASIAN SYMPOSIUM
Bangkok, Thailand
6-10 December 1994

Theme
The theme of this 9th ICASE-Asian Symposium will be “Increasing the effectiveness of Science Teaching in the Classroom: A Challenge for Scientific and Technological Literacy for All.”

Sub-themes for concurrent sessions include:
- The use of computers in the teaching of science subjects.
- Promoting awareness of environmental problems and issues through the teaching of science.
- The use of locally produced equipment and teaching materials.

Objectives
The symposium will provide an opportunity for science educators and teachers in the Asian region to meet together in order to:
- share ideas and experiences on science and technology teaching.
- interact with educators in the fields of biology, chemistry, physics, mathematics and primary science.
- recognize the need for scientific and technological literacy for all.

Organizer
The Institute for the Promotion of Teaching Science and Technology and The Science Society of Thailand under the Patronage of His Majesty the King in conjunction with The Association of Science and Technology Education
The Science Teachers Association of Thailand supported by ICASE and UNESCO PROAP Bangkok

Programme
There will be plenary, keynote lectures, symposium lectures, workshops, poster displays and exhibits.

Details of the programme will be available in the second announcement.

Call for Papers
Contributed papers highlighting news and recent development in the areas covered by the symposium are invited.

The closing date for receipts of titles and abstracts (not exceeding one page) is June 30, 1994. The abstracts should be camera-ready on A4-size paper (297 mm x 210 mm) the text must be typed within the frame of 220 mm x 150 mm. The name of the speaker is to be underlined. Instructions for typing camera-ready manuscripts may be requested from the secretary of the organizing committee. Full Text of accepted papers must be submitted by September 1, 1994. On request, the secretariat of the symposium will send a personal invitation for participation in the symposium. It should be understood that such an invitation is only meant to help participants raise travel funds or obtain visas, and is not a commitment on the part of the organizers to provide any financial support.

Language
The language of the symposium will be English. The national language is Thai. English is widely spoken in tourist centers and hotels.

Local Information
Climate: December is the dry and comfortable month in Bangkok with the temperature ranging between 20°-29°C.
Visa: Those visitors who require a visa to enter Thailand should consult the nearest Royal Thai Embassy or Consular Office for visa information.

Accommodation
Accommodation will be reserved upon request. Special room rates will be arranged at the venue of the symposium and in nearby hotels, details of which are available from the secretariat.

Registration Fees
The registration fees are as follows:
- Active participants
  - Before September 30, 1994 U.S. $100
  - After September 30, 1994 U.S. $120
- Accompanying person U.S. $80

(All payments must be in Banker’s order or Bank draft)

GLOBAL CHANGE CURRICULUM WORKSHOP

The workshop, jointly organised by COSTED (Committee on Science and Technology in Developing Countries) and ICSU CTS and held in Madras, India, November 22-26, 1993, was designed to:

1. Make participants more familiar with the Global Change interdisciplinary teaching materials prepared for the student 16-19 age group by CTS;
2. Suggest modifications and additions to these materials taking note of the developing country educational systems; and
3. Plan new educational units on Global Change.

The workshop was run by Professor Joe Stoltman, secretary of CTS and Professor of Geography at Western Michigan University, Kalamazoo, Michigan, USA. He was ably assisted by Peter Nicholson and Graham Lenton, writing team members from the UK. The hard work of hosting and organizing the workshop was admirably handled by Professor Roy Daniel, Dr. Babuji, Dr. Veena Ravichandran and the rest of the COSTED team. The participants, from a number of Asian countries, examined the first four units and detailed amendments and additions which COSTED plans to collate and print. All participants welcomed the materials as worthy additions to the resources available to teachers, although opinions were mixed about the ability of teachers in the Asian region to incorporate much of the material into their current teaching programmes.

This workshop was seen as important from the ICASE viewpoint as the goals of the Global Change materials are in line with steps to enhance scientific and technological literacy—a major thrust by ICASE within Project 2000+. Comments that such materials may be difficult to include in the teaching programme are thus a matter of concern. The challenge we face is to find ways to incorporate material that attempt to promote data interpretation, decision making and communication skills, if the wish to move towards more meaningful science teaching is welcomed by teachers and teachers wish to meet the goals being set for Project 2000+. Unfortunately curricula design rarely illustrate ways of promoting such skills, even though objectives usually allude to them. Teachers having short term goals and adhering only to the viewpoint of teaching so that “students pass the examination” are not likely to welcome the units.

ICASE strongly supports these materials and wishes to promote their trialing and evaluation in schools around the world. If any teacher would like to be part of these trials, teaching some or all the units (or activities from the units) and sending feedback to Jack Holbrook (address given under list of ICASE officers). Jack will be pleased to send a set of the units (unfortunately, at present, without the suggested amendments at the Madras workshop).

(Above) Some of the participants at the workshop in Madras, India
1994

April 7–23
Sixth Edinburgh International Science Festival
Location: Edinburgh, Scotland
Contact: Marion-Jane Pate, Assistant Chief Executive, Edinburgh Science Festival Ltd., 1 Broughton Market, Edinburgh EH3 6 NU, Scotland, UK
Following the success of the 1993 Festival which attracted over 200,000 people to 367 events, preparations for the 1994 Festival are now well in hand. Major themes include: (1) Being the right size; (2) Molecule of the day; (3) Science myths of out time. In addition, exhibitions, talks, debates, workshops (including Madlab, Computer Arcade, FUNDamental Physics, Science Dome), family events, performances, tours, and conferences will be featured in the program.

April 10–13
International Symposium: When Science Becomes Culture
Location: Montréal, Québec, Canada
Contact: Quand la science se fait culture, Université du Québec à Montréal, CP 8888, succursale A, Montréal, Québec, Canada H3C 3P8
Symposium themes include: (1) Realities of today’s scientific and technological culture—how far have we come? National reports on accomplishments; (2) Methods and practices of scientific and technological culture; (3) Practitioners of scientific and technological culture; (4) Sharing of knowledge and democratic accountability; (5) Taking up the challenge of sustainable economic development. The deadline for receiving full papers (conditions apply) for consideration by the scientific committee is 1st February 1994.

June
Schola Ludus: Science and the Public
Location: Bratislava, Slovak Republic
Contact: Schola Ludus, Faculty of Mathematics and Physics, Comenius University, Mlynská dolina F2, 2 15 Bratislava, Slovakia
This international conference will feature four themes: (1) Building up a hands-on science center; (2) Supporting lifelong education; (3) Building up an open and consistent learning about the universe and life on Earth; (4) Finding the essence of real scientific, human, technical and environmental problems. The conference sessions will be conducted in English and Slovak/Czech.

July 4–8
CONASTA 43
Location: Launceston, Tasmania, Australia
Contact: Donna McWilliam, CONASTA 43, PO Box 1922, Launceston Tas 7250, Australia, Fax (003) 34 2598
The theme for the 43rd annual conference of the Australian Science Teachers Association (CONASTA 43) is ‘In from the cold.’ The program brings contemporary developments and information to teachers within an atmosphere of support. Hear about new ideas and approaches in science and technology, keep abreast of latest developments, evaluate new resources, and meet teachers from all over Australia and beyond. Keynote addresses, workshops, displays, social events and a family program make Launceston an exciting place to be in July 94!

July 17–22
Fifth InterAmerican Conference on Physics Education
Location: Texas, USA
Contact: Robert Beck Clark, Texas A&M University, College Station, Texas, 77843-4242, USA, Fax +1-409-845-2590
The theme of ‘Building bridges for cooperation in physics education’ will feature sessions in English and Spanish.

July 27–August 10
London International Youth Science Forum
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal annual meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

August 8–12
13th International Conference on Chemical Education
Location: San Juan, Puerto Rico
Contact: Ram S. Lamba, Chairman 13th ICCE, Inter American University of Puerto Rico, PO Box 191293, San Juan PR 00919-1293
This will be the first time that an ICCE meeting will have been held in the Caribbean Region. The objective of this conference is to bring together chemistry teachers from the pre-college and college levels to share ideas and learn from each other about innovations in the teaching and learning of chemistry. The theme is 'Chemistry: The Key to the Future.' The Conference will feature plenary lectures, symposia, lecture presentations, workshops, poster sessions and exhibitions. Scientists and science educators from around the world will report their work.
The World Population Explosion and Related Issues: The I.A.S.C. Questionnaire Results

\section*{A Need for Unity in Diversity}

by B. J. K. Tricker

isle of Wight, United Kingdom

\section*{Abstract}

International Association of Science Clubs sees the human population explosion as the greatest problem ever to have been faced by humans. It may be portrayed by one simple graph which should provoke thought, discussion and action.

The most important answers to the I.A.S.C. Opinion Forum Questionnaire show:

1. that the respondents would, on average, like to see a lower world population than exists at present;
2. that they see this as unlikely;
3. that measures should be taken to contain the problem;
4. that young people, once they know about the world population problem, resolve, on average, that they should have smaller families than they had previously considered appropriate.

Among the factors contributing to population increase is a considerable ‘ostrich effect’—failure to face up to the problem, and even hiding knowledge of it from others.

The UNFPA effort, while admirable, praiseworthy and considerable is seen as being mathematically inadequate.

I.A.S.C. therefore welcomed the 1993 New Delhi Conference of National Academies of Science which, having the word ‘population’ in its title, did not deviate from this, the most important issue in the history of humans.

I.A.S.C. is interested in running another forum of the kind that set the currently reported work in motion, provided that it is sponsored to an extent that its news is likely to have a significant world impact.

\section*{Introduction}

This paper is produced in response to Dame Anne McLaren, Vice President of the Royal Society of London acting on behalf of the President, Sir Michael Atiyah.

During this time there has been a growing awareness of the population problem, but it has also become evident that there is, even among intelligent people, an ‘ostrich effect’ of a hiding from what could be done. In the name of a better quality of life for more people, alternatively expressed as sustainable development, it seems foolish to suppress understanding.

The I.A.S.C. argument begins with the facts that the world is finite and in a state of complex and often delicate balances. It seems paramount that the world should not be overloaded with people, and as no one knows the limits, that nations should err on the side of caution.

The questions are a mixture of choices and invitations to express opinions. In this way we feel it has intellectual advantages over the pure multiple choice type of survey. Each batch of returns has been consistent in the points listed in the Abstract. Questions 2 c, d, and e contain the kind of contradictions one encounters in the social sciences and the replies given by the respondents are by no means exhaustive of all possibilities.

\section*{Aims}

1. To sample opinions on the population explosion and related issues.
2. To suggest action in the light of the findings.

\section*{RESULTS}

Respondents were not called upon to justify their replies. They were free to leave blanks, and also offer further words as they felt inclined.
1. There are now more people alive in the world today than have ever lived in total before.
   (a) Is this idea new to you? Yes: 20% No: 74%
   (b) Do you believe it? Yes: 79% No: 15%
   Not sure: 2%

2. The population graph shows no signs of leveling off.
   (a) Do you see this as a serious matter?
      Yes: 90% No: 4%
   (b) Nature should be allowed to take its course: 14%
      Measures should be taken towards a steady level: 72%
   (c), (d), (e) Please see Appendix 1.

3. (a) Do you agree that the greater number of people, the less the room for wildlife?
       Yes: 79% No: 12%
   (b) Does this concern you? Yes: 73% No: 17%

4. Would you like to have children of your own in time?
   (Those with children already were counted "yes.")
   Yes: 85% No: 4%

5. How many children would you like to have?
   No. of children
      0, 0-1, 1, 1-2, 2, 2-3, 3, 3-4, 4, 4-5, 5, 5-6, 6
   No. of respondents
      13, 1, 14, 20, 174, 33, 41, 6, 11, 0, 0, 0
   Average: 2.13 children per couple

6. In view of world overcrowding, how many children do you think you should have?
   No. of children
      0, 0-1, 1, 1-2, 2, 2-3, 3, 3-4, 4, 4-5, 5, 5-6, 6
   No. of respondents
      20, 6, 72, 46, 140, 14, 6, 3, 2, 0, 0, 0
   Average: 1.67 children per couple

7. What do you consider to be the optimum level for the world's human population assuming that it is desirable for all people to have a fair quality of life, etc.?

   Opinions on Optimum World Population

In the discussion and analysis the following figures based on U.N. data will be mentioned:
Year in which the population reached this number:
1 2 3 4 5 6
Number in billions

8. Please refer to the graph at the end of question 8. In order to keep the expense of responding to the questionnaire down—the copying was done by the respondents at their own expense—it was necessary to keep it to a single page. It was not possible to explain the inset graph in the space available, and it is evident that people interpreted it in different ways. Choices 6 and 7 were meant to represent population low levels after some catastrophic event, but it seemed that some chose 6 or 7 without being aware that a prior catastrophe was implied. However, the following table is, it is felt, still worth recording.

   Inset graph number
   1, 6, 7, 2, 3, 4, 5
   number of respondents:
   (a) most likely to happen
      113, 3, 6, 141, 15, 8, 4
   (b) preferred
      3, 11, 15, 43, 135, 69, 22

   Discussion
   While some maintain that social science is too confused to warrant calling it a science, thinking citizens have to make decisions based on the best evidence available at the time.

   It is increasingly accepted that the world population explosion is unsustainable and also that the longer it continues unabated the worse are the prospects we are leaving for future generations. Ninety percent of the respondents saw the matter to be serious.

   Re: 2(b), if human nature is taken to be a part of nature, the choices given could be taken to mean much the same thing. The 14% wanting nature to take its course were not asked whether planned intervention came within their interpretation, but the 72% wanting measures taken show a clear majority for action.
Answers to 2(c), (d) and (e), (Appendix 1), being
unencoded, indicate topics which were uppermost in the
minds of the respondents. There is much argument on
population issues as to which factors are causes, which are
effects, which are partially related and to what degrees.
The author’s opinion is that with such complex issues,
attacks on the problems should be made at all points
possible. In the present context of the population problem,
he last word goes to a citizen of the U.S.A. at a UNFPA
meeting in New York held in March 1993, “The best
contraceptive is the contraceptive.” He was frustrated by
his indirect approaches being advocated.
The seven most commonly named consequences which go
with overcrowding with, in brackets, the number of times
each was mentioned, were as follows: 1. disease and bad
health (89); 2. starvation and famine (85); 3. poverty (62);
1. unemployment (62); 5. food shortages (60); 6. poor
housing, slums, shanty towns and squalor (53);
7. pollution (51).

Similarly, the most acceptable population control measures
were: 1. contraception and birth control (165);
2. & 3. family planning/counseling (44), and education
(44); 4. legal restrictions (29); 5. & 6. incentives for
small families (25), and abortion (25); 7. taxes on
children (13).

Inacceptable control measures were:
1. killing (unspecified) (69); 2. & 3. forced sterilization
(33), and genocide/ethnic cleansing (33);
4. & 5. infanticide (32), and abortion (32); 6. legal
restrictions (23); 7. euthanasia (14)

Three respondents mentioned the point that famine relief
efforts to invest in misery for greater numbers in the long
run. A comment by a respondent in CSIRO’s H.Q. in
Canberra makes a powerful summary, “I think the time has
come when necessity overrides people’s rights to have
limited families.” State care for the elderly would go a
long way towards removing perhaps the most valid reason
for having large families in many parts of the world.

Question 3. The high value placed on wildlife and,
although no one in the survey mentioned it specifically,
genetic diversity, is encouraging, but the 17% declaring no
care to the author, seem alarming. Over 100
years ago, John Stuart Mill declared that the world would be
a poorer place if everywhere was altered for the
requirements of Man. It has to be admitted that our
species is responsible for so much confusion and havoc
that a more modest approach than to consider ourselves the
ultimate beings is required.

Questions 4, 5 and 6. There is a small but growing number
of people who believe the world is no longer a fit place for
children of their own. However, I do not believe that this
category will be large enough to make a significant turn in
the population curve, at least for some time yet. The 85%
hoping to have children of their own represent an overall
feeling of optimism which, if the small family becomes
more widely accepted and large ones become viewed, with
the spread of understanding, as selfish, could lead the way
to that glorious heaven on earth so far always just round
the corner.

The table of responses to questions 5 and 6 show an
overall willingness to accommodate; a desire for an
average of 2.13 children per couple being reduced to an
average of 1.67 in the light of knowledge of the world
population explosion. Several contributions considered
the Chinese control methods unacceptable, but it has to be
admitted that the Chinese solution is the only one to have
worked on a large scale so far (I.A.S.C. information from
Beijing states that the present Chinese population growth is
1% per year, the controls being concentrated on cities. It
would appear that their methods, whatever you may think
of them, are adjustable to governmental perceptions.)
Another point to be made before returning to the start of
this paragraph is that population decline need no longer be
equated with decrease in national strength. An economy
large enough to support modern technology will guarantee
both that and a rising quality of life for its citizens in
material terms. Alarm expressed when some populations
are seen to decline or be near to it is here considered to be
outdated.

Thus the willingness to decrease family size as a result of
education could be the voluntary answer, and being
voluntary, more positively acceptable than solutions which
are seen as being imposed. The investment must come in
the education, and just at present, every nine months there
is a new population the size of that of France to be
educated which did not exist before.

Question 8. The vast majority envisage the population will
go above what they think would be best. Ten respondents
were in the happy position of believing that what is most
likely to happen will be the same as they think best, while
four saw it settling below their idea of their preferred level.
The statements in this paragraph depend, of course, on
inspection of the individual returns.

The UNFPA reports that its goals for the year 2000
include:

- reducing the number of children born per woman in
order to reach the UN “medium variant” population
which is shown on Fig. 3 or Appendix 2;
- increasing female literacy to at least 70% and
achieving universal enrollment of girls in primary
schools;
- increasing contraceptive use to at least 59%
I question the adequacy of this last point. If 40% of women are not guarded by contraceptives, this means that as many women as lived in the early 1940s will not be guarded. The clock is thus set back 50 years, and in 50 years time the explosion of population will be again at the level it is today. Are we H. Sapiens or H. Stultus? The money required is but a fraction of that spent on armaments. To plan to guard all women now would be economically sound in the long term. Floods start through gaps.

The wishes of the respondents to the Opinion Forum reported here favor what the UN call their “medium low variant,” (labeled on Fig. 3, Appendix 2), not the medium one. Their preference, were it to be achieved, would ease environmental stress whereas the medium curve will exacerbate it.

The series of wars, famines, climatic and ecological disturbances of today make one wonder how near we are to the catastrophe level indicated by point 1 of the inset graph of the questionnaire. It has certainly arrived locally as far as those subjected to the stresses of war and famine are concerned. Crisis points for the varying hare (Appendix 2, Fig. 2) arrive without warning.

National planning must take account of two main headings:
1. internal considerations,
2. the nation’s effect on the world environment.

Conclusions

A. General
1. There is much concern over the world population explosion, especially among the young people of today who will have to live with its consequences.
2. This concern is expressed in the I.A.S.C. Opinion Forum, the most important result of which is the general voluntary desire to have smaller families.
3. An adequate education program is paramount, backed by practical measures which at present, while growing, appear to be inadequate for the rapidly worsening situation.

B. Particular
1. The work started at the International Young Peoples Forum in Canberra in 1988 should be repeated when there is a promise of financial backing sufficient to enable a significant world impact to be achieved. Any organization willing to sponsor this event is invited to send word to the I.A.S.C. Headquarters.
2. In the meantime I.A.S.C.’s Chairman, Professor V. S. Griffiths, and the Committee strongly suggest that organizations world-wide collect their own data using the I.A.S.C. Questionnaire. Such data collection will greatly expand dialog and heighten awareness of the global concern.

Acknowledgments

The author wishes to thank all those who have responded to our Opinion Forum, and also all those who so kindly made provisions enabling returns to be possible.

In particular thanks are due to the Australian taxpayers who sponsored the Canberra Forum in 1988 through CSIRO and the Australian National University. We also thank the Australian Academy of Science for kindly allowing the Forum to hold its final Plenary Session in their remarkable building.

We acknowledge also the work done by members of staff of the following establishments in organizing class returns; Hvitfeldsga Gymnasiet; Gothenburg; Eton College; Loughborough Grammar School; Cheltenham College Junior School; the U.K. Association for Science Education.

Financial help with this work has been provided by Mrs. A. V. Seller, Professor John Fines and C. K. V. Owen Esq. Printing was kindly done by J. Skipper Esq.

APPENDIX 2

The Population Explosion

The I.A.S.C. sees the world population explosion as the greatest problem ever faced by Man. The need to face up to it must be apparent from the extraordinary steepness of the curve. A question put to the Oxford Global Forum of Religious and Political Leaders on Human Survival, (1988), on what should be done produced a long silence by some four hundred delegates! To whom then should we turn?

Effective I.A.S.C. work on the subject became possible at the International Young Peoples Forum we held in Canberra with the Australian Double Helix Club shortly after the Oxford Conference. Two thirds of the delegates (teenagers) said the extent of the problem was new to them. The general concern by all the delegates on both this and related environmental issues gives cause for positive hope since they had been put in the position of being ambassadors for the future. They were by no means stuck for ideas on what could be done within the limits generally acceptable in civilized societies.

The key result summarizing their returns to the questionnaire, when put in one sentence reads:

When these young people knew about the population explosion, they resolved, on average, that when they have children of their own they should have fewer than they had considered appropriate before knowing about the problem.

This finding has been repeated in Sweden (1992) along with disclosure of greater awareness of the problem. The population graph is beginning to appear in school textbooks, but calls to debate and action are few and far between.

Fig 1 (B. J. K. T., 1979) shows the curve along with two prognostications on a logarithmic scale. The steeper dashed line produces the acceleration suggested by the points for 1950, 1960, and 1970. The less steep dashed
line produces the trend of the curve from 1650 to 1950. While nobody would see the upper right hand areas of the graph as representing future reality, it is as well seriously to question tendencies in that direction. The new point now added for 1990 gives a glimmer of hope but no cause at all for complacency.

Population explosions are by no means the preserve of humans. There are “ladybird years,” “dandelion years,” “lemming years” and so on. Examine, for example, Fig. 2 of the records of the varying hare and the arctic fox. The phases nearest to the present human population explosion are those of the hare between the years 1859-1863 and 1881-1885. (You can imagine all the happy hares with their nice big happy families! Nothing seems in the way of apparently boundless economic expansion and growth!)

The United Nations was in 1987 predicting a world population of 10 billion for the year 2050, but seemed to have nothing to say on what might follow. Because the U.N. had made this prediction, it not only became accepted but was widely seen as going to happen without trouble. Fig. 3, plotted from their 1992 tables, acknowledges a range of possibilities, (added to Fig. 1 as the lines between two circles for 2150), but is so great as to be practically meaningless. However, the recognition of a diversity of possibilities is important.

The Hudson Bay records should tell us that there is no guarantee that population growth curves are always smooth or sigmoid in shape. Clearly, when a species exceeds its limits nature spares nothing to return it to lower levels. One can but imagine the stresses on the individual hares and foxes during the times of population collapse. Were they up to conceiving ideas such as “quality of life” and “sustainable development” they would have found them all blown away on the wind.

Man’s powers of forethought distinguish him from all other species. It must be within these realms that the solutions lie.

To us it is clear that an educational drive to show the world position to all people is the primary necessity. While efforts are being made in a few places, the current total world effort is nowhere near enough. The record of the Chinese is the only large scale planned achievement so far. The main valid reason for having large families, so that there are enough children left to give support in old age, is a matter for national governments to solve through the creation of welfare support.

If will-power, such as the resolve expressed at IYPF I turns the curve, there will be far less total stress than if control is left to the ruthlessness of nature. We must surely begin to view the world as a pint pot into which a quart’s worth of population just won’t go. Population levels should be aimed to give safety margins at the provincial level rather than be such that they are constantly hammering at the limits. All the details fill books so cannot be listed here in this brief article.

Were the education given for self control to be achieved—so that, for example, it becomes regarded as selfish to have more than one’s fair share of children—then, but not until, does it appear reasonable to entertain ideas of sustainable growth and a fair quality of life for all on the sort of time scale that we, on behalf of the generations of the future, should be considering. Something very close to only one child per adult, or two for a couple, is the requirement whether we like it or not.

(If you are interested in the further presentation of this argument, please make an appropriate offer to I.A.S.C. H.Q.)

Conclusion: New generation > Sum (old generations). In other words, given the above conditions, there are now more people alive today than have ever lived before.

Case 2.
Exponential Growth.

The Sum, S, is the area under the curve.

\[ S = \frac{1}{2} \cdot e^t \cdot dt. \]

\[ S = e^t \]

or, at any time, the Sum of those who have lived < the number of people alive at that moment.

Case 3.
Start with 2 people. Say each couple has 4 children at 30 years of age. Let the lifespan of each couple be 60 years.

University of the West Indies
Barbados

Introduction
For the purpose of this paper, the Caribbean region embraces all the countries in the Caribbean Community (Caricom) group. These countries range from Belize, on the Central American mainland, to Guyana on the South American mainland—a span of about 2,700 miles. Between these two countries lies an arc of islands: Jamaica, St. Kitts/Nevis, Antigua and Barbuda, Anguilla, Montserrat, Dominica, St. Lucia, St. Vincent and the Grenadines, Barbados, Grenada, and Trinidad and Tobago. The total population is approximately five million.

Each country has its own peculiarities in culture and aspirations, yet they are quite similar in many respects. The countries are at varying points along the development continuum and most are fully independent, but a few are still British colonies. The long history of a connection with Britain has meant that educational systems are largely patterned on the British system.

This paper seeks to trace the various influences on Caribbean science education, to examine some criticisms of science education, and points the way forward. Clearly there are certain imperatives if there is to be an increase in the quality of instruction in science. Of primary importance are: increased quality and quantity of teacher development activities; much stricter adherence to effective strategies of curriculum planning and implementation; and a deeper realization that the classroom/laboratory is where teaching/learning transactions survive or fail, depending on the students’ previous knowledge, needs and aspirations.

Science in the School Curriculum
Formal science instruction begins at the age of 5 with primary school. Although nursery education is developing in the region, the bulk of the activities are not owned or funded by governments. Science at the primary level is integrated, and all countries have well-organized curricula for this 5-11 age range. In some countries science forms part of the selection examination used for entry into the secondary school at 11+-13+. It seems that much more importance is accorded science education in the countries where it forms a part of the selection examination.

In the first two or three levels (ages 11-14) of the secondary school, science continues to be integrated. At age 13 or 14, students select from one or more of the separate sciences—biology, chemistry, physics or an integrated science course. At 16+ the regional examination body, the Caribbean Examination Council (CXC) examines in all the options mentioned.

After secondary school students may follow one of several pathways: (a) continue in the sciences and complete external examinations set by British (especially London and Cambridge) examination boards and possibly continue on to university, (b) enter a university with a four year degree program, (c) enter the teaching profession.

At teachers’ colleges, science is integrated, since the majority of graduates teach at the primary level. At University, science is separated into the traditional areas. Some university graduates return to that institution to pursue postgraduate diplomas and higher degrees.

Factors That Influenced Caribbean Science Education
Science education in the Caribbean has been, and continues to be, influenced by several factors, including socio-historical background; impact of international movements; development of science knowledge, skills and attitudes relevant to the Caribbean situation; rationalization of science as a part of the curriculum at all levels; intervention by external funding agencies; impact of regional and external examinations; design of strategies for teacher development in science. Some of these factors
need elaboration. The socio-historical background of the teaching of science is especially interesting.

The first attempts to establish science in the school curriculum failed due to a multiplicity of factors. Chief among these factors was the religious bodies’ reluctance to have newly freed slaves involved in studies, mainly agriculture, that were too closely related to the conditions before slavery was abolished. Added to this was the apparent stigma attached to “practical education” at that time when classical education was greatly sought after. Indeed the decision makers of the time were more interested in producing “pale replicas” of citizens of the Mother Country than producing persons who would be more suited to agriculturally-based Caribbean countries.

Various factors contributed to change the status of science education and the teaching of science in the Caribbean in the more recent past. These factors include: political changes resulting in the march to independence in the 60s; the establishment of the University College of the West Indies—especially the development of the Faculty of Medical Science (1952); Faculty of Natural Sciences (1954); Institute of Education (1953); Faculty of Agriculture (1962)—formerly the Imperial College of Tropical Agriculture (1927). Equally important were economic pressures—began in the 1950s as the expanding economy moved away from agriculture into industry and technology and social movements as citizens sought social identity and value of their own heritage. Finally, new advances in scientific knowledge brought science education into its own.

One can hardly doubt the important influence that international developments and trends have had, and continue to have, on Caribbean science education. There are few countries in the world that can claim no influence on their science education from developments in other countries.

One of the first, and perhaps one of the most long-lasting impacts from international science education, has been the child-centered approach. Resulting from a reaction to the mainly didactic, chalk-and-talk approach previously accepted as the sole method of teaching science, child-centered approaches are operationalized as discovery learning, learning by doing, and the inquiry approach.

But, there are other international movements that have impacted, and continue to impact science education in the Caribbean. For example, the matter of teaching by using the process approach. The primary science program in Trinidad and Tobago is built entirely on the process approach. This program has spawned the development of a series of textbooks, Science: A Process Approach of Trinidad and Tobago, which seeks to forge linkages between existing ideas and new experiences, testing the former against the evidence of these new experiences and situations.

Two other international movements or trends bear some mention—integrated science and teaching of science using the project approach. Indeed, it is interesting to note that both of these have seen their elaboration and refinement in the work of the Caribbean Examination Council (CXC) Science Syllabuses.

As Caribbean countries moved from colonial ties towards independence they were forced to become much more aware of the type of education that is most relevant and appropriate to the region’s development. These changes were even more critical as the countries attempted to move from mere producers of raw materials to manufacturers, inventors, and innovators in science and technology. Thus, from the vast body of knowledge and experiences that is science, Caribbean science educators have had to carve out the type of knowledge, skills and values that would be most important in the move towards industrialization and technological advances. Besides, there is the question of science education for citizenship and scientific literacy. And perhaps most pressing need to inculcate science values and attitudes so important in the development of a scientific spirit.

Deficiencies in Science Education in the Caribbean

Despite the various impacts mentioned above, one still discerns areas of deficiency. There is still too much of a didactic approach in the teaching of science. It is still very common to visit classrooms where topics such as leaves—structure and function, are being taught with magnificent drawings on the chalkboard and being copied by students. This situation is so paradoxical when one considers that just outside the window of the classroom there are all shapes and sizes of leaves which almost no one will ever notice.

Many are the reasons for the lack of use of the environment and the failure to link classroom with real life outside. First and foremost is the lack of knowledge and skills of science. The existence of inadequately trained and under-qualified teachers is a persistent problem in Caribbean schools. In some countries as many as 70% of the teachers at the primary level are untrained, with a sizable proportion of those not having the qualification to enter teachers’ training college. The secondary system also has a large percentage of untrained (graduate and non-graduate) teachers. Another deficiency that is obvious in Caribbean science teaching is the almost complete absence of aspects of technology.

Science education at the present time seems not to cater to the development of scientific literacy. Clearly, only a
small percentage, in some countries as little as 5-10%, go on to A-level, and an even smaller percentage to university science. Thus, science for living and literacy in the modern world needs to feature more prominently in the goals of teaching at all levels.

Mention has already been made of the problems encountered in planning and implementation of science curricula. Many of these programs geared towards improving teaching/learning in science have been built without proper research into what teachers and educators perceive as the purpose of science education. A recent research study among 629 primary teachers shows that the rank order of aims of primary science is loaded towards “knowledge of basic facts of science,” while the curriculum materials are geared towards problem-solving, understanding social implications of science and so on. This is a large discrepancy which requires further probing and investigation.

Towards the Future
So far we have looked at the various forces which influenced Caribbean science education and some of the deficiencies as seen by this writer. This section of the paper focuses on some of the ideas, concepts and methods that should provide relevant up-to-date science teaching/learning for all citizens. In a very real sense this section attempts to recommend a set of ideas that would chart the way forward.

It seems to me that there are certain areas in which we need to develop in the future. These areas include:
(a) more emphasis on out-of-school approaches—instead of placing full responsibility on the school, (b) more infusion of science-technology-society in the curricula at all levels, (c) a constructivist approach to science teaching—building instruction much more on the students’ ideas and concepts which they bring to the learning situation, (d) greater study of design of strategies for teacher development—teacher preparation that goes hand-in-hand with activities that enhance student learning.

In the case of teacher development, I have long suggested, that any program devised should focus on the following:
1. integrated content-methodology course;
2. school teaching experience with supervision, using an observation schedule;
3. experiences consistent with the nature of scientific inquiry resulting in an understanding of the processes of science;
4. activities leading to the development of a positive attitude to science and science instruction;
5. experiences that emphasize the interrelationship between science, technology and society, resulting in enhanced socio-environmental behaviors; and
6. activities emphasizing the constructivist learning model.

Summary
This brief paper has attempted to outline the situation in science education in the Caribbean. Clearly, there have been developments and improvements in science education, especially over the last two decades. However, there is room for improvement in certain areas. Failure to make science education and teaching more relevant and meaningful to Caribbean learners will result in a perpetuation of what some consider as an impoverished scientific culture.

ICASE
The First 20 Years
1973-1993
A brief history
This new publication is a brief history of the International Council of Associations for Science Education.

It is not intended to be a comprehensive account, but rather an overview of the key happenings and milestones in the development of the organisation and the policies and strategies that have enabled it to reach its present position in the international community of science education.

It also looks forward to the future, especially to the turn of the century, and examines possible options for the continual development of ICASE as an umbrella organisation for science education associations and similar bodies.

STS APPROACH WITHIN SCIENCE EDUCATION IN ITALY
Luisa Viglietta
IRRSAE Piemonte
Italy

This article provides some information about the nature of STS education in Italy. It is always difficult to present the major trends in education in one's own country. Therefore, this paper will first sketch out our school system and outline the place of STS in the science curriculum, then provide an historical overview of existing projects and materials. The last section will discuss the main features of such materials and present some findings about their application in the classroom context.

STS IN THE CURRICULUM
As far as science teaching is concerned, the situation is as follows. Below age level 14, science was introduced only in 1964—unless some information about general aspects such as planetary motion or human anatomy may be considered science teaching. In the first eight years, the sciences are taught as integrated science; while, in the different streams of the upper secondary schools, the sciences are taught as separate subjects: physics, chemistry, biology, etc. It is a peculiarity of the Italian system that all the secondary schools streams have a rather extended common core of disciplines which includes the sciences. The sciences are therefore taught through almost all the curriculum.

STS education as such is not taught in a systematic way but some suggestions about STS issues are included in the programs. Let me briefly outline how this is done.

Primary School: Ages 6-11
At primary level, where science was taught in a very limited and didactic fashion, the Ministry in 1987 introduced a program, which includes science as one of the five fundamental curriculum areas.

Technology also is seen as an important aspect of science teaching. The new program states that:

Pupils should be aware of advantages and disadvantages bound to every human intervention and shall build a positive attitude toward the environment and technological progress and that students shall meet the surrounding world of manufacture and products and understand the connected problems associated with technological reality.

The problem of putting such goals into practice has to do with teachers education. Primary teachers in Italy usually don't have a university degree. They have studied science only in their secondary courses, which does not give an adequate preparation in theoretical foundations, and even less in experimental work.

A multi-year refresher plan for the Programs (PPANPSE) to involve all the primary school teachers was then decreed and the technical and scientific design of the plan was entrusted to the twenty regional institutes for educational research and teacher training in Italy (IRRSAE). The IRRSAE Piemonte developed a project of teachers training at a distance. The subject branches of such project cover each subject area. The Science branch proposes some teaching refresher units on the principal inquiry strategies and on the technological activities peculiar to Physics, Chemistry, Biology, Astronomy, Technology, Ecology.

The technology theme is treated by the PPANPSE in a teacher book, a teacher dossier which suggests a variety of activities, a teacher-trainer guide, a 30-minute video, a teacher video guide. However, at this primary school level, it is more a matter of technological activities, than STS.

Junior School: Ages 11-14
In 1964, with the unification of the junior school (11-14) a course, “observing nature” (Osservazioni naturali) was introduced; it was taught by the same teacher as the mathematics course. The course was not very successful: pupils observed textbooks more than nature, and learned by rote memory of information about animals and plants. In 1979, the course was changed to one is based, in principle, on practical work and even project work, done by the students in small groups with a substantial amount of general class discussion and planning. One of the aims of the new science program was that pupils should:

‘maturare il proprio senso di responsabilita’ nell’impatto con la natura e nella gestione delle sue risorse.’ (develop their responsibility as regard to nature and the management of natural resources)

However, science teaching in general and topics like these in particular are not for the most part dealt with in school practice. The mismatch between official program aims and reality is due to a variety of reasons, the most important of them being the lack of adequate teacher education.

In Italy all secondary level science teachers have a university degree in a specific scientific subject (biology or natural science; less frequently mathematics, rarely physics), but they have no special educational training.
Although they are supposed to teach integrated science, most of them have an orientation only towards the specific discipline of science they have studied. Besides that, the goals they emphasize are directed toward preparing students for further formal study. The STS issues seem therefore to be largely neglected.

Upper Secondary School: Ages 14-19
At upper secondary level the curriculum situation is almost opposite to the primary school just described. The national programs are very old and inadequate, and almost ignored by teachers: curriculum in the schools is established by tradition. Sciences are taught as separate disciplines, and their position in the general curriculum can vary a great deal. In the ‘licei’ sciences are considered as general culture subjects, in the ‘Istituti tecnici’ as a basis for technical courses and in most most other schools science is a secondary subject with very limited time allowed.

However, modification of the official program in a school are possible if an authorization is obtained from the MPI. Also the reverse process is possible (the MPI making a proposal to the school) and this is what happens now quite frequently at the upper secondary level. Since 1980, in an effort to merge the various experiences, the MPI proposed teaching experimental models to be adopted by the schools according to their specialization. Relevant features of these projects (perimentazioni assistite), according to the MPI are: (a) the knowledge of scientific and technological issues, fundamental for evolution of the production processes; (b) the training and formation, considered as a whole of logical competence, sustained by the personal attitudes toward evolution and change; (c) everlasting ties with the world of production and services.'

In the framework of these projects ‘school-work’ activities (such as visits to factories and stages for teachers and/or older students) are often organized. Such activities are meant to foster students awareness of the local technological environment and industrial production.

These projects, proposed and supported by the MPI, seem on the borders of STS education, their aims being more strictly those of pure technology education.

STS EDUCATION
The science and society approach, including the historical perspective and contemporary issues, has been of interest in Italy for more than a decade. And recently ‘Science and society’ was chosen as the theme of a conference—in memory of A. Bastai Prat—held in Torino, whose proceeding are published (Agnes et al., 1990).

However, as we have already seen, school curricula do not give official recognition to STS courses. In a system rigid and centralized like ours, it is difficult to devote much time to a subject not included in the official programs. STS issues are therefore introduced into the science courses on a more or less individual basis. No complete new course on STS has been produced, only materials which can be inserted at different stages and different levels in existing science courses. These add-on initiatives fall into several categories.

Environmental Education
An investigation using case studies concerning the introduction of Environmental Education in the educational systems of thirteen countries was recently carried out (Mayer, 1990). The findings show how environmental education can be a powerful instrument for introducing new aims and changes in the roles of the students and teacher. An attempt is also made to identify ‘quality indicators’ or criteria for evaluation of Environmental Education experiences.

According to the data, environmental education in Italy is quite widely spread at the compulsory school level (under age 14). The ecological aspect—mainly the problem of pollution—is dealt with on the basis of educational experiments due to teachers initiative (more often a single teacher with his/her pupils). School authority, local institutions, associations often give substantial encouragement and collaboration to these projects.

At upper secondary level, spontaneous initiatives are less common. Educational materials (Bastai, 1990) have been developed in the frame of a project known as “Uomo, ambiente, informazione” (Man, environment, information), which use our senses as means to collect and organize information from the environment.

Historical Approach
The historical approach to science roused much interest some years ago, fostered by political criticism, it rapidly expanded to very broad general issues such as the connection between science and capitalism. In many cases it gave rise to interesting collaboration between history, philosophy, and physics teachers. Materials (Baracca & Livi, 1976; Mattioli, 1979) in the field of social science and history of science had an influence on such initiatives. More recently, science historians, like Paolo Rossi (Sarton medal for history of science), have prepared sourcebooks of readings for schools.

The research group on history of physics of Pavia, in collaboration with the Deutsches Museum of Munchen, developed materials on historical experiments to be used in school. The same group has recently produced several interactive computer simulation of historical experiments.

The introduction of historical theme was certainly enhanced by the translation and adaptation of the Project Physics material (Bastai et al., 1977). The book ‘Calore,
materia e moto’ (Bastai, 1981) also contributed by weaving physics, history, and technology together.

Science and Weapons
A set of units on weapons to be used in school science or mathematics courses has been developed by a group of experts and teachers (Centro studi e documentazione Regis) in Torino. Another project (Bastai, 1990), called ICBlM, tries to show the interrelation between scientific, technological, military and political decision involved in the production of much sophisticated weapons.

Energy Education
As in many other industrialized countries, energy policies are fundamental to Italian economy, all the more so, since local energy resources are very scarce. The country is dependent on imported energy for more than 75% of consumption. A nuclear plant-building plan proposed years ago met, from the beginning, with strong opposition and was finally canned by national referendum. Hydro-electric power, available primarily in the Alpine region, is exploited already. Solar technology, which with our geographical position could make an important contribution, is not yet sufficiently developed.

It is no surprise, therefore, that Physics teachers have taken a special interest in energy education. The next section is devoted to energy projects.

Energy Projects
Since the so-called “energy crisis” broke out in the early 70s, some teachers have been working on new proposals to introduce issues such as the sources, uses and waste of energy throughout the world as well as the physical laws which govern energy transformation (Conforto et al., 1983). In the early 1980s, special lecture courses (Conforto et al., 1985) were given by experts on the various aspects of nuclear energy, its uses and risks. These courses, organized by a group of physicists and biologists from the University of Rome, were designed for use at the senior school level. A decision game surrounding home heating, used in the Association for Science Education (ASE) “Science in Society,” was translated and tried in Torino with excellent results (Brunatti et al., 1981).

Many other short ready-made packaged materials were designed to encourage flexible use. It was hoped and expected that teachers would choose material suitable for their own pupils and use in addition to or instead of their normal program of study.

Il Problema Dell’Energia (The problem of energy)
A first energy problem Project (Bastai, 1984; Viglietta, 1985) was developed in Turin by a group of university and secondary-school teachers.

The projects’ aims were: (a) To help the students to acquire information and analytic tools necessary for them to reach more thoughtful personal opinions on the energy problem; (b) to apply in a concrete and relevant context, concepts and methods taught in science courses; (c) to introduce the latest concepts and methods which were not yet taught in traditional science courses; and (d) to consider the complex relationship between science, technology, economical factors and political choices which characterize such a problem. The outcome was a set of 10 energy problem units (A.A.V.V., 1984), intended for use in Italian high schools (pupils aged 14-18).

The table presents the units grouped under four main themes. Emphasis is put on a systemic approach to the energy problem and just aspects of production.

Quaderni Scuola-Energia (School-energy books)
Another project on energy education in Italy, financed by the Department of Science, industries and energy agencies, was national in scale. It started in 1984 with a series of conferences and in-service teacher training courses. The final product was again a set of ten teaching-units (Viglietta, 1990) each written around a particular theme (Energy in the History, Energy & Economy, Energy & Environment, Energy Sources, Removable Energy, Electrical Energy, Energy Saving). One main difference, between these and the Turin materials, was the inclusion of a teacher’s guide in each volume. These guides suggested an organization for the teaching materials, outlined the approach, provided background materials, supplied answers to questions and solutions to problems in the text, and advised on how to prepare laboratory or fieldwork activities.

AIF Initiatives
A somewhat different Project on Energy Education was promoted by AIF—the professional association of physics
teachers in Italy. In 1984, an investigation from AIF revealed that, in the view of physics teachers, the second law of thermodynamics should be a major priority for in-service training. This topic was then chosen as the theme for an International Conference and for a course where secondary school teachers worked on three possible approaches to the second law: a macroscopic approach, a microscopic approach and a computer-based approach. The results of this work were published as a special edition of AIF Journal ‘La Fisica nella Scuola’ (1989).

MAIN FEATURES OF STS PROJECTS
Deciphering Technical Information
One of the main aims of the teaching materials was to improve the level of understanding of science, engineering, mathematical, statistical concepts, claims, and analytical methods. This was done by using more generally accessible explanations, case studies, and hands-on activities. Emphasis was on understanding what the experts say through a demystification of both terminology and phenomena.

As an example of such an approach let us consider the units: CONSUMPTION and RESOURCES. As one of the authors (Bastai, Prat 84) points out, the main goal in these units was to avoid simply giving a list of data, which would have been of little educational use, would probably be boring, and in many cases already available in books, newspapers, etc.

Some of the objectives for the ‘Energy Consumption Unit’ are as follows. Pupils should: (a) Understand the importance of reliable sources for data; (b) understand and apply in simple context economic indicators relevant to the problem (such as GNP, per capita quantities, elasticity coefficients, etc.); (c) understand the main assumptions on which medium and long term forecasts (or “scenarios”) are built; and (d) be aware of the difference between factual and political assumptions.

Appreciation of Social Context
Another important and somewhat more difficult aim is to bring out the complex interactions and trade-offs between scientific aspects of a problem and cultural, psychological, legal, institutional, economic, ethical impacts and influences. This would frame STS problems and potential solutions within a broad perspective, and help people to see why solutions should not be left to technical experts.

As an example of material fulfilling such an aim, let us look at the NUCLEAR ENERGY units. Here are some of the aims of these units. Students should learn to: (a) Apply basic physical concepts in order to understand the design of nuclear reactors; (b) understand and apply the basic techniques in the discussion of safety requirements (e.g., the probability tree) and the waste-disposal problem.

The units try to avoid two attitudes:
1. One is “don’t disturb the experts” position. People should insist on being informed and try to understand as far as possible the technical and political issues and the reasons on which decisions are taken.
2. The second is the “atom is the devil” attitude. The unit intends to stress that atomic technology can be understood by the layman as much—or as little—as any other technology. Shaping the Science Curriculum

STS instruction can be raised beyond the issue awareness level and become a force in shaping science curricula. An example of how this can be done is given in the ENERGY EFFICIENCY materials where the study of efficient use of energy is the ground for introducing topics like “availability” and “second order efficiency,” still largely neglected in current school teaching. Even when the new approach (Viglietta, 1990b) does not go beyond the conventional boundaries of science courses, it does build competence to investigate the STS energy issue.

IMPLEMENTING STS
Formal evaluation of a teaching program is not very common in Italy let alone on a subject like STS, which is still marginal in our school. However, some evaluation studies have been carried out on STS materials.

Project Physics Course
In coincidence with the publication of the project in Italy, the authors of the Italian edition organized a convention of teachers adopting the PPC course. Some problems connected with the adoption of the new program were discussed. The point was emphasized that the new approach was not only a matter of adding physical plus historic information, but to reach an “inside” integration. Obstacles to integration were felt as particularly strong in ITI (industrial school) for: (a) pupils have poor math preparation; (b) there is not a course in philosophy (as in “Licei”); and (c) the general history course (“parallel” to the physics course) cover Greece and Rome. In addition, the universities prepare both the physics and other teachers to be a specialist, thus increasing the difficulties for making connection between different subjects. Other concerns for the introduction of Italian PPC was noticed (Bastai, 1984).

The fact remains that it is very difficult to reach an equilibrium between the “Science” and “Society” components of such a course. In the usual physics course, there are some materials on the social relevance of scientific discoveries, but these are very superficial and often inaccurate. If the social aspect of science is stressed more deeply, there is a danger that the course may be based on the “ideas” of science, and not on science itself with its experimental and mathematical
components. This is a particular danger in a country like Italy, where teachers are not inclined to teach through experiments, and prefer chalk-and-talk methods.

A remedial action to such situation, undertaken by the PPC adapters, was a teacher training course that stressed the role of laboratory in the historical approach and the use of historical experiments.

As far as pupils reaction to the course is concerned, (Viglietta, 1980) conducted a study which confirmed results obtained by Aikenhead in 1974. The PPC course was found to provide more students with a positive image of science, in making science more relevant to them, and in stressing the interconnection between science and other subject of study. In addition, students' performance on the final examination were equivalent (or better) than control classes students. (It may be worth noticing that examination was carried out through oral assessment, traditional in Italian school.)

**Energy Units**

The preliminary version of the energy units "Il problema dell’energia" units were distributed to science teachers using professional teachers’ associations as a channel. Initial evaluation of these trial schools may be found in (Bastai et al., 1984). The assessment gathered accounts of the teaching situation from different points of view (a method sometimes called triangulation). A variety of instruments was used including: checklist to record classroom activities, teachers' reports, pupils evaluation scores, classroom discussion and outsider observer reports. Results showed that STS issues attracted students who had previously shown little interest in traditional approaches. However, a danger also appeared. This interest toward out-of-school aspects, STS, was only weakly linked to increased engagement in Physics content.

**Energy Efficiency Materials**

A small scale feasibility study was conducted using a preliminary version of the Energy efficiency unit (Sgrignoli & Viglietta, 1984, Viglietta, 1990c) in a few schools with teachers that were, in general, highly motivated (two classes of the units' authors were also included). All the teachers reported a relevant increase in the interest and the proficiency of the pupils. Pupils seemed to appreciate, in particular, the study of well known devices such as cars or washing machines instead of the tediously common abstract examples. On a wider and more objective scale, we received positive comments about the materials from science-educators and from many school-teachers. However, most teachers found the material more interesting for their own “intellectual development,” than for their classroom practice. Some wondered about teaching a topic they had not dealt with at the university and were just hearing about for the first time. On the other hand, teachers who were willing to apply the material complained that they had not been given all the help they needed.

A main cause of these pitfalls may have been the fact that the unit only contained the innovative material—material and activities which teachers had no previous experience. We also assumed that the traditional chapters, which needed to be covered, could easily be done with a conventional Physics textbook and that teachers would know how to merge the two components. Infusing the unit into their program of study left to the teacher. This increased the feeling of insecurity. Some experienced teachers reported they felt like beginners when using the unit.

Experience showed that construction phase trials in a few classes, followed by commercial distribution of the teaching material, is not enough to make an approach widely used. Materials for teacher-training on the subject, in-service courses, workshops and conferences are also be needed to support a new approach.

New materials were then prepared. These were designed to generate teachers confidence in the infusion process that would help pupils to achieve a deeper understanding of energy-related issues and to become more aware of the practical implications of the physics they learn. We also tried to place our approach in teacher preparation programs. For this reason, our teacher training not only referred to the content of the teaching unit but also included relevant energy issues, taken from current literature.

The training materials were used on many occasions and become the ground for a monograph (Viglietta, 1989). The monograph is intended mainly for teachers’ use, and contains suggestions for a revised teaching scheme about energy and its laws and about energy efficiency.

The new teaching-scheme was then applied in the context of the mentioned Project “Scuola-energia,” sponsored by the Department of Education and Energy Agencies. The “Scuola-energia” units will be published within the year. The Department of Science has promised to provide every secondary school in Italy with copies of it and extensive trials and evaluations of the use of the materials in the classrooms context have also been foreseen. It appears that a nationwide STS theme in Italian science teaching is underway.

Sixth Edinburg International Science Festival
Edinburgh, Scotland
1-23 April 1994

Following the success of the 1993 Festival which attracted over 200,000 people to 367 events, preparations for the 1994 Festival are now well in hand.

Major themes include
- Being the right size, Molecule of the day, Science myths of out time

In addition, there are
- exhibitions, talks, debates, performances, family events, tours, conferences and workshops including
  - Madlab, Computer Arcade, FUNdamental Physics, Science Dome

Introduction
The scientific community has been identified as holding the Mertonian norms of communalism, universalism, organized skepticism, and disinterestedness. Holding the value of communalism implies that information generated by scientific inquiry should be available to all interested parties, while holders of the value of universalism propose that experimental ideas should be judged solely on the basis of their importance to science and not according to the source of the information. According to the norm of organized skepticism, experimental information should not be accepted easily, but should be carefully tested for accuracy. Finally, disinterestedness means that theories should be judged objectively (Merton, 1973).

Norms of this type have led to a scientific society which holds priority in scientific discovery as its ultimate reward. Since priority has such a high value in this society, the competition level in science is extremely high. This drive for priority leads to a high level of competition. Nowhere can this competition be seen as fiercely as at the entry level, where pursuit for the “right” post-doctorate position leads to the pursuit for the “right” tenure-track appointment (Traweek, 1988).

Values of this type should lead to desirable consequences as well. For example, it would seem that the values of communalism, universalism, and disinterestedness would lead to a society where the individual member is valued only for their contributions to science and without regard to gender or race. It is well documented, that this has not been the case. For example, Lise Meitner, an extraordinarily creative physicist, had to do her research under extremely difficult conditions. She:

was required to work in a converted carpenter’s shop with a detached entrance, so as not to fluster her male colleagues. When the British physicist Ernest Rutherford met Lise Meitner (1878-1968) for the first time, he exclaimed with astonishment: “Oh, I thought you were a man.” Meitner spent the rest of Rutherford’s visit playing the role of hostess to Mrs. Rutherford (Booth, 1989).

Some might argue that although this was the case in the past, in modern society female researchers and male researchers are considered equal. Unfortunately, this is not the case. As illustrated by Stephen Brush (1992), women have even begun to lose ground in recent years. This decline in the number of women entering the scientific and engineering fields has become an issue of major concern, since the United States is facing a future shortage in the number of science and engineering graduates (Atkinson, 1990).

Description of Study
In order to examine the situation of women in scientific research information about two universities, one in the United States and the other in Pakistan, was gathered from public sources. The two universities are both considered excellent universities in their respective countries. Our primary concern in data gathering was to examine the number of female professors in the sciences at both universities.

Indiana University is a public research university. It is a large university, which offers a wide range of opportunities for both undergraduate and graduate students. Indiana University is considered an excellent state university, which provides a well-rounded education for its students.

Since Indiana University is a large cosmopolitan university, we might expect that the number of female faculty as a percentage of the whole faculty in science and related fields would represent a respectable sum. As is plainly shown in Table 1, the number of full-time female
faculty members in science at Indiana University does not approach equity. If this is true of what is regarded as a progressive, liberal country, what might the situation be in a developing country?

The same information about full-time faculty was obtained from an autonomous (public) university in Pakistan. Quaid-a-Azam University Islamabad (QAU) was named after the founder of Pakistan, Quaid-a-Azam Mohammad Ali Jinnah. The university is located in Islamabad, the capital of Pakistan. QAU is considered an excellent university with students attending from all over Pakistan. Nearly two thousand students attend the university, which has sixteen departments and offers M.S., M.Phil., and Ph.D. degrees. Admission to the university is based on merit without regard to race, ethnicity, or gender. Pakistan, itself, is a developing Muslim country, and you would expect women to have few opportunities for professional careers. The results of our survey, shown in Table 1, were not what one would expect.

Discussion

In neither country did the results approach parity. Since the United States has a population which is 50% female and Pakistan has a population which is 55% female, the expectation would be, if no gender discrimination exists, that the percentage of female science professors would be similar to the percentage in the general population. Women are definitely underrepresented in the professorial populations of these two universities. One can infer that similar findings might be the norm throughout university science communities in both countries. Because the two countries have very different cultures, the reason for these discrepancies are not the same.

In the United States it is well documented that females drop out of science at two sites along the pipeline. Female high school students are less likely than their male counterparts to choose science as an undergraduate major. The next point at which a large portion of female students leave occurs during graduate school. Female graduate students are less likely than male graduate students to complete their degree (Brush, 1991). Females who either fail to choose science or drop out during graduate school do so for a variety of reasons.

One reason for this failure to choose science may relate to the negative male stereotype of the scientist. Current research shows that the scientific image held by many American students is that of a white male nerd (Schibeci, 1986). Because the image is both male and negative, females are less likely than males to identify with that image. Since students are more likely to choose careers with which they can identify, science careers are not likely to be chosen by young females (Rossi, 1965). Females are also less likely to believe that they are capable of doing science.

The stereotypical image of the scientist is not, however, the primary reason that female students fail to complete their graduate programs. Instead they probably drop out due to the culture in which they find themselves. The scientific community demands a great deal of its members. These demands may be greater for females than they are for males. For example, the age at which most scientific professionals establish themselves coincides with the age at which most women have children. Since their male counterparts can delay having their families, women often feel that they must choose between their careers as scientists and having a family (Zuckerman, Cole, and Bruer, 1991). While women rarely encounter overt discrimination, covert discrimination still occurs. Women may encounter a range of "microinequities" as they traverse the ladder of scientific success. These microinequities range from being called on less frequently in class, lower likelihood of being appointed to powerful committees, and decreased probability of having adequate resources for teaching and research. These inequities prevent women from being as productive as they can be (Widnall, 1989).

Other practices that prevent women from participating in the sciences at rates equal to men in the United States occur at two levels. Women graduating from high school fail to choose science as a career, because they feel they are not capable of doing science and because the stereotypical image of the profession does not match with the self-image of most females. Women fail to complete their education in the sciences, because they are confronted with a set of community standards that many women believe are not compatible with their life goals. Women also face a wide variety of small obstacles that are usually not faced by their male counterparts. These small obstacles are additive in nature, and may lead to a decision on the part of women that the prize is not worth the effort.

The situation in Pakistan has not been as well studied. We can make a few general conclusions based on the culture and socioeconomic status of the country. Women, for the
most part, in Pakistan have a secondary status. Males and females are not allowed to attend school together until they reach college. The boys' schools are often better equipped for the teaching of science than the girls' schools (IPSET, 1989). The most important aspect of a girls' education is that it makes her attractive to future husband prospects (Hayes, 1972). As a result, only 47% of the girls of primary age are enrolled in schools. In rural areas this number drops to 37%. The percentage continues to drop as female students reach middle school age (20%) and as they reach high school age (10%) (Bhatti, 1986). Since few girls' schools are equipped to teach science, the number of females prepared to go on in the sciences at the college level is extremely low. The plight of the rural female is especially dire. Not only does she live in an area where schools are poorly equipped and understaffed, but also she lives within a tradition-bound culture, which precludes her even thinking about a career in science.

The female in Pakistani society rarely chooses a career in science, because few Pakistani females complete high school. For those female students that do complete high school, science careers are still not an option, because the single-sex schools which they must attend are rarely equipped or staffed to teach science (Planning Commission, 1987).

It is interesting to note that although neither university approaches equity in science the Pakistani school has twice the percentage of female faculty as the American school. There are two possible reasons for this inequality. In Pakistan one method by which upper-class females can increase their attractiveness for possible husbands is by increasing their level of education. One of the fields which women have chosen is science. The choice of science appears to be the result of the freedom which Pakistani females experience when they attend a university. Pakistani females may deliberately choose this field of study, because it is a traditionally male field of study.

The other reason Pakistani females choose science as a field of study may be the inadvertent result of their single-sex education. There is some evidence that when female students are in single-sex classrooms, they learn better. This may be due to the absence of males in the classroom. This absence may allow female students to more fully express themselves, since they no longer need to fear being seen as unfeminine by males.

**Recommendations**

It is clear that both countries need to improve the participation of women in science, however, the recommendations for that improvement differ for each country. In the United States we need to improve the message that we are sending to young women. We must convince them that they are capable of doing science, and that the stereotypical image of the scientist is a false one. This can best be accomplished by developing mentoring relationships between schools and scientists.

Additionally, the climate of the scientific community needs to be changed. We must develop a community that allows women to flourish as men have. In order to do this we must begin by eliminating the push for tenure. No one should have to choose between having a family and having a career. New methods for establishing tenure need to be developed. The pile of microinequities through which women have to dig in order to develop as scientists must also be eliminated so that women can become as productive as men in the sciences.

Although the problem in Pakistan has not been as well studied as the United States, certain steps for improving the participation of women in science and technology can be taken. We must begin by improving the girls' schools in Pakistan with particular attention being paid to rural schools, where 75% of the population lives. Teachers need to be provided with adequate equipment and provided with instruction in using local resources. Local resources should be used so that students develop an awareness of the science around them not just the science in books.

Along with improvement in the girls' schools, females should be given incentives to participate in science programs in college. Scholarships, job sureties, and female hostels should be provided so that more female students are attracted to science programs. Also, the attitude toward female scientists at the public and government level must be changed so that the climate is more favorable for females.

Although all of the changes are far-reaching, they should result in an improvement in the number of females participating in science in both countries. We can potentially double the number of scientists if we improve the climate for women.

**Bibliography**

**About the Authors**

Jacqueline K. Bowman is a graduate student at Indiana University in the final year of work on her Ph.D. Her primary interests are constructivist teaching, gender equity, and rural education. She can be reached at:

- Indiana University School of Education, Room 3130
  Bloomington, IN 47405
  (812)-865-8118, ext. 33090

Alys Q. Tahir is a graduate student at Indiana University. He comes from Pakistan where he is a Senior Curriculum Officer in the Institute for the Promotion of Science Education and Training, Ministry of Education. He can be contracted at:

- Indiana University School of Education, Room 3068
  School of Education, IN 47405
  OR (After May, 1994)
  Institute for the promotion of Science Education and Training
  Ministry of Education, H-8
  ISLAMABAD, PAKISTAN

TEACHING SCIENCE TO VISUALLY IMPAIRED STUDENTS

Practical Science and Drawing Science Diagrams with Blind Students Integrated Into a Nigerian Secondary School

Kathryn E. Hill, B.Sc., P.G.C.E., B. Phil (Ed).
Former Head of Biology
Chemistry and Integrated Science
Boys’ Secondary School
Gindiri, Nigeria

BACKGROUND

Boys’ Secondary School, Gindiri, Nigeria was the first Nigerian Secondary School to integrate a blind student and thus open up secondary education to blind Nigerians. This was in 1957 and the blind student, Bitrus Gani gained a Division I in his West African School Certificate which included a credit in Agricultural Science. He went on to study Physiotherapy at the London School of Physiotherapy. Other blind students followed him into Gindiri Boys’ and other secondary schools. As far as science is concerned they were and are mainly restricted to Health Science or Biology, with a few “branching out” into agricultural science. This science was and largely still is for the most part restricted to the theoretical parts of the syllabus, with practical work and the drawing of diagrams considered impossible for blind students. The West African Examinations Council excuses blind candidates from practical papers in science subjects.

The author taught biology, chemistry and integrated science at Boys’ Secondary School, Gindiri from 1978 to 1990 and became interested in involving blind students in practical work and the drawing of diagrams. The apparatus and techniques used for the teaching of diagrams and of two science topics are described.

DIAGRAMS

The various science syllabi are rich in diagrams which the student is expected to draw. This includes copying from the textbook or blackboard, and drawing actual specimens, sets of apparatus, etc.

Using a smooth rubber mat, a suitable plastic or Melinex sheet and a special drawing tool, blind students can be taught to draw. A raised (feitable) line is produced. However this imported equipment is very expensive so local alternatives were sought.

Car mats, smooth on one side, are available freely and one of these cut into four makes suitable sized mats. The elaborate system of clips, pins, etc., used to fix the drawing sheet to the imported can be replaced with a film of water which holds the plastic sheet in place (and is, itself, a good demonstration of the use of surface tension).

Various types of polythene sheets were bought and tried. The best turned out to be the polythene which a local firm (Nasco) used for their corn flakes. They kindly donate rolls of this from time to time and it is cut to size. This polythene is stiff enough for labels, titles, etc., to be brailled directly onto it.

An ordinary biro which has run out of ink, and which would normally be thrown away, makes an excellent “pencil,” and at little expense, you are ready to draw.

Two sets of apparatus are needed, one for the teacher and one for the pupil. The diagram is built up stage-by-stage with the teacher drawing a line, the student copying it, the teacher adding the next line, the student copying that, etc. This is labor intensive and time consuming, but is well worthwhile as it is an enormous help to concept formation as well as giving the student more complete access to the curriculum. It is important to keep it simple (KIS) as the eye loves detail, but the finger is confused by it. Diagrams, therefore need to be reduced to their bare essentials, and with beginners, a single line is often used in place of the normal double lines. As students become more competent, more detail can be included, more of the diagram can be drawn at each stage, and conventions like double lines observed.

INTEGRATED SCIENCE TOPIC—MEASUREMENT

This topic involves students in practical measurement of length, volume, time and temperature, and techniques and locally made/adapted apparatus have been devised for the first three of these.

(a) LENGTH: An ordinary wooden ruler, as used by most of the sighted students, was notched at 1 cm intervals using a razor blade. The blind student can now measure to
the nearest 0.5 cm—the same degree of accuracy as with the imported plastic rulers. A standard meter rule is turned into a tactile instrument by hammering cut-off pin heads at 1 cm intervals. This can be extended to having two pins at each 1 cm, one pin at each 0.5 cm and three pins at each 10 cm. Tape measures are readily available in the market. These can have holes punched at 1 cm (or 1 inch) intervals, like the imported ones, or, even better, have a staple fixed at each 1 cm mark.

(b) VOLUME: The above apparatus can be used to measure and calculate the volume of regular objects, but different techniques are needed for liquid volume and irregular objects. Now there are two methods of measuring liquid volume. The first is when the total volume of a liquid is measured; the second is when you wish to measure out a stated volume of a liquid. Both are possible to some extent for blind people. An imported light probe can be used to accurately determine the level of liquid in a measuring cylinder with tactile markings. But without a light probe an estimate can still be made. Graduated beakers of various sizes are marked by super gluing small pieces of gravel on the marks on the INSIDE then varnishing them with clear varnish. Using their fingers to determine the water level, and knowing the interval between each tactile mark, the blind student can make a very rough measurement of the volume of the water. This has a number of disadvantages in that it is far from accurate, and can only be used with harmless liquids like water, but it DOES convey the concept of the use of the measuring cylinder. In the same way a very rough measurement of the volume of irregular solids can be made by finding the volume of water, then adding the object and finding the new level. Again, far from accurate, but the concept is conveyed far better than by a mere description!

In place of a pipette for measuring out accurate amounts of liquid, a plastic syringe can be used. These can be imported ready notched or medical friends can be asked to save used syringes which are quickly and easily notched with a razor blade to enable the accurate measurement of various volumes. By using large and small syringes, accuracy of 0.1 cm$^3$ can be achieved (see “TITRATION” below). Blind students easily learn to use a “syringe-pipette” and are delighted to find that they can be as accurate as their sighted peers.

(c) TIME: Simply take an ordinary stop clock from the laboratory, remove the cover glass and super glue cut lengths of pin onto each second mark with longer lengths at the 5 second marks.

CHEMISTRY TOPIC—TITRATION
At first sight, titration with its reliance on seeing a color change in the indicator, and in the absence of a costly imported talking pH meter, might seem an impossibility for the blind Nigerian chemistry student. The solution was to use a “human talking pH meter” i.e., the teacher or a fellow student who, after each addition of acid made by the blind student, simply said “no change” or “change.” One could argue that as the blind student does not have to determine the end point for himself, the experiment is easier for him; but it can equally be argued that the problems his blindness cause in accurately carrying out the rest of the titration techniques are an “equal-but-opposite” disadvantage and thus even things up! Certainly, it is better for the blind student to perform this modified titration than to simply work with other people’s results.

A plastic beaker, labeled with a braille “A” is used for the acid and a glass beaker labeled with a braille “B” for the base. Using a large “syringe pipette” the stated volume of base is measured into conical flasks and indicator added in the usual way. The rough titration is made by adding acid 0.1 cm$^3$ at a time from a large pipette notched at 0.1 cm$^3$ intervals. When the “human talking pH meter” says “change,” the total volume added is noted. A volume of acid which is 0.1 cm$^3$ less than this amount is then added to the second flask. The blind student then changes to a 0.1 cm$^3$ “syringe pipette” which is notched at 0.1 cm$^3$ intervals, and adds 0.1 cm$^3$ at a time until the “human talking pH meter” says “change,” when the total volume is again noted. This is repeated until good replicates are achieved. An experienced blind chemistry student using this technique can achieve results every bit as good as the best of his/her sighted peers.

CONCLUSION
With ingenuity, a little money and much time, blind students of science subjects can be given nearly full access to the practical and diagrammatic aspects of science syllabi, improving their understanding of the subject, and thus enhancing their chances of success in examinations and their quality of education and hence of life.

REVITALIZING TEACHER PREPARATION IN SCIENCE
Lynn W. Glass, Russell Aiuto, Hans O. Andersen

The Path to Reform
Deans of Education, Deans of Arts & Science, and science educators representing nearly 20 of America's leading scientific organizations met in September of 1992 to address the question: Are we preparing teachers who are able to teach the new reform curricula?

An Agenda for Action
Major science curriculum reform presently is being influenced by several professional associations. The National Science Teachers Association is guiding the development of Project Scope, Sequence, and Coordination, and the American Association for the Advancement of Science is guiding the development of Project 2061. Both projects share several common characteristics. First, common science themes, developed by the American Association for the Advancement of Science, are used to organize the content in the curriculum projects of both Associations. Second, the projects of both Associations share the following characteristics:

- Sequenced instruction to corroborate intellectual development patterns exhibited by children.
- Integrated or coordinated curriculum activities from biology, chemistry, Earth/space science, and physics to support connections among these four areas of science.
- Spaced instruction using a spiral approach to permit students to build upon prior experiences and concepts, each time on a level of greater breadth and depth.
- Developmentally appropriate hands-on and minds-on curriculum to provide science instruction every day for all K-12 students.

Each of these characteristics is supported by research and is demonstrated in practice. Project Scope, Sequence, and Coordination and Project 2061 are unique in that no other science projects have incorporated all four characteristics into a single model for science instruction in the United States, although many foreign countries have adopted these characteristics into their science curricula.

Making science accessible and scientific literacy attainable for all students is a national need. If we are going to enter the 21st century as a world leader, our populace must be able to function in a scientific and technological society. We must also be responsive to the cultural, ethnic, social, and gender differences that are present in our society; and special efforts must be made to enfranchise minorities, females, and other groups traditionally unsuccessful in entering the scientific pipeline.

Considerable evidence exists on how we learn science. Students must be provided with developmentally appropriate opportunities to investigate, to explore, and to construct meaning for themselves. We need to use student-centered teaching strategies focused on a few major and powerful interdisciplinary ideas such as those presented in Science for All Americans. This is in contrast to our present orientation of teacher-centered instruction and the superficiality of concept coverage that is too broad.

Change in American K-12 education is a shared responsibility. In the last decades, grass-roots efforts have been building a new vision of science education for all Americans. Setting goals, developing strategies to achieve our goals, and carrying out the tasks needed to become the strongest scientific nation in the world are responsibilities we all share—government, the private sector, and elementary-secondary-collegiate education.

Because universities are among the agencies that share in the responsibility to bring about change, university presidents must dedicate senior, high-profile faculty in the sciences and education to the task of building programs that develop scientific literacy at all levels of instruction. University faculties must work as team members with elementary-middle-secondary teachers as well as with their university-level peers to bring about the changes. Reward structures, work assignments, and professional expectations must be changed to encourage and to reward individual and team efforts. Universities, as well as K-12 schools, need to use the strengths of the interactive technologies in developing and delivering programs to successfully improve the education of the youth of America.

The projected growth in the use of Project Scope, Sequence, and Coordination, Project 2061, and other interdisciplinary approaches to science teaching will necessitate the identification of effective models of preservice teacher preparation or the creation of new
models. Among the influential groups that can affect the
development of new models are the Holmes Group, the
Carnegie Commission, Project 30, and the Renaissance
Group. From the writings of these groups, six principles
can be identified to guide the development of exemplary
preservice science preparation models.

These six guiding principles are intended to focus on three
aspects of a comprehensive program—content/process
preparation, pedagogy, and the nature of human
development and learning. Thoughtful teacher education
efforts must focus on the intersections of these three areas
of expertise, we must also understand the interrelatedness
of these components. Each is affected by and in turn
affects a larger context or milieu, including, but not limited
to, issues of gender, social, and ethnic equity; reward
structures; ethics in science and science teaching; student,
classroom, laboratory, materials, and equipment
management; and scholarship expectations. It is not the
intention of this paper to suggest that these and other aspects
of a comprehensive preservice program are less important
or in less need of reform. Rather, it is to focus our efforts on
areas where the nation’s scientific research universities are
most capable of providing assistance. Too often our
efforts are concentrated on only one of these components
in preparing teachers, or, at best, the intersection between
two of them. These six guiding principles are meant to
emphasize the importance of how all three domains must
form the heart of the teacher preparation program.

A growing number of science teachers entering our
profession choose teaching as either a second career or as a
change in academic emphasis late in undergraduate
preparation. The six guiding principles proposed in this
paper can serve as points to begin the discussion on how
to best to prepare nontraditional students to meet the needs of
the 21st century classroom.

Guiding Principle One

Every elementary-middle-secondary science education
preservice student should experience the investigative
nature of science. Humans are natural investigators who
tend to lose that capacity due to a lack of opportunity to
use it. George Gaylord Simpson defined science as a
natural human investigative endeavor in which we
question, seek explanations to our questions, and test our
explanations. Although didactic teaching has its place, it
cannot impart an understanding of the investigative nature
of science, but direct investigative activities can. Hence,
all classes in the sciences and in the teaching of science
need to reflect the investigative nature of science in spirit
and substance. All teacher candidates—elementary,
middle, and secondary—should participate in at least one
open-ended investigation carried out over an extended
period of time. This experience should culminate in the
preparation and presentation of an appropriate scientific
report.

The most effective investigative experiences begin with
questions and problems that are generated by the students.
Like scientists and other professionals who generate their
own questions, preservice experiences should emphasize
this capacity to enhance lifelong learning. In addition,
students must be given opportunities to collaborate with
others—as scientists do—and to develop team work habits.
Opportunities for collaborative problem-solving are
numerous on major research campuses. In the various
research programs, students can be mentored in problems
of their choosing on such topics as scientific and
technological research, investigations of the nature of
learning science, and inquiry into the history and
philosophy of science.

Guiding Principle Two

Every elementary-middle-secondary science education
preservice student should have classroom and
laboratory experiences in biology, chemistry, Earth/
space science, and physics. It is desirable that all
precollege teacher candidates achieve competence in
science equivalent to at least a major that reflects depth in
one discipline and breadth across a spectrum of science
areas. It is recommended that half of the time a student
devotes to the study of science be concentrated on a single
discipline while the other half be divided among the
remaining disciplines.

Science at the collegiate level should reflect what is known
about how understanding and meaning is acquired in the
natural sciences. Students must have opportunities to
construct meaning from activities and courses which focus
on relatively few but powerful topics. Courses must be
designed to help all students acquire science literacy.
Special laboratory or discussion sessions that focus on
issues and problems relevant to the needs of students
enrolled in education, engineering, the humanities, the arts,
etc., should be developed. These new courses will form
the core of scientific understanding for college graduates,
and additional depth and breadth will be developed from
existing courses for majors in the specific sciences.

Guiding Principle Three

All elementary-middle-secondary science education
preservice students should understand the
interrelatedness of science disciplines and the
connections between science and other areas of
knowledge. Solving problems that are rooted in the
scientific and technological arena draws upon skills and in
the scientific knowledge that is multidisciplinary. Special
efforts must be made to assist students in understanding
the connections among areas of science and to recognize that efforts to learn natural science, social science, mathematics, philosophy, and literature complement each other. Team teaching with experts in other subject areas and specially designed courses are ways to accomplish this.

Guiding Principle Four

All elementary-middle-secondary science education preservice students should learn scientific content and thinking processes in the context of contemporary, relevant, personal and societal issues and problems. To be useful in decision making, the thinking processes and knowledge learned in the classroom and laboratory must have application to the real world. To accomplish this goal, curricula must be reconstructed and instructional strategies modified so that preservice candidates are able to think critically about integrating scientific-technical and social issues.

Guiding Principle Five

All elementary-middle-secondary science education preservice students must have a sound understanding of the nature of learning and how it can be applied to the learning of science. This understanding includes two important ideas: that science knowledge (content) and skills (processes) are through direct, appropriate experiences that have relevance to the learner; and that capacities related to learning are developmental and sequential within each student throughout the grade levels. Thus, content and activities must be selected to be appropriate and ordered to be cumulative over time. Currently, schooling provides an eclectic selection of science experiences throughout the grades. Such experiences are often presented to students at a time inappropriate to their capacity to comprehend the topic. Such experiences are often redundant (e.g., the topic of photosynthesis)—repeated at several grade levels without adding anything new. Such experiences are seldom conceptualized to contribute and link to more advanced understandings. It is through a sound understanding of learning and science that collaboration can take place among teachers at all the grade levels so that science frameworks and science experiences truly exemplify a hands-on, minds-on, science curriculum.

Guiding Principle Six

All elementary-middle-secondary science education preservice students should have several intense and extended clinical teaching experiences at a variety of Grade levels in diverse socio-economic and cultural settings. Each experience should be grounded in theory and pedagogical knowledge. These experiences should provide students with opportunities to demonstrate their teaching of the subject matter in an environment where they receive regular and systematic feedback from practicing science education is good teacher education.” master teachers, professors of science, and science educators. We have long known that our students tend to model the various ways in which they have been taught; hence, good science education is good teacher education. One way to change education in America significantly is to break the self-duplicating cycle of poor teaching at the point of undergraduate instruction in the sciences and education. Designing college courses to reflect the different learning styles of students and to incorporate higher-order questioning, cooperative learning, and problem-solving strategies will require intense and lively cooperation between faculties in education and the arts and sciences. With this capstone undergraduate experience the science teachers of tomorrow will be better able to meet the scientific and technological demands of the 21st century work force.

References

A father and mother approached me at the conclusion of one of our Celebrations of Learning with the following comments. “We just wanted to thank you for all your help in preparing our son to be a great teacher. Today was the first time in over 10 years of paying college tuition for our three children, that we have seen a real result or outcome. We can not believe how much growth our son was able to show, how many skills he now possesses and how clearly he stated his future goals.”

These parents had just attended a ninety minute exit presentation to an audience that is many times composed of the instructor, other class mates, family members, significant others, (spouse and/or friends), the student’s cooperating teacher, and others as invited by the student. This last category has included professors (from both Arts and Science and Teachers College), and present, part-time employers of the presenter. In addition, open invitations are sent to incoming methods students and the cooperating teacher that the methods student will have the following semester during his or her student teaching.

An Overview
In preparation for this presentation, students have taken at least one methods course, a science curriculum class, and had at least two separate semester-long practicums. All of this is synthesized as the student constructs a portfolio that is revised throughout their career. The portfolio contains at least four general categories and serves as the overlying structure for the final presentation: (a) a discussion of the teachers’ rationale for teaching, (b) samples of products, (c) evidence of growth, and (d) a clear plan for future growth and development.

The Presentation
The actual presentation takes place during finals week, although large classes have used part of the previous week as well. A sign up schedule with all possible open dates and times is posted soon after mid-term and is full within a few hours. Because of scheduling concerns, evening slots are also made available. This many times is the only way to get cooperating teachers free to attend.

At least one week before the presentation, each student must submit a complete lesson plan for the presentation and a guest list. The presentation must employ the skills of the pre-service teacher and be based on sound educational research theory. Many of the presentation plans have been built around the learning cycle and use such strategies as cooperative groups, activities, computer assisted instruction, as well as large group presentation skills. The key objectives for this time is to provide an overview of all four components of their portfolio while demonstrating appropriate teacher behaviors.

Students have also shown segments of pre-post video tapes, examples of products using multimedia including hypercard stacks, quick-time clips, scanned student products and had the audience (class) help critique growth.

Setting the Stage
From the very beginning of the semester, students are working on their portfolio. Table 1 represents a brief project description that is given to these pre-service teachers as part of their first methods course syllabus.

Table 1.
On the Road to the Celebration of Learning
A portfolio is a systematic, well organized collection of evidence used to monitor the growth of a student’s knowledge, process skills, and attitudes (Bonnstetter, 1992). Your portfolio will contain:

1. A well thought out and research supported Rationale for Teaching that describes your present vision and beliefs of teaching and learning.
2. Products from the Semester such as lesson plans, bulletin boards, exams, student projects, student evaluations, video tapes showing you working with large groups, small groups, and with individuals. Each of the tapes should be coded for teacher behaviors and critiqued in writing.
3. Evidence of Growth during the semester and/or career make up the third criteria. Examples include pre-post video tapes, revised products showing various stages of
understanding including lesson plans, assessment
instruments, student and teacher assessments and/or
journal entries capturing different stages of
understanding.
4. A Plan for Future Growth represents the final portfolio
section. This establishes a path or set of goals for
continued professional development.

Your portfolio is an organized and selective collection of
evidence that documents what you know and what you
know how to do in the teaching of science. Each section
should consist of documents and/or products which are
authentic evidence of your understandings or abilities as
well as evidence of growth.

Your portfolio must be developed over time, therefore it
will be a dynamic form of assessment that will be drafted,
revised, and updated constantly. In other words, be
prepared to add, replace, delete, and reorganize both your
goals and evidence as you move through the remainder of
your teacher preparation program.

Your portfolio is rationale-based. It is important for
someone reviewing your portfolio to clearly see your
vision of teaching science and that you are able to defend
this vision with a sound research-supported base of
knowledge. In addition to your rationale for teaching
section, a statement of your three or four most important
goals in each of the remaining sections will help introduce
and focus the reader to see the connection between your
goals and the evidence supplied.

Your portfolio is selective. From all the possible
documentation at your disposal, you must choose those
items that best demonstrate what you have accomplished
or how you are moving to accomplish a particular goal.
This is yet another good example of where the “right”
choices confirm the “less is more” statement.

Your portfolio is reflective. It is extremely important for
you to prepare short captions that either precede individual
pieces of evidence or are attached in some manner to
explain to the reader why this evidence has been included
and what it shows about your understanding of teaching or
your teaching abilities. This process will transform “stuff”
from meaningful evidence that portrays you as an
emerging teacher.

Your portfolio is collaborative. While you have the
ultimate responsibility for developing a portfolio that
documents your professional growth and development, you
need to remember that teacher preparation is not a
competition. You should consult colleagues for advice and
feedback as you collect and select evidence and make
decisions concerning presentation format. With the
growing role of technology, the use of hypercard stacks
and quick-time clips should be considered.

Your portfolio might include:
1. An introduction containing your rationale for teaching
but starting with three or four overall goals statements
and the advanced organizer for the reviewer about your
document. The “rationale for teaching” document itself
will take considerable time as you first draft thoughts
and then boil them down to a concise five or six page
statement. The rationale should provide insights into,
for example, your understanding concerning: (a) why
you will teach science, (b) what your goals for science
students are, (c) how you will decide what content to
provide, (d) what your curriculum will look like,
(e) what you would like students to be doing in the
classroom, (f) what you will be doing in the classroom,
and (g) how you will provide evaluation of your
program. Some of these sections will need
research-base documentation to both explain and justify
your vision.
2. A table of contents listing how you have organized your
evidence sections and what they include.
3. All items you have selected to document your
professional understanding and continued development.
4. Captions for individual documents that label, describe,
and focus the reader toward your intended purpose for
including this evidence. Captions should be brief, to
the point, and clear; they should tell the reader what the
document is, where it comes from, and what it suggests
about you.

Even though the primary audience for the portfolio is you,
the developing teacher, and your instructor, remember the
other potential readers and their needs. These additional
audiences might include cooperating teachers, school
district recruiters, colleagues, and other university
instructors. You may not be standing by for oral
explanations, so design your portfolio to clearly speak for
you and about you.

Final Thoughts Before Starting
Before any trip can begin, you must know where you are
going. During the first week of this class, course goals
will be reviewed and revised based on specific needs
identified by you and other classmates. These goals will
serve as the initial criteria for which you should start the
collection of evidence concerning your understanding of
science teaching and your professional growth to that end.
Therefore, to begin building your portfolio:
1. Clearly state a set of goals for professional development. In other words, list what you hope to accomplish this semester and throughout the rest of your teacher preparation program.
2. Create a personal list of course requirements in a format that makes sense to you and contains specific check points in terms of degree of completion with calendar dates.
3. Create a collection of documentation you already have, you will have, or you could develop that will demonstrate that you have met or are working toward each of the specific goals for professional development you have established.

This portfolio project description was developed after a review of the literature and with assistance from English Teacher Educator, Dr. David Wilson, who shared his syllabus containing the English Methods “ELATEP Portfolio Project.” In addition, ideas have been taken and adopted from Dr. Linda Vavrus’s classroom handout, “Guidelines for Developing a Portfolio to Showcase Professional Growth and Learning.”

The Developmental Phase
With the above guidelines for portfolio development in place, the methods sequence begins. Without going into another complete article describing the rather unique course itself, it may suffice to say that during the class, students are confronted with major paradigm shifts, the latest science and general education reform literature, and numerous opportunities to practice and refine their teaching skills and understandings. Examples of other learning opportunities that occur before student teaching include:

**Bulletin Board or Interactive Display.** Each class member is responsible for providing our Science Education Center with one or more Bulletin Boards or interactive displays. Students as a group define the characteristics of a quality display, and create their display, and evaluate their own as well as one other based on the agreed upon criteria. Pictures are taken for possible portfolio inclusion.

**Journal Article Review.** Students use the following 3R outline to describe their response to and analysis of one article dealing with the teaching of science. The 3R response format is divided into three categories: Reaction, Relevance, and Responsibility. These categories closely resemble Bloom’s Taxonomy of the domains of learning—the cognitive, the affective, and the psychomotor. The difference between the two nomenclatures is that the 3R Reaction scheme deals with the reaction of the affective domain first, rather than the cognitive. The rationale for the difference in placement is so the student can become aware of their affective response, and then deal with the cognitive merit of the learning regardless of the positive or negative affect associated with it. The 3R response format is also used by students as they make daily journal entries. When writing a 3R Reaction the following guidelines should be followed:

1. Reaction (Affective Domain, To Feel). What was the reader’s response (favorable, unfavorable, or mixed)? Give at least one example from the experience to support the point.
2. Relevance (Cognitive Domain, To Think). How pertinent is the event to the issue-at-hand (the conceptual framework of the event). The reader should be able to recognize and discuss how specific or important (meaningful) the event is to the course or issue and give at least one example from the reading to support the print.
3. Responsibility (Psychomotor Domain, To Do). How will the knowledge gained from the event be used in the everyday life of the reader? Give at least one example of possible application in your personal or professional life.

**Pre-Course Teaching Experience.** During the first week and again at the end of the semester students teach a ten minute lesson during class time. “You are to teach a topic of your choosing, based on what you know about teaching, and include a discussion within your lesson.” A lesson plan is also to accompany each presentation. Both lessons are videotaped and coded for teacher behaviors, interaction patterns and questioning strategy development.

**Fourth and Fifth Grade Teaching Experience.** Students prepare an activity, including a lesson plan for third through fifth grade gifted students. Each lesson is presented to our class and eight activities are revised for presentation in a nearby school. Only eight activities are presented to accommodate the school’s eight period schedule and to allow manageable class sizes for these neophyte teachers. This activity requires a full day and occurs approximately six weeks into the semester.

**Curriculum Project.** First students prepare a working definition of curriculum and then describe the components of their curriculum for a particular course of their choosing. The purpose of this activity is for students to become extremely familiar with a curriculum project, or a textbook series.

**Professional Involvement.** Each student is required to document a minimum of eight hours of professional involvement. Examples include Science Education monthly club meetings, and/or local, state, regional or national professional conventions. At least two of these hours should be volunteer work such as: science fair judging, Saturday science programs, Children’s Museum, or assisting with an inservice presentation. Documentation should include a complete description of activities plus personal perceptions as to the value of the experience. All of this material may have a place in the portfolio.
Unit Lesson Plan. (This experience is to be tied to the practicum.) Students are to develop a topic into a unit of lessons that will run approximately 15 class days. The unit plan should include at least the following: (a) general goals, (b) objectives/outcomes for the unit, (c) major activities or components of the unit, (d) rationale for this topic, (e) materials needed (include cost and source), and (f) list of hazards and safety considerations.

In addition, daily lesson plans must be developed that include at least the following:
1. Specific lesson objectives/outcomes.
3. A breakdown of components for each lesson with a time estimate.
4. Teacher behaviors predicted.
5. Student behaviors predicted.
6. Evaluation: (a) of student (included copies of assessments, portfolios, etc., and (b) of teacher.
7. Other items: (a) teacher questions that might be asked, (b) where the activity might lead (also extension activities), (c) how this might mesh with other topics in and out of science, and (d) space for teacher comments upon lesson completion.

Class Participation/Daily Assignments. There are numerous daily assignments. Much of the class time is spent in small group and large group discussions of reading assignments. Students are requested to prepare questions and/or comments over readings before these readings are discussed.

Inquiry Based Science Demonstration. Each class member prepares a three to five minute, teacher-centered demonstration, including a lesson plan handout for all class members. The presentation must model appropriate inquiry based teaching strategies. Portfolio entry should also be considered.

Weekly Journal Entries. This is an opportunity for students to "reflect" on their personal feelings and concerns toward teaching, as their philosophy emerges. A minimum of a half page entry per week is required and daily entries are required during special activities. Journal entries are electronically sent to the instructor at least once each week. All students are given a computer with modem at the beginning of the methods course and if necessary, they may keep the unit until the fall following graduation. The student computer loan program is composed of old IBM model XT's which have been donated by local businesses and other University departments as updated equipment is purchased.

Practicum Experiences. Each student will have had two practicum experiences at the completion of his or her methods and curriculum sequence. The first will entail a minimum of 40 hours of volunteer teaching in an informal setting. The second experience will require at least two periods everyday for 10 weeks. A list of recommended experiences for the formal practicum include:

1. Learn all students' names within the first two days,
2. Write and share observations of class sessions and particular students in assigned classes.
3. Assist with: taking roll, reading bulletins, handing out papers, and setting up and breaking down laboratory experiments.
4. Grade student papers.
5. Be familiar with school policies and procedures.
6. Create a bulletin board and/or window display.
7. Be involved with students in one-on-one and small group settings.
8. Observe one student over the semester and regularly log records on behaviors, interactions, class performance, physical changes, emotional reactions, and special needs.
9. Make explicit lesson plans based on student needs.
10. Teach as many lessons or portions of lessons as possible.
11. Plan and teach at least one topic area or complete unit as described in more detail in the major activity session.
12. Take time to reflect on experiences as a "Teacher Assistant."
13. Experience Team Teaching, not just turn teaching.
14. Demonstrate the use of checks for understanding.
15. Follow one student for as much of an entire school day and document and react to your findings.
16. Send reflections and reactions electronically to the university instructor, and other classmates when appropriate, at least once each week.
17. Administer an instrument to assess student perceptions concerning your interactions and teaching.

The Assessment Process
The cry nationwide concerning portfolios and presentations is focused on "how do we assess them." The first step is to rethink our traditional view of grading and assessing. Once this has been accomplished and an understanding of summative and formative assessment developed, we will look back and wonder how we ever justified our antiquated letter and grade point approaches. But as an intermediate step, the following generic grade rubric may serve as a guide. Each semester this rubric is redefined by the class to best serve their developmental needs (see Table 2).

You also may notice that the rubric applies only to the course outcomes as a summative assessment. The portfolio has no assessment rubric and is handled as a formative course component.
Table 2: Science Education Grade Rubric

A—In addition to carefully completing all course goals and fully participating in all discussions and field experiences, an “A” in the methods block indicates that a student is extremely well-qualified in terms of teaching skills and possesses the ability to be outstanding during student teaching. This student displays quality planning, interacts well with students, shows command of subject matter and has ability to discuss a number of issues in science education. This student shows creative flair as well as a strong commitment to education. This individual is well on the way to becoming a formal operational teacher. Furthermore, all of the above criteria have been systematically documented and presented in his or her portfolio and during the Celebration of Learning.

B, B+-In addition to completing all assignments and participating in all field experiences, a “B or B+” indicates that this student possesses ability to plan, interact and deal with issues in science education. This individual understands the subject matter and can implement effective lessons. Both the portfolio and the celebration of learning indicate areas of need that the student has identified and established a plan of action to correct.

C—This person possesses the basic competencies deemed necessary for science teaching. It is assumed that all course goals have been completed. This student may be quite successful in some areas and not so successful in others. A “C+” student may need special attention during student teaching to insure success and certification. The portfolio and the celebration of learning presentation should indicate areas of need but the student may not have developed a well thought out plan of action for further professional development.

C—A “C” grade indicates that the student is unsuccessful with the basic competencies even though this individual can direct a classroom given support and directions. This student may have achieved many of the course goals, but does not possess the basic competencies necessary to student teach. The portfolio and the celebration of learning presentation will show areas of accomplishment and how these skills will be redirected toward another career choice or how the student will back up and correct these deficiencies before being allowed to continue into student teaching.

D, F—Complete failure early in the term will signal a grade of “D or F.” This individual will be counseled to drop the class and redirect their professional goals based on individual strengths.

This Rubric was originally created by Dr. John E. Penick and has been modified to serve as a sample for each new class to rework.

Summary
Many of the students upon first examination of the course syllabus and goals immediately understand why the final is called a Celebration of Learning. As one student recently said, “Anyone who lives through this deserves to have a celebration.” But just as the course syllabus ends with the following statement, we as educators of educators must also remember, that “The love of learning is taught, not taught.” Portfolios provide the best option yet for each of us to catch a life-long love of learning. What about scheduling yourself for a portfolio presentation along with your students next semester?

THE INTERNATIONAL ASSOCIATION OF SCIENCE CLUBS

As a prelude to upcoming section articles this issue expands on the role of the International Association of Science Clubs as depicted in the feature article.

I.A.S.C.'s official aims include: 'Education' and the 'Fostering of International Friendships.' Others are 'Service to one's Community, and learning Social Responsibility,' and 'Making Provision for Jobs through Work Places in Science Clubs.'

This section focuses on the interface between non-formal, informal, and more traditional formal science education. Articles expose the world of out-of-school and public science experiences.

(Left) Staff from the China Association for Science and Technology, Department of Children and Youth Affairs with I.A.S.C. Secretary B.J.K. Tricker on the Great Wall. The Chinese significance of a picture of the Great Wall is 'everlasting life,' and an appropriate sentiment for associations to exchange among themselves.

I.A.S.C. passes on this sentiment, wishing ICASE everlasting life as well!

(Right) I.A.S.C. Secretary Brian Tricker teaching a teenager to operate the gears on Saddocks Farm Science Club's 1948 Fordson Major. I.A.S.C. formed in 1982 through international interest in the Saddocks Club, and now, among other things, owns a small village in Scotland being modified into a small science centre.

ASIAN WORKSHOP ON GLOBAL CHANGE EDUCATION MATERIALS
A Report by Dr. Jack Holbrook
Executive Secretary, ICASE

The Education in Global Change project, developed by the International Council of Scientific Unions Committee for the Teaching of Science (ICSU CTS) is a result of a worldwide collaboration between science teachers and researchers in Global Change. A series of six interdisciplinary units have so far been developed, entitled:
- The Global Carbon Cycle
- Remote Sensing: Window on Global Change
- The Changing Atmosphere
- Oceans
- Clues from the Past: Glimpses of our Future
- Population and Land Use

The idea of the units is to show how science is a force for good and that scientists have a vital role in enhancing the quality of our lives. However to show this it is necessary to appreciate what advice scientists can give to decision makers, be able to judge the quality of that advice, and appreciate what effect the advice, if accepted, will have on us. It is important that students, once in possession of the relevant facts and parameters, are able to make up their own minds about issues and that teaching should be geared towards these goals.

The units can be used also as a means of introducing important scientific principles to students in the age range of 16-20. A good understanding of these principles is necessary for the understanding of the environmental issues such as the protection of the ozone layer, the increasing greenhouse effect, and the destruction of rain forests.

Each unit has been written as a series of student activities supported by notes for teachers. The units, or just simply single activities within a unit, have been designed to be used in existing science courses. They may also be adapted for use in general students and other programmes.

In summary each unit has been designed to:
- Cover key scientific concepts;
- Illustrate science in context of important environmental issues;
- Encourage student participation;
- Encourage skills such as data interpretation, decision making, communication; and
- Illustrate the positive role played by scientists in society.

BOOK REVIEW

Science Is . . .: A Source Book of Fascinating Facts, Projects, and Activities
Susan V. Bosak, Douglas A. Bosak, and Brian A. Puppa
New York: Scholastic

This review was written by Julie Thomas, Science Education, University of Nebraska-Lincoln.

Once in a while, a science resource book comes along which every teacher should have. Consider Science Is . . . a treasure whose time has come. This book is a must!

Eight years of grassroots research has gone into the development of this book. Educators, scientists, parents, and children have come together in workshops, focus groups, interviews, classroom observations, field tests, and a review of over 1000 other science resource activity books.

Coined a “hassle-free resource that works,” this very well organized text includes everything a teacher needs in one place—on one page. Best of all, it is clearly created for teachers. Practical, hands-on activities are carefully organized and include step-by-step, easy-to-follow directions. Explanatory information is included for those teachers with limited science background. Illustrations and cartoons help explain activities, and fun fact notes are scattered throughout the book.

To provide maximum flexibility, there are three types of activities included in the book. “Quickies” require no preparation and can be used to introduce concepts or fill a few minutes. “Make Time” activities require some preparation and a few inexpensive materials. “One Leads to Another” activities are designed for investigation in greater depth and connect in a series of longer activities that build on one another. The ten broad subject areas include: Discovering Science, Matter & Energy, Humans, The Environment, Rocks, Plants, Living Creatures, Weather, The Heavens, and Applying Science.

Science Is . . . would be ideal for enriching an elementary or middle school curriculum, provide attention-grabbing introduction to more complex material for high school, and would be a useful as recommended or required resource for science teaching methods students.

Science Is . . . has received strong reviews including the support of National Science Teachers Association and American Association for the Advancement of Science. Written by Susan V. Bosak, Science Is . . . (ISBN 0-590-74070-9) includes 515 pages and costs $29.95. It is available through the National Science Teachers Association (800 722 NSTA) or Scholastic (800-325-6149).
Profile

CARIBBEAN SCIENCE EDUCATION LOSES
A STALWART:
THE PASSING OF FLORENCE
COMMISSIONG
by Winston King

Florence Commissiong died in Jamaica on August 18, 1993. Flo, as she was affectionately known, was one of the foremost science educators in the Caribbean, as a classroom teacher and innovator since the late 1950s. I remember vividly the first time I met Flo in October, 1973. We were attending a UNESCO-CEDO Science Conference in Barbados. The Secretary-Treasurer of a newly-formed International Council of Associations for Science Education (ICASE), Dennis Chisman, was there. All participants were impressed by her quiet manner, which hid somewhat the great wealth of knowledge and experience that she possessed. She was frequently quiet but when she spoke people listened attentively.

Flo spearheaded the development of the Caribbean Examination Council Integrated Science (Double Award) Syllabus beginning in 1975. That development is acknowledged, even by critics, as one of the most progressive and insightful that the region has seen. She worked tirelessly as well on the UNESCO RLA-142 Science materials for science teachers, producing one of the best selling science textbooks for the 11-14 age range, Integrated Science for Caribbean Schools. She planned and implemented many regional and Association of Science Teachers of Jamaica (ASTJ) activities and served as Chief Examiner for CXC until her death. To the best of my knowledge she did not miss one year of setting, marking and grading exercises since 1979.

But I have so far only spoken about her extracurricular activities. Indeed, she also produced a sterling performance in her full time employment as Senior Lecturer in Science Education, University of the West Indies, Jamaica. Let me share with you the impressions of her given by one of her former Diploma in Education students from St. Lucia: “That white-haired lady is so strict and serious about her work. She is a perfectionist and works you hard. However, if I had to do it all over again, I would choose to work with her.” I know that all of us with whom she worked would share these sentiments.

Flo was honored by ICASE for outstanding work in local, regional, and international science education in 1985. She was also recently honored by a group in the USA for distinguished work. These are the honors and distinctions I know about, but I am sure there are many others. My fuzziness on this point is due to the fact that Flo’s humility, modesty and passion for excellence continued to make her a person not given to public announcement of what she had achieved.

Flo and I kept in contact to the end. A few weeks before her death her daughter called me to decline an invitation given to her mother to help me in a science workshop in Montserrat. This was not like Flo, so I called. I was devastated to realize that she was so ill. From thence we spoke frequently. Even as she grew weaker she would insist that my calls should be put through to her. One day she intimated that she was contented with her illness and was peacefully prepared to meet her maker. She lamented, however, that there were so many other things she wanted to do in science education. I assured her that whatever she did was very well done. I hope that she believed me because it was true.

There are very few persons who met Flo who would not have been touched by her decency, gentleness, loyalty, and commitment. These are the legacies she leaves behind to her sorrowing daughters, grandchildren and other relatives, and colleagues; as all of us who had the honor to know her.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

ICASE WELCOMES NEW MEMBERS

CYPRUS CHEMISTRY ASSOCIATION

This newest member of our family of organizations has goals that include:

1. to promote the subject of chemistry at all levels of education,

2. to discuss and help improve the school curriculum, as well as the present textbooks in use,

3. to focus attention on the problems related to teaching high school chemistry,

4. Organise discussions and lectures on chemistry,

5. to encourage professional development by providing educational articles in the Chemistry Magazine published by the Pancyprian Union of Chemists,

6. Co-sponsor a chemistry conference every other year between Greek and cypriot chemists. (This year the conference will take place in Greece this September.)

7. Organize the Pancyprian Chemistry Olympiad which takes place every other year. (Selected students from this event represent Cyprus in the World Chemistry Olympiad. This years the World Olympiad will take place in Norway.)

ICASE members might be interested in knowing that Cyprus chemistry is taught for a total of five years. For more information please contact Vice President, Helen Papachristodoulou, 3 Philopimenos, 241 Limassol, Cyprus

ESSEX-MALAWI LINK

by Jane Giffould

For the last year ASE Essex Section has been having a link with STAM in Malawi. STAM has just been reviving itself from a long hibernation to become a very active organization. In Essex we appreciate the benefits of a Science Teachers Association and so have been encouraging Malawi in their efforts. This encouragement has been active in that we have hosted teachers from Malawi, have made book and monetary collections for Malawi and most recently have attended their conference courtesy of SEDW.

This STAM first annual conference was successful with many teachers participating and hopefully gaining plenty. It was impressive in that it had cross-curricular themes being in conjunction with MAM, the Maths Association. It also had an international flavour with input from both Essex Section and Kings College, London.

As part of the conference, Essex was invited to the national committee meeting in order to discuss the direction of the link for the next year. This was very
much a two way process which included Essex getting tips on how to hold Science Fairs. Hopefully Essex will be able to follow up the suggestions made for the help that they can give to STAM.

Overall we were impressed by the effort that STAM has made to become an interactive organization which takes consideration of what its members need. We note that they are outgoing in their fundraising rather than sitting back and waiting for things to happen. We look forward to the development of STAM and are proud to be associated with them.

This link between two organizations on different continents is important in the development of teachers to give a far wider view of education. We know that there are international bodies such as ICASE however we also appreciate the more individual personal attention of the link. We would recommend such a procedure to other countries.

VIETNAM SOIL ECOLOGY SOCIETY

Dr. Vũ Quang Manh

Center for Biodiversity Resources
Education and Development (CEBRED)
Hanoi National Pedagogic University I

I am very pleased to inform you that the 1st Congress of the Vietnam Soil Ecology Society (VNSES) has taken place in Hanoi, at 31.3.1994. The organisation is national, scientific, and non-government body.

The member of the VNSES are, mainly researchers, educators, teachers, policy-makers, administrators, as well as those working on an interested in the field of soil ecology, and concerned ones.

The main aims of the VNSES are to unite all above-mentioned persons and organisations; to improve their studies, their evaluations and proposals to appropriate authorities in the fields of management of biodiversity resources, of soil and soil fertility, of environment; to enlarge education and training; as well as to develop scientific relations and cooperations at national, regional and international levels.

The VNSES Executive Board consists of 10 members, by election of the Congress, working for a five year period (1994-1998).

Professor Dr. Vũ Van Tuyen is elected as Chairman, and Dr. Vũ Quang Manh is elected as General Secretary of the VNSES. The VNSES has only occasional journal, with editors of Vũ Quang Manh and Vũ Van Tuyen.

On behalf of the VNSES Executive Board I would like to ask you for full membership of the ICASE, and to express our respect and trust to you and to ICASE Executive Board.

GREECE-CYPRUS SCIENCE TEACHERS ANNUAL MEETING

The 5th annual meeting of science teachers from Greece and Cyprus took place from 18-20th March at the University of Cyprus in Nicosia. The meeting was held in Greek and all abstracts appeared in Greek in the conference programme. Over 200 participants took part and presentations were made in two parallel sessions covering teaching and curriculum concerns in the two countries. Further details can be obtained from the Science Association for Cyprus, P.O. Box 4863, Nicosia, Cyprus. The Corresponding member is Christos Neocleus.

Greece-Cyprus Science Teachers annual meeting March 18-20, 1994, University of Cyprus. The ICASE Executive Secretary with members of the Science Association of Cyprus Committee.
PROJECT 2000+ STEERING COMMITTEE MEETING

The international steering committee for Project 2000+, chaired by Colin Power, Assistant Director General for Education, UNESCO, met 9-10th February 1994 at the Commonwealth Secretariat, London. ICASE was represented by Jack Holbrook, the Executive Secretary and Sheila Haggis, an ICASE award holder. Dennis Chisman, ICASE treasurer, was also present as an observer.

Decisions were made to publicise Project 2000+ by printing brochures and to prepare a 10-12 page summary that could be sent to Ministers of Education and International agencies. Partners agreed to try to publicise Project 2000+ further at conferences around the world.

The steering committee reiterated the need for National Task Forces (NTF’s) to be created. These should not be seen as the end product, but as a means to an end—to enhance STL through initiating national projects. The work of the NTF’s was seen as:

- being in charge of carrying out a needs analysis (as necessary)
- being in contact with relevant institutions and organisations, funding agencies, industry, etc.

- ensuring strong links with the EFA (education for all) group within the country (if it exists)
- seeking sources of funding for projects
- receiving and developing project ideas and seeking funds, taking note of the broader development needs of the country.

UNESCO agreed that they would prepare a document on what is meant by an NTF as there was still confusion as to who should be setting these up and what functions they should perform. It was stressed that the NTF’s need not conform to any set structure and should be created with respect to the national situation so as to enable them to function effectively.

It was expected that Governments would take the lead and have membership of the NTF, but science teachers associations and other non-Governmental organisations would be expected to play vital roles and perhaps be the impetus to get things going.

The steering committee agreed that a newsletter was essential and that this should emanate from the international secretariat at UNESCO.

No firm decision was possible on what to do with the material collected for the 1993 international forum, but the steering committee is preparing to produce a number of monographs for which these materials would form the base. Suggestions from NGO’s are welcome.

ASE annual meeting, University of Birmingham, UK, January 6-8, 1994

EUROPEAN SYMPOSIUM IN
LAVILLETTE

Alicja Wojtyna-Jodko
ICASE
European Representative

European symposium on “Science and technology teacher training: what training for what type of teaching?” was held from March 30th to April 1st, 1994 in the City of Science and Industry La Villette in Paris.

This symposium, which is the part of the project “A secondary education for Europe” was jointly organised by the Council of Europe, the French Ministry of Education and the City of Science and Industry (Cité des Sciences et de l’Industrie) La Villette. It was mainly for specialists in education, e.g., trainers, researchers, administrators, inspectors from 38 signatory state of the European Cultural Convention of the Council of Europe.

The symposium was under the patronage of Mr. Francois Bayrou, French Minister of Education and Mr. Francois Fillon, French Minister of Higher Education and Research.

Program of the three days long symposium included plenary sessions, round table discussions and working groups.

Participants had also possibility of visiting La Villette’s expositions.

Each day of the symposium’s debate was focused on different problems:

1. Training policy of teachers in science and technology:
   - What are the training structures and systems for secondary education teachers in science and technology in Europe?
   - How are secondary teachers trained and recruited in Europe?

2. Disciplinary training, interdisciplinarity and culture:
   - How are the disciplinary sectors structured?
   - What links exist between the different disciplines?

3. Teacher training and the way of use resources:
   - Scientific and development knowledge is done out-of-school: University, industry and research work together: the broadcasting of this knowledge does not only belong to schools, museums, media, scientific organisations also participate in it.
   - What are the links between the school and its different structures?
   - How do these resources integrate into the system of teacher training?

These and many other problems were discussed during symposium.

People representing almost 40 European countries presented what are the answers given in their countries for questions mentioned above.

Summarising shortly the main outcomes of this symposium it is necessary to state that it would be impossible task to run through the specificities of every country since there are even variations within one and the same country.

I would like to quote a sentence expressed in the first round table discussion: “Any teaching system cannot rise above the average level of its teachers.”

That is why it is so important to deal with problems of teacher education.

General agreement seems to have been reached on the fact that in all countries there are the same kinds of problems which may be summarised as: having to make the level of average teacher high enough to fulfill the needs of the individual in the society.

There is no doubt that to live successfully in modern society everybody needs a sound basic scientific and technological knowledge.

It was also clear that although problems are very similar, solutions vary vastly from country to country due to different structures, political systems, cultural backgrounds (Cartesian Latin countries, pragmatic Anglo-Saxon minds, etc.). A feature in common in all systems is the dual aspect of education: preparation of specialists on one hand and general
culture and literacy on the other hand. This raises the problem of writing new curricula about the content of subjects to be taught and of preparing teachers to meet both these objectives.

It appears that beyond the diversity of national situations there seems to be mainly two models of teacher education: one, which may be called the sequential model (in which future teachers first get a sound academic knowledge in a specific subject and then get an appropriate pedagogical training) and a second one, generally known as the parallel model (where future teachers receive a very strong pedagogical preparation and study simultaneously one or, most often, two subjects).

Another problem was concerned with technology: it needs to be clearly defined. It is not just applied sciences, nor an extension of physics. It needs to find its proper place in general education, whereas, currently, it seems to be mainly found, until now, in more professional education.

The high rate of evolution of science and technology calls for a permanent updating of knowledge and of teaching methods of teachers.

A need is felt for more active methods of teaching and in this regard the contribution of exchanging teaching experiences among practicing teachers should not be underestimated. Science teacher associations can play an important role in organising such exchange of views and experiences in Europe.

There is no consensus on the criteria of selection and recruitment for it varies very much from country to country.

Another problem discussed was the teachers' motivation with regard to their continued education (time, money, moral rewarding, etc.).

There seems to be a general concern that teachers who most need professional updating are those who are least likely to take part in the actions organised. One of the questions put to the participants in this symposium is thus: how to motivate such teachers and how to motivate bright and active students to become teachers?

---

**ICASE**

**The First 20 Years**

1973-1993

**A brief history**

This new publication is a brief history of the International Council of Associations for Science Education.

It is not intended to be a comprehensive account, but rather an overview of the key happenings and milestones in the development of the organisation and the policies and strategies that have enabled it to reach its present position in the international community of science education.

It also looks forward to the future, especially to the turn of the century, and examines possible options for the continual development of ICASE as an umbrella organisation for science education associations and similar bodies.

FEATURE ARTICLE

TEACHING SCIENCE FOR SOCIAL RESPONSIBILITY

Roger T. Cross
Ronald F. Price

Introduction

Two developments over the recent past have made possible an improvement in science teaching which will both make it more meaningful and useful to the general school student and more genuinely scientific for those students who will go on to study science further. One of these is the examination of science itself, both on the philosophical and sociological levels (Latour & Woolgar, 1986; Rose & Rose, 1969). That science is a productive force in society has long been recognized, and perhaps no more elegantly revealed than in Lewis Mumford’s *Technics and Society* (1934). Mumford concludes with hope for the future that sends a powerful message down the decades to us:

All that has happened up to now has been little more than a rehearsal . . . for however far modern science and technics have fallen short of their inherent possibilities, they have taught mankind(sic) at least one lesson: Nothing is impossible (pp. 434-435).

The other is the widespread movement to introduce environmental issues into science teaching. Some of this is recorded in the writings of the Science, Technology and Society Movement (STS), e.g., the proceedings of the Bangalore Conference, (Lewis, 1987) and more recently by Yager (1992). Now we have the statement of the influential American Association for the Advancement of Science (AAAS) to support this approach. The AAAS project, *Science for all Americans: Project 2061* (1989), sets out the problems and recommends the necessary action:

The most serious problems that humans now face are global: unchecked population growth in many parts of the world . . . the extreme in-qualities in the distribution of the earth’s wealth . . . the list is long, and it is alarming (p. 12).

*Social Responsibility.* Is the proposed content likely to help citizens participate intelligently in making social and political decisions on matters involving science and technology? (p. 21).

It is here that a socially responsible science education has a vital role to play in the development of a more meaningful science education during schooling (Layton et al., 1993).

Many science teachers are worried by these developments, fearing unfamiliar approaches and often lacking help. Some fear the science is being replaced by matter which should be taught by other disciplines. In some cases superficial approaches and ‘preaching’ leads, not to interest, but boredom. Here at La Trobe University we have taken these doubts and problems into account and developed an approach to the social responsibility of science which concentrates on the special skills and responsibilities of the science teacher. It emphasises the principles and methods of science in such a way that they can be better related to the problems facing us in today’s and tomorrow’s world.

It was Joseph Schwab, in the post-Sputnik curriculum development days who complained that ‘the standard rhetoric of textbooks even at the college level’ was one known as a ‘rhetoric of conclusions’ (Schwab, 1963, p. 39). Our aim has been to get away from this and show how scientific theories are produced to describe and explain the observations that we make. We present a process for the preparation of the teaching of controversial scientific topics by teachers, it proceeds teaching and should be viewed as professional development by the teacher, because it involves personal research into the issues surrounding the controversy. We began from a consideration of the skills required which a training in science can provide. These are:

**The Skills Required:**

1. For understanding the arguments involved in the issue;
2. For judging the experts’ opinions;
3. For carrying out independent investigations, in the literature and in the field;

Following that we identified a number of procedures which teachers need to take in preparing to handle a particular social issue in science, whether the greenhouse effect, nuclear energy, or the use of CFCs.

In the course of working through these procedures
teachers will be able to decide on a unit and individual lesson plans. Many of the procedures will be repeated by the students in the course of the unit.

Professional Development Procedure:

1. **Defining the Projects:** the kind of social issues which are likely topics are usually too broad to be successfully handled as a single project and it is therefore desirable to begin by considering how they might be broken up into separate projects. Then you must decide whether to select only one of these for detailed examination or whether to allot different projects to different groups of students within the class.

2. **Sorting the Questions:** this step involves brainstorming the questions involved in the selected project (ionising radiation; water pollution; genetic diversity) and then grouping and sorting them. They need to be sorted in various ways: according to discipline type: ethical, political, economic, scientific, etc., and according to whether the answers are known or disputed. Decisions must be made as to which questions are too difficult, for whatever reason, to handle, and which will be of the most educational benefit to pursue.

3. **Handling the Arguments:** this is a particularly crucial step, involving setting out and analysing the steps of arguments to answer the questions selected in Step (2). What kind of evidence is involved (e.g., chemical, statistical)? Are there problems of terminology, conceptualisation or logic? What prior knowledge or skills are required of the students? This last leads to a choice of teaching methods but we see Handling the Arguments as a prior step. When handling the sociopolitical and economic aspects of a question an important consideration will be the identification of the various interest groups ("stakeholders") involved. As well as interests there are questions of values. Of course, during teaching students may bring up other arguments which you may not have anticipated. They should then be encouraged to follow a similar process of setting it out and analysing the steps.

4. **Considering the Concepts:** students appear to find this a very difficult task, often failing to understand that a concept is simply *meaning* of a term, something which may or may not require an unfamiliar word (table does not, metabolism probably does), but certainly requires definition. In handling an issue it is necessary to consider what is the minimum list of essential concepts, which, if any, are likely to give difficulty, and how to handle that difficulty. Drawing concept maps can help develop understanding of the ways in which concepts are linked together.

5. **Particular Teaching Methods:** consideration of stages (3) and (4) will reveal whether there are particular problems which require particular methods. Brainstorming and cooperative learning strategies (Hassard, 1990) are we believe the most appropriate. Empowerment of the students in terms of the acquisition of the desired skills comes from their own activities—rather than didactic teaching methods. One strategy that has been used is the debate. We have not found these at all satisfactory—they often degenerate into a simplistic two sides affair—a much more useful strategy is to be found in Value Tree Analysis—where various groups are stakeholders in an issue and cases for particular solutions to an issue are put with the view of finding a just solution (von Winterfeldt, 1986).

6. **Resources:** these will probably always be a difficulty, this is in part because a good issue is controversial and many of the resources will be partisan and in part because we will want to use up-to-date and therefore scattered materials. The materials often pose difficulties of language and style and too often lack details of the evidence required for successful learning of the skills of evaluation.

Having completed these steps teachers will be in a position to quickly develop the topic suited to the particular class. Many of the activities which the teacher will have carried out as part of the professional development of the resources and understanding of the controversial issue will be repeated by students in the course of the unit. They benefit from the teachers own experience and increased confidence in acting as a resource.

The Social Responsibility of Science in Science Education Research Group at the Graduate School of Education, La Trobe University, Melbourne, Vic. 3083, Australia would be delighted to hear from
any persons of similar interest in promoting science education.

Studies in Science Education

is an international review of research for all who are interested in the educational dimensions of science. It is not intended to compete with existing journals, but to complement them by providing reviews of research on specific aspects of science education and by drawing together, in analytical surveys, recent contributions which may be published in widely scattered sources. Its editorial policy is to encourage work which reflects a wide variety of viewpoints, including those of administration, anthropology, curriculum, history, linguistics, philosophy, politics, psychology, and sociology.

BOLIVIAN REFORM EFFORTS:
A STATUS REPORT

Hernan Garcia
Cochabamba Cooperative School
Cochabamba, Bolivia

and

Jon E. Pedersen
University of Arkansas
Fayetteville, AR USA

All across the world, educational systems are under a push for reform. In Bolivia, a country located in the central part of South America, the current battle cry is no different. Like many countries, the current educational system has dominated the horizon for many decades unyielding to the challenges of concerned patrons, teachers, and government officials.

The current system of education in Bolivia provides for four levels of instruction: preschool (two years, pre-kindergarten to kindergarten), elementary school (five years, first grade through fifth grade), intermediate school (three years, sixth grade through eighth grade) and secondary school (four years, ninth grade through twelfth grade). Most schools in Bolivia are state supported (88% of the enrolled student population) with far fewer attending private schools (12% of the enrolled student population) of which most are supported by the Catholic Church. It is also worth noting that the majority of the schools are found in the urban areas of Bolivia with few located in the rural areas.

The Issues

Even though schooling is obligatory by law, the Bolivian population has a large percentage of illiteracy. This is largely due to the fact that many individuals in Bolivia are segregated in rural areas and small towns and still maintain ancient cultural values which do not place an emphasis on “modern education.”

In regard to science education, it is fair to say that in general terms the quality of instruction offered to Bolivian students is low. Only the 12% or so that attend private schools have access to “modern” equipment, textbooks, technology, adequate physical plants, and other curricular resources. Unfortunately, private schools are very expensive and only the elite social classes of the Bolivian population can afford to send their children to these schools.

In addition to the aforementioned obstacles, there are other numerous factors which contribute to the poor quality found in many Bolivian schools. First, as previously mentioned, the educational system is elitist based and does not take into consideration the Bolivian social, cultural, ethnic and linguistic diversity of its population. This becomes even more critical in light of the fact that many individuals still hold to mystic or ritualistic beliefs about the nature of science. This is not a little disturbing since UNESCO’s declaration for Project 2000+ (1993) indicates that “[s]ound education is fundamental to the strengthening of higher levels of education and of scientific and technological literacy . . . that scientific literacy and technological literacy . . . that scientific literacy and technological literacy are essential for acting responsible and sustainable development” (p.6). Without the development of programs that take into consideration the diversity of the population, Bolivia meeting the goals of Project 2000+’s will be difficult at best.

Secondly, and closely related to the first concern, is the issue of language. The Bolivian educational system has ignored the fact that many individuals, especially in the rural and low socio-economic areas, do not speak Spanish as their first language or at all. Yet, few teachers prepared to teach in the Bolivian system are bilingual. Disconcerting as this is, it is even more so when one considers that scientific language or the style of language used in science can cause difficulties for students as they attempt to learn science concepts (O’Toole, 1993).

Finally, the teachers who are prepared to teach in the Bolivian school systems are, for the most part, trained...
in a perfunctory manner. Teachers are educated in a Normal School with an emphasis on science content and laconic methods for the transfer of this content to their students. Little time is spent on the methods of teaching science. Little time is spent on the methods of teaching science. Learning theory, or curricular theory. Most of these schools are poorly funded and lack the material resources (i.e., technology, curriculum, laboratory equipment, etc.) to provide the teachers with appropriate experiences in preparation for teaching science. The emphasis is placed on the coverage of content through repetition and rote memorization. In addition, many teachers in Bolivia who teach science have no formal training at all. These teachers called "interim teachers" are hired because of teacher shortages due to low pay. The teaching of science and math by teachers who are not qualified and educated to do so many times leads to rigid teaching styles. In addition, teachers tend to stick closely to notes that they have prepared and avoid dealing with student questing which could unveil the teachers true understanding of science (Stoll, 1994).

The Current Reform

Although the odds seem insurmountable, Bolivia is making headway regarding reform for science education and education in general. As a basis for the reform efforts in science, Bolivian educators agree that reform (or change) is never easy and the first steps to implementing change is recognizing that problems exist (Cushman, 1993). In addition, it is understood that the actual situation of the Bolivian educational system can not be improved by isolated and simple proposals and strategies, but by a deep transformation that will give solutions to the causes of the poor quality of education and provide for systemic change throughout the whole educational system. It is also apparent that in order for systemic change to occur, the school systems and teachers will need assistance. More specifically, Bolivian science educators will need an "[e]nvironment that is both enabling and motivational—providing sanction, protection, capacity, knowledge, resources, and the opportunity to change—combined with a set of expectations and the sensitivity to know when, where, in what direction, and how hard push" (Donahoe, 1994; p. 302).

In light of the aforementioned needs as it pertains to systemic reform, there are some basic designs for educational reform in Bolivia. A first step in the reform effort is to address the education of all students in Bolivia, both rural and urban. This follows the goals of Project 2000+ as Holbrook (1993) stated, "Project 2000+...[is] a scientific and technological dimension of basic education in the context of education for all" (p. 4).

This, however, will not be at a small cost. Consideration will need to be made for the diversity of students within the country itself. Curricula will need to be developed keeping in mind the cultural beliefs and practices of the students. As Stoll (1992) so aptly explained, many of the textbooks and curricula in developing countries are western in nature and do not into consideration the cultural, ethnic and linguistic diversity of a country such as Bolivia. The reform effort will focus on the development of new curricula which will utilize traditional technologies and crafts as part of the focus. In addition, an emphasis is being placed on the development and implementation of technology that will assist in the instruction process.

In addition to changes in the curricula, teacher education itself is being radically changed throughout the country. Science teacher preparation programs will no longer exist solely in the normal schools. Universities are implementing programs that focus on contemporary, quality pre-service education programs that have as their focus not only the learning of content, but also, learning about learning. More specifically, the education of teachers will focus on the cognitive, affective and physical development of students. Contemporary methods of teaching will also be taught to the pre-service teachers such as the whole language approach, constructivist method of teaching, and cooperative learning, etc. Emphasis will be placed on teaching children critical thinking and problem solving skills rather than the rote memorization of facts related to science.

The overarching goal of the program is to prepare teachers who can teach students to be scientific and technologically literate life long learners. In addition, substantive changes are being made to educate teachers who are bilingual and can address the needs of the students who are non Spanish speakers or at best, have Spanish as a second language.

In addition to the above, plans are being made to implement the following:

- Develop ongoing in-depth staff development programs for existing teachers.
- Create summer and winter institutes for continued development of teachers knowledge base.
• Institute advanced degrees in the area of teacher education.
• Develop research programs which examine critical issues in education pertaining to Bolivia.

Implement assessment strategies which are more closely tied to the current changes in instruction and curricula.

Conclusion

Overall, this is a big step for the entire educational system in an underdeveloped country that is moving towards systemic reform. Overhauling the science teacher education process; the development of new curricula which is sensitive to the nature and needs of the students; scientific literacy, the development of problem solving and decisionmaking skills as a critical component of students education, as well as empowering students to be life long learners are all worthy goals that will take time and substantial effort to implement. However, taken together these changes could have an immense impact on the future of Bolivia.

Although there may be many reasons to doubt the changes will occur, the vision has been established. Without a vision of what can be, we will never start our journey. And, it is through this journey that we encounter difficulties that provide us with experiences, and experiences in turn bring us wisdom to understand change.

The Present Education System

There are three clear sectors—the primary sector, the post-primary/secondary sector and the post-secondary sector.

Qualifying examinations mark the transition from one sector to another and also several within-sector transitions. These examinations act as hurdles in some cases. The first hurdle is the Common Entrance Examination taken at age 11. The level of success in this examination determines the type of secondary school to which the student goes. The older established traditional schools are generally favored over the new sector schools with the result that places in the traditional schools are in great demand. Consequently, only those students who have scored very high marks on the Common Entrance Examination gain entry to these schools. This represents only a small percentage of the secondary school intake. The remaining students attend the new sector schools.

The goal of free secondary education for all has not yet been achieved. The present provision is for about 75% of the eligible students. The remaining 25% either repeat the Common Entrance Examination if they are young enough, or else they may proceed to the post-primary sector. There they take the School Leaving Examination after a further two years, success in which may help them gain entry to the Youth Camps or Trade Centers for vocational training.

A qualifying examination (the 14+ examination) marks the transition from the Junior Secondary school to the Senior Comprehensive school. This examination does not really serve as a hurdle because the transfer from one level to the next is automatic. The 14+ examination is supposed to serve as a diagnostic examination to assist with the placement of students in appropriate tracks at the Senior Comprehensive level, but it is doubtful that it really serves this purpose. Students who are admitted to traditional schools or Composite schools do not write the 14+ examination.

Students from both new sector and traditional sector secondary schools write the regional Caribbean Examinations Council (CXC) examinations after five years of secondary schooling. For many students, this represents the end of their secondary schooling. Some of them seek employment at this stage. Moderate success in the CXC examination enables students to move on to tertiary institutions such as the technical institutes and the teachers’ college for primary teachers. Less successful students may enter the Youth Camps or Trade Centers. Students who excel at the CXC examinations usually continue in secondary school for a further two years and take the Cambridge CGE “A” Level examinations at the end of this period. Successful “A” Level candidates can enter university (local or foreign) or some other tertiary institution, or else join the work force.

Emphasis of Science in the Basic Education Cycle

In Trinidad and Tobago, the basic education cycle as defined by the Commonwealth Secretariat covers the primary school and the first two years of the secondary school, the first nine years after the start of compulsory schooling. A more natural segment of the system is the first ten-year period, that is, the period from the start of the primary school to the end of the third year of the secondary school when students in the Junior Secondary schools transfer to the Senior Comprehensive schools. This is the segment that will be referred to in this discussion.

Science is compulsory for all students for the first ten years of schooling. It is offered as “science” at the primary level and variously as “general science,” “integrated science,” and the separate subjects of chemistry, physics and biology in the first three years of secondary school. Individual secondary schools have some measure of freedom in deciding how science is to be taught in the first three years.

Science A Process Approach for Trinidad and Tobago (SAPATT), the official science curriculum for primary schools in Trinidad and Tobago, was derived from the American SAPA—Science A Process Approach. This curriculum is tested in the science component of the Common Entrance examination. Teachers’ Guides giving detailed suggestions for lessons are available. Student workbooks which match the outlines in the Teachers’ Guides are also available. This curriculum is very heavily biased towards the science processes; the science content/concepts in each lesson serve only as the vehicle for teaching/learning the designated science processes.

At the lower secondary level, the situation is not as clear-cut. In the new sector schools, there is an official government syllabus which stresses both content and process. The schools in the traditional sector, however, all tend to construct their own syllabus which is in many instances patterned after
one of the popular science texts for that level. In such cases, the emphasis is usually very much on content.

**Strategies for Teacher Training**

Within the recent past, a short induction course has been organized by the Ministry of Education for persons about to begin teaching at the primary and secondary levels. However, there are no full pre-service teacher training programs in Trinidad and Tobago today, though this system has operated at the primary level in the past. Both primary and secondary school teachers are now trained in inservice programs, the former group at the government-run Valsayn Teachers' Training College and the latter at the Faculty of Education at the local campus of the University of the West Indies.

The course at the Teachers' Training College lasts for two years and requires full-time attendance. Teachers typically teach for 23 years before they gain acceptance into the college. To gain entry to the college, teachers must possess passes in 5 CXC (or GCE "O" Level) subjects, including a science subject. The core curriculum covers the general education foundation areas, methods courses and content courses in the various subjects taught at primary school. Students must also choose one subject (called an elective) in which to specialize at a more advanced level. Typically, the advanced science group consists of no more than 15 students in any one year. This is but a small percentage of the total college population (See Table 1). The core science curriculum at the college has been designed to mirror the process-based curriculum in use in the primary schools.

Secondary school teachers are trained at the University of the West Indies on the Diploma in Education (Dip. Ed.) program. This is a post-degree, one-year, inservice program. Teachers attend lectures during the school vacations, beginning with an intensive session in the summer of each year. They also attend lectures for one day during the week during term time. University tutors visit teachers in their home schools at intervals to monitor and tutor them in their classroom practice.

In addition to a core curriculum consisting of the normal foundations of education courses, there are specialist curriculum courses. Each student must register in one curriculum area. Roughly 20 students register in the science curriculum area each year. The general aims of the science curriculum component of the Dip. Ed. program are that teachers will (i) apply understandings about science as a discipline, (ii) apply general education principles through the teaching of science and (iii) develop and manifest favorable attitudes to the learners, science, technology, their teaching and their self-development.

There is a large backlog of untrained secondary school teachers since only about 100 students can be trained in the Dip. Ed. program each year (Table 1).

Workshops are also mounted periodically for both primary and secondary school science teachers by the Ministry of Education. Sometimes, these workshops are a joint effort of the Ministry of Education, the Association for Science Education of Trinidad and Tobago (the local science teachers' association) and the Faculty of Education of the University of the West Indies. Issues that are of specific concern to teachers (for example, school based assessment) are addressed at these meetings.

**Commentary**

Science as a school subject is held in high esteem in the society at large. This does not mean that the teaching of science in the schools is non-problematic. Problems exist particularly at the primary level and two main reasons can be advanced. First, many of the primary school teachers (who must all teach science) have a very weak background in science. Some of the older teachers did no science at all after their third year of high school. These teachers are forced to teach science because it is examined at the Common Entrance examination, but many feel very insecure doing so. The second reason is intricately linked with the first. The process-based approach is radically different from the traditional way of teaching science. Primary school teachers are therefore not only faced with teaching a subject in which they do not feel they are competent, but they are also faced with the problem of teaching it in a new and strange way. Many of them adopt the coping strategy of sifting out what little science content there is in the lessons to be taught (and the topics are usually not logically connected) and giving the students copious notes on these topics. The net result is that many students leave primary school not liking science.

The problem is less acute in the secondary schools because here teachers are likely to be university graduates in science or at the very least, hold GCE "A" level passes in one or more science subjects. There is however the continuing problem of science being taught as a body of facts only. Teachers in the Junior Secondary schools continue to complain that
the official syllabus is too demanding for students. Some of them have done their own modifications to this syllabus.

It is not likely that there are any easy solutions to these problems. At the Junior Secondary level, the solution would seem to lie in training teachers to understand their students and the contexts in which they work and to develop skills in adapting official syllabuses and guidelines to meet their own situation, pulling on the resources of their particular environment.

At the primary level perhaps a whole new administrative approach to the teaching of science is needed. Some schools have already begun to experiment with re-organizing their staff so that the teacher with the best science qualifications (perhaps science at the elective level at the teachers' college) can function as a specialist science teacher in the school. This emerging model holds some promise and needs to be researched and tested in a serious manner.

Both at the primary level and at the lower secondary level there is the perennial problem of lack of equipment for practical activities. Process science cannot be taught without equipment, though such equipment need not be costly or elaborate. Low-cost equipment initiatives have not featured very much in Trinidad and Tobago and may well be pursued. Even with such a strategy, one needs to be mindful of the amount of time that a teacher can reasonably be expected to spend making equipment, given other pressing duties. Perhaps woodwork and machine shops in schools as well as Youth Camps and Trade Centers can be organized to help in this area. There has been a suggestion here in Trinidad and Tobago that a mobile laboratory be developed to service primary schools. This is a worthwhile idea, though there are serious cost implications here.

Despite the problems outlined above, students have passed through the system and done well in science. However, this is but a small percentage of the student population and there is thus the need for systematic research and development activity that is aimed at the wider school population. If science is to play its role effectively at the basic education level in Trinidad and Tobago, much time, money and effort must be put into working with science teachers and setting up appropriate support systems.

USING MINDS-ON SCIENTIFIC DISCREPANT EVENTS TO MOTIVATE DISINTERESTED SCIENCE STUDENTS WORLDWIDE

Girish Govindarajan, Ph.D.
Emmett L. Wright, Ph.D.
Kansas State University
Manhattan, Kansas

Introduction

Science teachers worldwide would mutually agree that when children are confronted with a science problem-solving task, they construct characteristically individual representations of the given task; and, they will base their orientation of approach, whenever appropriate, from prior experiences in similar settings. Thus, children’s viewpoints are a combination of cognition, personal interpretations, and psychomotor skills. In general, then, “A learning experience commences with some new encounter which the learner interprets and makes sense of in terms of his or her existing cognitive structure” (Appleton, 1993, p. 269).

Providing all learners with motivating experiential activities is an important didactic strategy, especially when teaching abstract science concepts and principles. Each learner is unique in terms of their receptivity toward learning science. Thus, worldwide, teachers always come across some disinterested students who are reluctant to participate in the learning process. However, disinterested students are eager to learn when their curiosity is triggered, or when a novel idea is presented which poses a conceptual conflict in their understanding.

Experiential activities, which may be thought-provoking (minds-on) or hands-on activities, must stimulate curiosity and motivation to comprehend a phenomenon. The more contradictory the phenomenon appears to their strongly-held notions of the event, the better is their approach to overcome the contradictions.

Piaget’s cognitive position on the subject of curiosity has been aptly summarized by Charlesworth (1969) thus:

Intellectual change or growth is the end result of a chain of events beginning with the disruption of cognitive equilibrium by a conflict between incoming information already stored in the central nervous system. The conflict produced by the discrepancy between these two sources of information has the capacity of motivating curiosity (exploratory) behavior, and the latter has a high probability of leading to information that can be used by the organism to reduce conflict. Conflict reduction consequently reinforces the curiosity behavior, thereby insuring continued contact with novel features of the environment (p. 273).

Discrepant Events

Motivating disinterested science students to successfully learn and apply concepts and principles is not particularly difficult when an inquiry approach to teaching science is used by the teacher. To initiate and sustain motivation, discrepant events serve as excellent sources of pragmatic learning. In fact, “Discrepant events provide teachers with many simple, concrete and easy-to-use examples of events or situations that encourage good teaching practices” (Kavogli, 1992, p. 10).

According to Wright (1981) and Wright and Govindarajan (1992), a discrepant event is a phenomenon which occurs such that it seems to run contrary to our first line of reasoning; and, it is a good device to use in stimulating student interest in learning science concepts and principles. Kavogli (1992) points out the merits of using discrepant events, thus:

It is obvious that when students are strongly motivated conditions are favourable for learning. Therefore, any method that helps generate this motivation is worthy of investigation. Thus, discrepant events capitalize on the students’ curiosity, helping him/her gain a better understanding of science (p. 10).

A related viewpoint arrives from the conceptions of learning and approaches to learning; this viewpoint attempts to clarify on how students go about the business of learning. Iran-Nejad (1990), citing interesting research reports, highlights the findings of several researchers [see Iran-Nejad, 1990], by dentifying the types of learners:
The majority—more than two-thirds—view learning as knowing more, memorizing for later reproduction, or acquiring and using facts. These students tend to take a surface approach to go about the business of learning. In sharp contrast are those—less than one-third—who believe that learning involves insights into the subject matter, new ways of thinking about reality, and personal growth. These students take a deep approach to learning (p. 577).

We believe that most disinterested science students are in the former—more than two-thirds—group of students (surface learners). And, as discerning and conscientious teachers, it is to this group that we must provide them with appropriate experiential and motivating activities so that they may enjoy the benefits of taking a “deep approach” to learning, just as their counterparts (the deep learners) do.

Minds-on Examples

Our intention in this article is to go beyond providing solely theoretical constructs and implications for the use of scientific discrepant events. The reader may find it interesting to peruse the informative resources authored by Kavogli (1992); Wright (1981); Thompson (1989); Wright and Govindarajan (1992), (1993); and, Cobb and Darling (1990). We have provided here a list of minds-on examples [see Figure 1] which the science teacher may use to dramatically introduce concepts and principles to students. We would like to emphasize, however, that the examples should be used to provide a medium to enhance students’ inquiry skills—an essential learning aspect fundamental to the development of problem-solving skills. We emphasize this because “Unfortunately discrepant events are often misused in classrooms. Teachers use them as shows of magic rather than for the science principles they demonstrate” (Thompson, 1989, p. 28).

Considering the utility value of using scientific discrepant events in the science classroom, we agree with Kavogli’s (1992) observation that,

Although there is considerable value in the use of discrepant events, it is obvious that these cannot be developed for every topic or scientific principle. In the absence of an appropriate discrepant event, it is entirely acceptable to present non-discrepant events in which the students have a chance to observe or perform some kind of investigation. The main point to remember is that the event is used as an incentive to student involvement. Discrepant events are [to be]

presented whenever possible, supplemented with non-discrepant events whenever needed (p. 10).

We hope science teachers all over the world will enjoy using the examples provided here; and, motivate students to work with their peers to research further and develop practical skills of report writing and presenting to the public. We also encourage teachers to add more such discrepant events to their library of knowledge. In closing, we would particularly welcome you to share your examples with us. Please write to:

<tr>
<td>If you carve your name on the trunk of a tree at five feet above the ground in 1994, after 50 years the name will be several feet higher (assuming that the tree has not been cut down). True or false?</td>
<td>True.</td>
<td>False. The name will remain at the same height. The growth region is in the tips of the plant and in the cambium. Therefore, the region where the name has been etched remains unaffected in terms of vertical growth.</td>
<td>In plants growth is largely at the terminal ends. The greatest amount of cell activity takes place at the apical regions of roots and stems and the branches. Of course, plant growth also occurs on the lateral surfaces of the stem and roots; however, this growth is a result of a single tissue, cambium, which gives rise to tissues forming the bulk of cells in the plant body. In leaves, however, there is an exception to this principle. Growth and enlargement is fairly uniform throughout the laminar surfaces. Ask students to work in groups on library research work to determine the factors and conditions under which leaf growth takes place in plants, and also why leaves of different plants differ in size.</td>

Teaching Materials and Strategies

IN-SERVICE AND INITIAL TRAINING OF PRIMARY TEACHERS:
A FLEXIBLE RESPONSE

Eric Parkinson and Don Plimmer
Canterbury Christ Church College

This article describes an innovative initiative between Canterbury Christ Church College, UK and the Commonwealth of Learning, Canada. It describes the use of flexible learning materials to support initial and in-service training, and curriculum development, in primary schools. This collaborative operation has implications for potential users world-wide, with special reference to those in developing countries.

These days, it seems the only consistent feature in INSET and initial training is Change. This is a somewhat daunting prospect for all concerned.

Changes in patterns of delivery, changes in content, in professional emphasis and indeed, in recruitment patterns have required constant adjustments to courses. In response, staff have had to consider new and imaginative modes of course design and delivery.

At Christ Church College, over seven years ago, a piece of inspired thinking produced the basis for a new generation of course materials which might, it was thought, have the capacity to weather the changing vistas on the horizons of science education. The outcome, “Success with Primary Science” was a flexible learning package which could be used in both in-service and initial teacher training programmes and in a wide variety of different conditions and delivery modes.

The resulting product offers support to teachers in their classroom practice and at the same time develops their understanding of science. Also, through the medium of the classroom, professional issues are tackled and considerable emphasis is given to the issue of reflecting upon and analysing the classroom performance of the course participants themselves.

Initially the materials were used to support local in-service courses, but soon the word spread and so did the materials, as partnerships developed with Local Education Authorities in the UK. A copy of the materials found its way as a gift to a pioneering multiracial teacher training college in the period before the dawning of the “New” South Africa and so it was that the internationalisation of the materials began.

Originally, Success with Primary Science had been devised in a somewhat random fashion so that teachers would be attracted to “do some science” with their classes by virtue of working through the materials themselves, in pursuit of an in-service course. This reflected the pre-UK national curriculum atmosphere of 1987 in which science was a “do some if you can—but not to worry if you can’t” Cinderella subject in primary schools.

A re-write was undertaken in 1991 to accommodate the UK National Curriculum, with its new, dedicated language embracing terms like “attainment targets” and “statements of attainment”. Soon however, reflecting this theme of change, the national curriculum itself underwent a revision and the materials were once more out-of-step.

By 1993, it was becoming clear that the materials needed yet another substantial re-write. This time the bold decision was taken to write out references to the UK national curriculum. Chasing what seemed to be a biannual revision of the curriculum was a game that could be ill-afforded so the editors stopped playing “chase the attainment target”!

The third edition of Success with Primary Science is now arranged in small units which address key issues of professional concern as well as core conceptual areas. Teachers have found that they can use these, both as part of their teaching programme, and alongside it as essential background reading.

The materials have thus become even more flexible, since they can be used directly in schools to support the teaching and learning of the children and teacher alike!

Naturally that does not mean that the whole course revolves around flexible learning materials. Canterbury Christ Church has developed a number of support systems to accommodate and manage a range of course types. It is recognised that local meetings of participants, with, and sometimes without a tutor, are valuable. So too can be a network of telephone numbers for contact between participants and the tutor.
Arising from the rapid spread of Success With Primary Science, a flexible follow-on course was devised. This course, “Managing Primary Science”, focuses on the challenge of professional and curriculum development, not at the individual teacher their classroom level, but on the whole school. As such it reflects a natural progression in In-service development.

The application of flexible learning materials to INSET is one field, but increasingly they are being used for the initial training of teachers as well. They are an ideal way of assisting in the provision of differentiated learning opportunities, especially in environments in which increasing student numbers may put a strain on traditional means of course delivery.

The materials for Success with Primary Science, and its follow-on cousin Managing Primary Science can be shared on a world-wide basis. The Commonwealth of Learning (COL) based in Vancouver and Canterbury Christ Church College hold the publishing rights to these materials. COL is dedicated to the dissemination of flexible learning materials with particular reference, as their name suggests, to the Commonwealth.

Fax COL on int. + 604 660 7472 for further details.

Canterbury Christ Church College can be contacted on Fax int. + 227 470442

There is a final added bonus to be gained from the use of these flexible learning materials which is as follows. Many developing countries may look towards flexible learning materials in order to optimise limited resources. However, evidence suggests that there is massive potential for professional and curriculum development to be gained by re-writing and restructuring the materials to fit local needs and conditions.

The flexible learning materials offer a central spine of ideas. Teachers can take these ideas and adjust them to fit in with local circumstances. They can, for example, develop a whole new generation of workshop materials for colleagues to deliver.

And of course, both the products and the processes of curriculum development are of significant benefit.

The Commonwealth of Learning and Canterbury Christ Church College, both with a great fund of international consultancy experience, are keen to develop world-wide links with all who seek further information.

Eric Parkinson and Don Plimmer are both Senior Lecturers at Canterbury Christ Church College. Between them they have wide experience of education not only in the UK, but also in the Caribbean, Far East, North America and most recently, South Africa. Both are currently involved in a project which seeks to upgrade teacher confidence and understanding of basic concepts in science, with course participants drawn from South Africa.

Three Primary Science teachers are hard at work on an electricity and magnetism unit during a tutorial meeting.
Science Teacher Education and Leadership

THE LESOTHO INDUCTION PROGRAMME

Poul Klindt
The National University of Lesotho

The section editor would like to thank Leo de Feiter of DCDS, Free University Amsterdam for assistance in editing and background information on the induction program.

Introduction

Lesotho is a small, mountainous country surrounded by South Africa. It has been an independent country since 1966. Prior to that it had been a British Protectorate. Its educational system is still largely modeled after the British system. One of main problems in education is the retention of newly trained teachers. Many leave the profession within a few years to work in South Africa. Especially in science and mathematics there is shortage of qualified teachers.

The Problem of First Year Teaching

The first year is probably the most eventful and by far the most difficult in most teaching careers. The beginning teacher, just out of university or college, and most likely with little or no previous teaching experience, faces a host of tasks, all unfamiliar and difficult to handle, and more often than not with precious little support during these first crucial months. Vonk (1984) has researched extensively in this area, and much of the material described in the following is based on his work and ideas.

It is during the first year that the teacher forms her attitudes towards the teaching profession in general. Ways of handling problems relating to classroom management, choice and administering of teaching methods and teaching aids, administration of the curriculum and staff room procedures have to be developed. One has to find ways of fitting in with the administration and management of the school and the whole educational system. Not to speak of dealing with parents and extra-curricular activities. The list is endless.

This section focuses on the education of science teachers, and aims to communicate ideas and strategies which will assist science teacher educators to enhance and enrich their programs.

In Lesotho, like in many other third world countries, the problems of beginning teachers are magnified by factors like the high student-teacher ratio, often exceeding 50, poorly equipped schools, in particular in the sciences, little cooperation between colleagues in the school due to high staff turn-over, the recruitment of unsuitably qualified teachers and expatriate teachers, and the tendency in many schools to hold on to educational habits introduced in the colonial era.

The gap between theory and practice is real and the teacher training institutions attempt to prepare their students for the new situation they are to face. Some are more successful in their endeavors than others, but no matter how well the pre-service instruction is geared towards helping the novice teachers getting started, there will always be that reality shock when the new teacher faces the classroom situation for the first time.

It is exactly to try to help the beginning science teacher to deal with this situation that the Induction Programme of the Science Education Department of the National University of Lesotho came into existence in 1988.

The Start of the Induction Programme

The idea of starting an Induction Programme to help the new Science and Mathematics teachers get a better start in their profession was developed at the Centre for In-Service Education of Mathematics and Science Teachers (CIEMST), which forms part of the Science Education Department of the National University of Lesotho. Approval was obtained from the Ministry of Education, and the programme started with a Pilot Year during the academic year 1988-89. Funding was granted from the European Community (EC) and the Netherlands Government for the running of the Induction Programme for a period of 4 years from 1989 till 1993. The programme constitutes a
cooperation project of the National University of Lesotho with the Vrije Universiteit Amsterdam.

**Development of the Induction Programme**

In the Pilot Year (1988-89), 7 Beginning Teachers, all graduating in Science (including Agricultural Science) and Mathematics in the secondary sector, participated in the programme. The following year (1989-90), 19 completed the programme. A rapid growth was experienced in the following two years, and the Programme has now stabilized with a participation of between 70 and 80 beginning teachers every year. The target group of Science and Mathematics teachers was expanded with a smaller group of Home Economics teachers from 1990-91, and most recently 10 teachers of Business Studies graduating from the National University have been invited to participate as well. In the last couple of years, after the programme has become known and accepted, the enrollment percentage stands at between 85 and 90 out of those who are given the option to join the programme.

As from July 1993, the Induction Programme has been requested to extend its offer of support to teachers of the humanities as well. This is now happening with the result that the programme will grow to about twice its former size.

**Approach of the Induction Programme**

One important principle in the programme is that participation is voluntary. However, an agreement is entered into with the beginning teacher, committing her to participate in all the activities of the Induction Programme once she has joined it. No credits are awarded for participation. On the other hand, no cost for the participants is involved, all expenses being covered from project funds.

Furthermore, it is important that the head of the school, where the new teacher has been employed, agrees to her participation in the Induction Programme. The activities of the programme are partly school based and partly centered around workshops and seminars, for which the teacher has to travel. However, these mostly take place during holidays and weekends. That way the Induction Programme does not impose on the daily routines of the teacher.

**The Programme**

The Induction Programme, in its present form, operates with the following aims and objectives.

The **Aims** are to help the Beginning Teachers taking part in the Programme to:

1. develop confidence in themselves as teachers and to acquire a positive attitude towards the teaching profession;
2. learn to care for their pupils and to appreciate their individual strengths and weaknesses;
3. become able to realize their own potential as teachers and to improve their teaching;
4. fit into the school environment as members of staff and departments; and
5. as a result of the above to gain job satisfaction, expressed as a wish to remain in the teaching profession (teacher retention is a major problem in Lesotho schools).

Thus the **tasks** of the Induction Programme staff are:

1. to devise and administer a package of in-school support to be used by the beginning teachers during their first teaching year;
2. to identify and appoint suitable mentors in the schools and to provide the necessary training for them;
3. to regularly arrange seminars and workshops, linking up with the school based activities and providing necessary and useful input for the participants;
4. to facilitate visits to the schools in order to introduce and set up programme activities and later to monitor the progress of the individual participants as well as to offer any assistance needed; and
5. to provide a natural link between the learning institution and the schools receiving the Beginning Teachers.

The **activities** of the Induction Programme as seen by the participants presently are:

a. Participation in the programme is offered to all graduating Secondary and High School teachers within the science subjects.

b. Participation is voluntary.

c. Participation is subject to the approval of the Principal of the school where the beginning teacher is employed.

d. A mentor is found at the school to assist the beginning teacher. Training is offered to this mentor.

e. An Agreement, specifying the roles of the beginning teacher, mentor, school and the Induction Programme, is drawn up and signed by the four parties.

f. During the induction year, seminars and workshops are held to keep mentors and beginning teachers informed about the
programme activities, school principals are welcome to participate in these activities.

g. In the school the beginning teacher is anticipated to enjoy continual and sympathetic support from the mentor who is specifically trained to perform her/his duties.

h. Regional peer meetings for the beginning teachers in a particular geographical area are arranged twice per term. During these meetings they will, in a non-threatening atmosphere, share common problems and ideas.

i. A system of teacher self evaluations conducted by the beginning teachers, pupils' questionnaires, lesson observations and informal consultations between beginning teacher and mentor form a structure of in-school support.

j. Regular visits from the Induction Programme staff take place to ensure the smooth running of the programme in the schools.

k. Staff members from the university may on request visit their ex-students in their schools to discuss content related problems with them. Likewise, the beginning teachers get the opportunity to meet their former lecturers during workshops and seminars. Due to the small size of many schools in Lesotho, mentors often do not have the same subject specialization as the beginning teacher.

l. Beginning teachers, with the assistance of mentors, are issued with a fill-in School Information Booklet, which enables them to collect all relevant information about their schools immediately after taking up a teaching post.

m. A handbook is issued to the beginning teachers, containing relevant materials developed to support them in their work.

Components of the Induction Programme: The Mentor

When the beginning teacher has found employment at a school, and the principal has agreed to her participation, a mentor is identified. The mentor is preferably a teacher at the same school with some years experience, if possible teaching the same subjects as the beginning teacher or at least related subjects. The mentor will during special training workshops receive instruction in his/her role in helping the beginning teacher, and is considered a participant in the Induction Programme.

The mentor assists the beginning teacher in a variety of ways. Most important is that the mentor is available whenever the new teacher feels the need to discuss problems arising. The administering of the various evaluation methodologies described below, even though left with the beginning teachers, are expected to take place in close cooperation and dialogue with the mentors.

School Visits

The Induction Programme coordinator visits the beginning teachers regularly in their schools. During these visits, problems, which the beginning teacher and the mentor have failed to solve, or just want to discuss, are taken up. If the beginning teacher faces problems of a nature which calls for expertise from other members of the staff of the Science Education Department, the coordinator will assist in approaching the lecturer in question for a visit to the school and teacher concerned. During the induction year, a beginning teacher may receive roughly between 3 and 8 school visits (averaging 4.3), all depending on the degree of difficulties experienced in each case. Since no evaluation of the performance of the beginning teachers takes place during these visits, they can be conducted in a relaxed and conducive atmosphere, and in almost all cases they are welcome and highly rated in ensuing evaluations.

Peer Meetings

Once quarterly, the beginning teachers meet a regional centers, with 5 to 15 teachers attending each meeting. These peer meetings are very informal, with no fixed agenda, and the purpose is to give the novice teachers an opportunity to exchange experiences in a non-threatening atmosphere. No other persons are present during a peer meeting, but a mentor is normally asked to be around, so that the participants can call upon his expertise in particular cases arising from their discussions. Evaluations carried out amongst the peer meeting participants show a high appreciation of the meetings, in spite of some logistical problems experienced in convening them.

Seminars and Workshops

All beginning teachers and mentors are invited to participate in workshops which last for two or three days. Also principals are invited, but rarely turn up. An Introduction Seminar, in which the Induction Programme is explained, is held in July. In October and in January two Follow-up Workshops are held, in which the experiences of the teachers and the mentors during the Induction Year are discussed. Selected topics of interest for beginning teachers are presented as well. These can be of content related nature, or general educational issues, or of the kind that helps the new teacher to get acquainted with the overall
educational set-up in the country. In May or June, the last Seminar is held. This includes an evaluation of the Induction Year. Around this time, the Induction Programme is also introduced to the new graduates of the Science Education Department.

Experience has shown that both beginning teachers and mentors highly appreciate the opportunity given through the seminars and workshops to get together with colleagues for professional development as well as socially. The average participation rate is very high for a voluntary programme, normally between 80 and 90% of the invited teachers.

**Teacher Evaluation Methodologies**

A variety of methodologies has been developed to help the beginning teacher to get a picture of her own performance as perceived by herself and others, and to measure the progress made. Whereas the evaluation tools described below are designed for the Lesotho Induction Programme, two of them, the Diary and the Pupils’ Questionnaire are based on instruments originally designed by Vonk (1984) and used in the Netherlands.

**a. Teachers Self Evaluation—The Logbook**

This self evaluation instrument is designed for use over 2 teaching weeks once every 3 or 4 months. In the logbook, the beginning teacher will record what activities were planned for the lesson, the deviations from the plan and positive and negative experiences gained from the lesson. The entries in the logbook are then analyzed using a category system. This enables the teacher to identify strong and weak areas as well as to register any changes observed during the Induction Year.

Even though all beginning teachers appreciate the value of the logbooks, quite a few fail to put them into full use, due to the amount of time it takes them to work with this evaluation tool. Also the analysis categories may still be too complex. Some adjustments have been made to the original logbook format, but the same problem still prevails to some extent. Because of this a new **Teacher Self Evaluation Instrument** was developed in 1992. Experience so far seems to indicate that the latter tool, gives better results during the first few months of the Induction Year, while the Logbook stands a better chance of a high appreciation rate if introduced after 3-4 months’ teaching.

The mentors are trained to play an active role in helping the beginning teachers in using the above as tools for reflection.

**b. Pupils Evaluating the Teacher—The Pupils’ Questionnaire**

The mentor, on behalf of his protegee, administers this questionnaire with 10 students, selected at random, who are asked to respond to 20 statements about the teacher, all dealing with various aspects of teacher behavior in the classroom. The responses, which are given on a five point scale, are analyzed and categorized. This way the teacher can get an indication of how aspects within her teaching performance are perceived by the learners. The 20 statements are categorized into four areas:

- Communication skills, instructional skills, classroom management and teacher-pupil relations.

The pupils’ questionnaire presently in use, was developed together with a group of beginning teachers and mentors during a workshop. It is based on the original version, an adaptation from Vonk (1984) and new materials, kindly provided by Vonk during a visit to the programme in 1993. The workshop then adapted the material to the local situation, and a trial version was tested by the workshop participants before the final version was produced.

Both students (pupils) and teachers are in general appreciative of this evaluation tool, and the use of it often spreads to other teachers in the school, when they get the wind of what is going on. Mentors are being trained in ways of providing feed-back to the beginning teachers based on the analysis of the questionnaires.

**c. Lesson Observations**

The third way in which the beginning teacher can get useful feedback on her teaching, is by using lesson observations. In most cases, it is the mentor who observes. During special mentor training workshops and in programme seminars, mentors and beginning teachers are given instructions in the way these observations can be planned and conducted in order to serve their purpose. Models of Clinical Supervision are introduced, and a non-threatening, result-oriented approach is always emphasized.

**Conclusion**

After four years of operation, the Induction Programme has become fully accepted in the schools all over the country. It is in regular contact with the Ministry of Education and often calls upon its civil servants to assist in presenting topics of interest to the participants during the seminar. The Association of
Headmasters and Headmistresses follows the development of the programme with interest and appreciation.

Ongoing evaluations more than indicate that beginning teachers taking part in the Induction Programme have an easier and therefore more successful first year of teaching than they would otherwise have had. There is less possibility of disenchantment resulting in a negative attitude to teaching or resignation. Experience so far seems to suggest that the retention rate amongst the Science and Mathematics teachers has grown considerably during the life span of the Induction Programme. In fact that the Ministry of Education in Lesotho has officially requested the National University to extend the programme activities to encompass novice teachers in all subjects is significant as an indicator of achievement. Thus the aim of getting better and longer serving Science and Mathematics teachers to the benefit of the secondary and high school learners in the schools of Lesotho is seen to be achieved. Yet much is dependent on developments in South Africa. For example, if wages in South Africa (for all kinds of alternative jobs) remain considerably higher, it will still be difficult to retain teachers. If South Africa would rapidly increase spending on black education, it might well hire away the better trained Lesotho teachers. In the latter scenario they would be retained in the profession though not in Lesotho.

INFORMAL SCIENCE TEACHER PREPARATION

David E. Chesbrough
School of Education
Duquesne University

Introduction

As traditional United States teacher preparation programs are being challenged, museums and science centers are gaining recognition as alternative training environments. Gardner, in his book The Unschooled Mind (1991) claims that “museums have retained the potential to engage students, to teach them, to stimulate their understandings, and, most important, to help them assume responsibility for their own future learning.” In a review of the research on museums as science learning environments, Ramey-Gasser, Walberg III and Walberg concluded that, “Indeed, informal learning environments such as zoos, natural history and cultural museums, and science centers have the potential to captivate and arouse interest, motivate learning, and allow students to build connected knowledge through meaningful experiences” (1993, p. 20).

Additionally, recognition is growing that museum educators are “specialists in developing and presenting exciting educational experiences that engage the learner in exploration and discovery” (Mintz, 1992).

Questions Guiding the Study

- How would the improvement, if any, be judged for the preservice elementary teachers in this pilot, with the myriad of changed variables over the university setting with a single university professor?

The Problem

The purpose of this descriptive study was to determine the effects of conducting a university elementary science methods course at a science center on the attitude toward teaching science of a sample of preservice teachers.

To explore the problem and focus on improving preservice teacher preparation, Duquesne University and The Carnegie Science Center developed a collaborative effort to move instruction for selected elementary science methods courses from the university to the new, $40 million Carnegie Science Center. The methods course would be offered in the science center setting using the varied resource and educational opportunities and taught by qualified science center educators. The pilot project hoped to take advantage of the suggested affective impact of science center settings. The partnership also responds to the clarion call for collaborative efforts which result in systemic change in the nation’s educational system (Smith & O’Day, 1990; Lund & Wild, 1993).

The Importance

There is growing exploration around the country in science center/university collaboratives to improve undergraduate and graduate level instruction in elementary science methods courses (Anderson, 1993). The Duquesne University/Carnegie Science Center pilot, if shown to have positive affects on preservice teachers’ attitudes, could serve as a model for other university/science center collaboratives as a viable model. Productive models of many forms which fit the resources of the different communities are needed in the national effort to improve the preparation of elementary teachers in the area of science teaching.
Literature Review

The problem being explored, that of improving attitudes toward science teaching among preservice teachers using science center resources, requires an investigation in two areas. This dual approach is necessary as the project is focused on identifying a problem and relationship in the formal education domain and seeking methods to improve the situation through informal education resources. Herein lies the powerful potential in finding new ways to deal with old problems through new collaborators which bring together the formal and informal education players.

The first area of research is in the relationship between attitudes toward science and science education and teaching efficacy. Science teaching efficacy is defined as a teacher's belief that the or she has the ability to teach science effectively and to affect student achievement (Riggs, 1988).

The second is in the area of affective impact, especially in teacher preparation, in science centers and museums. Affect is identified as part of Benjamin Bloom's "taxonomy of educational objectives" and relates to feelings, emotions, attitudes and values (Roberts, 1990).

Importance of Science Attitudes in Elementary Teachers

Koballa and Crawley state, "there is widespread consensus that the term attitude toward science should be used to refer to a general and enduring positive or negative feeling about science" (1985, p. 223). In the same work, the authors state that "The assumptions that students will acquire positive attitudes toward science as they learn more science facts is no longer valid" (1985, p. 222). This position has widespread support, including the work of Piel and Green which leads them to suggest that it is impractical to address elementary teacher competence in science through added coursework before appropriate attitude adjustment process have been planned and implemented (1992).

Westerback reports, in a review of the research, that there appears to be agreement that negative attitudes toward science and teaching science are commonplace among elementary teachers, leading to avoidance of teaching science, passing negative attitudes on to students and interference with the learning process (1982).

If negative attitudes impede the subsequent effectiveness of elementary teachers in the areas of science, there is research to suggest that the logical corollary is supported. Ramey-Gassert concluded from her study that personal science teaching efficacy among elementary teachers correlates positively with attitude toward science, and with choosing to teach science (1993).

While it may not be possible to predict that positive attitudes among preservice teachers toward science result in more effective teaching (Koballa, 1986), the research supports the position that a positive attitude toward science is one of the critical prerequisites to the potential of effective science teaching by the preservice teacher.

Affective Impact of Science Centers and Museums

What is the special nature of a science center or museum? Some in the field of education suggest that, "Science museums are unequaled in the affective realm, able to excite curiosity and motivate learners. They can substantially increase the number of students 'turned-on' to science" (Mintz, 1992, p. 3). Yet, while attitude has been carefully researched in the formal education domain, there is no equivalent research base in the informal education field. Research efforts often deal with the affective domain of learning. Roberts reports that "It is the nature of our institutions—multisensory, three-dimensional, interactive—that they should appeal so strongly to that part of the brain concerned with space, image, affect" (1990, p. 19).

Affect is often considered as having an number of components, including attitude (Anderson & Roe, 1993). Additionally, museums and science centers have a wide array of focal points for visitor experiences, including exhibits, programs, interaction with, and observation of, live animals, and general overall experiences for the child, adult, family, teacher and school group. Research that is done often focuses on the impact and attitudinal response from a particular interactive exhibit or interactive space (Borun, 1989; White, 1990; Perry, 1993; Anderson & Roe, 1993).

Within the informal education field, one of the numerous challenges to research is attributed to the differing opinions of the goals of informal education. Target areas in informal education include informing and educating, knowledge gains or conceptual understanding, and perceptions and attitudes, with it being recognized that there are difficulties in measuring changes in the affective domain (Crane, 1994).

In a review of literature, Roberts assess the dilemma as such:
The role of affective modes of knowing in learning processes remains an elusive, fragmented area of study. Not only does research cross many disciplinary boundaries, but language about affect changes from one individual to the next. Literature searches and discussions with a variety of academic and museum professionals reveal frustratingly little work on "affective learning" per se. (1990, p. 19)

However, there have been a number of descriptive studies which have found positive attitudinal changes from science center experiences in field trips (Prather, 1989; Bitgood, 1993), student experiences (Tuckey, 1992), and teacher activities (Leroux, 1989; Anderson, 1993). Other studies have findings which suggest positive affective and attitudinal impact of science center or museum experiences, such as Bloom's research into science career choices of girls and minorities (1985).

More specific research into the affective impact of science centers would be obviously helpful as informal education resources are looked to play a larger role in the educational reform effort. Existing research, descriptive studies, and popular opinion suggest that a powerful potential does exist. Anderson and Roe probably best stated it with the point that, "A little-understood concept—and a hope of many of us—is that museum and science centers make real impressions on lifelong learning" (1993, p. 9).

It is hoped that the descriptive study presented in this report takes one small step forward in building a greater understanding of the impact science centers can have on the improvement of elementary teacher preparation for enhanced science learning of all children.

Method

Design of The Elementary Science Methods Course
The pilot elementary methods course was designed with several key features distinguishing it from more traditional methods courses:
Hands-on activities—The course design focused on the preservice teachers engaging in, and then conducting, hands-on activities using pedagogical approaches such as inquiry learning and guided discovery. Exposure was provided to a wide variety of activity resources, ranging from inexpensive, supplemental materials such as AIMS and GEMS modules to more comprehensive packages such as Science & Technology for Children.

Science center observations—Observations time was required of all preservice teachers. Each participant could choose science center spaces and/or activities of interest where children engaged in free choice science activities. Primary spaces included exhibit halls, Ports of Discovery which included two hands-on spaces with discovery boxes, age appropriate exhibits, water tables and live animals, and science center children's classes.

Variety of course instructors and guest teacher—Course instructors were science center educators with master's degrees in education whose position involved an emphasis on hands-on science experiences and professional development of teachers. Lead instructors also had classroom experience. A number of staff educators and scientists were engaged as guest instructors in areas of their particular interest, such as live animals, the science center's weather service, or the live pacific coral reef aquarium. Attention was given to providing female role models for the predominantly female preservice teacher population.

To accommodate the changes in instructional strategy, the university's usual two day per week, 1-1/2 hour/class format was changed to a once per week, three hour format conducted at the science center facilities (a combination of the new facility and the educational annex) three miles from the university campus. Students had to provide their own transportation, but were provided free parking. This study reports the findings of the first three sessions of the course: Fall 1992, Spring 1993, and Fall 1993.

As in all developing courses, certain individual sessions and course features worked better than others. Adjustments were made in the syllabus and the assignments from semester to semester. However, the basic elements of a hands-on activity approach, use of qualified and enthusiastic science center staff, and integration of science center resources and observation experiences remained constant. A female staff member was added for the third session as an instructor to complement the original two male lead instructors.

Determining Course Effectiveness
The various features of a preservice course at a science center would be deemed successful if the students demonstrated an improvement in their attitudes towards teaching science. The survey results were collaborated with weekly journals to
provide a more qualitative response regarding the preservice teachers’ experiences and attitudes as they progressed through the one semester, three credit course.

Student Enrollment
There was no effort made to enroll select students in the Elementary Science Methods course. The vast majority of the students were taking the course in their junior year prior to student teaching. The course was to be noted in the college catalog as being taught at the science center, which was done for the first and third sessions, but not for the second one. The students in that course were only informed on the first day of class that the remainder of the course would be instructed at the science center. In the first and third sessions the students had the option of selecting a traditional elementary science methods course on campus.

The Instrument
The instrument chosen was the Revised Science Attitude Scale, revised from the original developed in 1974, and recommended as a “reasonably valid and reliable scale ready for use in comparing treatment effects of groups of preservice teachers toward the attitude object of teaching science” (Thompson & Shrigley, 1986, p. 342).

This 22-item Likert scale instrument (see Appendix A) was used to assess the attitude of the participating preservice teachers toward science. The Science Attitude Scale uses a five choice scale which the developers identify as having four subcomponents: Comfort-discomfort (9 items); Need (5 items); Time (3 items); and Equipment (5 items). The developers report that examining data for correlation between the four subcomponents suggested a “moderate interrelatedness and at the same time an independence of the four subcomponents. The former verifies a single subject; the latter suggests four subcomponents” (Thompson & Shrigley, 1986, p. 336). Previous research by the developers indicated that the reliability (Cronbach’s coefficient alpha) for the total attitude scale is 0.91 (Shrigley, 1974).

The 22 questions from the Revised Science Attitude Scale were left unaltered, but imbedded intact among other questions regarding background and assessment techniques used in the course.

An additional qualitative approach was taken through the use of journals. Weekly questions were presented to the participants which they responded to in their journals. The open ended questions provided an opportunity to explore the factors in antecedent experiences which might have contributed to attitudes brought to the course, as well as reveal insights into what factors during the course may have had an impact on attitudes as measured at the end.

Procedure
The attitude survey was administered during three consecutive sessions of the elementary methods course taught at the science center during the 1992 Fall, the 1993 Spring and 1993 Fall sessions. The preservice teachers were administered the attitude survey at the start of the first session of the course by a science center staff member without the course instructors present. Names were not given, but student numbers were written on an attached piece of paper. The surveys were taken by the staff member and filed without the instructors seeing them. The procedure was repeated on the last day of the course. The surveys were then compared to make sure there was a matching and post-course response sheet. Those without matches were not included in the results.

The journals were reviewed periodically during each course and at the end of the course. With the purpose of this study focused on the attitude results, and due to time constraints, the journals were not systematically evaluated. However, they were all read for comments which related to attitude to identify particularly informative comments or case studies which might shed light onto qualitative elements related to the survey results. No further analysis on the qualitative nature of the responses was done. Students were asked permission to quote passages with the understanding that their names would be kept confidential.

Results

Attitude Survey
The student pre-and post-responses from the three sessions were combined to yield a sample size of 48. The design of the survey suggests that it relates to one construct and the data was analyzed on a summed response to the 22 questions. Responses were given on a Likert scale with Strongly Agree given a value of 1 and Strongly Disagree a value of 5. Since statements were posed in both the positive and negative, the negative responses were converted by subtracting from 6.

The scores were combined for all the students and a precourse and postcourse mean calculated, as well as separate precourse and postcourse means per session, as shown in Table 1.

The results of this descriptive study indicate that for the three sessions of the Elementary Science Methods course taught at The Carnegie Science Center, the preservice teachers' attitudes toward teaching science changed in a positive direction.

Journal Entries
In addition, a review of the weekly journals revealed numerous accounts of changes in attitude, increased confidence in teaching science, and a desire to make science interesting for their future students. The following quotes are selections from student journals.

Student One. To the first question of the course to relate her past experiences in science education she wrote:

I distinctly remember my seventh grade science class—a constant barrage of boring, meaningless lecture. I think my final grade was a C or D. My next notable science experience was in the 10th grade with a woman I admired. I remember I liked her, but, again, science or biology didn’t interest me. I had already been convinced I was stupid.

To a question near the middle of the course, she wrote:

We need to erase or stop putting the idea in kids (sic) heads that only a few can do science. I like this science class and it has changed my perspective. I was amazed over at the Science Center.

To the final question of the semester which was to reflect on this course, her response was:

Well, my attitude towards science has changed. I feel as though I would be able to teach science. I need more information. I basically lack the theory of many sciences, but have discovered that I can learn them. . . . I enjoyed my experience at The Carnegie. I am a hands on learner and the methods used in this course made science available to me for the first time. I helped my self esteem. I actually succeeded in this course with little difficulty. I have told all my friends about the course. . . . Whether or not the science is made available to students will depend on me and not the book. I feel as though I’ll be able to offer the possibility of success to my students.

Student Two. “This course has enabled me to feel comfortable with scientific hands-on approaches. I no longer fear doing experiments alongside my students. I’ve learned how the process is just as important as the product, if not more.”

Student Three. To the question “What have we done so far that has positively impacted your thinking and feeling about science education?”, this student responded:

What haven’t you done so far that has positively impacted my thinking and feeling about science education? Most important, everything we are doing in this class is interesting and relates to all of us in one way or another. We are each taking part in learning about science—this is the key to being interested in science and in turn developing a positive (sic) about the subject of Science itself. Unfortunately, my science education consisted of being drilled with facts and numbers and tests! The only experiments I can remember doing consisted of following a step by step procedure you had to follow word for word. This did not allow the exploration and creativity; as a result, I never liked science. This science class allows me to return to my elementary days and relearn everything I didn’t learn and most importantly—to have a ton of fun at the same time!
Discussion

The attitude surveys and journals indicate that there is an overall ability of the course to improve preservice teacher attitudes toward science teaching. Comparing the results per session, combined with student journal entries offer further insights.

Preservice teachers in the first session, Fall 1992, started with the most overall positive attitudes toward science teaching and displayed the smallest positive gain in attitude. It suggests that with the extra explanation regarding the course which took place at the university, there may have been more conscious selection by the students to take the science center methods course if they were more positive toward science. Student journal and verbal comments during the sessions revealed that the drive to the science center and the need to find parking were significant issues in the minds of many of them. Enough so, that given an opportunity, students who did not consider the science center course as a positive option, chose to take the traditional course on campus.

This natural selection process is further supported by analyzing the results from the Spring 1993 session. Due to an error in the written course information, more preservice teachers were unaware when they registered for the course that it would be taught at the science center. The initial attitude survey indicated that this group had the least overall positive attitude toward teaching science and displayed the most significant gain. The indication is that this group was more indicative of the general elementary education majors on campus and that attitude gains would be more significant among all the sessions if there was a blind registration process between the science center and university options.

Students cited numerous experiences in their journals which indicated an impact on their attitudes through many features of the course, with the three major components all cited—the hands-on focus, the enthusiasm and modeling of the instructors, and the resources of the center.

Questions for further research

- What features of the science center course contributed the most to the preservice teachers’ improvement in attitude?
- Could the course be replicated elsewhere, even on campus, with the same results?
- What are the attitude improvements with similar methods courses being experimented with at other science centers?
- Will the attitude changes last over time and yield more actual hands-on teaching when the preservice teachers teach their own students?
- Will they use informal education resources, like the science center, in their students’ learning experiences?

Conclusion

Since many studies indicate that there are positive gains possible in preservice teacher attitudes toward science through a variety of approaches (Westerback, 1982; Ramey-Gassert, 1993), it cannot be said that the science center course option was an improvement over the regular university offering. However, the methods course as developed and taught at The Carnegie Science Center clearly was successful in improving the attitudes toward science of the preservice teachers who participated in the three sessions.

The science center methods course should be maintained and is worthy of consideration for modeling where other science center/university collaborations are possible.

References

The American Psychological Association, in conjunction with the Mid-Continent Regional Educational Laboratory (McREL), have recently completed an exhaustive review of the research base resulting in the identification of 12 key factors (principles) that positively effect learning for all students.

Using these 12 findings, summarized below, they are now developing a battery of assessments which measure (a) teachers' assumptions and beliefs about learners, learning, and teaching; and (b) teachers' perceived classroom behaviors. In addition to these instruments, two companion scales assess student perceptions of their teachers' classroom practices and their administrators' perceptions of school practices, in relation to the "Learner-Centered Principles."

The model is based on the premise that teacher behaviors and practices are a function of (a) their beliefs and assumptions about learners, learning, and teaching, (b) administrative policies, practices, and resulting school culture. In turn, teacher behaviors and practices directly impact student motivation, achievement, and learning outcomes.

This battery of instruments will enable teachers to examine their own teaching beliefs and strategies in order to facilitate positive changes, provide specific information on how to most effectively impact individual students, and identify needed areas of personal staff development. In addition, this component of the project will help set the stage for systemic change by engaging students, teachers, and administrators in the reform process.

Five factors with 12 underlying principles were identified as critical to effective learning. These are: **Meta-cognitive and Cognitive Factors**: Principle 1: *The nature of the learning process*. Learning is a natural process of pursuing personally meaningful goals, and it is active, volitional, and internally mediated. Principle 2: *Goals of the learning process*. The learner seeks to create meaningful, coherent representations of knowledge regardless of the quality of data available. Principle 3: *The construction of knowledge*. The learner links new information with existing and future-oriented knowledge in uniquely meaningful ways. Principle 4: *Higher order thinking*. Higher-order strategies for "thinking about thinking"—for overseeing and monitoring mental operations—facilitate creative and critical thinking and the development of expertise. **Affective Factors**: Principle 5: *Motivational influences on learning*. The depth and breadth of information processed, and what and how much is learned and remembered, are influenced by (a) beliefs about personal control; (b) saliency of personal values, interests, and goals; (c) personal expectations of success or failure; (d) affect, emotion, and general states of mind; and (e) the resulting motivation to learn. Principle 6: *Intrinsic motivation to learn*. Individuals are naturally curious and enjoy learning, but intense negative cognitions and emotions (e.g., feeling insecure, worrying about failure, etc.) thwart this enthusiasm. Principle 7: *Characteristics of motivation-enhancing learning tasks*. Curiosity, creativity, and higher-order thinking are stimulated by relevant, authentic learning tasks of optimal difficulty and novelty for each student. **Developmental Factors**: Principle 8: *Developmental constraints and opportunities*. Individuals progress through stages of physical, intellectual, emotional, and social development that are a function of unique genetic and environmental factors. **Personal and Social Factors**: Principle 9: *Social and cultural diversity*. Learning is facilitated by social interactions and communication with others in flexible, diverse (in age, culture, family background, etc.), and adaptive instructional settings. Principle 10: *Social acceptance self-esteem, and learning*. Learning and self-esteem are heighted when individuals are in respectful and caring communities.

---

Science Education International, Vol. 5, No. 2 June 1994
relationships with others who see their potential, genuinely appreciate their unique talents, and accept them as individuals. **Individual Differences:**

**Principle 11**: Individual differences in learning.

Although basic principles of learning, motivation, and effective instruction apply to all learners (regardless of ethnicity, race, gender, physical ability, religion, or socioeconomic status), learners have different capabilities and preferences for learning mode and strategies. **Principle 12**: Cognitive filters. Personal beliefs, thoughts, and understandings result from prior learning and interpretations become the individual's basis for constructing reality and interpreting life experiences.

SCIENCE EDUCATION PARTNERSHIPS: MANUAL FOR SCIENTISTS AND K-12 TEACHERS
by Chris Deeter

'The way we usually market education innovation leaves little room for enlisting the power of teachers or providing for a continuing relationship between schools and universities. Teachers are typically confined to their classrooms with schedules that preclude significant interaction with other educational professionals," so writes Bruce M. Alberts, Ph.D. and president of the National Academy of Sciences in this new publication edited by Art Sussman. This book is must reading for anyone at all interested in changing the paradigms of traditional science education.

Art Sussman, former director of the UCSF Science and Health Education Partnership and current director of the Far West Regional Consortium for Science and Mathematics Education, has collected numerous articles that clearly and concisely explain the development and advantages of teacher/scientist partnerships in education. The book is divided into five units of emphasis: Introduction, Teacher Centered Activities, Student Centered Activities, Evaluation and Resources, and The Big Picture.

A true highlight of the book is A 10 Step Recipe for Starting a Partnership Program. This article provides answers to many of the most pressing questions as one begins to develop partnerships between school districts and scientists. Throughout the teacher centered activity section are ideas for initiating and planning partnerships. These partnerships include summer work positions for teachers, joint summer research expeditions, innovative summer workshops, and experiments with constructivist teaching in science education. The student centered section contains articles on attracting underrepresented minorities to mathematics and science disciplines, health and medical partnerships with local medical and dental colleges to provide the students information about dental health and physical and mental maturation, and contests designed to allow students to write their own lesson plans. The task of evaluating these innovative programs is discussed with the difficult reality that the old paradigm of evaluation must be replaced with a newer more flexible one. The evaluation articles are followed by four articles meant to provide suggestions for some realistic ways to fund these partnerships.

The rewards and benefits of these partnerships emphasize that although the vast majority of this book deals with partnerships based on the West Coast, the partnership idea is one which must be pursued worldwide.

This book can serve as a great resource guide for anyone who is presently considering the development of a scientist/teacher partnership. It is also a refreshing way to introduce new ideas into a working teacher scientist relationship.

JOURNAL OF SCIENCE FOR PERSONS WITH DISABILITIES

The Science Association for Persons with Disabilities (SAPD) is an organization composed of teachers, parents, college professors, students and scientists who are concerned with making science courses, content and career opportunities available to persons with disabilities. Our membership comes from many countries around the world.

We publish a yearly journal, biennial newsletter, and a current bibliography of articles on science for persons with disabilities from 1924 to the present. These publications are made available to our membership. We would like for all teachers who have had or will have a student with a disability to become members of our organization. Many special education teachers also teach science curriculum. Won't you please join us and help spread the news that science knowledge and opportunities are important everyone? And tell a colleague or friend! Thank you. Membership information is furnished below.

To become a member of the Science Association for Persons with Disabilities, send $10 (US$16 for overseas members; make check payable to SAPD) to:

Science Association for Persons with Disabilities
P.O. Box 17411
Boulder, CO. 80308-0411.

If you wish to receive an updated bibliography, please include an additional $5 ($8 overseas) with your membership application.
Call For Manuscripts and Reviews

Unsolicited JSPD manuscripts are welcomed. You are encouraged to share views of the status of science for persons with disabilities, effective teaching practices, curricula and exemplary work samples that are student produced. Use APA style, double space with wide margins and submit two copies of the manuscript (if printed). Contributors may also send manuscripts on floppy disk. Please use either Microsoft Word (Macintosh) (preferred) or WordPerfect 5.1 (IBM).

Send manuscripts and reviews by October 1, 1994 to:

INARTICULATE SCIENCE?

Perspectives on the Public Understanding of Science and Some Implications for Science Education

by
David Layton, Edgar Jenkins, Sally Macgill, & Angela Davey

The public understanding of science is a matter of concern in most countries. This is not simply because educators or scientists wish to promote a wider understanding of scientific ideas as worthy of the attention of all thinking citizens. Such understanding is commonly regarded as essential for the effective implementation of a wide range of social, economic, technological, medical, employment or other policies which have a scientific dimension. This book explores the ambiguities and limitations of the concept of 'public understanding of science' and, by means of case studies, addresses the meanings and social uses which science has for members of the adult public who are not themselves professional scientists. Drawing upon a substantial literature to place the case studies in a broader context, the final chapter examines the implications of the research for science education.

POLICY, PRACTICE AND PROFESSIONAL JUDGEMENT: SCHOOL-BASED ASSESSMENT OF PRACTICAL SCIENCE

by
J. F. Donnelly, A. S. Buchan, E. W. Jenkins, & A. G. Welford

Practical work has had an important place in British science education for many decades. However, it was only in 1988, with the advent of the science examinations occurring at the end of compulsory schooling. The innovation was welcomed by many science teachers, but it was also seen as the problematic part of the new examination in science. The study reported in this book involved an in-depth examination of the implementation of this policy. It took place between 1990 and 1992, and involved extensive fieldwork in schools together with a national questionnaire. The findings raise important issues, both about the role of practical work and its assessment in the curriculum, and about how policy decisions in education are taken and implemented. Those issues are of increasing significance as science education practice becomes even more subject to centralized control in the context of the National Curriculum.

THE HARARE GENERATOR—INNOVATIVE IDEAS AND TECHNIQUES FOR SCIENCE EDUCATION IN AFRICA

by Knapp Hill

A package of materials is now available from ICASE Publications offices representing the output from the Harare Generator, held in Harare, Zimbabwe in 1991.

The Harare Generator was not a conference in the conventional sense, but rather an event bringing together African science educators and other resource persons to share experiences and generate new ideas for science teaching and teacher education. The package of materials consists of a book describing the event itself and also ways in which it
could become a catalyst in the on-going process of regenerating science education in Africa and elsewhere. But, the major part of the book describes the experiences and outcomes of 18 group projects and suggests various ways in which these could be used in pre- and in-service teacher education.

There are two sets of colour slides, one showing the concept of the Harare Generator, the other illustrates various innovative approaches to science education being developed with students during the meeting. And there is a three-hour video tape made up of classroom scenes and interviews with teachers and students to illustrate various techniques.

The cost of the components of the package are as follows:

- Book (260 pages) $10.00 (£7.25)
- Slide set A (60 slides 35mm) $20.00 (£15.00)
- Slide set B (60 slides) $20.00 (£15.00)
- Videotape $20.00 (£15.00)
- Postage and packing add 50%

ICASE Publications
Knapp Hill

Petersfield, GU31 5LR UK

The result of this work was an integrated system designed for large scale, low cost operations, including: equipment, written materials, transportation and administration.

The equipment itself takes the form of a type of highly compact science exhibit, consisting of 11 multi-activity workstations for pupils to explore. A range of these exhibits were developed, each set focusing on one basic science topic. Schools keep the exhibit for, on average, two days.

A schools service incorporating this system began in January 1993 in London. During its year it served some 120,000 pupils at an approximate cost of £0.30 per pupil. This year it is on target to reach 220,000 pupils at a cost of £0.25 per pupil, and is operating in many areas of the UK outside London.

Teachers especially like the service because it offers small schools access to resources which would otherwise either be too expensive to buy or too difficult to produce for themselves. Pupils gain valuable additional learning experiences which compliment their class teacher’s work without disrupting or over-burdening him/her.

A further significant feature of the SchoolWorks approach is that it can reach pupils regardless of gender, ability, social background or location.

SchoolWorks is part of a non-profit organisation called Science Projects based in London, UK. Science Projects is keen to work with educators in other countries interested in setting up operations of this kind.

For additional information contact: Peter Trevitt, Science Projects Limited, 20st. James Street, Hammersmith, London, W6 9RW.
July 17–August 10
**London International Youth Science Forum**
Location: London, UK
Contact: LIYSF, PO Box 159, London SW10 9QX, UK
The Science Forum is the principal meeting in Britain of young scientists. Over three hundred students attend from some fifty nations to make this an international event of major significance. The program features lectures, seminars and demonstrations from leading scientific names, and an extensive range of visits to university and industrial research establishments.

August 8–12
**13th International Conference on Chemical Education**
Location: San Juan, Puerto Rico
Contact: Ram S. Lamba, Chairman 13th ICCE, Inter American University of Puerto Rico, PO Box 191293, San Juan PR 00919-1293
This will be the first time that an ICCE meeting will have been held in the Caribbean Region. The objective of this conference is to bring together chemistry teachers from the pre-college and college levels to share ideas and learn from each other about innovations in the teaching and learning of chemistry. The theme is ‘Chemistry: The Key to the Future.’

August 21–27, 1994
**15th Biennial Conference of the Asian Association for Biology Education**
First Circular
Location: The Conference will convene at the Art Hall of Tokyo Gakugei University, Koganei, Tokyo
Contact: Secretariat: Secretariat, 15th AABE Conference c/o Department of Biology Tokyo Gakugei University Koganei, Tokyo 184, JAPAN
Fax: (81)-423-24-9832 (to H. Kitano or N. Katayama)
Tel: (81)-423-25-2111, ext. 2674 (to N. Katayama)
The special theme for the 15th AABE Conference is “Biology Teaching to Non-biology Majors.” It will enable a focus to be made on the content, methods, approaches and outcomes required in biology programs designed for students who do not intend becoming biology majors or biology specialists. There will also be time allocated for the usual country reports. General sessions will cover all aspects of biology education, and will be grouped as far as possible according to themes.

September 24–29, 1994
**WOCATE Conference**
Sponsored by the World Council of Associations for Technology Education
Location: the University of Banská Bystrica, Slovak Republic
Contact: WOCATE Secretariat, Mrs. Doris Traberth, Schlosserstrasse 9, 99084 Erfurt, Germany
The conference is meant to discuss various aspects of innovation, production, small scale industry management and education. Especially those projects developed by companies that bring technology education, economy and management closer to young people. The possibilities for transferring special experiences in school-industry-link projects will be discussed.

December 6–10, 1994
**The 9th ICASE Asian Symposium**
Location: Bangkok, Thailand
Contact: Dr. Janchai Yingprayoon, Secretariat: IPST Sukhumvit Rd. Ekamai, Bangkok 10110 E-mail: OICST@CHULKN.CHULA.AC.TH
The theme of the symposium is “INCREASING THE EFFECTIVENESS OF SCIENCE TEACHING IN THE CLASSROOM: A CHALLENGE FOR SCIENTIFIC AND TECHNOLOGICAL LITERACY FOR ALL.”

January 5th–7th, 1995
**The Association for Science Education Annual Convention**
Location: The University of Lancaster, UK (which is 200+ miles north of London)

Canterbury Christ Church College
A New ICASE Institutional Member

Canterbury Christ Church is a College in the University Sector with a long history of expertise in in-service education and significant fund of international experience.

The Science Department has expertise in both Biological and Physical sciences to Ph.D. level. It is a National leader in Science and Technology Education for primary teachers by distance learning techniques, with courses at Certificate, Diploma and Masters levels.
The Department is undertaking research into communication styles in text-based learning materials.
The Science staff have been responsible for the development and implementation of a major in-service science training programme for primary school teachers, 'Success with Primary Science', which has been used by Education authorities throughout the United Kingdom. A key feature of the developments pioneered at Canterbury has been the initiation and encouragement of locally tutored courses using the materials developed by the college staff and backed up by the College.
The Science staff have unparalleled experience in delivering flexible learning programmes in the United Kingdom and are uniquely qualified to assist the development of courses overseas, having had practical experience in the Middle East, Indonesia, Africa, the Caribbean, North and South America.

If your country needs teachers with an awareness of
• core concepts in science,
• scientific skills
• effective ways of teaching and learning science;
then Canterbury Christ Church College can, in a cost effective way:
• provide core course materials which can be adjusted to suit local conditions thus giving local "ownership";
• provide tutor support materials to assist effective delivery;
• provide an in-country consultancy service to promote local writing workshops;
• train those responsible for course delivery in our intensive residential workshops in the U.K. at Canterbury, or in the home country.
We don’t just supply a ‘whole course,’ but rather we help your trainers to develop a programme ‘custom-made’ for your country’s needs.

Christ Church College is situated in the historic City of Canterbury, a place of pilgrimage for travellers world-wide. Canterbury is in the South East of England, only 96 kilometres from London with good communications in the U.K., and with the Continent, being only 30 minutes from the Channel Tunnel.

YOUNG REPORTS FOR THE ENVIRONMENT MEETING
JUNE 19-20, LUXEMBOURG

Jack Holbrook
Executive Secretary, ICASE

On Sunday 19th June national operators of “Young reporters for the environment” met for the first time to launch the project on a European scale. The agenda covered strengthening the national structures and strategies, defining the mission topics, communication circuits for 1994-5 and agreeing the precise calendar of the project.

Present in the meeting were representatives from Denmark, France, Greece, Germany, Ireland, Portugal and Romania. The meeting was chaired by Philippe Saugier the charge de mission and European coordinator for the project, operating under the Foundation of Environmental Education in Europe (FEEE). From the discussions it appeared that the use of e-mail, a fundamental component of the operation, was problematic in many cases and ways were explored for getting schools to utilise this facility. The expectation was that this problem would be less severe in the future as more and more schools acquired modems.

Much interest was shown in the missions being proposed to which one student from each country would be invited to participate. Problems were discussed related to timing of the missions so that they did not clash with examination programmes etc within the European countries. It was anticipated that a mission would get good support even if the systems in some countries meant that they could not participate in all.

Ways of encouraging schools in more countries to participate in the “Young Reporters for the Environment” were explored and the models by which the project could operate within a given country were discussed. It was felt that science teacher associations could play an important role especially if they linked with groups having access to financial sponsorship.

The 20th June was seen as a very important working day for the future of the project and was held in the Luxembourg headquarters of the Commission of European Communities. The objective of the meeting was to evaluate the potential of the Young Reports project to encompass different levels of society—a fundamental issue for an innovative project that expects to reach the general public through intensive actions within the school community.

Following greetings, an introduction was provided by M. Ole Lovig Simonsen, President of FEEE and a deputy in the Danish parliament. Thomas Joly gave an overall picture of the Young Reporters project and Philippe Saugier expanded on this and explained the current position. Comments and other aspects were provided by a small group of ‘experts’ invited to the meeting giving the project more perspective and allowing FEEE to appreciate the value of the “Young Reporters for the Environment” approach.

Philippe Saugier in his presentation explained that the Young Reporters is a network of secondary schools covering the whole of geographical Europe, involving students in the 14-20 year age range. Like a specialised press agency, students are involved in initiating field inquiries about topics involving scientific research and the environment to write journalistic articles and then exchange and debate these articles with other young reporters of the network before diffusing this to the local, national and international public. In so doing Young Reporters strives to:

- improve students’ about important environmental issues
- bringing about changes of behaviour with respect to the environment
- enable students to feel more involved in the educational process
- encourage teaching through issues which confront society
• direct students to confront issues in a real life context and make contact with persons involved
• enable student groups to communicate with other groups beyond national borders
• address the general public with a new perspective that shows the capacity of youth to perceive and communicate about crucial environmental issues in a scientific manner.

For more information contact Philippe Saugier, FEEE, Ecole, 74130 Brison, France.

INTERNATIONAL CONFERENCE FOR SCIENCE AND TECHNOLOGY AND MATHEMATICS EDUCATION

An African regional conference on Learning for Life was held in the University of Botswana from 27 June to 1 July 1994. It was attended by more than 100 participants from 12 African Commonwealth countries and Mozambique as well as from Britain, Cyprus and the Bahamas. The Conference was sponsored and hosted by the Ministry of Education of the Government of Botswana and co-sponsored by the Commonwealth Secretariat, CASTME, UNESCO, and ICASE.

The meeting was opened by the Minister of Education for Botswana, The Hon. M. R. Molomo and the Vice-Chancellor of the University of Botswana, Prof. T. Thou. The Founder President of CASTME, Dr. Maurice Goldsmith, was represented by Vice-President, Dennis Chisman, who read a message from the President.

Plenary sessions were given by Kabir Shaikh, Vice-President of CASTME, on the theme Value for Money in Science, Technology and Mathematics Education; by Prof. P. Makhurane, Vice-Chancellor of the University of Bulawayo on African Science, Technology and Mathematics Education, Quality for all Africans; by Jack Holbrook, Executive Secretary, ICASE on Project 2000+; and by Professor L. P. Makhubu, Vice-Chancellor, University of Swaziland on Recent Issues in Science, Technology and Mathematics Education; A Vision for the 21 Century.

Most of the work of the Conference was carried out in small group discussion sessions which gave rise to a number of proposals for follow-up action in the form of projects to be submitted for further consideration by the Council of CASTME and by Commonwealth Secretariat. There was also an agreement to establish a regional branch of CASTME for the African region. The Chairman of this new branch will be Dr. T. Mokoena, Chemistry Department, University of Botswana.

The conference was closed by the Director of the Botswana Confederation of Commerce, Industry and Manpower. A formative evaluation of the conference was undertaken by Bryan Wilson, Vice-President of CASTME. The report of the meeting is expected to be published later in 1994.

CASTME is a member of ICASE.

CASTME participants hard at work
REPORT FROM THE NORDIC REPRESENTATIVES OF THE INISTE/UNESCO MEETING

April 28-29, 1994
Hosted by the Swedish National Agency for Education-Skolverket
Kungsgatan 53, Stockholm

by M. Anna Garner
c/o Fjölbraitaskólinn Breiðholti
Austurbergi 5
111 Reykjavík
Fax: 345 1 670389

Review of Educational Changes. Recent Events in Science and Technology Education

Sweden

The Swedish educational system is going through a process of change.
• There is a move to decentralisation with greater responsibility being transferred to the local authorities.
• A complete school reform for the 6-18 sector is in progress.
• The National Board of Education (approximately 700 personnel) has been closed down and replaced by The National Agency for Education (approximately 200 personnel).
• The tasks of the agency are evaluation, development and supervision.

A particular development task of the agency at the present time is to increase the number of students in science and technology education by 50% during the current five year period.

Finland

Changes in 1994 concern the New National Curricular Guidelines which give:
• A school based curriculum.
• Freedom of choice at all three levels, e.g., at upper secondary level only 45 courses of 75 are compulsory.
• Focus towards quality learning rather than quantity.
• Management by results assessment.
• Flexibility.

Denmark

The new Education Act takes effect for the 1994 school year.
• The subject content is less defined.
• There is a cross-curricular emphasis.
• Goals concern central areas of knowledge.
• Science and technology is introduced as a specific subject in the primary school, i.e., prior to the 7th year.
• Environmental matters are entering the curriculum on an increasing scale.
• Changes have caused frustration among teachers who now have "counted hours" and less say in school affairs.

Iceland

A parliamentary committee has been working for the past 18 months to prepare a plan for educational reform and new Education Acts. The report of the committee and the proposed Act for the Upper Secondary level has been published. This has not yet been discussed in Parliament. The pre 16 proposals are not yet published.

Some of the proposals contained in the report and proposed Upper Secondary Act are:
• An emphasis on increased opportunities in vocational education.
• A pruning of choices in the non-vocational sector.
• A new National Curriculum and Guidelines to be written.
• Lengthening of the school year.
• Reorganisation of length of courses.
• Teachers having a reduced say in school committees.

Science, technology and environmental education at all levels has suffered from cut backs. Ministerial posts for officers with special responsibility for these disciplines have been recently abolished. A committee is working on reorganisation of mathematics education.

Science Teacher Associations are most active at the upper secondary level and shoulder a considerable amount of responsibility.

Discussions are taking place at the University regarding a wider based and more varied degree qualification in the sciences. The Ministry for the
Environment is to issue it’s policy statement concerning environmental education in June.

**INISTE Activities**

Finland and Sweden have been the most active.

Finland recognised that too few students were entering the scientific and technology disciplines. FINISTE established a national network to aid the developments needed to make these disciplines more attractive and efficient. One half million Finnish marks were invested in the FINISTE project but total returns were nearer 15 million marks due to grants from industry and teacher time, etc.

The network concentrated on new teaching methods, and teachers who wished to participate were enabled to do so. This program has been working for 5-6 years and is considered to be a success.

The Swedish activities under INISTE and ASP (Associated Schools Project) have mainly concentrated on the Baltic Sea Project which started in 1989. Regional groups of teachers were established into a network and the project is now very well established with several hundred schools taking part.

Sister projects are commencing, for example The North Sea Project.

Denmark and Iceland have so far not created any specific projects but some Icelandic and Danish schools intend to participate in the North Sea Project.

Nordic INISTE conferences have been held in addition to the above activities. The first was held in 1985, the second in Finland in 1989, and the most recent in 1991 was hosted by Norway. The proposed 1995 conference is to be hosted by Sweden.

**The Future of INISTE and the Nordic INISTE Group**

The original initiatives behind INISTE were from UNESCO headquarters in Paris. In recent months the drive and enthusiasm from UNESCO have waned to such an extent that the Nordic representatives were uncertain of the network’s future.

All delegates felt that there is much to be gained by the Nordic countries continuing to communicate in this type of network. No one was aware of any other existing Nordic network between education departments that is specifically related to science and technology education.

**The Fourth Nordic INISTE Conference**

Sweden has taken on the responsibility of hosting the proposed 1995 conference. The proposed time is late April or early May. Changes in the form of the meeting were discussed.

**Conclusions and Recommendations**

**General**

1. The Nordic nations have basically the same educational aims for science and technology education.
2. The methods of approaching the goals seem to be developing differently in the different countries. Developments seem to be at different stages.
3. There is a definite need for much greater communication and information exchange concerning scientific and technological education policies, curriculae, teaching methods, etc., between the Nordic countries.
4. Representatives intend to continue to work at sustaining and building the Nordic network.

**The Nordic INISTE/UNESCO Network**

1. Clarification of UNESCO’s views regarding the future of INISTE and the Nordic groups role in the network was needed.
2. The position of Norway in group participation is uncertain. Attempts to contact suitable agencies in Norway will be made.
3. During the next six months the group will assess the different possibilities and means of continued cooperation either within or without the existing network.

**Nordic Meeting 1995**

1. It is proposed that the planned conference entitled Science and Technology in Society will take a slightly different form.
2. The proposed form is for a Nordic working seminar to consider the Nordic issues, views, trends and policies concerning Science and Technology in the Nordic-European Society.
3. Three to four delegates would be invited from each of the Nordic nations.
4. Arrangements will depend on answers from UNESCO headquarters.
LATIN AMERICAN ASSOCIATION FOR SCIENCE EDUCATION

Kenneth Tobin, Professor
Science Education, Florida State University

The Latin American science educators have organized themselves into an association and August 17, 1994 was the opening ceremony of the first meeting in Panama City, Panama. The association had its genesis in the annual meeting of NARST in Atlanta. A large contingent of Spanish speaking researchers attended the NARST meeting and, with the assistance of people like Alejandro Gallard, the seeds were sewn for an association and its own meeting in Central America.

More than 200 delegates attended the opening ceremony that was addressed by the inaugural President of the association and the Minister of Education in Panama. For the next three days an exciting program of papers and symposia featured research that remains largely unknown to most of the world. There were participants from about 11 Central and South American countries and keynote plenary speakers from the USA, England, France, and Spain. There is a book of proceedings in Spanish (Memoria) that can be obtained from Deyanira Barnett (419 pages). The main organizers of the conference feature some familiar names—Deyanira Barnett, Maria Rosa Montanari, Alejandro Gallard and Armando Contreras.

Interestingly, the main sponsor for the conference was the Education Ministry in Panama who provided $35,000 and a variety of other sponsors that included the Smithsonian and UNESCO.

REPORT OF THE 1994 DORTMUND SUMMER SYMPOSIUM

Jack Holbrook

The 1994 Dortmund Summer International Symposium on Problem Solving and Misconceptions in Chemistry and Physics, held at the University of Dortmund, Germany and organised by Professor Dr. Hans-Jurgen Schmidt.

This 3 day meeting, sponsored by the University of Dortmund in cooperation with ICASE represented the 12th Dortmund summer symposium and was held 25-27th May 1994. The programme allowed 40 minutes for each speaker to present their paper followed by a further 40 minutes for discussion, a well tried approach that again proved highly successful, although users of English as a second language found it difficult to fit their presentation into the allotted time. Presenters came from a number of European countries notably the UK, Belgium, Netherlands, Germany, Norway, Portugal and Greece.

Professor John Gilbert from the University of Reading, UK began the symposium with an overview of research being undertaken in science education in some European countries. He gathered information by means of a questionnaire and sought patterns within the data across these countries. His presentation considered the data within the context of attempts to create a closer relationship in science education research within the European Union.

Alan Griffiths, a speaker from Newfoundland, Canada gave an analysis of research undertaken on students' chemistry misconceptions. He extensively reviewed the literature, identified the main areas where misconceptions were found and listed the specific misconceptions. The paper gave the nine main areas as—Equilibrium Systems, Acids and Bases, Physical and Chemical Change, Combustion, Electrochemistry, Matter, Bonding, Dissolving and Solutions, and Stoichiometry.

Bob Fairborther, King's College, London, UK analyzed information on problem solving and learning by students. His first part of the paper reveals that students do not know how to revise and more generally do not know how to take control of their own learning. The second part of his paper illustrates that students can learn to make decisions for themselves but it entails making clear to them the criteria by which they are being judged. The major conclusion is that teachers spend too much time teaching the subject matter and not enough teaching students how to learn.

Philip Adey, King's College London, UK expounded on the strategy to help students with chemical problem solving capability. He suggested that efforts should be geared to improving general
information-processing capability. The paper reviews what is known about approaches to the development of general thinking, explores the evidence for the success of different methods and discusses the applicability to chemical problem solving.

Vivi Ringnes, University of Oslo, Norway, examined students’ understanding of chemistry and their learning difficulties related to chemistry concepts, exploring the textbook, curricula, written examinations, teaching and the students themselves. Student understanding of the areas of nomenclature, chemical elements, chemical bonding, redox and electrolysis, acids stoichiometry and equations were examined from written answers to multiple choice and open-ended questions.

Reinders Duit, University of Kiel, Germany examined, within a constructivist framework, the learners preinstructional ideas of chaos-theory and discussed the research approach and the preliminary findings.

Christoph Von Rhoneck, Pedagogische Hochschule Ludwigsburg, Germany investigated the interactions between achievement in physics, psychological background and social interactions by means of a questionnaire. Students were divided into continuous and sporadic learners and the differences between these two subgroups were analysed.

Dieter Nachtigall, University of Dortmund, Germany lamented the poor teaching approaches adopted by teachers in many physics classes and explored teaching strategies that motivate students and encouraged them to learn.

Marie-Jose Janssens, University of Leuven, Belgium details her Ph.D. study on the analysis of teacher-made test items in chemistry. Among the findings was that only 10% questions set by teachers demanded a higher intellectual skill and that large discrepancies occurred between schools and between teachers in the same school.

Kerstin Prokoph, University of Halle, Germany presented the initial instigatory approaches to looking at the possibilities of including natural development processes in chemistry lessons and to analyse the level of treatment of the topic that is suitable.

Georgios Tsapartis, University of Ioannina, Greece examined mechanisms that block problem solving from Pascual-Leone’s M-space perspective. Using this perspective a mental capacity (M-Capacity or M-space) is attributed to each subject and an M-demand is postulated for each problem. One block is the lack, in the subject’s repertoire, of any single step in the solving process. A second block is the non-equivalence of the part steps that make up the solution process. Two further hindrances are the presence of noise in the problem statement and the logical structure of the problem.

Iris Pigeot, University Mainz, Germany described the graphical chain model which allows for variables to be regarded, in statistical analysis, simultaneously as responses and as explanatory variables, where some of the variables may be quantitative and others qualitative. In the paper examples are given to illustrate the process. This approach is seen as a powerful alternative to path analysis.

Jeannine Acampo, Utrecht University, the Netherlands, described her Ph.D. study on chemistry teachers’ learning processes: a study of teacher training and reflection on classroom activities. The presentation concentrated on teachers’ problems related to the teaching of electrochemistry. Data was collected from in-service training programmes and from classroom observations. The report gives results concerning changes in conception and strategies of chemistry teachers.

Gabriela Jonas, University of Hamburg, Germany presented a pilot study on physics teachers’ and student teachers’ thinking about laboratory work in physics classes. A comparison was undertaken between the thoughts of experienced physics teachers and student teachers regarding experiments in physics classes through the use of questionnaires, interviews and classroom observation. The outcomes can be used to help clarify why experiments in physics classes often don’t have the expected success for students’ learning.

Mary Atwater, University of Georgia, USA discussed bridging chemical problem solving and misconceptions in different contexts. The paper focussed on problems solving strategies of African-American students in two different settings, problem solving strategies of university students enrolled in two different kinds of laboratory settings and misconceptions of high school and college students in different types of bondings.

Geeske van Hoeve, University of Utrecht, Netherlands described her Ph.D. research into a new approach to teaching chemical bonds. A new chapter on chemical bonding was written after critical
analysis of textbooks. The educational structure had two main characteristics. First a chemical context is chosen as a starting point and secondly, the emphasis is on the making of knowledge as a human activity. In the unit a story is told.

The discussions were extensive and detailed. Generally there was an appreciation that a theoretical model was important for research studies, even if the research was qualitative in nature. It was also recognised that potentially there is much to be gained by pan-European cooperation in research and the opportunity to present and discuss research findings in such a setting. Ph.D. students, in particular, had much to gain from such symposia.

Once again Hans-Jurgen Schmidt is to be congratulated on organising a well run and interesting symposium. It was very gratifying to learn that he proposes to run a further symposium in two years’ time.

Proceedings of the symposium will be printed later in the year and copies can be bought from the ICASE secretariat at US$12 (including airmail).

Conference organizer, Hans-Jurgen Schmidt (far right), joins participants for a little sight seeing.

Ed van den Berg, far left, appears to be mentally formulating thoughts for his article later in this issue.
SCIENTIFIC AND TECHNOLOGICAL LITERACY FOR ALL—THE ROLE OF EDUCATORS

Jack Holbrook
Executive Secretary,
International Council of Associations for Science Education
(ICASE)

Abstract

Last July over 400 participants met at UNESCO headquarters, Paris, to discuss how, in future, scientific and technological literacy can be achieved for all. The forum was called to mobilize support for enhancing scientific and technological literacy for all worldwide and to launch Project 2000+, an internationally conceived drive to improve scientific and technological literacy worldwide through a range of nationally devised projects. The immediate outcomes from the forum were three-fold:
(a) a declaration for Governments
(b) a report summarizing the forum discussions and suggestions
(c) a call for task forces to be created in countries around the world and for the science education community to be mobilized to encourage greater use of research in the classrooms, better curricula that cater for all students and more emphasis on the non-formal sector to enhance the popularisation of science.

Project 2000+ is thus now in need of translation into projects at the national level. Concerns need to be identified nationally, project ideas defined and priorities for projects specified on a national scale. Within the formal sector crucial factors are teacher education and linked with this, the role played by teachers, areas where professional science teacher associations are expected to play a major role.

This paper sets out the rationale for greater attention to scientific and technological literacy and to examine how teachers need to be prepared to guide students towards such literacy, in line with the declaration and forum report mentioned above.

In pointing to the need for better curricula and more appropriate assessment procedures, the paper stresses the importance of placing emphasis on prior teacher education and puts forwards suggestions of how this might be initiated by teachers or teacher organizations, even in the most centralised systems.

Also stressed are the need for teacher acceptance that:
(a) ‘science for the scientist’ is often irrelevant for life within society and that a more social and technological approach to science teaching is needed so that science as a school subject can appeal to students in general and
(b) the heavy overcrowding of science curricula can only be overcome by a radical rethink of the objectives of science education and the emphasis placed on them.

Project 2000+

Project 2000+ is an initiative (ICASE/UNESCO, 1992) that sets out to mobilize worldwide support for action in which governmental and non-governmental bodies collaborate at the country level to achieve a greater level of scientific and technological literacy, perceived necessary for the 21st century. A declaration (UNESCO, 1993a) put forward by participants at an international forum highlights the action needed by Governments and other bodies (appendix 1).

The Rationale for Project 2000+

The World Conference on Education for All (1990) declared that “... every person . . . shall be able to benefit from educational opportunities designed to meet basic learning needs. These needs comprise both essential tools (such as literacy) and the basic learning content (knowledge, skills, values, and attitudes) required by human beings to be able to participate fully to improve the quality of their lives, to make informed decisions and to continue learning.”

It is clear from the above quotation that today’s educational concerns need to be geared to preparing citizens who are empowered to lead productive lives and to enjoy the best possible quality of life. To achieve this, it must be recognized that there is a need to resolve a variety of societal problems which deal with issues such as population, health, nutrition, environment, and sustainable development at local, national and international levels. These societal issues need an increasing degree of scientific and technological literacy on the part of the populace for both understanding and the decision-making involved to stimulate the necessary action. Yet, it would appear that in many countries much basic education in schools includes little that will help students achieve such literacy or feel confident either in
applying their knowledge or in dealing with societal issues and the need for a responsibility for action.

Project 2000+ recognises the growing need for a scientifically and technologically literate society and seeks to:

a) identify ways of promoting the development of scientific and technological literacy for all:

b) create educational programmes (both formal and non-formal) in such a way as to empower all to be able to satisfy their basic needs and be productive in an increasingly technological society;

c) encourage the formation of national task forces [involving personnel from Government, Inter-Governmental Organizations (IGOs), and from Non-Governmental Organizations (NGOs) such as Associations for Science Education] to initiate programmes for greater scientific and technological literacy and to identify and support projects promoting aspects of scientific and technological literacy;

d) support the development of a wide range of projects that aim to improve quality of life and productivity in society and that lead to promoting solidarity and cooperation in achieving scientific and technological literacy for all;

e) provide guidelines for the continuous professional development of science and technology educators and leaders;

f) support the evaluation of existing and projected programmes to ensure scientific and technological literacy goals are being met.

The Target

By the year 2001 there should be in place appropriate structures and activities to foster scientific literacy and technological literacy for all, in all countries.

Scientific and Technological Literacy

As the meaning of achieving scientific and technological literacy is an area of debate, it is appropriate at this stage to put forward the following 17 points, suggested by the National Science Teachers Association of America, as defining a scientifically/technologically literate person (NSTA, 1990-91). The NSTA suggests a scientifically and technologically literate person:

1. uses concepts of science and of technology, as well as an informed reflection of ethical values, in solving everyday problems and making responsible decisions in everyday life, including work and leisure.

2. engages in responsible personal and civic actions after weighing the possible consequences of alternative options.

3. defends decisions and actions using rational argument based on evidence.

4. engages in science and technology for the excitement and the explanations they provide.

5. displays curiosity about and appreciation of the natural and human-made world.

6. applies skepticism, careful methods, logical reasoning, and creativity in investigating the observable universe.

7. values scientific research and technological problem solving.

8. locates, collects, analyses, and evaluates sources of scientific and technological information and uses these sources in solving problems, making decisions, and taking actions.

9. distinguishes between scientific and technological evidence and personal opinion and between reliable and unreliable information.

10. remains open to new evidence and the tentativeness of scientific technological knowledge.

11. recognises that science and technology are human endeavors.

12. weighs the benefits and burdens of scientific and technological development.

13. recognises the strengths and limitations of science and technology for advancing human welfare.

14. analyses interactions among science, technology and society.

15. connects science and technology to other human endeavours e.g. history, mathematics, the arts, and the humanities.

16. considers the political, economic, moral and ethical aspects of science and technology as they relate to personal and global issues.

17. offers explanations of natural phenomena which may be tested for their validity.

The Project 2000+ targets for basic education are:

a) Promoting the teaching of science and technology linked to relevancy in society.

b) Encouraging positive attitudes towards science and technology.

c) Increasing skills in decision making, problem solving communication achieved through science and technology teaching.

d) Development of a greater degree of teaching
resource packages.
e) Reinforcing the use of interactive teaching methods as the mainstay of science and technology education.
f) Development of more relevant curricula in science and technology for scientific and technological literacy for all.
g) Enhancing teacher education programmes.
h) Encouraging a greater involvement of teachers and NGOs in the development, dissemination and evaluation of programmes.
i) Development of more relevant assessment programmes.
j) Implementation of effective evaluation strategies.

The Way Forward

Examining the Issues
Whilst the case for scientific and technological literacy has been stated and an indication of its meaning has been put forward, and whilst much research in science and technology education has given suggestions for curriculum development, popularisation of science and technology and a more enlightened public, the actual direction and method of operation in achieving the goals of Project 2000+ is far from clear.
Issues such as the following are of major importance for education for the 21st century and need to be discussed:

a) the nature of scientific and technological literacy, how to achieve it, what assessment mechanisms are most valid;
b) the degree to which science and technology should be studied for their own sake, or made directly relevant to the concerns and demands of the society and how far basic education in science and technology should establish the groundwork for students wishing to pursue scientific careers;
c) the inter-relation between science education and technology education; and their place as integral parts of the formal school curriculum;
d) the poor representation in some countries of girls in science and technology courses; under representation of women in the practice of science and technology, and in the places where decisions about them are made and, equally important, exclusion from the benefits of science and technology.
e) the popularisation of science and technology

Creating National Task Forces
With the above in mind, the international steering committee overseeing Project 2000+ recommended the setting up of national task forces by Governments. It is envisaged that these task forces would involve partnerships between public and private educational bodies and councils, universities and other institutions of higher and further education, libraries and museums, public and private bodies active in the fields of agriculture, environment, health, industry and commerce as well as organizations and individuals specially concerned with science and technology education.

Suggested Duties of the Task Force
1. To initiate, and to encourage the initiation by others, of national projects (*) in both the formal and non-formal sectors of education (including projects that link both sectors) to enhance STL.
2. To solicit ideas for projects from sources within the country and to undertake needs assessments.
3. To support and liaise with groups initiating STL projects.
4. To prepare proposals for funding by Government, industry, etc within the country as well as for external support.
5. To liaise with the regional centre for Project 2000+, to suggest regional projects and to put forward requests for support and guidance.
6. To advise Government on the priority of projects and on participation in regional cooperative projects.

*The term project here is used to indicate a carefully planned approach and may involve stages (undertaken concurrently or in parallel) that include piloting and feedback, creating resource, training programmes, assessment and evaluation. Projects may be developmental (e.g. curricula related) or research oriented (e.g. needs assessment).

The Role of the Ministry of Education
The local part of Project 2000+ are NATIONAL PROGRAMMES operating at the Governmental, non-Governmental, or both levels. These programmes are planned locally, directly locally, implemented locally and evaluated locally. The role of the Ministry of Education is seen as receiving, and seeking ways to implement, project suggestions from the national task force. At the same time the Ministry of Education is seen as encouraging
non-Governmental developments, particularly by educational institutions and professional teacher associations that initiate national projects by providing data, material and support for national task forces.

National Programmes put forward by task forces could be:

1. adapting, equipping or restructuring existing centres or facilities for supporting the improvement of science and technology education throughout the country, or if necessary creating new ones.

2. providing support for the establishment or reinforcement of professional associations for science and technology teachers which will make important contributions to achieving both the qualitative and the quantitative goals of Project 2000+.

3. providing support for groups or institutions working or willing to engage in the popularisation of science and technology (museums, exhibitions, the media, etc) particularly to help them to focus on people’s needs and to establish good links with the educational system.

4. publicising the need among the general public for greater scientific and technological literacy for all.

5. promoting the status of science and technology education within the community using the formal school sector, the media, and greater community involvement.

6. undertaking a rethink of policy for science and technology education.

7. designing new curricula implementational strategies, resource materials assessment techniques for supporting formal informal and non-formal learning.

8. encouraging more valid assessment instruments to use with students and greater attention to the evaluation of programmes for scientific and technological awareness and literacy.

The Role of Professional Teacher Associations

Major ways in which teacher associations can be involved in promoting Project 2000+, and hence in enhancing scientific and technological literacy, are by:

a) persuading teachers to support the new direction and helping them realise its educational potential;

b) developing materials and other resources to help teachers prepare for a new direction and encouraging teachers to trial them in their classrooms;

c) providing in-service support for teachers through seminars and workshops to introduce plan trials and evaluate strategies and materials related to the new direction;

d) providing resources which teachers may find useful for updating;

e) lobbying the Ministry of Education to take joint action to encourage the ideas and allaying the concerns of teachers;

f) playing a leading role as a member of a national task force in initiating and implementing projects.

An important approach in persuading teachers is through the development of teaching materials that are attractively easy to use and highly motivational. These materials can be directly related to the syllabus e.g. reorientation of the teaching approach that has as its goal:

(i) greater relevance to everyday life

(ii) greater educational value in meeting skills

(iii) greater student involvement

(iv) more logical and interestingly looked at from the students point of view or, encouraging the professionalism of teachers, the materials can be made available for teachers from which teachers select what they consider appropriate.

Besides the above goals, these materials can also:

(v) carry new scientific information

(vi) be a source of information for teachers from which they then develop their own materials

(vii) be interdisciplinary

The Role of Research Institutions (and Professional/Teacher Associations)

If national task forces are to seriously consider the work before them, it is important that they can receive support from research and be able to gather ideas and opinions.

Research is needed in areas such as:

1. curricula needed to achieve scientific and technological literacy and what assessment mechanisms are most valid.

2. the degree to which science education should be directly relevant to the concerns and demands of the society and how far it should establish groundwork for further learning for students wishing to pursue a scientific career.

3. the extent to which technology education

Science Education International, Vol. 5, No. 3 September 1994
should be an integral part of the formal school curriculum and taught separately from science? Whilst these two subjects areas have unique components, there are also areas of great overlap and literacy issues between these subject areas, in which science tends to take on a societal slant, are often heavily interrelated. For developing countries, hard pressed to provide specialised facilities (such as that demanded by pure science), the attractiveness of a technology—science mix for all, may not only be desirable, but could prove doubly attractive when consideration is given to the less expensive, more flexible, facilities that would be required.

4. appreciating, managing and having a sense of responsibility for the environment. This leads to education for sustainable development and how it can be achieved, given that the world is united in concerns such as global change, ozone layer depletion, the fitness of energy reserves and the impact of deforestation.

5. traditionally science education attracted boys, either by offering choice at an age when boys are more easily motivated toward science, or by orienting the science topics for study so that girls have studied science and technology, the research shows that they achieve equally as well as boys. Equity in science and technology education means recognising the importance of science and technology education for all citizens and then seeking to provide a wide range of experiences so that its appeal is appreciated by all.

Appendix

Project 2000+ Forum Declaration

We, participants in the Project 2000+ Forum, meeting at UNESCO, Paris, France, from 5 to 10 July, 1993:
1. Recalling the World Declaration on Education for All, in particular its recognition that sound basic education is fundamental to the strengthening of higher levels of education and of scientific and technological literacy and capacity and thus to self-reliant development and, further recalling recent worldwide expressions of concern for the environment and for the quality of human life, especially those contained in Agenda 21, the output of the United Nations Conference on Environment and Development, Rio de Janeiro, 3-14 June 1992;
2. Believing that scientific literacy and technological literacy are essential for achieving responsible and sustainable development;
3. Declare our full commitment to the promotion of science and technology education for all in keeping with the World Declaration on Education for All, and our readiness to contribute through Project 2000+ to the concerted action set out in the Framework for Action to Meet Basic Learning Needs;
4. Call on governments, industry, public and private sector interests, and education and other authorities in all countries to:
   a) review critically existing provisions for science and technology education at all levels and in all settings with the aim of giving appropriate attention to development and maintenance of learning programmes responsive to the needs of individuals and communities;
   b) assign priority to the development and introduction of programmes leading to scientific literacy and technological literacy for all with the aim of achieving responsible and sustainable development;
   c) take such steps as may be necessary to ensure equity of access for everybody to science and technology education, notably for women and girls, young children and other under-represented groups;
   d) develop appropriate in-school and out-of-school opportunities programmes,
5. Urge United Nations Agencies and other inter-governmental organizations to work together to initiate and support programmes which will advance the ability of countries and of populations to shape their own future in a scientific and technological society and which will increase the capacity of countries for designing, planning and implementing scientific literacy and technological literacy programmes;

6. Urge non-governmental organizations active in fields of science and technology education, as well as the social sciences, and professional associations of teachers and educators and educational organizations at all levels to:

a) enter into partnership with, and make their knowledge and experience available to, United Nations and other inter-governmental bodies as well as establish innovative programmes in a common effort to achieve the goal of scientific literacy and technological literacy for all; and

b) participate in national, regional and international programmes for the enhancement of scientific literacy and technological literacy for the improvement of the quality of life in all societies and for the achievement of sustainable development;

7. Recommend that UNESCO makes provision, within its Medium Term Plan (1996-2001) in the field of education, and in the context of Project 2000+, for an international programme to develop co-operation among all countries in the field of science and technology education, with particular reference to the promotion of scientific literacy and technological literacy for all:

This programme, conducted in partnership with the relevant and competent governmental and non-governmental organizations and agencies, should focus on regional and subregional co-operation and on strengthening networks for exchange of ideas, information, human and material resources for science and technology education, and actively seek to promote world-wide:

a) understanding of the nature of, and the need for, scientific literacy and technological literacy in relation to local culture and values and to the social and economic needs and aspirations of each country and its peoples, and also in accord both with the general aims of education for the all-round development of human personality and with human rights and basic freedoms;

b) identification of those issues concerning the applications of science and technology which are of special importance for personal, local and national development and their embodiment in educational programmes;

c) establishment of teaching and learning environments as well as supporting structures conducive to the achievement of scientific literacy and technological literacy for all;

d) formulation of guidelines for the preparation and continuous professional development of science and technology educators and leadership coupled with assistance to countries in giving effect to them;
c) development of effective communication, both verbal and visual, assessment strategies and evaluation programmes designed to enhance general levels of scientific literacy and technological literacy;

f) support for the non-formal and informal sector in its own right and support for development strategies which will help to stimulate and maintain lifelong scientific literacy and technological literacy;

8. Recommend that by the year 2001 there should be in place appropriate structures and activities to foster scientific literacy and technological literacy for all, in all countries.

SCHOOL OF EDUCATION, UNIVERSITY OF LEEDS
EDUCATION FOR CAPABILITY RESEARCH GROUP

The Education for Capability Research Group was established in 1989 within the School of Education at the University of Leeds. It aims to foster and disseminate research concerned with any aspect of education for capability and its membership reflects a wide range of academic and professional interests and expertise. Further information about the activities of the Group may be obtained from A. Anning, School of Education, University of Leeds, Leeds LS2 9JT, U.K.

The following Occasional Publications of the Groups are available.

Yeomans, D., & Williams, R. (1993). Then and now: Technology in ten of the original TVEI pilot schools. (£1.50).

All prices include postage and packing. Orders should be addressed to the Secretary, Centre for Studies in Science and Mathematics Education, University of Leeds, Leeds LS2 9JT, U.K. Cheques/P.O. should be made payable to The University of Leeds'.

Chameleon Condos, Critters and Critical Thinking

Author: Craig A. Berg
ISBN: 0-9640844-2-4
Publication Date: 1994
Price: $9.95

Suggested Audience: K-12 Science Teachers, Elementary Teachers

This book will show you how to build and use condos; 5-18 bottle habitats that teachers and students make from 2-liter recycled plastic soda bottles. Condos are designed to provide classrooms with low-cost, highly visible habitats that house anoles, cricket farms, ant colonies and provide more close encounters with living things that catch and eat other critters, undergo metamorphosis, change color, lay eggs, hide, and build homes. In addition, the author demonstrates via flowcharts, examples and students blackline masters how to use condos and children’s questions to initiate an interdisciplinary creative problem solving model. Fifty-six pages of activity-based life science for elementary and secondary classrooms to help turn kids on to science.

Pakistan is one of the South Asian countries entering into strong industrial and productive infrastructure by the end of this century. New and powerful educational forces around the world are giving signal to our nation to develop necessary reforms in education on a permanent basis rather than adhocism before entering into the 21st century. No doubt this is time of science and technology. A decade from now our science education programs will have great impact on the national development. We need to think now. Can our science education programs fulfill the national objective as productive citizen? Does our science curricula reflect a 21st century vision of Pakistani society? Did we design the instructions for the children who, born in 1993, will receive their elementary and secondary science education in the 21st century? Are our schools equipped to meet the requirement of a child of science in the coming century? What research evidence is needed to ensure that we are going to set directions to achieve our national objectives? In this paper some guidelines have been suggested for developing the science education programs for the 21st century in Pakistan and at the end, a proposed practice model has been included.

The twentieth century has witnessed an upheaval of societies resulting in fundamental changes in the political, economic, cultural and intellectual through systems both in the developed and developing countries of the world. This indeed has been the century of accelerated social change which has immensely influenced our concept of education and led to radical reconstruction of educational theories and practices. This is precisely opposite to the intellectual orientation of the 19th century. Perhaps the most spectacular development in all societies has been the application of science and technology in our daily life. The 21st century is the century of exploration of personal and professional growth. The science education must provide an environment where personal and professional growth flourishes.

The enrichment of science and technology education through primary, secondary, technical and higher education is essential to produce the manpower which is required to man the specialized positions in both the public and the private sectors. The supply of manpower through educational institutions must correspond in quantity and quality to the jobs being offered by the national economy. This requires very systematic manpower planning for the 21st century because production of one additional Ph.D (foreign) in specialized subject like physics may cost the nation around a 2.5 million rupee, while the production of one MBBS doctor or an engineer (local) may cost around 600,000/- rupees. If each one of them is not absorbed in the national economy, one may imagine the colossal loss which a developing country like ours will have to bear because of unplanned supply of science graduates in various fields of specialization.

On the qualitative dimension, we need to adopt a prognostic outlook as the students who are opting for science subjects today will play their active role in national economy in the 21st century. The educational planners engaged in developing science education programs must foresee the complexity of scientific and technological operations in the future to develop a viable curriculum for primary, secondary, technical and higher educational institutions.

Our attitude towards science curriculum has been generally conservative. Science curricula reforms now seem to be the concern of every pressure group of our society ranging from politicians to the clerical staff and labor. Besides the present-day context, a science curricula reform undertaking has to take full cognizance of the factors that may emerge as a reality after a decade or two when the children of today participate in the actual life activities of “their time”
i.e. somewhere in the 21st century. So the science curricula reform for that period is to keep a working balance between the triangular forces which bind it.

- Preparation of established content inherited from the past;
- Relevance to the present day needs of both the individual and the society, and
- Projection and incorporation of future requirement of the individual and the society to enable the individuals to respond to "their times."

The science curriculum and the instructional practices of the 21st century institutions must reflect the following principle:

- Student's interest and curiosity increases with provision of individual's involvement in relevant learning experiences.
- Learning science is by doing and students can relate their knowledge to new situation.
- Ample opportunities for students to ask questions.
- Science as process rather than product.
- Every student earns according to his capability.
- Encouragement from society is essential towards the students' progress.
- Use of educational technology and local resources plays important role in learning.
- Emphasis on information related to the environment and society.
- Emphasis on raising awareness of the ways in which science and technology interact with individuals, society, agriculture, industry and the environment.
- Science as way of thinking and dealing with problems.
- Think globally, act locally.

With the massive increase of knowledge of science our schools are no more in a position to handle the situation with conventional teaching methodology. Obviously the school timings cannot be increased indefinitely while there is no end to the process of knowledge explosion which has started in the 20th century. The only possible way to face the challenge of 21st century in the country like Pakistan is by adopting a new approach towards science teaching methodology, production of textbooks and educational technology. The crux of the problem is to ensure effective assimilation of maximum content of knowledge by our students in the shortest possible time. The following guidelines may help our science educationist in planning the strategies and tactics of teaching science in our schools in 21st century.

- Select the fundamental science content.
- Design the instruction for all kinds of students (good, average, weak, male, female, urban, rural public and private).
- Include the content to ask questions frequently.
- Provide opportunities for exploring the scientific concepts.
- Include interested and tested activities from the local situation.
- Sequence the content keeping in view the student's psychology.
- Suggest the methods of teaching science which involve the student's participation and rapid absorption of scientific informations such as inquiry discovery and mind capture etc.

Perhaps the most critical factor which will influence the entire process of science education in Pakistan is the examination system. Most efforts to improve science curricula, textbooks and teaching methods can be stumbled because of the perpetuation of a system of examination which has been least able in past to reform and innovation. The system of examination in Pakistan is beset with various critical issues which continue to remain unresolved in spite of volumes of literature written by national and international experts and organizations since the creation of Pakistan in 1947. The present system of examinations is based on summative evaluation. There is no continuous assessment of students' performance. The final examination is the yardstick for all type of subjects and levels. While planning for the 21st century, we need to think about the following:

- Does the evaluation of science subjects cover the functions for which these are going to design?
- What weightage is to be given to continuum(internal) and final assessment?
- When, where and how the evaluation is to be done?
- Are the fair?
- Do science courses have different grades, norms and criteria?

Table I gives the detailed picture of existing practices in science education in Pakistan and suggests corresponding practices for the 21st century in order to develop science education programs in Pakistan and for the countries of the same.

ICASE
The First 20 Years
1973-1993

A brief history

This new publication is a brief history of the International Council of Associations for Science Education.

It is not intended to be a comprehensive account, but rather an overview of the key happenings and milestones in the development of the organisation and the policies and strategies that have enabled it to reach its present position in the international community of science education.

It also looks forward to the future, especially to the turn of the century, and examines possible options for the continual development of ICASE as an umbrella organisation for science education associations and similar bodies.

Copies can be ordered from:

SCIENCE EDUCATION IN NEW ZEALAND
Lydia Austin
University of Auckland
Auckland, New Zealand

Introduction
New Zealand is a country founded by two cultural groups, Europeans and Maori. In recent years there has been an influx of people of many different nationalities, particularly Pacific Islanders. However, the educational system is founded on the British system complete with school uniforms and formal examinations at the end of forms five and seven. When the National party was returned to power, the new Minister of Education requested a redevelopment of the science curriculum for year 1 to year 13.

School Science
In the primary school which caters for children aged 5 to 11 there has in the past often been very little science instruction. Primary teachers usually have little or no formal science instruction themselves beyond high school. From the ages of 12 to 13 (two years) students attend intermediate school where science is taught by non-specialist teachers with varying amounts of training in science. From the ages of 13 to 17 students attend high school and receive science instruction by specialist science teachers who have bachelor’s degrees and often diplomas or masters degrees as well. In forms three to five (ages 13 to 15) students usually take general science. In some schools physics, chemistry and biology can be taken as separate subjects but there is rarely insufficient time on the timetable for more than two of these. At the end of form five the students may sit an external, school certificate examination in general science, biology, chemistry, physics or human biology. In the sixth and seventh forms students take more electives and less compulsory subjects although English is still required. Those who are science bound take three sciences together with mathematics, English and one other subject.

Assessment takes place internally for the award of sixth form certificate. However students are awarded these certificates based on a complex formula for moderation between schools. On the basis of the marks obtained by the students of particular school in the fifth form school certificate examination, the school is allowed to award a proportional number of certificates at various levels from one to six. At the end of form seven students can sit for a bursary examination. Admission to university depends on attaining a minimum grade in these examinations with various faculties setting their own minimum requirements depending on the demand and places available in various programs.

Factors Influencing the Need for Reform
In the education system prior to the reforms of the 1990’s a number of problems in science education had been identified.

1. The internationally recognized work of Roger Osborne from the University of Waikato on children’s learning in science classes (the Learning in Science Project) was widely disseminated. This work supported the growing misconceptions literature and gave further evidence of the need to ascertain children’s intuitive ideas before and during instruction.

2. As a result of the increase in unemployment, many more students were beginning to stay in school beyond the age of compulsory schooling. For many of these students the current science courses were inappropriate. The cognitive demands were often too high, students needed more motivating and encouraging, and many social issues raised as result of advances in science and technology were seldom addressed.

3. The school certificate examination in general science, say by most pupils at the end of form five, had been virtually unchanged for 20 years. The examination, for the most part, assessed knowledge of factual information. Students had the option, in some schools, of taking each of the three traditional sciences separately, but generally the pressures of time for other subjects precluded this. It was quite possible to do well on the examination without ever having completed any laboratory work. The examination tended to reward rote learning at the expense of genuine understanding and encouraged expository teaching.

4. Pressure from government and industry to produce scientifically literate high school graduates was increasing as it was for all students to take science at least to form five.

5. Pressure from Maori leaders to take account of Maori views of science and their science knowledge was mounting.

6. A considerable increase in the diversity of students’ cultural backgrounds, achievement levels and motivation, demanded new approaches to classroom practice.

7. For science education to begin in the primary schools, considerable teacher re-education was necessary for practicing teachers to upgrade their skills.
A New Science Curriculum
Under the strong influence of the findings of the Learning in Science Project and the constructivist viewpoint, a draft curriculum for science from entry to form five was produced in a short time by a team of 13 writers. One of these was from a university, three from colleges of education and the rest school teachers. That input from the universities was so meager, was a direct result of the perception that the university science faculties had dominated the high school curriculum for too long and were interested only in perpetuating a science methodology and content aimed at the pre-university student. An advisory group of 12 people commented on various stages of the drafts. However, these comments seem to have only been heeded when they supported the general philosophy that the writers espoused. Any dissension was apparently dismissed.

Within each of the six strands of the curriculum statement are eight levels with each level specifying four achievement objectives. These objectives are very broad and emphasize investigative skills. It is suggested that the learning should be contextual and sample contexts are given together with possible learning experiences. An instructional plan, consistent with these general objectives is devised by each school to respond to the needs of the students in that particular school. The whole document is a radical change from the prescriptive statements of the past. The draft statement was circulated to many interest groups to solicit reactions. Many school teachers applauded it, many scientists were appalled at the lack of conceptual framework, the missequencing of objectives and the unsuitability of objectives for various levels. As combination of post-modernism and constructivism lead to the notion that the understanding that the child builds for herself about the world as a result of observation and social interaction is as valid as any other understanding of the world including that of scientists, came in for a great deal of criticism. This prompted articles in the popular press, public meetings and seminars and which divided the educational community. Nevertheless the draft was approved and became the official curriculum with only minor changes.

The teaching methodology demands a more investigative approach than is current practice, requiring that teachers receive in-service training to upgrade their skills. This has been implemented through programs in which a facilitator (a teacher co-opted to the Advisory Service) works with a group of teachers in a cluster of schools over an extended period to support the teachers individually in their attempts to modify their teaching. It remains to be seen whether these interventions have any lasting effect.

Implementing the New Curriculum
Only very broad guidelines as what should be taught at each level are provided in the statement. This means that each school must develop its own instructional plans. A suggested contextual methodology may be recognized as relevant to students interests but encourages a fragmented accumulation of science knowledge rather than establishing the coherent framework of the conventional approach. While the larger, urban schools have several, experienced teachers in each science area who can work together to produce a coherent overall plan, this may be more problematic in the small school and with less experienced teaching staff. There is a need for greater formal lines of communication between teachers to share resource development. With the lack of prescription and consequent lack of uniformity in subject matter, there are few suitable texts. This means that teachers have the task of collating their own reading material and resources for each of their classes. While this enables teachers to adapt their teaching to local conditions and resources, it also puts an extra strain on teachers' preparation time. Instead of implementing the new curriculum on a one-year-at-a-time basis, the whole is being implemented simultaneously. This means that the instructional materials that may be suitable to say a fifth form class that is new to the investigative approach may not be suitable for a fifth form class that has been initiated into this form of learning in form three. This puts an extra burden of preparation on the teacher.

Summary
This paper has attempted to outline the developments in science education in New Zealand in response to research evidence and the requirements for universal science learning. A fundamental change in the philosophy and methodology of science teaching may produce a more scientifically literate citizenry. It remains to be seen if the lack of a coherent knowledge framework is disadvantageous to students who wish to pursue science at the tertiary level, and whether or not a constructivist approach does result in better fundamental understanding of science for the average student.

Science Education International, Vol. 5, No. 3 September 1994
SOME ISSUES AND PROBLEMS RELATED TO SCIENCE TEACHER EDUCATION PROGRAMS IN KOREA

Hae-Ae Seo
John Penick
University of Iowa

Introduction
The highly scientific-technological nature of Korean society requires quality science education in schools. Efforts have been undertaken to assure that science teacher education programs provide quality instruction in educating new science teachers in response to this need for better science education. Training effective science teachers is one of the most important steps for the improvement of science education. In Korea, science teacher education programs are designed to carry out the major role of training science teachers according to the Korean educational law.

However, research indicates that most teacher education institutions do not have an effective science teacher education program even though the Korean public continues to call for greater accountability from teacher educators, better quality of science instruction in schools, higher standards of the qualification of teachers and increased teacher competencies in order to improve science education in schools. If a science teacher education program is to meet these demands, as well as to maintain and improve the curriculum, specific attention must be paid to the professional needs and problems of science teacher education programs.

Science Teacher Education Programs in Korea
Three major programs in Korea educate middle and secondary school science teachers: (a) programs offered by teacher education institutions with the completion of bachelor degrees; (b) programs offered by non-teacher education institutions with professional education courses for the completion of bachelor degrees; and (c) program offered by graduate schools of education for the completion of a masters degree. In order to qualify as a middle or secondary science teacher, teacher trainees must complete more than 140 credit hours in the areas of general education (university studies), professional education, and a specialization in science as a field of study. In addition to these requirements, since 1991 teacher trainees must take an examination, administrated by the Ministry of Education, in order to be employed by schools. The examination is designed to improve the quality of teaching.

Issues Related to the Certification Processes
Lack of an exam to certify teachers' subject area competency led to many problems. The certification process with no examination allows anyone who completes the required credit hours in a teacher education institution to be a middle and secondary school science teacher. Park and Lim (1986) noted that teacher education programs did not have any system to differentiate the quality of certified middle and secondary school teachers. Kang and Lee (1987) pointed out that teacher education programs created a surplus of teachers by supporting the perception that anyone could be a teacher. In addition, the quality of teachers had become questionable.

In order to select better qualified teachers for schools, the new education law was established in 1991, requiring middle and secondary school teachers to take an examination to be employed. Lee (1991) summarized the functions of the new system of administrating an examination to certify teachers upon the completion of teacher education programs. First, the administration of an examination would ensure the quality of graduates of teacher education programs with no examination. Second, the procedure and content of the examination would influence the management and organization of the curriculum of teacher education programs. Third, the people's perception of teachers would be improve in terms of trust and respect.

However, the examination has often led preservice teachers to study and memorize rote knowledge in preparation for the examination. Park (1992) reported that some senior students in teacher education programs avoided attending classes, choosing to spend their time memorizing for the exam. Some teacher education institutions reduced the number of laboratory courses and offered a new course designed to prepare students for the examination. The new certification process with the examination raises problems in relation to the fundamental procedure and purpose of selecting better qualified teachers due to the fact that the organization and management of the examination were not carefully considered.

Issues Related to Curricular Characteristics
Although the number of required credit hours for graduation is 140, most teacher education institutions require more than 140 credit hours for the completion of the teacher education programs. While students are completing many courses, some feel this does not ensure their competence.
Jung (1991) claimed that there is no close relationship between the content of courses in the fields of study and the content of middle and secondary school science courses. The content of the courses in the fields of study needs to correspond to those of secondary school curriculum. Practicing secondary science teachers strongly expressed that they need to have a curriculum of interdisciplinary science courses (Soo, 1993). Professional education courses also are seen to provide any connection between educational theories and teaching in classroom. Lee (1991a) claimed that the content of these courses was often overlapped, too theory-oriented, and only partially organized, depending on the instructors’ major areas of research and interests. Students, not satisfied with these subjects, consider these courses as a waste of time. They view these courses as superficial credits for teacher certification.

Park (1984) surveyed instructors’ opinions on science teaching methods courses from 59 science education departments. He found that no instructor was satisfied with four credit hours for science teaching method courses and all proposed more credit hours. Seventy-one percent of instructors suggested that 10-14 credit hours were the most reasonable range for the courses. Moreover, instructors noted that problems included a shortage of teaching materials, minimal qualification of instructors, and poor facilities and financial support for research in science teaching methodology.

Kim and Kim (1989) analyzed the content of science teaching methods courses among 18 biology education departments. They found that only 40% of the content of the science teaching method course was related to teaching methods and the remaining 60% was related to learning biological knowledge. Thus, methods courses were, in many ways, content courses rather than methods courses. They concluded that concrete objectives and proper goals for science teaching method courses are badly needed.

For student teaching, Seok (1985) insisted that four-week student teaching was far too short for students to experience and understand teaching in any meaningful way. In addition to the short period of time, Jung (1991) stated that one of the most difficult problems was the insufficient number of middle and secondary schools to accommodate the preservice teachers. Because of this problem, several other difficulties arose in student teaching such as too many students in one middle and secondary school and too few opportunities to experience actual classroom teaching. Further, there was no close relationship between instructors supervising preservice students and practicing teachers supervising preservice teachers. The instructors at teacher education programs supervised preservice students by sending them to middle and secondary schools. On the other hand, practicing teachers at middle and secondary schools tended to be reluctant to let preservice students take over their classes because they took more time in teaching a certain content than practicing teachers did.

Issues Related to Instructional Characteristics
With respect to issues related to the instructional characteristics, the Association of Korean University Education (1988) stated: “The common instructional materials for science teacher education have been chalk, chalkboard, a textbook and the use of the lecture method. Various audio-visual materials, computer systems, books related to science education, development of textbooks, microteaching, development of module of experiments, planetarium, and a specimen room have not have been considered as related to classroom teaching in science teacher education programs. More surprisingly, such conditions of science teacher education programs have been naturally accepted as normal.”

Kwon (1991) found that the courses in science teaching methods in science teacher education programs are based upon theory-centered lecture methods. Science teacher educators usually gave theory-oriented lectures about inquiry teaching methods and other instructional approaches in the science teaching methods course. They teach far differently than they say teachers should. Little time was spent in developing preservice science teachers’ ability to actually practice or experience inquiry teaching methods. He noted that one of the important roles of science teachers in the classrooms is to facilitate students learning scientific knowledge through problem solving skills and scientific methods. The science teacher’s role in the classroom is not to help students to learn how to memorize scientific facts but to learn how to use and understand them. Thus, the course in science teaching methods should employ discussion-centered teaching in order to develop preservice teachers’ ability to practice different instructional approaches including inquiry and problem solving in their science classroom in schools.

Issues Related to Science Teacher Educators
In Korea, there is an extreme shortage of teacher educators who majored in science education and in science teacher education programs in Korea (Kim & Oh, 1991). In the early 1980s, only two of
174 faculty members in Korea had obtained doctoral degrees in the area of science education. Most science teacher educators in science education programs spent little time on research in science education and developing teaching materials. Rather they spent their time on conducting research in the areas of science, not science education. They lack science education background and this affects their ability to teach a science teaching method course and to supervise student teaching as well as their interests in science education as a discipline. Obviously, more professionally educated science educators are needed in Korea.

Conclusion
These issues and problems in teacher education programs in Korea deserve attention from science teacher educators, policy-makers, and administrators. Reform for these problems must be implemented at every level and in a significant fashion. We must see broad perspective in improving science teacher education programs in Korea while creating an agenda for discussions with science educators and related professionals around the world.

NARRATIVE AND SCIENTIFIC LITERACY

Dr. Paul Strube
University of South Australia

Abstract
Many current science curricula make specific demands on students for the achievement of some level of scientific literacy. The details of what this means, and how it is to be achieved, have often been left for the teacher to elaborate. This paper argues that narrative offers a structure that allows scientific concepts to be (1) more easily integrated into other conceptual understandings, and (2) more easily recalled.

Narrative Defined
What is narrative? Given the enormous literature that has arisen around this word and its place in human language and thought, a more appropriate question might be; what will narrative be taken to mean here? It is tempting to apply the word story as a working definition of narrative. But of course story itself is badly in need of more precision of definition, as well as conveying, perhaps unfortunately, a hint of something immature and unable to deal with the rigorous analytical and descriptive needs of science. Through the work of scholars of language, it has become clear that stories per se do not encompass or define what should be understood by the term narrative.

For our purposes, it is enough to adopt a common sense interpretation, and think of narrative as the telling of sequential events in a way that portrays a meaningful, coherent whole. It implies a teller, referred to from now on as a narrator, and a receiver, or narratee. It is familiar to us in the countless narratives we tell ourselves and others every day; how I lost and found the car keys; who I met at the dentist; how will I organise my next seminar; why did he look at me like that? Narratives are not bound by length, or time of telling, or skill of narrator.

Specific arguments for narrative
In what follows, two specific arguments for the usefulness of narrative in science education are presented. They are based on, firstly, considerations of curriculum integration, and secondly on the value of narrative for structuring curriculum content in the mind.

1. Curriculum Integration
For the purposes of this paper, let us assume that the various science curricula’s content satisfy contemporary demands for student exposure to current cultural concepts as these impinge on, or are influenced by science. It is argued here that these curricula lack a recognised integrating mechanism to bring about the anticipated and valued links between content in various curricula areas outside of science. Not surprisingly, I take the view that narrative, or more simplistically that literary form generally referred to as story, can provide such a mechanism.

In the past, there have been competing attempts to identify a skill, or theme, or process by which to braid into a single cable the separate strands of the curriculum. At one time ‘critical thinking’ was seen as the adhesive force; ‘Language Across the Curriculum’ (Marland, 1977) represented another attempt, one closer in principle to what is argued for here. These approaches rightly tried to find commonalities in the structures of the separate disciplines (i.e., they all are based on conceptual thought embedded in language), or in a skill that is seen to be useful in the analysis and evaluation of them all (i.e., problem solving or critical thinking). If narrative is to fare any better than these past efforts at playing such an integrating role, it must display some clear advantages. One such advantage it has at the outset is that it can, even with no stronger claims being made, prove valuable by contributing to meeting SACE demands for scientific literacy. A full analysis of the nature of scientific literacy is beyond the scope of this paper; suffice it to say that narrative may not only be a stepping stone to student competence with the formal language of science, but may indeed be the preferred mode of scientific language at the student level. Leaving that aside, what can narrative offer in terms of the science curricula?

One powerful argument in favour of narrative, suggesting that it is one of the wired-in, essential

Science Education International, Vol. 5, No. 3 September 1994
representatives of human thought itself, will not be examined here; reference can be made to the work of Hardy (1975) and Kerby (1991). Instead, the weaker claim is made that narrative allows easier transfer of knowledge across disciplines. That is, if the student has placed discipline knowledge, gained through the hard-won (and still contested) methodologies of that discipline, into a narrative structure that is personal and clear (to them as narrators, and clear to the narratees), then the narrative form itself will place that knowledge in such multiple contexts that it is no longer compartmentalised, but integrated. Put another way, the narrative structure can be seen to be similar to a concept map, but one that explicitly links disparate understandings into a coherent whole (that of the narrative) and values those links (because they form and allow narrative to occur). Narrative is thus seen, not as a common element of all discipline knowledge, nor as a skill that should be applied to them all, but as an adhesive force, a binding force, that brings diversity into coherence.

We are bound one to another by the narratives we share (and can share); the more narratives we have in common, the more tightly we are bound to the culture that contains such stories. If we increase the number of narratives we share, we increase our coherence between a wider range of cultural elements. Put in a specific context, to establish curricular coherence with science, students need to share in the stories about matter and energy and life that scientists tell each other. They can do so by reading the narratives directly in the research articles, of course, though this requires a degree of knowledge and experience with science that usually lies at the end of schooling. Or they can encounter such narratives through the work of the popularisers of science. Just as importantly, if not more so, students can also construct their own narratives in which science plays a natural, unforced, necessary role. It is in this second activity, as creators of narratives involving science, that the opportunity exists for them to use narrative to forge the links between disparate knowledge. Science concepts can take their place in the narrative alongside history (discipline or personal history), poetry, human relationships, political thinking, or whatever, simply because the narrative form is infinitely flexible and accommodating.

2. Narrative as a Pedagogic Tool

A second argument for the value of narrative in science education is based on the pedagogic value of narrative. In this view, narrative, by its very structure, places concepts in acceptable, easily assimilable and memorable form. Put simplistically, it suggests that what we encounter couched in narrative form, we remember. This view is argued for on at least two grounds.

First, the narrative format is one of great, if not universal, familiarity to all cultures. If someone from our Western culture states “Once upon a time...” we all know what is to come. We remember such narratives because they are couched in a format with which we are all familiar. The way the narrative is sequenced (from beginning to end) appears to permit if not actually demand easy recall; one event immediately suggests its successor. This sequential structure is familiar in many more artificial mnemonics, or aids to memory, where objects to be remembered are chained in the right sequence into an artificial story; as the story unfolds, the to-be-recalled objects appear on demand.

Second, sequence alone is not enough, of course. The narrative must not be so artificial that memorisation is by rote, as the Koran is chanted by those who speak no Islam. For it to be put in the personal, meaningful form, the narrative must also be couched in the appropriate language of the narrator. For readers of such narratives, it is a question of the selection of narratives written by others which do this most successfully, with the ultimate aim of being able to read narratives as found in the mature discipline. For the writers of such narratives, it is a question of finding ways of becoming more and more competent at the production of narratives that more fully reflect the scientists’ world views as well as maintaining personal connections to the knowledge. In other words, the narrative must be as true to actual science as possible while still being the student’s narrative; it must tell both the true story of matter and energy while fully representing the world of the narrator. If it does both, then it will be more fully present to the mind as an object of contemplation whenever desired.

Teaching Materials and Strategies

PRE-SCIENCE EXPERIENCE KIT (PEK)

Tushar Tamhane
Sanjeevan Vidyalaya Trust, PANCHGANI
Maharashtra, India

Abstract

Multi-sensory kits can be powerful scientific teaching aids. To help lower-primary children learn science concepts, a kit was developed along with a Cassette of rhymes. Five such hands-on activities using readily available materials were initially developed and tested. The activities were fun using toys that employed various science concepts and principles. The toys were made by the children themselves so that they could gain manipulative skills. After the activities, scientific hands-on experiences were reinforced through rhymes for which an audio cassette was prepared as an integral component of the kit. The children enjoyed the program and held favorable opinions about it. The kit is inexpensive, and for five activities the cost per kit is less than 20 cents U.S.

Introduction

There is no doubt that the education of young children should take into account their play tendencies but care must be taken that play activities should not stimulate interest and fun alone, rather the activities should lead to learning. The unstructured play activities must be extended to directed structured activities to induce learning. Furthermore, even new science concepts can be learned from rhymes.

Inexpensive and improvised toys not only provide children fun but give them hands-on experience in simple technology, design problems and aesthetics. The fun in learning provides freedom to the children to express themselves and such freedom is essential in the process of growing up. It was observed during the program that the make-yourself-toys with readily available materials, make children active participants in comprehending the functioning of the toy.

Education should afford young children opportunity for manipulation of materials and improvisations which implies avoiding that which is already ready made. In such a situation only the child’s experience can lead to self expression and encourages creativity. For this, as it was realized during the program that a teacher of young children has to be like a child in spirit and unsophisticated. This kind of mental make up of the teacher can draw out the best in a child.

The PEK program is based on the idea that children can learn science from simple toys made from discarded or inexpensive materials.

PEK encourages:
1. hands-on experience in making the toy (learning by doing).
2. free play with the toys as an unstructured activity.
3. investigation with the toys as structured activity.
4. reinforcement of scientific terms with rhymes.
5. providing each child a personalized inexpensive kit.

The main intention of developing the kit was to use it as a teaching-aid in popularizing science, particularly the basic knowledge of the physical world among children in the age group of 5 to 7 years of age. From a survey of folk toys the following five toys were identified for the trial phase.

<table>
<thead>
<tr>
<th>Toy</th>
<th>Materials</th>
<th>Related Concepts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Go-cart</td>
<td>Empty match box (1), Empty refills (2); Injection bottle rubber caps or buttons (4); needles or stiff wires (2); thread (1m)</td>
<td>Forces; motion; friction</td>
</tr>
<tr>
<td>Jerky-Perky</td>
<td>Empty refill (1); thick thread (1); cloth clip (1)</td>
<td>Types of motion; mechanical energy</td>
</tr>
<tr>
<td>Clapper</td>
<td>Cardboard pieces (4cm x 4cm); Rubber band (1)</td>
<td>Sound; transformation of energy</td>
</tr>
<tr>
<td>Paper pin-wheel</td>
<td>Stiff paper (10cm x 10cm, 1); Pin (1); Empty refill (1); reed or pencil (1)</td>
<td>Kinetic energy; work; non-conventional energy</td>
</tr>
<tr>
<td>Paper pressure-tube</td>
<td>Paper, foolscap (1)</td>
<td>Air exerts pressure; pressure gauge principle</td>
</tr>
</tbody>
</table>
The improvisations were carried out to make it feasible for children to assemble these toys without sacrificing quality.

The PEK was developed to impart basic science concept with the help of the toys which rural and semi-urban children generally make and play with. It has been observed that children play with such toys unconscious of the instructional potential of the toys as far as science principles and concepts are concerned.

**Components of the Kit**

The kit has four components which constitute the complete teaching-aid package as shown in the following table.

<table>
<thead>
<tr>
<th>Component</th>
<th>Brief Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hands-on Kit</td>
<td>This consists of an assorted collection of readily available materials in a shoe box to make five toys to impart hands-on experience on low level physics and technology.</td>
</tr>
<tr>
<td>Do-it-yourself instructional sheets</td>
<td>These activity sheets carry instruction for assembling the toys. These sheets are mainly for the teacher for demonstration of toys.</td>
</tr>
<tr>
<td>Sing-song Booklet</td>
<td>This booklet gives the words of rhymes on each of the five toys of the kit.</td>
</tr>
<tr>
<td>Audio-Tape</td>
<td>The audio cassette consists of the recorded rhymes sung by the students and teachers who were involved in the development and trial of the program.</td>
</tr>
</tbody>
</table>

A sample activity instruction sheet is as follows:

**Go-Cart**

1. Take an empty cigarette box and remove its inside foil.
2. Make two holes in each of the two long sides of the box, near the ends.
3. Pass stiff wires or thin round reeds through the holes to work as rolling axles.
4. Flatten the four crown caps to work as wheels.
5. Make holes in the center of each crown cap using thick nail, nut and hammer.
6. Take four pieces of bicycle valve-tubes nearly 3 to 5 cm. long.
7. From one end of the valve-tubes make it sharp by cutting it obliquely with scissors so that it passes half-way easily through the four crown caps (with holes in the center).
8. Attach the four wheels to the rolling axles neatly by inserting valve-tubes.
9. Tie a thread to the go-cart for pulling it.

**Additional Activities**

**Rhyming and Singing**

After the children have performed the activities and interacted with the teacher, the related science concepts, facts, terms, principles are reinforced through singing of rhymes and songs written by the members. To make the task easier, an audio-tape was produced. Care was taken to fashion the rhymes on the tunes of well-known nursery poems. As singing combines the fun with learning, the children are able to remember the concepts, terms and facts of basic science easily and relate them to the activities already performed by them in making the toys.

Below is a portion of the Go-Cart Rhyme.

**Go-Cart**

Make a go-cart just now,
Pull the go-cart just now,
Push the go-cart just now,
See the wheels roll just now,
See the go-cart move just now,
Remove its wheels just now,
Sliding is hard just now,
Fix the four wheels just now,
Rolling is easy just now

**Trialing**

One 40-minute period per day was given in the regular school time-table to each activity of the Pre-science Experience Kit as per the following schedule:

<table>
<thead>
<tr>
<th>Table II. Weekly Schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>First day</td>
</tr>
<tr>
<td>Second day</td>
</tr>
</tbody>
</table>
Third day  Structured activities with the students involving investigations and findings out.

Fourth day Discussion and ideas for further activities from the students.

Fifth day Feedback from students and any further improvisations with the toy.

Sixth day Singing of the rhyme based on the preparation and science concepts involved with the toy.

First, the pre-assembled toy was shown to the class and they were asked to identify its components and materials. Very enthusiastically, children started responding and then we went and collected things from the immediate surroundings.

Then with relevant instructions, they made individually the toy and played with it as they liked.

Later on some structured activities were performed with each toy. One example of the structured activities carried out by the children is as follows:

**Go-Cart**

Each child was allowed to run his toy down an inclined plane to find out which one goes farthest? They also measured the distance. This was followed by a discussion to find out the reasons for variation in the distance moved by the Go-carts as they rolled down the inclined plane.

**Children’s comments:**

* I liked my Go-cart because it moves. I can play with it and we can have a race.

* I can decorate it by using nice designs.

**Comments of the Team members:**

* During the development of the toys, I had a big question in my mind, could anything worthwhile be done through such inexpensive and throwaway materials? But while trying in the classroom situation, the overwhelming response of the children and the satisfaction the teacher had in the class, I realized the potential of such an exercise. I felt immensely happy to see the children enjoying and learning simultaneously.

* Holding the script, while working in the kitchen or drawing-room or during a walk made my mind like a tape-recorder playing tunes continuously. Some fitted in popular tunes without effort, though the original words had to be constantly changed to adjust the rhythm.

Next day when I hummed these songs in the class, children raised their eyebrows, gave a surprised grin and joined instantly. Well that worked!

### CALL FOR PAPERS

**NSTA 1996 INTERNATIONAL CONVENTION**

NSTA invites your proposals to present a session at its 1996 International Convention on Science and Science Education, to be held December 27-30, 1996 in San Francisco, USA.

The convention, to be chaired by NSTA Executive Director Bill G. Aldridge, will bring together scientists and K-college science educators from dozens of science and science education societies and organizations worldwide. Invitations have already been sent to societies in more than 30 countries. Holding the event in San Francisco, it is hoped, will especially encourage participation from Pacific Rim countries.

At this convention, participating teachers and science educators will present sessions in their areas of expertise (interdisciplinary approaches are encouraged) to scientists who are not as familiar with the classroom. In turn, scientists will present sessions about their work to nonspecialist scientists and to educators less familiar with the latest news from the research laboratory.

For proposal forms, contact NSTA 1996 International Convention on Science and Science Education, c/o Convention Office, NSTA, 1840 Wilson Blvd., Arlington, VA 22201. If your organization would like to participate, request details and deadlines regarding blocks of sessions.

Completed proposal forms due December 1, 1994.

Meeting space is limited, so proposals sent after the above deadline but before February 1, 1996, will be considered only if space is available.
The classroom: While researchers are debating the merits of all kinds of complicated teaching methods and many of us are discussing the lofty goals of project 2000+, I often visit classrooms (in the Netherlands and abroad) where very elementary things go wrong. For example, many students have not done their homework, teachers know little or nothing about the ideas (alternative conceptions) students bring to class, a whole period may be spent on laboratory work without a clear and articulated purpose, the crucial post-lab discussion on what we learned from the lab experiment rarely takes place (in my experience), pre-lab discussions on “what we want to find out” and brainstorm on “how could we” are rare, lessons are not being evaluated on effectiveness, little distinction is made between main objectives and irrelevant details, and sad but true, sometimes classroom discipline is absent and nothing is learned. Meanwhile the debates of researchers and policy makers continue, on the merits of constructivist teaching, on activity or laboratory based science teaching, on student-centered methods, etc. However, in many cases preconditions for the use of the “haute couture” of teaching methods are not being met.

The examples mentioned above, are rather trivial. It should be trivial that a teacher should evaluate the effectiveness of a lesson and monitor student understanding, yet frequently it does not happen. The many variables involved in teaching (20-40 students with their characteristics, curriculum demands, national exams, school policies and meetings, relationships with colleagues, etc.) easily distract the teacher from main goals and from the good teaching behavior which should be trivial.

Walberg (1991) has conducted nation-wide studies in the USA to find out which elements in teaching correlate with good student achievement. According to him successful teachers practice the following steps:
(b) daily review, homework check, and, if necessary reteaching;
(b) rapid presentation of new content and skills in small steps;
(c) guided student practice with close teacher monitoring;
(d) corrective feedback and instructional reinforcement;
(e) independent practice in seatwork and homework; and
(f) weekly and monthly review.

Other researchers of “effective teaching” have come to similar lists of elements of successful teaching.

Please note the emphasis on 1) student work and 2) teacher monitoring and feedback. So a decent part of the lesson (up to 50% ?) should be used for work by students while the teacher can go around and check on their progress and understanding, and find out whether homework has been done. This self work by students frequently gets replaced by more teacher monologue or it degenerates into student talk about “everything”. What is needed are meaningful (and motivating) tasks and exercises for students to do as work at home or in school and a teacher who is disciplined and has sufficient subject matter mastery and pedagogical skill to monitor student work. And not to forget, in many countries textbooks for students are the major (or even only) resource for doing their assignments. Is all this information new ? No, of course we knew this already. What did we learn then? That before we try to achieve difficult and risky changes in teaching methods used by teachers and curriculum goals (project 2000+), we better look whether the basics (student work and teacher feedback) still need to be improved. Also “modern” teaching methods and certainly constructivist methods will not work without these two elements.
Some interesting hints for student exercises are given in various publications of Nachtigall (1992). He distinguishes nine kinds of exercises for conceptual learning but I will only discuss a few:

1. **Explain in your own words the following terms ...**
   (just fill the new concepts you want to exercise).
   Realise that correcting an exercise like this can demand considerable subject matter mastery of teachers.

2. **Acceptable or not? Explain!** Here one could use statements produced by exercise 1 and have students decide whether they are acceptable for the scientist or not. One could also use statements from misconception tests.

5. **Solve problems** (just the common textbook problems). One could say this is exam training for typical exams. It could be made more meaningful by teaching some general problem solving behavior rather than only physics or chemistry, or math problem solving. For example, one could require students to always make a drawing or diagram of the problem, to **explore** the problem in different ways before starting to solve it. One could get students to make a prediction first of what could be a reasonable outcome. Then they could start solving the problem while at the end they would be asked to look at their result and decide whether it is **reasonable**.

6. **Write a summary of the lecture or chapter.**
   Students should learn to distinguish main points and minor points. Remember that the preparation of a “spiekpapier” (notes for cheating at an exam) was always a very good exercise as long as it was not used during the exam! So let them make it!

Now if student work and teacher monitoring and feedback are working well, and if other trivial elements of effective teaching are also in place, then we can move forward past the basics and get to the exciting stuff. For example, student investigations rather than “cookbook” worksheets, projects, etc.

**In-service teacher education:** In a review of research of in-service teacher education (in the USA) Joyce and Showers (1980) distinguish between “tuning (conventional) teaching skills” and “mastering new teaching strategies”. These conventional teaching skills could include: involving students more, asking more penetrating questions, managing logistics more efficiently, increase the clarity and vividness of presentations and illustrations, etc. The new teaching strategies could include switching to student-centered strategies or to constructivist teaching. The conclusion of Joyce and Showers is that learning new strategies (amongst others) requires considerable in-class coaching of the teacher and that often there is a dip in performance before the benefits of the new methods are realized. On the other hand, “fine tuning” of conventional strategies is a simpler and more evolutionary process with a better chance of success. Many preservice and inservice programs in high-income and low-income countries do not fulfill the condition of availability of expert in-class coaching.

In short, before promoting relatively large changes in teaching strategies, it would be wise to check whether preconditions for success have been fulfilled (coaching by expert teachers). Furthermore, it would be wise to seriously compare various alternatives for investment in improvement of quality. In low ranked schools (bottom 40-50%) in low-income countries provision of textbooks (1 textbook per 5 or 6 students is quite common) and training of teachers in how to use them (!), might pay off more than a complete switch to other teaching methods.

An alternative line of reasoning is that conventional teaching skills are basic tools for any kind of teaching, conventional and otherwise. So skills like explaining, asking questions, guiding discussion, blackboard writing, demonstrating, etc. will have to be trained in any teacher education program whether conventional or not.

Another reason for taking conventional teaching seriously in a teacher education program is that graduates need survival skills for their first years of teaching, to survive between colleagues and pupils. To survive new teachers need to be competent in the basics. The opportunities for innovation will only present themselves when the new teacher has shown competence in the basics. This may be even more true in low-income countries than in (perhaps) less hierarchical high-income countries.

In short (total duration 2 years) teacher education programs in Indonesia our colleagues and I focussed first on common conventional methods and trained students in improved versions of those (table 1). The
improvements we sought and trained were teacher-student interaction (including attention to student conceptions), more use of interactive demonstrations and other ways of making science "visible", frequent linking of school science with every day life examples in the local environment and technology. Furthermore we emphasized meaningful student assignments and exercises and proper teacher feedback. One of the demonstration methods we trained was the Predict-Observe-Explain (POE) demonstration type of White and Gunstone (1992). Many experiments for POE demonstrations were taken from a book with counterintuitive experiments which do not demand any extraordinary equipment (Liem 1987). Another type of demonstrations was using teaching aids or "making things visible" through the use of convenient objects (in mathematics and physics one can often take objects from the classroom or even student bodies to illustrate shapes, three dimensional relationships, or interactions between atoms). Yet another type was to explore a phenomenon (such as induction current) by investigating the influence of various factors (windings of coil, movement of magnet with respect to coil, etc.) through an interactive demonstration. One could call this "process" or "inquiry" demonstrations. Obviously such interactive demonstrations require good classroom discipline and an open atmosphere.

Science in science teacher education: Mastery of school science (and subject specific pedagogy) should be number one and is a prerequisite for almost all teaching skills (from preparing a lesson, writing test questions, to investigating student understanding). Knowledge of common student alternative conceptions by the lecturer may guide the teaching/remediation of school science in the pre-service program as well as in in-service programs! Research of alternative conceptions has shown very clearly for both low and high-income countries that students entering university only partially comprehend many of the school science concepts. Even after university science courses many alternative conceptions persist. Therefore a preservice program should contain courses on school science (Aarons, 1990; McDermott, 1990).

In teacher education school science should be remediated in such a way that it is not perceived as plain repeating of school science courses, so the teaching should clearly deviate from the dominant mode. This is a good opportunity to expose students to alternative teaching methods and/or to model the way pre-service students are expected to teach later on. Furthermore, courses on teaching methods can be used also to improve school science mastery. In micro-teaching lessons deficient subject matter mastery shows clearly.

In short, before promoting relatively large changes in teaching strategies and curriculum goals, let's check whether prerequisite science and teaching skills are mastered. If so, then we can move forward past the basics. If not, first things (basics) first.

Locally Produced Low Cost
EQUIPMENT FOR TEACHING OF CHEMISTRY
A monograph based on the work of the Edutronics Group, University of Delhi
Second Edition
K. V. Sane, University of Delhi
D. C. West, University of Mauritius

The monograph describes the fabrication, use and maintenance of three instruments (a pH meter, a conductometer and a colorimeter) having widespread utility for student level laboratory work in chemistry. Also described are the fabrication of two test instruments (a continuity tester and a OVA source which are useful either for trouble shooting or for calibration) and of several accessories like a magnetic stirrer, a zero-cost electrode for pH measurement, and a conductance cell. Brief theoretical sections in electronics and in chemistry are included to make the presentation self-contained. No previous experience in instrument fabrication is assumed; practical techniques like soldering, PCB making and circuit board assembly are consequently described in detail. The monograph is liberally illustrated and uses a highly visual style in which constant reference is made to the figures.

The equipment described in the monograph has been developed under the project entitled Low Cost Equipment For Chemical Education sponsored first by IUPAC CTC and UNESCO and then by the DST and by the UGC. Valuable assistance has also been received from IDRC, ICSU CTS, and from the Commonwealth Foundation. The immediate aim of the Project is to develop teaching-oriented instruments for chemistry which are simple, reliable, inexpensive, easy to fabricate, and easy to maintain. A wider aim is to influence the laboratory teaching by making it more purposeful, exciting and innovative. The know-how developed under the Project is, therefore, being disseminated through hands-on teacher training Workshops. Twenty-five such Workshops have been held outside India in every continent under the auspices of UNESCO while 35 Workshops have been organized all over India under the sponsorship of UGC.

The kits/equipment described in the monograph are being manufactured, under a DST License, by the Low-Cost Teaching Aid Charitable Society, 389/7 Dilkush Bagh, G. T. Karnal Road, Delhi-110033. The work-force of the Society—a Registered organization—consists of handicapped personnel and school dropouts trained by the Edutronics Group.

MOBILE MUSEUM LAUNCHED IN LUXEMBOURG

Children are discovering the world around them in an unusual way—inside a bus.

The new Musée Bus 2000, on show in the courtyard of the Foire International, made its first appearance in Troisvierges on 5 May. That a project under the auspices of the Ministry of Culture made its debut in a town so far from the capital is indicative of its purpose. The bus—which represents a 50 million franc investment—is designed to be a transportable laboratory, providing information about nature and science to people of all ages.

For many years, Luxembourg City's Museum of Natural History has offered guided tours of their exhibitions for school groups—but 43 communes out of the Grand Duchy’s 118 never took advantage of the offer simply because they were too far away from the capital city. It hardly made sense, for example, for a school in the far north of the country to take its students on a 90-minute journey to the museum for a two-hour tour, and then make another 90-minute journey back.

For this reason, the museum started taking exhibitions to various parts of the country a few years ago, but there were always the considerations of finding appropriate space for the displays and having to carefully transport the materials.

In 1991, following the examples of the 'Bibliobus' mobile library in Luxembourg and the 'Umweltmobil' environmental awareness bus in Schleswig-Holstein, the Ministry of Culture proposed the idea of a travelling museum of natural history.
The idea was approved, and the State provided roughly two-thirds of the needed funding—the rest came from private donators, Assurance Barthelemy, Eltrona diffusion, Electro-distribution Luxembourgeoise and the Enterprise Henri Bruch.

“The initial response to the bus has been very positive,” said Stéphane Risch, who is in charge of the project. “Children, in particular, are very interested in it, and if they are enthusiastic there will be a chain reaction—they will tell their parents and friends about it.”

Risch’s hope is that the bus—with its displays about different types of landscapes, animals, insects and plants—will educate both children and adults about the connection between their own lifestyles and the environment, and about the importance of preserving nature.

The mobile museum will tour schools free of charge and will be available for other interested groups for a small fee. The bus has space for 25 people at various work tables, has exhibition panels, stuffed birds and other animals, microscopes and binoculars.

Communes may hire the bus for cultural and educational activities, and clubs and other organisations may also rent the bus for a nominal fee. As the bus has just been launched exact prices and schedules have yet to be determined.

For more information, contact:  
Stéphane Risch  
Musée Bus 2000  
7, Rue De La Boucherie  
L-1247 Luxembourg  
46 76 60 or 47 93 30-249.

—Luxembourg News, 1994

The Musée Bus 2000 quickly turns into an interactive hands-on learning center.
Resources

RECENT ICASE PUBLICATIONS

The Status of Science-Technology-Society Education Worldwide

This 1992 ICASE Yearbook (140 pages), edited by Professor Bob Yager, University of Iowa, USA, has four sections: STS definition and rationale; Examples of STS initiatives; Evaluation of STS efforts; and STS in various countries.

Price—£5.00 ($8.00) plus 25% postage and packing.

Empirical Research in Chemistry and Physics Education

This book (195 pages) contains the papers presented in English at the biennial seminar on research in science education held in Dortmund, Germany, organised by Professor Dr. Hans-Jurgen Schmidt, in June 1992.

Price—£5.00 ($8.00) plus 25% postage and packing.

Sustainable Development for a New World Agenda

The World Environment, Energy and Economic Conference held in October 1990 in Winnipeg, Canada had as its main theme Sustainable development strategies and the new world order. The report of that meeting, with the main papers and discussion reports is now available as a major ICASE publication (250 pages), edited on behalf of ICASE by Professor John Penick, University of Iowa, USA. It contains a variety of viewpoints presented by specialists from many countries on the nature and complexity of problems associated with sustainable development and on educational strategies for introducing aspects of sustainable development into science curricula.

Price—£10.00 ($18.00) plus 25% postage and packing.

Education-Industry Partnerships

This is the report (125 pages) of the second ICASE European symposium, held in Arnhem, Netherlands in November 1992, on approaches to science education and industry liaison partnerships. The objective of the symposium was to strengthen the network of organisations and associations involved in industry-education links and to review the contribution of media and science centres towards the public understanding of industry and science.

Price—£5.00 ($8.00) plus 25% postage and packing.

Education in Science and Technology for Development

This is a report (260 pages) of a conference held in Trinidad in 1991 on the theme of science and technology education for development—perspectives for the 21st century. There are three sections: Issues in education; Curriculum and educational strategies; and Science and technology and education.

Price—£6.00 ($10.00) plus 25% postage and packing.

ICASE—The First 20 Years

This is the history of the first 20 years of ICASE from the beginning in 1973 until 1993.

Price—£5.00 ($8.00) plus 25% postage and packing.

ICASE Journal—Science Educational International

Published quarterly, the ICASE Journal is available at £10.00 ($17.50) per year for individual subscribers. Postage is included. The Journal has sections devoted to Science Technology and Society, Science Teacher Education, Primary Science and Research in Science Education, as well as feature articles and general news items.

Stepping into Science Newsletter

This is another quarterly publication from ICASE concerned with resource notes and practical ideas for primary school science. The annual cost of this is £5.00 ($8.00), including postage.

ICASE Publications may be obtained from the ICASE Treasurer, Knapp Hill, South Harting, Petersfield, GU31 5LR, UK.
POLLUTION PREVENTION
PROBLEMS AND SOLUTIONS

Edited by:
L. Theodore
Department of Chemical Engineering
Manhattan College, New York, USA

R. Dupont
Department of Civil and Environmental Engineering
Utah State University, USA

J. Reynolds
Department of Chemical Engineering
Manhattan College, New York, USA

Engineering and science professionals have studied the management of hazardous and toxic wastes extensively, and it is clear that the principal option of the future will be waste minimization, or pollution prevention. At present, however, few practicing professionals have a working understanding of this approach, educators are just starting to teach course material in this field, and students are finally beginning to receive the necessary training to implement pollution prevention in their future work environment.

An applications workbook of more than 100 exercises, Pollution Prevention: Problems and Solutions covers a variety of topics closely relevant to this field. The lessons are organized into the categories of basic concepts, pollution prevention principles, regulations, source reduction, recycling, treatment, chemical plant/domestic applications, case studies and ethics.

The workbook is the result of a National Science Foundation College Faculty Workshop designed to generate new ideas and innovative educative approaches in the emerging interdisciplinary field of pollution prevention. Therefore, teachers and students of undergraduate and graduate courses on waste management will find the book especially useful, but decision makers and practicing professionals in industry can also appreciate this effective learning tool.

Pollution Prevention: Problems and Solutions
Price: $40.00/£00
Postage and Packing (per copy) $5.00/£3.00

1994-1996

1994

September 17-19, 1994

Fourth Interdisciplinary General Conference of Teachers on: "Light in Teaching Science and Technology"
Location: Czestochowa

The Fourth Interdisciplinary General Conference of Teachers is devoted to the many aspects of light in teaching scientific and technical branches.

September 24-29, 1994

WOCATE Conference
Sponsored by the World Council of Associations for Technology Education
Location: the University of Banska Bystrica, Slovak Republic
Contact: WOCATE Secretariat, Mrs. Doris Traherth, Schlosserstrasse 9, 90084 Erfurt, Germany

The conference is meant to discuss various aspects of innovation, production, small scale industry management and education. Especially those projects developed by companies that bring technology education, economy and management closer to young people. The possibilities for transferring special experiences in school-industry-link projects will be discussed.

October 13-15, 1994

NSTA Fall Convention
Location: Portland, Oregon, USA

Contact: NSTA 1994 Area Conferences, ATTN: T. Brent, 1840 Wilson Blvd., Arlington, VA 22201-3000

November 3-5, 1994

NSTA Fall Convention
Location: Minneapolis, Minnesota, USA

December 6-10, 1994

The 9th ICASE Asian Symposium
Location: Bangkok, Thailand
Contact: Dr. Janchai Yingprayoon, Secretariat: IPST Sukhumvit Rd. Ekamai, Bangkok 10110 E-mail: OICST@CHULKN.CHULA.AC.TH

The theme of the symposium is "INCREASING THE EFFECTIVENESS OF SCIENCE TEACHING IN THE CLASSROOM: A CHALLENGE FOR SCIENTIFIC AND TECHNOLOGICAL LITERACY FOR ALL."

December 15-17, 1994

NSTA Fall Convention
Location: Las Vegas, Nevada, USA

1995

January 4, 1995

ASE/ICASE International Symposium
Location: The University of Lancaster, UK

This will be held in conjunction with the ASE annual meeting.

January 5th-7th, 1995

The Association for Science Education Annual Convention
Location: The University of Lancaster, UK (which is 200+ miles north of London)
Contact: Dr. David S. Moore, General Secretary, College Lane, Hatfield, Herts. AL10 9AA
March 22-April 2, 1995

**United States Science Education Tour**
Location: Philadelphia, PA; Baltimore, MD; and Washington, DC.
Contact: Dr. Jack Holbrook, Executive Secretary, 72B Blue Sea House, 28th October Street, Limassol, Cyprus

The tour will feature various levels of science education, school visits and home stays with American families. Three days of the tour will be spent at the National Science Teachers’ Association Convention in Philadelphia, PA.

March 23-26, 1995

**NSTA National Conference**
Location: Philadelphia, PA, USA
Contact: NSTA 1994 Area Conferences, ATTN: T. Brent, 1840 Wilson Blvd., Arlington, VA 22201-3000

March 27-29, 1995

**Science Education Research in Europe**
Location: The University of Leeds, UK
Organised jointly by The Centre for Educational Studies, King’s College, University of London and The Centre for Studies in Science and Mathematics Education, The University of Leeds

April 7-11, 1995

**Science Education Research in Europe**
Location: The University of Leeds, UK
Organised jointly by The Centre for Educational Studies, King’s College, University of London and The Centre for Studies in Science and Mathematics Education, The University of Leeds

April 22-25, 1995

**NARST International Conference**
Location: San Francisco, CA, USA

Late June/Early July 1995 (exact date to be announced)

Location: Johannesburg College of Education
Johannesburg, South Africa
Organised by the STEME (Science, Technology, Environment & Mathematics) EDUCATION ASSOCIATION on behalf of the FEDERATION OF SCIENCE & MATHEMATICS TEACHERS.
Contact: Dr. Peter Glover
PO Box 32198
Braamfontein 2017, Johannesburg, South Africa

August 27th-September 1st, 1995

**Partners in Chemical Education An International Conference on Industry-Education Initiatives in Chemistry**
Location: University of York, York, UK
Contact: Miranda Mapleton
Chemical Industry Education Centre, Department of Chemistry, University of York, York, YO1 5DD, UK
Co-Sponsors: International Union of Pure and Applied Chemistry (Committee on Teaching of Chemistry) and Royal Society of Chemistry (Education Division and Industrial Division)

August 29th–September 2nd, 1995

**The International Conference on Industry – Education Initiatives in Chemistry**
Location: University of York, York, UK
Organisers: IUPAC Committee on Teaching of Chemistry
The Royal Society of Chemistry
University of York

The first major international conference sponsored by IUPAC which specifically aims to promote links and dialogue between concerned industrialists and teachers from higher education, secondary and primary schools, and educational decision makers; and to evaluate and encourage good practice and discuss issues of industry – education collaboration. Correspondence/Conference arrangements:
Dr. J. F. Gibson
The Royal Society of Chemistry
Burlington House, Piccadilly
London WIV OBN
UK
Tel: +(44) (0) 71-437-8656
Fax: +(44) (0) 71-734-1227

September 4-15, 1995

**Fourth World Conference on Women**
Location: Beijing, China
Contact: Conference Secretariat: Division for the Advancement of Women, PO Box 500, A-1400 Vienna, Australia Tel: 431/21131, Ext. 4270;
This conference will:
1) review and appraise the advancement of women since 1985 in terms of the objectives of the Nairobi Forward-looking Strategies for the Advancement of Women to the Year 2000.
2) mobilize women and men at both the policy-making and grass-roots levels to achieve those objectives.
3) adopt a "Platform for Action," concentrating on some of the key issues identified as representing a fundamental obstacle to the advancement of the majority of women in the world. It will include elements relating to awareness-raising, decision-making, literacy, poverty, health, violence, national machinery, refugees and technology.
4) determine the priorities to be followed in 1996-2001 for implementation of the Strategies within the United Nations system.

September 24-29, 1995

CONASTA 44
Location: University of Queensland, Brisbane, Queensland, Australia
Contact: David Tulip, Centre for Mathematics and Science Education, Locked Bag No. 2, Red Hill, Queensland, Australia. E-mail: D.Tulip@qut.edu.au
Tel: +64 7 864 3345 or Fax: +64 7 864 3985.

While the conference program is not finalised at this stage, it is envisaged that it will include theme lectures, symposia based on science education and workshops either based on current science research or science classroom practices. All symposia and workshop sessions will allow for personal choice and will cater for Primary, Secondary and Tertiary science teachers and science teacher educators. Educational tours of the Great Barrier Reef, tropical and subtropical rainforest, whale watching and other unique geographical and biological features of Queensland, will also be offered three to seven days prior to or immediately following the conference. A detailed synopsis of the speakers, a framework of the conference activities and a call for abstracts of papers will be available by July 1994.

September 25-29, 1995

3rd European Conference on Research in Chemical Education
Location: Lublin (Poland)

Contact: Department of Chemical Education, Maria Curie-Sklodowska University, PL.M.C. Sklodowskiej 3, 20-031 Lublin, Poland, dr Ryszard M. JANIU LIK Tel: (81) 37-56-91 Fax: (81) 336-91 e-mail: JANIUK@PLUMCS11

The previous two conferences were held in Montpelier, France in 1992 and in Pisa, Italy in 1993. The next conferences are planned to be held every two years. The conference in 1997 will be held probably in UK. The organizers of the conference are the Federation of European Chemical Societies and the Chemical Society of the country in which the conference is held.

1996

March 28-31, 1996

NSA National Conference
Location: St. Louis, MO, USA

July 14-19, 1996

14th International Conference on Chemical Education
Location: Brisbane, Australia
Contact: The ICCE Conference Secretariat (Sally Brown), Continuing Professional Education, The University of Queensland 4072 Australia
Tel: (07) 365 6360 Intl: +61 7 365 6360 Fax: (07) 365 7099 Intl: +61 7 365 7099
E-mail: chemed96@ceu.uq.oz.au

The 14th ICCE will be held in Brisbane from July 14-19, 1996. It is only the second time this conference has been held in the southern hemisphere. The biennial conference brings together chemistry teachers, chemists and science educators from school, industry and university settings to share ideas and learn from one another about innovation in teaching and learning and the discipline of chemistry. The theme, Chemistry: Expanding the Boundaries, acknowledges the centrality of chemistry through its expanding relationship with many facets of science and everyday life. Conference participants will be challenged to develop this theme with the view of enhancing our understanding of the important relationships which chemistry forms with the new frontiers of human endeavour. Implications for chemical education beyond 2000 which give a "science for all" perspective will be encouraged.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

ICASE WELCOMES NEW MEMBERS

ESTONIAN ASSOCIATION OF CHEMISTRY TEACHERS

The Estonian Association of Chemistry Teachers (EACT), which began in the '70s, was created to facilitate annual meetings of chemistry teachers. Most of those annual meetings have been international, with participants from Russia, Latvia, Lithuania, Armenia, Finland, Sweden, Denmark, the Netherlands, and Germany.

Members of the EACT include chemistry teachers, university lecturers and education officials. The number of active members is approximately 100.

The aims of the EACT are as follows (from the statutes):

- to promote creativity and social activities of chemistry teachers;
- to collect and distribute the latest information on chemistry, teaching of chemistry, research work in the field of didactics of chemistry;
- to organize special culture—education seminars, exhibitions, etc., activities;
- to establish contacts between chemistry teachers and organizations, universities, companies and private persons in Estonia as well as abroad and promote co-operation;
- to assist members of the EACT with up-to-date teaching materials;
- to organize inservice training of chemistry teachers;
- to organize various economic activities, to support projects concerning improvement of chemistry teaching and their training;
- to protect the rights and interests of the members of the association.

Main Activities and Goals

EACT is looking for co-operation with the associations of science teachers of other countries. EACT welcomes other associations to participate in inservice training, seminars, introduction with Estonian industry, etc. We are planning to collect all kinds of publications in the field of science education.

EACT has published methodological collections for teachers and teaching materials for students.

One of the aims is to increase students’ interest in chemistry. Consequently, there is a club of young chemists which prepare performances for other schools (during the last two years there have been about 20 performances).

EACT has good contacts with the Finnish association of science teachers. Through cooperation with teachers from Vantaa (Finland), a joint seminar was organized in 1993. Teachers from Vantaa also participated in the summer camp for environmental research organized by students. The near future, we plan to organize national olympiade in chemistry for students where the level of the tasks enables students without special training to participate.

The members of EACT have organized for students different kinds of summer camps (in 1994 an environmental camp for students from three schools of Estonia was organized).

THE “SCIENCE TEACHER EDUCATION PARTNERSHIPS (STEP) CENTER”: AN INTRODUCTION AND OVERVIEW

Introduction

A proposal for the creation of a “Science Teacher Education Partnerships (STEP) Center” was prepared by M. O. Thirunarayanan, an assistant professor in the School of Education, and approved on September 21, 1993.
Major Goal of the STEP Center
The major goal of the STEP Center is to initiate and sustain mutually beneficial and long-term partnerships between the School of Education at Indiana University-Purdue University Fort Wayne (IPFW) and various formal and informal science education agencies such as the Fort Wayne Children’s Zoo, Science Central and school systems in Northeastern Indiana. The primary emphasis of such partnerships will be on the preservice and inservice education of science teachers.

Objectives of the STEP Center
The objectives of the STEP Center are as follows:

i) to provide a forum for the facilitation of partnerships between IPFW and various formal and informal science education agencies such as Fort Wayne Children’s Zoo, Science Central, school systems in Northeastern Indiana, and other appropriate agencies;

ii) to offer ongoing professional development opportunities for preservice and inservice science teachers; and

iii) to facilitate communication and interaction among various agencies involved in and interested in the preservice and inservice education of science teachers.

Activities of the STEP Center
In order to achieve its goals and objectives, the STEP Center will:

• Organize workshops and seminars for inservice and preservice science teachers on various topics related to science education (e.g., energy education, environmental education, hands-on approach to teaching science, authentic assessment, technology in science education, using toys to teach science);

• Arrange talks and presentations by visiting experts from other universities and by experienced master teachers;

• Publish a newsletter;

• Establish and maintain a collection of science education resources, such as books, CD-ROMs, computer software, films, interactive videodiscs, journals, kits, and videotapes;

• Create placement opportunities for preservice science teachers in museums, zoos and other informal science education agencies;

• Identify and provide job-shadowing opportunities for preservice science teachers in research laboratory settings;

• Conduct summer institutes and workshops for preservice and inservice science teachers;

• Organize special events such as conferences for inservice and preservice science teachers;

• Involve preservice and inservice science teachers in developing activities, lessons, units and other ideas for implementing the recommendations of the National Science Education Standards; and

• Establish and maintain an electronic bulletin board to facilitate communication among partners.

INTRODUCING ALMAWRID

The idea of establishing a center that facilitates the professional development of teachers has emerged as a reaction to the deteriorating educational situation and the general plunge in the quality of education in the West Bank. Almawrid Teacher Development Center was established to empower teachers to ameliorate the present educational situation, and to develop the educational system by making it more responsive to the needs of the Palestinian Community.

The Center believes that the teachers have to play a major and active role in developing the educational system, and that any steps towards improving this system would be unrealistic and futile if they ignore the teachers. Consequently, the Center has attempted to provide a suitable environment for teachers to meet, discuss problems, suggest and implement solutions and educational projects.

The Center focuses on activities that allow teachers to exchange knowledge and experience, to reflect collectively on their teaching practices, and to clarify, evaluate, test, and modify their beliefs. Consistent with this emphasis, the Center is organizing different workshops for the teachers of different school subjects.

During the academic year 1992/1993, teachers of mathematics have produced student worksheets, while English Language teachers produced a booklet for teachers that deals with pedagogical issues in
teaching English for fifth grade. Science teachers, on the other hand, produced a group of activities for teaching the topic of sound for grade nine.

During the academic year 1993/1994 ninth-grade teachers of science, mathematics, Arabic language, and social studies are meeting on a weekly basis to plan how to teach the newly introduced curricula in these subjects and evaluate the implementations. The Center provides to each group subject-matter and educational consultants. Courses for enhancing various teachers' competencies are offered at the Center. One of the most attractive courses has been a basic computer literacy course.

In addition to this, the Center has established a workshop and a library in order to provide the material resources teachers need. Teachers are allowed access to the workshop to produce instructional materials and to design school science experiments. The library is to be developed to hold subject-matter and educational books and references, school curricula from other countries, and video cassettes. Teachers are given borrowing privileges to most of the library materials.

Over the last year a significant number of teachers participated in the activities of the Center and used its facilities. This vindicates the philosophy of Almawrid and encourages the Center to continue and develop its work.

Post-Graduate Certificate of Education which leads to UK Qualification Status. Science Education Lecturers based in the Cecil Powell Centre teach the M.Ed. in Science Education programme which attracts students from overseas and at home and the Centre is also used by the Department of Continuing Education in the University for its science programmes.

The Centre for International Studies in Education was set up in 1989 as a development from the Centre for Overseas Studies in recognition of the long-established work in professional studies and research carried out in the School of Education for overseas governments and with overseas students. There is a strong programme of taught M.Ed. modules which focuses on development issues and the management of curricular and other changes and currently staffed from the Centre for International Studies, which includes those from the Cecil Powell Centre for Science Education, are undertaking work in 10 countries.

Both the Cecil Powell Centre and the Centre for International Studies welcome enquiries and visitors world-wide and are happy to discuss proposals for study and/or research. For further information, please contact:

THE CECIL POWELL CENTER FOR SCIENCE EDUCATION

AND

THE CENTRE FOR INTERNATIONAL STUDIES IN EDUCATION

The Cecil Powell Centre for Science Education is part of the School of Education in the University of Bristol, UK. Named after one of the University’s Nobel Laureates, it was established nearly 30 years ago to facilitate the education of science teachers, both preservice (initial teacher education) and inservice (professional development). Currently 60 science graduates are undertaking the

FOOD FOR THOUGHT
To Double Your Success
You Must Double Your Failures.
WORLD VIEW, CULTURE, AND SCIENCE EDUCATION

William W. Cobern, Ph.D.
Associate Professor of Science Education
Arizona State University West
Phoenix, Arizona

In the last few years many science education policy documents, including those from Project 2000+, have noted the need for further knowledge and understanding of how people individually and as members of social and cultural groups learn and teach science. To this end science educators have studied cognitive development and mental capacity. They have explored the effectiveness of various instructional strategies. Among other things they have investigated the errors students make. However, what students believe about the physical world, belief rooted and nurtured in students’ socio-cultural environments, has received far less attention. In a non-Western economically developing nation one speaks of traditional culture in contrast to the culture of science where educators understand that science is a second culture for students. In Western nations such as the USA science educators have long assumed that scientific explanation is a natural part of student culture. But this is not necessarily a wise assumption. Many Western societies are increasingly pluralistic. Moreover, not only is there widespread disinterest in science among Western students, there are several cultural subgroups traditionally under-represented in science. In the USA these include, for example, women, African-Americans, Hispanics, American Indians, and those who are religious conservatives.

Cultural Studies

Bearing in mind the significant differences between nations east and west, north and south, economically developed and developing, it is perhaps time for science educators to consider the possibility that science is a second culture experience for most students regardless of where they live. What I have set out below is a brief discussion of cultural research in science education based on a world view. The study of culture has typically been the bailiwick of the cultural anthropologist. However, scientists, historians, and literary critics among others, have in recent years joined the study of culture. What unifies these eclectic cultural scholars is that they “take a subject whose working assumptions are considered natural and attempt to demonstrate that they are culture-bound” (Heller, 1989, p. A8).

We live in a rich experiential world brought to us by our senses. But the data of our senses is an amorphous mass of confusion until interpreted by our world view. Sociologist Peter Berger (1979) argued that a people’s world view provides a special plausibility structure of ideas, activities and values which allows one to gauge the plausibility of any assertion. This shared world view is a fundamental aspect of any cultural group. In my view, science education has a cultural identity of its own, and teachers typically assume that students operate within the plausibility structure accompanying that identity (Cobern, 1991 & 1993a). The original notion of heretic was someone who decided things for himself instead of employing society’s plausibility structure or world view. I suspect that science classrooms are filled with heretics operating within other plausibility structures, and that many can be recognized by their alleged misconception.

Talk of misconceptions . . . carries with it the suggestion that something has been botched or bungled, or that something has gone amiss . . . And there is often the further implication that the student is the culprit: that he or she is the one who has gotten something wrong . . . There is more to error than meets the eye (Hills, 1989, p. 174).

Indeed, there is more than meets the eye. Young children in the classroom are in the process of world view and plausibility structure formation. What was long known about children in cultures outside the West is now being found to equally apply to children in countries like the USA; that is, that school does provide the principal, let alone the sole influence upon this formative process (e.g., Phelan, Davidson, & Cao, 1991).

Moreover, with young children one is not likely able to separate world view development from other aspects of conceptual development. World view theory supports those researchers whose interest is in the contexts of meaning in which children construct.
knowledge. Bloom (1989a) noted that, “children’s thinking is guided by an ever-changing variety of knowledge, frameworks of belief, mental processes, and emotions” (also see Bloom, 1989b). In the literature anthropocentrism, anthropomorphism, and zoomorphism have all been given as examples of children’s frameworks of belief. Science educators will likely find that these types of belief in children adumbrate world view presuppositions to come. In childhood however, it would be a mistake to see world view as a distinct conceptual development. Older children on the other hand come to class with well developed world views. These students enter the classroom with culturally validated ideas about the world. But again, the principal formative agent is not likely to be the school. Because the school is not the principal agent, educators tend to pejoratively label students’ views as misconceptions.

As noted by Smolich and Nunan (1975), Nadeau and Desautels (1984), and Duschl (1985), science education has long been dominated by a scientific perspective central to which is that science is above culture. Thus, the only concern of science with culture is that culture not hinder science. From this perspective, the first objective of science education is the elimination of all traditional thought that is deemed a hindrance to science, and of course, to replace that traditional thought with scientific thought. In other words, science education is quite imperialistic. The early work done on teaching for conceptual change, though probably unintentional, was based on this view. It was argued that conceptual change would take place when students saw that scientific explanations were superior to the untutored, commonsense beliefs brought by students to the classroom (Posner, Strike, Hewson, & Gertzog, 1982). Researchers quickly discovered that it is not that easy to demonstrate the superiority of scientific explanations. Conceptual change approaches tend to work best with students who already share the plausibility structure of the science teacher and the science textbook. It is ironic then that a frequently stated goal of science education is to develop a scientific outlook or scientific world view, for it seems to me that this goal is tacitly presupposed by much of science instruction.

Of late science education researchers have embraced constructivist ideas (Yager, 1993). Constructivist thought breaks with traditional science education thought in that science and culture are seen as inseparably linked. The constructivist view is that science always exists in a cultural context and that the cultural matrix of science education in which science is embedded may not be one widely shared by students. This does not mean that science is relative. Science content is science content regardless of culture to be sure, but not so with its communication nor the policies that support and direct science. In the jargon of education, there is always hidden curriculum and this raises three issues. The first is the frequently cited concern that traditional culture hinders science education. The second and third issues are much less discussed. While a traditional culture might hinder science education there is as well the potentially adverse influence of an alien hidden curriculum on the integrity of a traditional culture. Moreover, a hidden curriculum may in fact adversely influence science education among those who are alienated by the hidden curriculum.

I understand that culture changes. Any new idea brings change as people in a host environment react and adapt to new ideas. Modern science will influence a non-Western culture as surely as it has influenced and continues to influence Western culture. The concern is not cultural change per se, but unwarranted change. Must African nations, for example, adapt to science and adapt science to African culture exactly as the West had done? This concern arises first because relatively speaking modern science and science education are newly imported phenomenon in the cultures of most developing countries. And, science is indeed a powerful cultural force. Moreover, as educators around the globe adopt the Project 2000+ goal of scientific and technological for all, M. F. D Young’s (1976, p. 53) comment of seventeen years ago bears repeating:

school science separates science from pupils’ everyday lives, and in particular their non-school knowledge of the natural world. It is learnt primarily as a laboratory activity, in a room full of special rules, many of which have no real necessity except in terms of the social organization of the school.

And though Young wrote these words in 1976, recent work demonstrating the importance of everyday thinking (e.g., Cole, 1990) shows that the significance remains current. If science educators can come to a better understanding of the different everyday ways that people have of viewing the world and why they have those views, perhaps the structure of science education can be changed so that Young’s separation is closed.

To this end the following questions need to be addressed by science educators for the communities and societies in which they live.

1. What do students believe about the world around them, especially the physical world?
2. How do students understand their own place
in the world, especially their relationship to the physical world?

3. What is the cultural milieu in which these student beliefs, values, and relationships are grounded and supported?

4. What is the culture of science and how is that culture interpreted in the school science classroom?

5. What happens when student cultures, teacher culture, and the culture of science meet face to face in the classroom?

6. When science is resisted, is it the science people object to or is it the context of the science?

7. When pupils are influenced by science education, are they influenced solely by science? Or, are they influenced by science plus the context in which it is presented?

In other words, it is important for science educators to understand the fundamental, culturally based beliefs about the world that students bring to class, and how these beliefs are supported by students’ cultures; because, science education is successful only to the extent that science can find a niche in the cognitive and socio-cultural milieu of students.

World View Theory

World view, which offers one approach to these questions, is a concept borrowed from cultural anthropology. It refers to the culturally dependent, generally subconscious, fundamental organization of the mind. This conceptual organization manifests itself as a set of presuppositions which predispose one to feel, think, and act in predictable patterns.

Kearney (1984, p. 1) referred to world view as: culturally organized macrothought: those dynamically inter-related basic assumptions of a people that determine much of their behavior and decision making, as well as organizing much of their body of symbolic creations... and ethnosophology in general.

To be rational simply means to think and act with reason, to have an explanation or justification for thought and action. Such explanations and justifications ultimately rest upon one’s world view. Thus, world view is about epistemological levels antecedent to specific views that students hold about physical phenomena, whether one calls those views commonsense theories, alternative frameworks, misconceptions, or valid science.

In 1984, Brent Kilbourn pioneered the use of world view in empirical science education research by using Pepper’s (1940) root metaphor approach. More recently, logico-structuralism was adapted from cultural anthropology for use in science education research (Cobern, 1991). The power of the logico-structural model of world view lies in its composite structure of inter-related, universal categories: Self, Non-self, Classification, Relationship, Causality, Time and Space (Kearney, 1984). Each category is composed of logically related presuppositions. In principle groups of people and even individuals can be identified by world view variations which result from the content variation of categories. This composite nature of the logico-structural model focuses the researcher's attention on the complexity of world view, and yet the categories themselves provide access to that complexity. And while the composite nature of the model makes it less likely that the researcher will oversimplify the notion of world view, one can still speak of world view unity based on salient presuppositions within the seven universal categories.

In a recent study based on logico-structural theory, I investigated the contrasting conceptualizations of nature held by college biology professors and women students who were successful in the biology courses but were not science majors (Cobern, 1992 & 1993b). The study is an example of a different way of looking at students and teachers prompted by world view theory. In the study it was found that students and professors can be summed up with the phrase, depth versus breadth. In the research interviews the professors very quickly began to talk about nature in scientific terms and in quite some depth. In contrast, student conversation contained little science but ranged broadly over topics from religion to aesthetics to emotional states. It is not surprising that a biologist without any prompting would voluntarily choose to speak of nature in biological terms. Nevertheless, when laid side by side the difference between the student and professor conceptualizations of nature, one of breadth versus depth, is striking. One cannot help but wonder how such divergent viewpoints interact in the classroom and with what consequences. Of course, this is exactly the direction of future research (Cobern, 1992 & 1993b); and ultimately, the value of logico-structural world view theory in science education will rest on the fruitfulness of the research it precipitates, and the understanding of culture this research provides.

Classroom Application

The first thing for teachers to remember is that the interaction between culture and science education is rarely evident in a single teaching episode. It is an interaction that manifests itself over a period of time. It is not nearly so important to construct a culturally sensitive lesson as it is a culturally sensitive
curriculum. Therefore, over the course of a teaching year teachers need to find ways of encouraging their students to grapple with the problem of forming a culturally authentic view of science. My immediate suggestion is that teachers frequently ask of themselves the seven questions listed earlier. In so doing they will prompt themselves first to monitor the cultural appropriateness of their own instructions and second to monitor the opportunities they are affording their students to engage in a cultural dialogue with science.

DEFINING “INTERDISCIPLINARY”: CREATING AN EFFECTIVE TEAM FOR MIDDLE LEVEL INSTRUCTION

by

Laurie A. Hokom
Goodrich Middle School
Lincoln, Nebraska, 68521, USA

Introduction

I remember when I realized that “real” learning wasn’t necessarily about what I read in textbooks or observed in a classroom. I was in the sixth grade at the time, and the high school science club was going to take my class to a local campground to help us learn about science in our world. I couldn’t really fathom that high school kids knew as much as Mrs. Shea, my teacher—at least in science.

Science was what happened in Mrs. Shea’s room. Hadn’t we already learned about rats by raising one? Learned about plants by growing them? Learned about crystals by providing conditions so that they could form? What could high school kids possibly teach me about science?

My friends and I were nonetheless excited about the whole concept when we jumped off the bus. Not particularly about science, mind you, but there were other factors. No classrooms. Mud. Cute high school boys. Canoes. Bunkbeds. Dumb sixth grade boys. Above all else, this was going to be fun. We were going to have An Experience.

Now, almost fourteen years later, I mainly remember that they did have something to teach me. I do remember the high school kids getting in trouble for running off somewhere during the campfire, but I remember being amazed at the little organisms swimming around in pond water, that a blackbird compared to a black bird with an orange swish are not the same, that moss has a tendency to grow on one side of a tree more than another, that I could write poetry about insects, that I could imagine how it would be if I were a pioneer traveling without a compass, and on and on.

I also remember that in high school I signed up for science club because I knew that I could teach sixth graders something about science that maybe Mrs. Shea’s classroom couldn’t. Looking back, I remember the countless hours spent after school planning and creating with fifty other students to make sure the two days had something for everybody, including us (since we were in charge of it). And including science.

If nothing else, I learned about science then, too. But this time I realized that science worked with a whole bunch of areas. Science was found in the kitchen with why yeast is important and how it rises. Physics and physical education were found standing up in (and falling out of) a canoe of water. Anatomy and mathematics and linguistics were combined when we tried to guess how many more giant marshmallows Mrs. Sykes and Stuart Zetterman could each stuff into their mouths while trying to say “fuzzy bunnies.” Science was found with English and music in the songs and stories shared around the campfire. Astronomy was linked to English again as we struggled to find different mythological creatures in the stars. And on and on.

What brought these memories back was that, as a teacher of middle level students, I am in the process of trying to make my curricula as dynamic as possible, and I believe that means I need to apply it to the real world. The problem is that seldom is the world divided into neat curricular areas. I started thinking that some of the things I wanted to try overlapped with other subjects taught in isolation at my school. What I am interested in is making my teaching more integrated for my students to learn, retain, and apply to their own lives.

In the reformation of middle level schools, there are several key components, one being interdisciplinary education. Indeed, as Roberts (1993) states, “At no other level of the student’s development nor in the organization of schooling is the concept of holistic and interdisciplinary learning more likely to take root and flourish” (p. 39). Since the focus of the middle school education is on students, the interdisciplinary approach is a convenient way to make the middle level program match students’ needs (Roberts, 1993).

How schools and educators define “interdisciplinary” will ultimately show the extent to which they implement the interdisciplinary approach. According to Webster’s Ninth New Collegiate Dictionary (1987), interdisciplinary is defined as “involving two or more academic, scientific, or artistic disciplines” (p. 630). One step above this is interdisciplinary instruction, commonly referred to as IDI, which Mitman and Lambert (1993) define as a type of teaching which “demonstrates relationships...
between two or more disciplines so as to foster student understanding of important problems, issues, or themes" (p. 510). Finally, Mac Iver and Epstein (1993) define interdisciplinary teams as “composed of colleagues who teach different subjects to the same group of students” (p. 526).

Not all educators have come to an agreement on the definitions of the above descriptors, which may be a reason that the interdisciplinary approach is constantly under scrutiny and may also be a reason that there is such a lack of research on which disciplines constitute effective interdisciplinary teams at the middle level (Plodzik & George, 1989).

Teams are one way to implement the interdisciplinary approach, but how and why these are organized should be a concern for the total staff as well as the community. Most frequently, teams consist of four core teachers—social studies, English, science, and mathematics, although teams may range from two to five teachers in a variety of subjects (Mac Iver & Epstein, 1993; Vars, 1987).

There are natural links between core subjects to which interdisciplinary teams address, but these core teams often overlook courses essential to middle level philosophy: the exploratories. By laying other departmentalized subjects next to the core, certain links also appear. Art, computers, business, foreign language, technology, and health are a few areas that can easily integrate with the core areas. Even Erb (1991) states, “The curriculum should not be organized around basic and exploratory classes but around the notion that the common core, exploration and special interests should be integrated into every aspect of the middle grades program” (p. 26).

**Effects of interdisciplinary teams**

By examining problematic or controversial topics which are meaningful to students, teachers are “expected to help students make wise decisions in these crucial matters based on thoughtful examination of the alternatives and their consequences” (Vars, 1987, p. 16). When departmentalized teachers are expected to do this by themselves with many students, they may end up feeling frustrated. Thus the teaming component comes into play with middle level philosophy. When a group of teachers share common students, they can work together to create measures and alternatives which are in the best interest of the student.

What does all of this mean for the structure of effective middle schools? Research has shown benefits for interdisciplinary teams and also pointed out the drawbacks of only using core interdisciplinary teams. Going back to the premise that the interdisciplinary approach is only one way of looking at middle level instruction instead of the only way, what are characteristics of effective teams—teams which go beyond core studies?

**Characteristics of effective middle level interdisciplinary teams.** Unfortunately, there is a lack of research specifically directed toward middle level education as to which subjects (or if all subjects) constitute an effective interdisciplinary team. There tends to be more literature addressing problems with creating effective teams.

According to Mitman and Lambert’s (1993) study, teachers identified seven main obstacles in their development of interdisciplinary curricula which had direct impact on team effectiveness: lack of plan time, scarcity of materials, difficulties in sequencing and timing of units, relating themes to more than two disciplines, poor participation, lack of principal monitoring, and lack of teacher self-evaluation.

However, one key report by Plodzik and George (1989) determined the level of development of seventh grade interdisciplinary teams in New England middle schools. Principals of 159 out of 311 middle schools in six states completed questionnaires which indicated the presence or absence of 28 team behaviors associated with George’s Four Phase Model.

Seventy percent of the principals stated interdisciplinary team organization existed in their schools. Actual composition of those teams was not given, but as a whole, the teams had a median of four teachers. Following the sample study, telephone interviews were conducted with 20 principals as to what factors contributed to their effective teams. Flexibility, academic strength, desire to be a team member, and knowledge of the middle school child were all significant characteristics of middle level teachers influencing team growth. Common plan-time, clearly-stated expectations by the administration, and team building strategies were other factors in aiding effective teams.

What this study meant for middle level was a validation of literature dealing with opinions and generalizations by middle level theorists and practitioners (Clark & Clark, 1987; Vars, 1987) because “the confusion for the middle school teaching team often occurs over just what our stuff is. Is it students? Is it discipline-based knowledge? Is it both or something else altogether? We must learn to dialogue in such a way that our stuff becomes explicit, agreed upon. It is not enough to build interdisciplinary teams because the current descriptions of middle schools all call for them; we have to know what the stuff of those teams is” (Kain, 1993, p. 29).
The whole idea of an effective interdisciplinary team is working together to create the links of education appropriate for students’ needs. Yet few middle level teachers have been specifically prepared for interdisciplinary planning and teaching (Vars, 1987). Mitman and Lambert (1993) elaborated Vars’ point by stating, “Indeed, across-subject teacher teams are often organized as a first step towards facilitating interdisciplinary instruction, although the existence of teacher teams is no guarantee that meaningful connections across disciplines will be designed” (p. 510).

Since teams can only be as effective as the people who work on them, who is on the team becomes an important issue in effectiveness (Arhar, Johnston & Markle, 1989). Maeroff (1993) goes forward with that thought by saying, “At a time when schools are replete with talk of cooperative learning—an approach that calls for teachers to teach groups of students collaborate in their learning—there is no concomitant move to encourage collaboration among professionals” (p. 514). Therefore, it really doesn’t matter which subjects are represented on a team. What is more important is that “teaming needs support of teachers, so involve teachers carefully. Use core teachers, elective teachers, and school staff in the selection and development process to enhance communication and articulation of expectations” (Smith, 1991, p. 21).

Clark and Clark (1987) caution about including too many people on a team due to more difficult management, planning, scheduling, grouping, integration, and facilities use. They also warn that “team members should not expect to integrate all the concepts in the respective subject areas. Rather, team members should examine the content and look at areas that are easily integrated” (p. 2).

Conclusions

There are many ways of organizing the interdisciplinary approach. Ideally all subject areas (including exploratories) should integrate to make related learning that is appropriate for the middle level student. However, there are numerous factors that hamper the formation of such a team. Furthermore, educators need to come to a consensus on a specific definition for the interdisciplinary approach so primary, middle, and high schools can easily identify and relate to the concept without confusing other approaches with which they are more familiar.

Secondly, making connections for middle level students is a vital part of middle level education and the interdisciplinary approach can be one exciting way to meet this goal. By asking students to evaluate an interdisciplinary unit for the benefit of others gives the student a sense of power as well as allowing the students to help in planning the unit is currently a little used strategy. Teachers and students can attain benefits from an interdisciplinary approach, but it does not necessarily benefit all students, and teachers must really communicate and cooperate to attain theirs.

Next, administrators who may have inadvertently formed teams based solely on core subjects may want to evaluate teams to see how effective they are for students’ needs. Furthermore, efforts should be made to explore options for other types of teams as well as departmentalized instruction for all interested teachers. While problems with scheduling a common plan time might hamper a team’s effectiveness, other factors are also involved and both the team and the administrator should be aware of these in order to keep a good team strong.

Finally, the serious lack of research dealing with effective interdisciplinary middle level teams and their effects of students needs to be addressed. Organization, implementation, and evaluation of teams by teams can be as invaluable to the entire school as to the middle level reform movement. For now, the interdisciplinary team approach must be given time and commitment in order to see the overall effects and possibilities it has for learners.

There is no answer based on the research as to why exploratory teachers are not included on core teams. Several reasons have been alluded to this question, but no studies have pursued this specific question. By researching this area, perhaps more insight would be gained about the interdisciplinary approach as a whole.

**DISCREPANT EVENTS**

Ed van den Berg

The June 1994 issue of Science Education International contained an interesting article on discrepant events by Gvindarajan and Wright. I would just like to list two additional resources for using discrepant events in teaching:

a) *Invitations to Science Inquiry* is a book containing instructions for over 400 discrepant event demonstrations most of which do not require any special science equipment. I have used earlier editions of this book for 14 years in Indonesia and in the Netherlands in science courses as well as pre-service and in-service teacher education. Our teacher education students in Indonesia used the book as a resource for microteaching assignments and practice teaching in the schools, even though usually they avoided English language books. We did provide special training in the use of discrepant events in one of our teaching methods courses. The book also constitutes a popular resource for in-service activities. Most demonstrations concern junior and senior high school physics and chemistry. There are some big demonstrations for Earth Science and Biology. Complete information for ordering is as follows:

T. L. Liem: *Invitations to Science Inquiry* (2nd edition). Published by Science Inquiry Enterprises, 14358 Village View Lane, Chino Hills, California 91709 (telephone: 909-590-4618). The book is also available through the National Science Teachers Association in Washington. The list price is $45.00, however, discounts for bulk orders and for orders from developing countries seem to be possible. The ISBN number is 1-878106-21-X.

b) A chapter in the book *Probing Understanding* by Richard White and Richard Gunstone gives excellent suggestions for when and how to use discrepant events in teaching (called Predict-Observe-Explain demonstrations). The book is an excellent resource for courses in teaching methods with various techniques to probe the understanding of students such as concept maps, interviews and how to analyse them, student drawings, etc. I use the books as a graduation present for my teacher education students. However, I give the book long before graduation so we can still use it during the teaching practice. The complete reference for ordering is:

INTEGRATED SCIENCE TEACHER EDUCATION IN NIGERIA: HOW EFFECTIVE IS IT?

Sunday N. Wuye*
Science Education, University of Jos Plateau State, Nigeria

Dr. Anthony D. Turner
Science Education Department, Institute of Education
University of London, London, WC1

Abstract
This paper, the first of two papers, seeks to describe the background of and research into integrated science teacher education in Nigeria and to compare the teacher training programs with the practice in schools. The paper describes, too, the development of integrated science curriculum in schools and how pupils and teachers have responded to it. It goes on to identify the need for research into the match between teacher training and curriculum demand in integrated science in Nigerian schools. By means of questionnaires and interviews in schools, colleges and universities, data have been collected which describes the views and practices of teacher trainers, classroom teachers and student teachers in some Nigerian institutions. This paper concludes by summarizing the research methods.

Introduction
The wind of change of science curriculum reform that blew across the world in the '60s and '70s, particularly in the area of developing new and suitable science curricula for the primary schools and junior classes of the secondary schools, led to the emergence of the Nigerian Integrated Science Project (NISP). The Science Teachers Association of Nigeria (STAN), which spear-headed the science education curriculum reforms in Nigeria, of which the NISP is one, developed the first version of integrated science curriculum for the first two years of the secondary school education in Nigeria. The NISP was concerned with the teaching of science through inquiry and discovery approach in which the students come to understand and develop science concepts by investigating and experimenting on their own.

This effort by the Science Teachers Association of Nigeria in integrated science assumed a national significance in the '80s when, with the introduction of the new age phases in the education system (6-3-3-4 system), the Federal Government produced a national core curriculum in integrated science. In accordance with the National Policy on Education (1981), which stipulates that science should be one of the core subjects taught in the three-year junior secondary school (JSS) education, the core curriculum in integrated science is presently being implemented as the compulsory core science subject in the JSS (ages 12-14) in Nigeria. The integrated science core curriculum was, among other objectives, introduced with the aim of laying an adequate science foundation in pupils. This is hoped to enhance and encourage their choice of further studies of specialized science subjects and science related careers.

Trends in integrated science teaching in Nigeria
Despite the well-defined objectives that underscored the introduction of integrated science into the school curriculum in Nigeria, such process was not accompanied by any specifically well-defined teacher education program to support its effective implementation. Even after about a decade of introducing the new curriculum into the classroom, apart from the simple methodological attention given pedagogical courses of science education to undergraduate students, there was no traces of appropriate and specific certificate courses for integrated science teaching in teacher training institutions (Jegede, 1981). Teachers with qualification in single science subjects and/or some elementary science background constituted the support for its teaching.
Further research studies carried out to evaluate the progress and influences of integrated science in school pupils such as their attitudes towards the subject, cognitive achievement and their choice of science and science-related careers, were carried out by a number of science educators (Odubunmi, 1981; Mani, 1981; Bajah, 1982; Olarinoye, 1983; Akinmade, 1988; Jegede, 1983; Maduabum, 1990). The results revealed, among other things, that pupils taught integrated science were not performing up to standards. This is to say that the objectives of the course were not being attained. In respect of the pupils choice of careers, evidences abound that students’ enrollment in science and science-related careers were still on the decline (Ajakaiye, 1989). A number of factors such as the lack of or poor infrastructural facilities (laboratory building and equipment), low readability of the curriculum materials, scarcity of well-qualified teachers were listed as principal contributors to this unsatisfactory condition. On the performances of integrated science teachers in particular, Maduabum (1990) observed “much of what passes for integrated science teaching at our Junior Secondary Schools today is far from being satisfactory thereby raising serious doubt about the accomplishment of the objective of the programme.” In terms of adequate number of qualified integrated science teachers teaching the subject in the classroom today, Maduabum (1990), Nkpa, (1991), Ikeobi, (1991) observed that a majority are not qualified and competent. Maduabum particularly described the whole lot of the integrated science teaching force in the words of Coombs (1968) as “enough willing warm bodies to keep order in the classroom.”

The teacher factor pointing to the dearth of relevantly trained teachers of integrated science has become a major concern in the attempt to correct the imbalance.

**Teacher Training**

To meet the challenge of teacher education and relieve the acute shortage of teachers for integrated science teaching in Nigeria, some universities and colleges of education began to introduce preservice teacher education courses in integrated science by the mid- and late 1980s. These initial efforts by some colleges and universities were as a response to their own internally identified needs. The teacher training curricula, therefore, were as diverse as the number of institutions offering the training. However, the training curricula in the colleges of education were largely influenced or exclusively reflecting those of their universities of affiliation who were responsible for moderating their academic standards and certification.

Since the late 1980s, the number of universities in Nigeria introducing degree and other forms of certificate courses in integrated science teacher education have been on the increase. These trainings cover preservice, inservice and further training for integrated science teaching. Furthermore, the National Commission for Colleges of Education (NCCE) has, by 1992, introduced into all colleges of education in the country a national core curriculum for integrated science preservice teacher training. The implementation of this new core curriculum comes under a project: “The Nigerian Integrated Science Teacher Education Project” (NISTEP). The Nigerian Integrated Science Teacher Education Project was, until 1992, exclusively based in Ahmadu Bello University, Zaria and her affiliated colleges of education spread within the Northern part of the country. This university and three of her affiliated colleges were among the sample institutions for this research.

**Purpose Of Research**

The purpose of the research described here is to survey preservice teacher education for integrated science in Nigeria, with the aim of establishing its characteristics, quality and appropriateness of the training in fitting the teachers to their job. There is no evidence in the science education literature of studies which examine the substance of integrated science preservice teacher education in Nigeria. Rather most of the studies focused on teacher qualification and competence, readability of pupils’ and teachers’ text materials, teachers’ interpretation of the curriculum, pupils’ cognitive and affective achievement, laboratory facilities, classroom teachers’ perceptions and classroom interaction patterns (Jegede, 1981; Bajah, 1982; Bomide, 1983; Onocha & Okpala, 1990; Maduabum 1990; Nkpa, 1991).

This study specifically sought to determine: (a) the efforts and characteristic features of the preservice teacher training; (b) the relevance and usefulness of the teacher education program for integrated science students for their role in schools, bearing in mind the background of the students entering the program; (c) the concepts of integration implied and reflected in both the junior secondary school national core curriculum for integrated science and in the curriculum for preservice teacher education; further to compare and contrast the views found; (d) the perception of “integration of science” in schools held by practicing integrated science teachers, student teachers and the teacher trainers; and (e) to compare and contrast their views, particularly in areas of agreement and areas of discord.
Method, Instrumentation and Data Analysis

It was decided to study the integrated science teacher training program in two universities and those of their affiliate colleges of education. By means of questionnaires and interviews with staff and students in the two universities and their six affiliate colleges of education, data have been collected from the respondents in these institutions. Four categories of respondents-Integrated Science Course Coordinators; Teacher Trainers and Student Teachers (all from the sampled teacher training institutions) and Practicing Classroom Teachers of integrated science (from the secondary schools), responded to the questionnaires and interviews.

The questionnaires and interviews were administered personally and sought such information as: the respondent’s background and general information, the teaching of integrated science in schools, the substance of the preservice teacher training, perception of the meaning of integration in science and relevant issues for integrated science teacher education in Nigeria.

The field work was undertaken in Nigeria for a period of six months and data was obtained from a total of 263 respondents. The data is presently being analyzed and details would follow in subsequent publications. However, further inquiry in respect of this research can be directed to the London address above.

A CHILEAN APPROACH TO PREPARING SECONDARY SCHOOL SCIENCE TEACHERS

Mercedes Salfate, Bradford School & Ramon Espinoza
Universidad Metropolitana de Ciencias de la Educacion
Santiago, Chile

Philip R. Pankiewicz, Director
Secondary Science Education
State University of New York College at Cortland

The Universidad Metropolitana de Ciencias de la Educacion (UMCE) in Santiago together with the Universidad de Ciencias de la Educacion Playa Ancha (UPLACED) in Valparaiso are the two major institutes preparing Chilean science teachers. Until rather recently, both had prepared science teachers in a fairly traditional manner, but since 1989 the Metropolitan University of Educational Sciences has embarked upon a new program to license science teachers and award them a Teachers’ Diploma. The following is a brief description of that program:

The UMCE program, devised after examining many national and international teacher preparation programs, involves students in three major areas:

1. General Pedagogy, which embraces about 30% of the total teacher education curriculum. This area includes Fundamentals of Education up to the theories and methods of science education.

2. Subject Matter (Biology, Chemistry, Physics, or the Natural Sciences), taking 60% of the overall schedule and intended to provide future secondary teachers with basic and updated principles in their major discipline.

3. A specialized Pedagogical Area combining General pedagogy with Subject Matter. This portion includes Technological Didactics, Teaching Methodology, and Educational Research.

This portion of the program lasts eight semesters (four years) and leads to the Licenciatura degree. Table 1 shows the required courses for the eight semester program.

After completing the Licenciatura degree, students continue at the University to obtain a Teacher’s Diploma. This one to two-year program involves practical experience and the writing of a thesis or dissertation. Table 2 shows a typical 9th and 10th semester sequence. The writing of a thesis or dissertation usually extends beyond the 10th semester.

Science Education International, Vol. 5, No. 4 December 1994
Advantages of the Metropolitan Preservice Program

The metropolitan program for preparing science teachers provides preservice teachers with courses and skills that are sometimes missing from other programs. One key component is the 7th semester Educational Statistics course. This course introduces students to the value of using educational statistics in doing educational research. The course is followed by a seminar in educational research. This course builds upon the statistics course and students are exposed to the reading of science literature and the application of this knowledge to their own scientific research. The Metropolitan University plan is certainly worth considering as one alternative to preparing more effective science teachers.

LOOKING FOR ACADEMICALLY SUPERIOR INTERNATIONAL STUDENTS

The National Youth Leadership Forum on Medicine, a nonprofit educational organization founded to help better prepare secondary school students for their future professional careers, is planning eight intensive eleven-day programs to be conducted in Boston, MA, Houston, TX, San Francisco, CA, and Washington, DC during the summer of 1995 for students who demonstrate an interest in medicine. This is the first time that international students have been invited. The goals of the forum are threefold: to educate, to inspire and to motivate.

As one of the 1994 students said, "The conference made me want to be a doctor even more. It's wonderful to be able to change people's lives for the better. I've learned that being a good doctor is not something you learn from books but by caring and knowing about your patients."

The National Youth Leadership Forum on medicine is conducted in close cooperation with internationally recognized physicians and health care professionals from some of the United State's most prestigious and technologically advanced hospitals, research facilities, and medical schools.

Criteria for Admission

In addition to academic achievement and a special interest in medicine as a career, candidates must be outstanding high school juniors and seniors who are highly motivated and demonstrate leadership qualities.

The comprehensive conference fee of $1,465 covers accommodations, breakfasts and dinners, instruction and supervisory personnel, program materials, all Forum activities and local transportation during the Forum. Transportation to and from the city in which the Forum will be conducted is not included. Financial aid information is available.

Research on Curriculum, Teaching, and Learning

Section Editor
Jon Pedersen
314 Graduate Ed.
University of Arkansas
Fayetteville, AR 72701 USA

Valuable insights on curriculum, teaching and learning may be gained from research and it is the aim of this section to bring significant research information to the attention of science teachers, with a view of helping them in their important work.

HOW TO CHANGE TELLERS TO TILLERS: NEEDED RESEARCH IN SCIENCE TEACHER EDUCATION IN AN ERA OF MAJOR REFORM

James A. Shymansky
University of Iowa
Iowa City, IA 52242

Challenge to Reform

Science education is once again in the throes of a major reform effort. Project 2061 (Rutherford & Ahlgren, 1989) and ICASE 2000+ (Holbrook, 1993 & 1994) are two of the better known current reform efforts. The goal of both of these projects is science literacy. But the most recognized aspect of these projects is captured in the expression, “less is more.” In its simplest translation, less is more (LIM) promotes the practice of spending the same time on fewer science ideas. If it hasn’t already done so, LIM will probably soon replace “hands-on” as the expression most uttered by teachers at science teacher conventions.

Still relatively unknown by teachers but moving up quickly in the catch-phrase ratings is the term “constructivism” (including all its word forms). The idea that students construct their own meaning for ideas using previously held notions as filter, foundation and mortar is also being promoted heavily in Project 2061, ICASE 2000+, and the general reform literature.

Obstacles to Reform

The LIM theme and constructivist seem friendly enough in principle, but their translation into practice is fraught with obstacles. For instance, there is the chance that the LIM theme could be taken as license to move traditional science courses in biology, earth science, etc. into lower and lower grade levels (a practice already evident in the “middle school” movement). Constructivism could also be misinterpreted to mean or support “hands-off, laissez faire” teaching where students are simply set free to explore and discover on their own, reminiscent of the discovery learning/inquiry teaching in the post-Sputnik reform years.

Initially teachers and teacher educators will probably simply dismiss reform ideas as new fads. After it is realized that the LIM theme is more than cutting a topic or two from a syllabus and that constructivist teaching is much more demanding than saying “what do you think?” a period of denial may set in, characterized by teachers saying, “these reform ideas don’t apply to me, I am already doing LIM” and/or “I am already a constructivist teacher.”

Once the initial stages of dismissal and denial pass, there will be a need for research on the LIM theme and constructivist teaching strategies. From a science teaching perspective, a major implication of the reform ideas of Project 2061 is the need for teachers to shift from the role of “teller” (disseminator of knowledge) to the role of “tiller” (cultivator of student minds) in the classroom. But the teller paradigm is well established with teachers, students and parents. Assuming that constructivist principles apply to any group challenged with new ideas, convincing students, teachers and parents of the logic and effectiveness of “tilling” strategies will take time and challenge the best tilling strategies of the teacher education community (Hand, 1993; Shymansky, 1992).
Needed Research

Science teacher education research will best serve the teaching community by addressing questions of how telling and tilling roles compare and contrast; how variations in tilling strategies impact student learning; and what models of teacher preservice and inservice are most effective in turning out tilling teachers. Indeed many classroom teachers are searching for guidance on how to restructure their science curriculum and revise their teaching strategies. Teacher educators are busy trying out new models of teacher inservice based on reform documents, perhaps more important than the research and development of inservice models however, will be the work done to restructure the science courses and the professional education programs of preservice science teachers. Research at the preservice level has the potential for facilitating reform that will carry science education to the year 2000 and beyond.

PHYSICS TEACHING (ENGLISH EDITION)

Physics Teaching is a magazine of intermediate academic level published by the Chinese Physical Society. It was first published in 1978 and more than 150 issues have been published up till now. The major target readers of the magazine are secondary school physics teachers, with also college physics teachers and students in mind. Major contents include advances in physics, studies in pedagogy and teaching materials, development in equipment and experimental design, physics and its daily relevance, etc. At present, the circulation of the magazine is around 40,000.

In order to strengthen the tie with readers outside China, the Editorial Board and the Hong Kong Association for Science and Mathematics Education (HKASME) decide that beginning from 1994, an English edition of Physics Teaching will be published. The English edition will be published annually with translation of selected articles from the Chinese edition.

Physics Teaching (English edition) is edited by the Editorial Board of Physics Teaching (Chinese edition), translated, published and distributed by HKASME.

STUDENT SELF EVALUATION: THE LEARNING PROCESS

Ruiss Van Fossen Bravo
Chemistry Department
Indiana University of Pennsylvania
143 Weyandt Hall
Indiana, PA 15705-1090

Abstract
Many students have not thought about how they learn and about what types of studying activities are most profitable for them. One way of getting them to seriously consider their own learning process is to have them assume part of the responsibility for monitoring and evaluating the quality of their own work. The mechanism chosen to accomplish this was to have the students in an Organic Chemistry course maintain a portfolio in much the same way that art students do. The students were instructed to include items in four categories: (a) description of steps taken, (b) descriptive material on learning practice, (c) products of learning, and (d) self evaluation. Thus, they had a chance to select, prepare, and explain items that they felt accurately represent their actual performance. This activity is successful not only in causing a greater reflection by the students on the learning process, but also fosters greater interaction between student and professor and between students.

Introduction
Recent literature speaks of “the scholarship of teaching” and points out that the teaching portfolio has promise as a tool for assessing such scholarship (Edgerton et al., 1991). Portfolios can also be used to assess student performance in science courses (Barrow, 1993).

Over the years, I have taught organic chemistry courses in Chile, Brazil, and the United States. I have often observed that part of the difficulty that students have with organic chemistry is due to poor study habits, unrealistic ideas of what is expected of them, and unwillingness to do the hard work necessary to understand the concepts of organic chemistry. Many students do not improve as the semester progresses because they do not think about why they do poorly. They do not evaluate their own performance versus courses expectations.

In order to stimulate such self-evaluation, I decided to have the students maintain a portfolio. At present this activity is optional, and students elect to do a portfolio, they may substitute the portfolio grade for one of the exam grades (three exams are given during the semester and a final at the end of the semester). The majority of the students choose to keep a portfolio.

Theoretical Basis
Constructivism is the theoretical basis for using the portfolio as an assessment tool. This is learning by constructing meaning out of the student’s own experiences. The ability of students to answer questions related to a limited number of situations can be tested by exams. However, the constructivist teacher must also be able to examine the student’s performance in other ways. Competence cannot be determined on the basis of one performance but rather on the basis of continued and varied performances (Wiggins, 1989). The portfolio gives the instructor a way of assessing non-traditional performance of each student. It also gives students a chance to choose what they think should be included in the assessment.

Method
The first questions students ask are, “What is a portfolio? What do I put into a portfolio?” In order to answer these questions, they receive a document which defines portfolio, gives reasons for using portfolios in the course, and indicates possible and required items to be included in the portfolio. (See Appendix A.) Approximately one week after receiving this information, students communicate
their decision to the instructor by signing a “contract” form (see Table 1). Once students make their decision, they are responsible to abide by that decision.

In order to insure that students work in a continual manner on their portfolios, some assignments must be handed in during the course of the semester. These are not graded, but points are given for each one. Also, the students may be requested to turn in their portfolios at any time during the semester so that the ongoing nature of their work may be verified.

The documents that students turn in during the semester include:
1. an objective statement in which students state what they hope to accomplish with the portfolio and how they plan to accomplish these goals;
2. a mid-term progress report in which students explain what they have done up to that date;
3. a self-evaluation, written immediately after taking each exam, in which students evaluate their performance and tell whether their study methods were effective in preparing for the exam;
   a. If not, why?
   b. How would they change them?
   In addition, the students comment on the exam itself:
   a. Did the questions match the material?
   b. Were the questions clear or ambiguous?
   Their perception of the exam length.
4. an evaluation, written after receiving the graded exam, in which the student states whether the previous self-evaluation was accurate. If it was not, the student is asked to determine what led them to overestimate or to underestimate their performance. Students may also comment on the grading of the exams; and
5. a final report, turned in at the end of the semester, in which students assess their overall performance and learning during the whole semester.

Results

This method was used in one section of Organic Chemistry II during Spring semester of 1994 and is currently being used in one section of Organic Chemistry I. The results, therefore, are not complete, and so this is, in reality, a preliminary communication of ongoing work.

The idea of the portfolio was introduced in the syllabus and discussed briefly during the first class of the semester. The document explaining portfolios was distributed to the students by the third class, and the contracts were signed by the students at the end of the second week of classes. During Spring semester 48 of the 56 students opted to do the portfolio (Fall semester: 49 out of 63).

The objective statements were handed in at the beginning of the third week of classes. A wide variety of goals were mentioned in these
1. to obtain a grade of A (B or C, depending on the student);
2. to improve study techniques;
3. to improve time management skills;
4. to gain insight into how one learns;
5. to keep from procrastinating;
6. to be able to use it as a tool in the future;
7. to find out how organic chemistry relates to their major or to everyday life;
8. to show the instructor how much work was put into learning;
9. to investigate the role of organic chemistry in history; and
10. to understand organic chemistry better.

Other ways cited to help accomplish goals included: keeping journals, forming study groups, doing extra problems, making study tools (flash cards, charts, etc.), teaching fellow students, reading current literature, recopying notes, writing summaries, asking questions more frequently, and interviewing other persons.

The portfolios were collected on the day of the final exam. The evaluation was based on the required documents that had previously been collected (maximum 60 points), on the quality of the content of the portfolio, and on fulfillment of activities in the student’s original, or revised, objectives statement.

Conclusions

The use of a portfolio in Organic Chemistry has been very well received by the students. Many felt that it should be a required part of the course rather than being optional. One student even complained on the student evaluation forms that it was unfair that they had not been required to do a portfolio.

Does a portfolio improve student performance? Almost every student said that their performance was improved by working on a portfolio. Quite a few indicated that they intended to use this method in other courses. With such a small sample, it is really difficult to determine if the portfolio improved performance. However, the portfolio grade was similar, in most cases, to the average grade that the student had obtained on the exams. Only one student who did a portfolio obtained a grade of D; none of them failed the course, whereas the failure rate was much higher among students who did not do the portfolios. This may be due to the fact that students
who did not want to spend time on portfolios also did
not spend much time studying.

About a third of the students who did portfolios commented that they were repeating the course and that, at least in their opinion, the portfolio was responsible for keeping them focused and enabling them to understand Organic Chemistry. The top three grades in the course were obtained by these repeaters. Others obtained grades of B and C.

Portfolio students felt that they had more control over their own learning, spent more time thinking and discussing how they learn and deciding whether their methods were effective. The portfolio also provided them with opportunities to discuss their activities and ideas with other students (as evidenced by their journal entries) and with the professor. In this sense the portfolios seemed to foster a greater sense of community.

In summary, portfolios hold promise as a method to give students more input as to what they feel is important for their own learning and intellectual development. They, also, help the student become an active participant by making them aware of the fact that passive learning is not possible.

APPENDICES

Appendix A

**Student Handout on Portfolios**

**DEFINITION:** A portfolio contains evidence of the student’s strengths and learning achievements. It reflects the knowledge obtained in a course, skills that have been developed, ideas and reflections about the learning process, and comments concerning applications to the student’s major field of study and to their lives. A portfolio can be used for varying purposes. In this course the portfolio will be used to show student progress in ways that cannot be evaluated by exams. In turn, it will be used by the professor as an aid in assessing student performance in organic chemistry.

**General Information**

The portfolio:

1. must be related in some way to organic chemistry.

2. must have a purpose or objective statement concerning what the student wishes to accomplish and how they propose to attain stated goals. A copy of this statement should be turned in to the instructor by the end of the third week. A second copy of the statement should be placed in the portfolio.

3. must contain a mid-term progress report (due at the end of mid-term week) and self-evaluation (one after taking each exam and one after receiving the graded exam) during and at the end of the semester. Copies of these should be turned into the professor and a second copy placed in the portfolio.

4. should be a *selective account* that highlights what is unique to each person; including, approach to learning and relating course subject matter to things that they find interesting.

**Reasons for Using Portfolios in This Course**

1. Learning is a complex and individual process. Each student has their own way to approach learning. A portfolio permits documentation of the process on
an individual basis.

2. The portfolio involves each student in evaluating their learning progress. It places part of the responsibility for monitoring and evaluating the quality of one's own work in the hands of each student, giving them a chance to select, prepare, and explain entries that they feel accurately represent their actual performance. In that sense, it gives each student an opportunity to set their own standards for effective learning.

3. Hopefully, the portfolio will prompt a greater reflection on the learning process and on how to improve it.

4. Discussion of portfolios among students is also hoped to stimulate cooperative work and open communication.

Possible Items for Inclusion

A. Description of Steps Taken:
   A journal which contains a record of:
   1. daily or weekly efforts made and time spent;
   2. outside reading of articles;
   3. exchange of information and material with peers and others;
   4. attempts to try “new” methods (film, computer, etc.) and to evaluate effectiveness;
   5. participation in study groups and/or discussion groups;
   6. preparation of study materials and of reports;
   7. conferences with professor, tutors and/or others;
   8. steps taken to emphasize the interconnectedness of organic chemistry and other areas.

B. Descriptive Material on Learning Practice
   1. copies of problems solved independently or with groups;
   2. explanations of choice of problems and/or methods;
   3. written decisions of ideas;
   4. written critiques of articles;
   5. reports on group activities;
   6. self-reflective essays;
   7. examples of study materials that were prepared (flash cards, outlines, student-made tests or exercises, etc.)
   8. identification of individual strong points and/or weak points.

C. Products of Learning Practice
   1. copies of graded exams, quizzes and exercises
   2. self-evaluation reports (evaluations by peers and others may also be included);
   3. mid-term progress report;
   4. final progress report;
   5. copies of graded work done in other classes that demonstrate the student’s ability to use organic chemistry in another field.

Other items that the student thinks may be appropriate may also be included. It will be helpful if students indicate the reason for including them.

---

**BRITISH COUNCIL
INTERNATIONAL SEMINAR**
(Seminar Number 9486)

Science Education: Providing a Curriculum of Quality

March 19, 1995 to March 31, 1995 York
Directed by Professor David Waddington and Dr. Bob Campbell

The seminar will enable participants to share experiences and contribute to curriculum review and development. Main themes will include:

- styles of curriculum development
- impact of research on curriculum development
- links between science and industry

The seminar will include lectures and presentations, school visits, and participative sessions. The programme will be of particular interest to advisers, inspectors, teacher educators, and senior teachers.

**Fee:** £1,590 (includes seminar programme, accommodation and meals)

**For further information, contact:**

(Please quote the seminar number in all correspondence)
Karachi has often been called “a city of contrasts.” This city of between 7 and 9 million people is home to the richest and poorest in Pakistan, a developing country in South Asia. Schools in Karachi reflect this contrast. At one end of the spectrum are schools that have well-equipped computer laboratories and send almost all of their graduating students to the most prestigious colleges and universities in Pakistan or in the U.S.A. and Europe. At the other end are schools run in cordonned off areas of quieter streets, where several students share a textbook, and about a half drop out before completing grade five. In between are schools that offer a wide range of learning experiences to their students: these are schools that are owned by the government or private parties, funded by trusts or run on commercial grounds, with English or Urdu (the national language) as medium of instruction.

In 1983 a small group of heads and teachers began to meet regularly to work out some ways to bridge this gap between schools. Their mission was to share resources, information and expertise among schools; to replace the culture of isolation with cooperation between schools; and to provide a forum for the professional development of teachers. They began to make plans for setting up the Teachers' Resource Centre (TRC), with schools as institutional members, teachers and other interested people as individual members, and an elected governing body made up school representatives to oversee the work of the Centre. While members of this group were very articulate about the need for such a place and the potential functions of TRC, they did not know how to give it a legal framework and seek funds for it. The Education Officers of the Aga Khan Foundation (AKF), an international funding agency with an office in Karachi, heard about the activities of the group and encouraged them to write a grant proposal. Drawing upon the expertise of friends, acquaintances and parents of students in their schools, the group began to make a rudimentary proposal. The local British Council invited an educator with the appropriate experience to help crystallize the group’s ideas into an acceptable format for a grant proposal. The TRC was finally set up in 1986, funded by AKF for five years, during which it had to gradually reduce its financial dependence on AKF and to build up an endowment fund. At the end of this period, it operated with its own funds for one year, after which it was given another major grant by a national agency called Trust for Voluntary Organisations. Its current endowment fund is about half of the amount needed for total financial independence.

The governing body employed teachers to fill all of the professional positions at TRC. Based on their personal knowledge of what teachers need to learn and how they learn it most readily, they began to conduct and organise workshops for teachers. So, for example, in one of the early workshops teachers were helped to see connections between the official primary science curriculum document and the prescribed textbook. Before this most of the teachers had never seen a curriculum document and used the textbook as the only guide for their curriculum. In another two-week workshop, secondary science teachers were helped to construct models and design experiments using inexpensive or scrap materials. Again, for most of them this was something quite novel. They had not encountered teacher constructed models or simple experiments using everyday materials in their own learning of science in schools or in colleges. Even those who had been through a
formal teacher education\(^1\) program either did not learn to do these or had jettisoned this “scholastic knowledge” from their minds, as soon as the need for its “performance” was over (Gardner, 1991).

To bring together schools as whole units, large scale annual events were organized. The Science Exhibition was one such event. Twenty-two schools put up a collective exhibition of models and experiments, and about four thousand students and teachers, as well as a few parents visited this exhibition. Science exhibitions had been held in the city before but the hallmark of this event was the collective effort that teachers made to help display each others work and share organizational responsibilities. In the past, space was allocated and schools were asked to set up their own stalls and compete for prizes for the ‘best’ exhibits. This exhibition was organized by themes rather than by schools and no prizes were offered.

On a broader level the major achievement of TRC has been the establishment of a collegial professional forum for teachers. Almost all teachers who come for the first time to TRC, whether it is for a workshop or for specific advice, remark about the hierarchy free and caring atmosphere which helps them learn better. School teachers who are mostly women, working in a low paid, low status profession, especially appreciate this. However, not all of their professional needs can be met by TRC and they leave in frustration because no other forum is available to them.

Teachers need more and different subject matter knowledge, particularly in science and mathematics, than what they learn in college. Many of them have inadequate understanding of scientific and mathematical concepts that they are required to teach. Even when their own understanding matches what the ‘experts’ believe to be true, they are ill prepared to transform their knowledge into appropriate representations for school children (McDiarmid & Ball, 1990). The TRC is staffed mainly by primary school teachers who themselves are not well-grounded in science subjects, therefore, their capacity to help teachers in this area is limited. When they monitor workshops they are able to tell whether teachers are actively engaged or not, but it is hard for them to assess whether the participating teachers’ learning is fundamental to understanding the subject and its teaching. Workshop leaders who have more ‘expertise’ in terms of higher degrees, often use arguments and examples that are peculiar to their discipline, but not necessarily understood by teachers who do not share their background. The lack of a combination of pedagogical and subject matter expertise leads to problems which TRC has not yet been able to address. Teachers attending TRC workshops pay greater attention to and subsequently only ask for, workshops that give them “bright ideas” for teaching on Thursday afternoons, or “tips and tricks” for making next week’s lesson more interesting. Their more fundamental needs remain unaddressed, and they are often unable to extend themselves beyond what they learn at particular workshops.

Another area where TRC has not been able to give teachers as much support as they need, is in their classrooms. When teachers learn new teaching strategies they ask for workshop leaders to help them try out what they learned in their classrooms. Because the workshop leaders are most often teachers themselves, they don’t have the time to visit anyone during the school day. Even when a TRC staff member is the workshop leader it is very difficult for them to give follow-up support to teachers, because TRC’s “productivity” and thus the value of the work of its staff is counted more in terms of numbers of workshops run and teachers served. Rather than the more invisible but very time consuming work of follow-up support.

TRC leaders have recently been re-assessing what they have achieved in the last eight years and are also deliberating the future of the Centre. The sharing of ideas, information and resources among schools has continued, but it is still done ad hoc and in reaction to external stimuli rather than as a part of the school culture. Heads and teachers from different schools meet more often for professional purposes than they did before, but they do not routinely include contact with other schools in their work life. The most dramatic change that has taken place, however, is in the importance now given to teacher development by policy makers, administrators and teachers themselves. Several new initiatives for teacher development have been taken in the public and private sector. These include school based, university based and mobile short term training programs. Leaders of some of these programs have tried to keep exchanging ideas with TRC staff, while others have preferred to evolve their own models. Meanwhile, TRC has developed a niche of its own. While it does not try to be everything for everybody, keeping its egalitarian stance while maintaining high standards,

\(^1\)Many teachers in Pakistan have not gone through formal teacher education programs (editor)
reaching out to those who cannot pay for its services but also trying to become financially independent, and developing the expertise of its staff who will not sell themselves as “experts,” continue to be the challenges for the future.

References

Section Editor’s Note: In both industrial and developing countries teachers often work quite alone and isolated in their classrooms. Talks with other teachers are too frequently limited to routine matters such as test results or naughty kids. However, when motivated teachers do get together and start a process of shared professional development, miracles can happen and real pedagogical subject knowledge can develop.

This article provides a fluent description of a teacher resource centre run by teachers in Karachi, Pakistan. Actually, the description might be too fluent and not show sufficiently the difficulties faced by the author and her colleagues in establishing and running such a centre in a developing country with very low teacher salaries, rather hierarchical and bureaucratic structures, and a relatively low priority for education (compared to other developing countries). A World Bank “Pakistan: Education Sector Review” reported in 1988 a literacy rate of only 30% and identified teacher education as one of the main problems. A rather large proportion of teachers in Pakistan have not gone through formal education programs.
THE THIRD INTERNATIONAL MATHEMATICS AND SCIENCE STUDY: AN OVERVIEW

David F. Robitaille
Department of Mathematics and Science Education
University of British Columbia
Vancouver, Canada

Abstract: The objective of TIMSS is to compare the teaching and learning of mathematics and science in some 50 countries. The results of the study will assist participating countries in planning ways to enhance their curricula, teaching practices, and student achievement. In addition, the results will provide feedback to countries about how their educational systems compare to others participating in the study.

Introduction

Large-scale, cross-national research studies provide rich opportunities for increased understanding across national boundaries. Educational studies such as the Third International Mathematics and Science Study (TIMSS) offer particularly fruitful opportunities for such increased understanding, partly because of the nature of the educational enterprise, but also because of advances that have been made in our understanding of effective teaching and learning practices, measurement theory, assessment practices, and curriculum analysis.

Some people, particularly those who are not part of the educational community will be interested in a study such as TIMSS because of the current increased international focus on the relationship between education and economic prosperity, increasing global competitiveness, and sweeping political changes in many areas of the world. Governments around the world are facing similar problems of having too few dollars and too many obligations. The need to provide the most effective education system possible while containing expenditures is a powerful stimulus to find out more about what makes an education system effective.

To improve the effectiveness of an educational system requires information about what students are capable of doing. Educators in any national school system may well believe that students are challenged to their limits by the curriculum; but self-examination, that is scrutiny of the familiar, cannot produce the same information as comparative research will reveal. It is not possible to examine in a critical and productive way significant aspects of any single system from within that system, since the unquestioned will remain unexamined. In this era of increased globalization and international competition, it is vital to answer the important questions of how to improve educational practice. International comparative research studies in education provide a vehicle for such analyses.

Value of International Studies

Critics of international surveys of achievement have commented that these studies require large expenditures of time, energy, and money on the part of participants as well as the investigators. In addition, questions have been raised about the significance and the impact of the findings from such studies. Support for the value of international comparisons in education, on the other hand, has come from a variety of sources including, most recently, two publications produced by the U. S. Board on International Comparative Studies in Education (Bradburn & Gilford, 1990; Gilford, 1994).

Insofar as the practical value to be derived from participation in international studies is concerned, Husén (1967) has described how international studies use the “world as an educational laboratory.” International studies provide investigators with an opportunity to assess the importance of variables which it might be impossible to manipulate from within their own jurisdictions: for example, class size, single-sex schools, out-of-school tutoring (Eckstein, 1982). A number of countries have initiated curricular and school policy reforms based on the
basis of results from previous international studies, when a comparison of the results indicated the need for review of their national agendas (see, for example, Degenhart, 1990).

The educational system within a given country is typically rather uniform with regard to variables such as class size or age of school entry, with the result that it is not possible to manipulate those parameters to investigate the extent of their influence on variability within the system. However, by studying the influence of variables across countries, with an accompanying increase in natural variability, one can better examine the implications of alternatives. Hence, the central comparative question each country may well ask is: How do other countries educate their youth differently, and with what degree of success? Different approaches to the same goal can be compared, and their impact evaluated.

The efficacy of an educational innovation may be evaluated by examining its implementation and operation in another country. New approaches to teaching may be found by observing classroom practices of teachers from other countries. Stigler and Perry (1988) suggest that cross-cultural comparisons also lead researchers and educators to the development of a more explicit understanding of their own implicit theories about how children learn mathematics. In all probability, this principle can be generalized to other content areas, including science. Without comparisons, we tend not to question our own traditional teaching practices and we may not even be aware of the choices we have made in constructing the educational process.

International Association for the Evaluation of Educational Achievement

The International Association for the Evaluation of Educational Achievement (IEA) was established more than 30 years ago in response to growing interest in comparative education research and the need to develop standards for conducting empirical research in this emerging field. Chartered in Belgium and with a permanent secretariat in The Hague, IEA includes representation from over 40 educational systems in 35 countries around the world. IEA conducts a cycle of studies on a regular basis approximately every decade. Each of these school-subject studies is curriculum-based, issue-centered, and interdisciplinary in scope.

IEA is well positioned to conduct international studies because comparative research is its raison d’être. For over 30 years, the IEA network has been setting standards for international survey research: study design, test construction tied to international curricula, scientific sampling, data analysis, and dissemination of findings to a wide international audience of policy makers, researchers, and educators. IEA studies not only generate important univariate comparisons across individual test items and subscales, but also explore observed differences through multivariate analyses tied to a conceptual model.

In the early 1960s, the first IEA survey was conducted in 12 countries. Since then, academics, educators, administrators, policy-makers, and political representatives have looked, in increasing numbers and with increasing frequency, to the findings of IEA studies to provide a context within which to draw conclusions about the state of their educational systems. The emergence of the concept of accountability as a significant factor in determining funding levels for educational systems has undoubtedly contributed to this trend. Educational administrators and representatives of governments now, more than ever before, seek to rationalize and justify the amounts of funding needed to operate school systems at appropriate levels of service.

The organizational structure of IEA facilitates efficiency in carrying out comparative international survey research. That structure includes the General Assembly with representation from each member institute, a chairperson (currently Professor Tjeerd Plomp from the University of Twente in the Netherlands), a Standing Committee (Board of Directors), and a permanent IEA Secretariat located in The Hague. Each IEA-sponsored project has its own international coordinating center which is responsible for carrying out the study. The ICC is in its turn supported by an International Steering Committee and the IEA International Headquarters.

Results from Earlier IEA Studies

Previous IEA studies have reported on cross-national differences with regard to participation or retention rates, the extent of tracking or streaming, gender differences in achievement, the content of the curriculum, teaching practices, and many other variables of importance to the teaching-learning process. Many of the findings from these studies challenge the conventional wisdom which underlies educational practice, and they demonstrate that radically different approaches to the teaching and learning of mathematics and science are not only viable, but demonstrably successful.

A number of important variables have been identified in international studies over the past 25 years. Course content, or opportunity to learn, has been shown to be an important variable in accounting for differences in achievement among students from
different countries. But opportunity to learn also provides information on what is possible for students at a given age or grade level to learn.

International studies have shown that educational systems can retain very large proportions of the age cohort in the study of academic mathematics or science at the senior secondary level without penalizing the best students. Secondary analyses of the data from the first and second IEA studies in mathematics and science indicate that the highest ability students from almost all systems performed at about the same level on topics which they all had studied. The major differences among the best students appeared to be mainly a function of opportunity to learn.

Previous IEA studies of mathematics and science have produced valuable insights into a number of aspects of the teaching and learning process. In addition, they have provided a number of important lessons with respect to the design and conduct of large-scale international research projects in education. TIMSS has built on this foundation, and it will provide further information about a number of important matters such as:

- current national and international data which countries can use to compare and contrast their curricula, teaching practices, and student outcomes with those from other countries of interest.
- an assessment of the potential impact that alternative curricular offerings, teaching strategies, and administrative arrangements have on learning.
- an identification of what is possible in the teaching of mathematics. For example, results from SIMS showed that extremely high growth rates were evident in Japan and France. That finding indicates that more significant growth rates might be possible in other countries, and that we must strive to identify the underlying causes of those high growth rates.
- a greater understanding of how and why student attitudes change, and what relationship the development of positive attitudes bears to classroom practices. Such an understanding is crucial to the development of a more complete picture of how mathematics learning takes place.

Earlier IEA studies have provided glimpses of the nature of teaching and learning in mathematics and science. In addition, they have laid foundations on which to build a deeper understanding of what takes place in the teaching and learning process.

**Research Design for TIMSS**

TIMSS is the largest and most comprehensive study of educational practices in mathematics and science ever undertaken. The goal of this study is to examine the teaching and learning of science and mathematics for students at three levels: the pair of grades containing almost all 9-year-olds (Population 1), the pair of grades containing almost all 13-year-olds (Population 2), and the final year of secondary school (Population 3). Students will provide information about their attitudes toward science and mathematics, their family and school circumstances as well as completing an achievement survey. In addition to student data, information about teachers, schools, and administrative structures, as well as national or system-level information will also be collected.

The study will be of interest to a wide range of audiences including parents, academics, educators, policy-makers, researchers and politicians. The groups will have varying perspectives and interests in the results. These will certainly include:

- educational policy-makers who wish to investigate possible linkages between indicators of school performance and economic strength in order to develop or modify educational policy;
- educational researchers who wish to employ improved measures of educational performance, along with a variety of other educational indicators, to further their research goals;
- curriculum specialists in mathematics and science who wish to improve their understanding of the nature of the relationship between curriculum and student outcomes;
- teachers of mathematics and science who wish to increase their knowledge of effective instructional practices;
- the public who place high expectations on the educational system of their country.

Over 50 countries are intending to participate in TIMSS, and they are listed below. The list of participants includes representatives from all geographic areas and all levels of economic growth, although some parts of the world—such as Africa, the Indian subcontinent, and South America—are under-represented. Such broad participation indicates the widespread interest that exists in understanding

---

**FOOD FOR THOUGHT**

A grade is an inadequate report of an inaccurate judgement by a biased and variable judge of the extent to which a student has attained an undefined level of mastery of an unknown proportion of an indefinite amount of material. —Dressel, P. (1957, Winter). Definition of a grade. Basic College Quarterly, 6. Michigan State University.

Iran            United States of America

\^aParticipation uncertain.

The study is operating on a tight timeline with several major activities scheduled for 1994. Some of these involve the piloting of achievement items and questionnaires. There have already been a number of activities in the collection of national-level \^lata, and analysis of curriculum.

January - April 1994
  Field trial for Population 3 booklets
March - May 1994
  Field trial of Populations 1 and 2 booklets
September - November 1994
  Main data collection in southern hemisphere
March - May 1995
  Main data collection in northern hemisphere
June 1996
  Publication of first international report

An important facet of educational research is obtaining an understanding of the context in which the educational event of interest occurs. This is an even more important component of cross-national comparative research, when it is evident that significant aspects of a nation's culture can exert powerful influences on the educational system. An example of these contextual factors is the level of societal expectation with respect to education. What are the views of the society about the nature of education, the status accorded to educators, family and community support for school activities, accessibility to post-secondary education, or the view of society with regard to lifelong learning?

Obtaining this kind of information is difficult. There are problems of sampling, costs, and perhaps a lack of motivation on the part of respondents: Who wishes to participate in yet another survey? There is a further problem of how to match what people may say in a general way about education, with a useful critique of curriculum.

One approach that has been taken in TIMSS to understanding some of these context variables is a comprehensive curriculum analysis, since what is in the curriculum can be assumed to reflect, to a reasonable extent, what is valued by the society. Curricular reforms generally take place following broad consultation with various sectors of society. In this way, the curriculum can be viewed as a proxy for what is deemed to be important by a society in preparing young people for their future. In TIMSS, efforts to understand some of the differences in student achievement will be based on an examination of science and mathematics curricula more intensively than has been done in previous studies.

**Curriculum Analysis**

There are three kinds of curriculum that are the focus of various activities in TIMSS. The broad view of curriculum in science and mathematics is being examined to provide information about the specific topics that are important to mathematics and science educators, and constitute a significant part of the curriculum in nations participating in the study. This has served as the basis for the development of the achievement survey. Second, particular topics are being reviewed in detail to provide data about curricular organization and approach not only at the age levels selected, but throughout the full span of grades. Finally, curriculum experts in each country have been asked to review developments in the past five to ten years, the effect of reforms, and curriculum changes forecast for the next five years. While no individual can foretell the future, the time required for design, development and implementation of curriculum changes places those knowledgeable about curriculum developments within a country in a better position than others to make such forecasts.

TIMSS will explore the intended, the implemented and the attained curriculum in a
variety of ways. The conceptual relationships among these three versions of the curriculum and their contexts are displayed in Figure 1.

Figure 1. Conceptual Framework for TIMSS

The intended curriculum consists of the mathematics and science content as defined at the system level. The locus of decision-making in this regard varies. In some countries, authority may be placed in the hands of many small, local jurisdictions; in others there may be a highly regulated central authority for a large jurisdiction. Nonetheless, the intended curriculum is embodied in textbooks, in curriculum guides, in the content of examinations and in policies, regulations, and other official statements generated to direct the educational system. The intended curriculum, the mathematics and science content which students are expected to study and learn, may be described in the form of mathematics and science concepts, processes, skills, and attitudes.

The intended curriculum is set within an educational context that includes institutional arrangements for the system. Educational decisions made at the system level include such features as decision-making structures, school organizational patterns, teaching assignments, and fiscal and human resource inputs.

The intended curriculum, the perspective from the system level, is situated within the larger context of society. The societal context includes those variables which influence system-level institutional arrangements and curriculum content. Illustrative aspects of this context are: the goals, expectations, and values society holds for schooling; overall participation rates; the role of private schooling; the expectations held and the arrangements made for professional preparation of teachers; the professional status accorded to teachers in society; as well as the resources society has and the proportion of those allocated to education.

The implemented curriculum is the mathematics and science content as it is interpreted by teachers and made available to students. Previous research has shown that the implemented curriculum, even in highly regulated educational systems, is not identical to the intended curriculum. However, the implemented curriculum is influenced by the intended curriculum, and it can be described in terms of concepts, processes, skills, and attitudes.

The implemented curriculum is set in an educational context that consists of institutional arrangements made at the school and classroom level. These are influenced by and, to some extent, dependent upon the system-level arrangements. This level of institutional arrangements differs from the system-level arrangements in that the locus for decisions is at the school or classroom level. These are comprised of such things as teaching practices, aspects of classroom management, use of resources, teacher background, and so on.

The implemented curriculum, the perspective from the level of the school and classroom, is situated in the context of the local community. In some cases, this is a mirror image of society-at-large, and the same features are important. In other cases, however, local communities within an educational jurisdiction vary a great deal. Illustrative features of this context are the socioeconomic status of the community, expectations held for schooling, and the participation rates of students and parents in the community.

The attained curriculum consists of the outcomes of schooling: the content of mathematics and science students have learned in the course of their studies. What students learn will be influenced by what was intended and by the opportunities that were made available to them. The attained curriculum can be described in terms of the concepts, processes, skills, and attitudes in mathematics and science.

The attained curriculum is set in the educational context of the individual student, and it consists of the institutional arrangements the student makes or has made for his or her own learning: the amount of homework the student does, the effort the student expends, the student's classroom behavior patterns, and so on. While these factors are greatly influenced by both the system and classroom level arrangements, they differ in that the individual student has some direct control over these arrangements.

The attained curriculum is situated in the context of the student's personal background, and is likely to reflect the society and community contexts.
However, the student’s personal context is not likely to be exactly the same as those other contexts. Thus, it is important to add this additional sphere of influence in order to obtain a comprehensive view. Illustrative of these features are the attitudes about education that the student brings to school, aspirations, perceptions of ability to succeed, parental expectations for student’s success, and economic well-being of the student’s family.

The boundaries between the content, the institutional arrangements, and the societal context are not always distinct. Nor is it important that they be clearly delineated. The important point is that the variables of three different kinds of curriculum must be considered in light of three different levels of institutional arrangements, within three different societal contexts. Together, the content and institutional arrangements of the intended, implemented, and attained curricula, and features of the society-at-large, the local community, and the student’s personal context comprise an appropriate description of the educational environment.

**The Importance of TIMSS for Teachers and Curriculum Developers**

In the Second International Mathematics Study comparisons were made of mathematics curricula, of teaching practices employed in the teaching of specific topics such as integers or rational numbers, and of streaming or tracking of students. Similar research components can be found in the Second International Science Study. Such studies provided a view of what can be accomplished, a context in which decision makers in each participating country can view their own system.

In the development of TIMSS there has been a concerted effort to identify the relationships among the components of the educational system: policy, administration, teachers, and students more clearly. At the teacher level, a synthesis of the research provided by Porter and Brophy (1988) outlines four areas of influence on teachers’ instructional practice that focus the research questions: teachers’ personal experience and professional education; teachers’ development of classroom routines; teachers’ planning; and teachers’ knowledge and convictions regarding content, pedagogy, and student needs.

There is also a commitment to the reporting of the information from the study in ways that are useful to practitioners. The goals set for the reports published by TIMSS include:

- to provide descriptions of the learning and teaching of mathematics and science in classroom contexts.
- to ensure that such portrayals are valid, reliable, and meaningful for educators to read.
- to provide science and mathematics educators with descriptions and results that they can use to improve their own teaching practices and classroom environment.
- to provide curriculum planners and policy-makers with decision-making data grounded in the lives of those most affected by such decisions.

The information provided in the tables in Appendix C is preliminary, and presented to show the differences in content and instructional intention as found in the document analysis part of the curriculum study. Not only are there striking differences between content, particularly at the Population 2 level, it is clear from the description of student expectations that curriculum developers and textbook authors reflect very different intentions in the programs that are designed to meet a country’s needs. The more interesting information will be the investigation of the relationships between curriculum as intended, as implemented and as attained—what the students actually know and can do. The premise is that for increased effectiveness of an educational system it is not sufficient merely to know what does not work. It is essential to know what works, and what students in other nations can do, as revealed by the intended curriculum and their achievement. For teachers this is also important information for their own professional growth.

The ways in which teachers in other countries provide instruction on particular topics can also be of direct relevance to teachers. TIMSS will not only provide information about the range of approaches that teachers throughout the world may find to be effective, it may also provide some reassurance that certain topics are not easy for students to grasp in any educational system. In the second mathematics study, for example, all students had difficulty with the algebra items, in spite of a wide range of instructional approaches reported.

**Current Status of the Study**

One of the major objectives for the study in 1994 is to finalize the development of the instrumentation for the investigation of the implemented curriculum and the attained curriculum. This includes the achievement survey instruments, as well as the questionnaires to be administered to students, teachers, and school principals. All of the instruments need to be provided to participating countries with sufficient lead time for them to be translated where necessary.

With respect to the investigation of the intended curriculum, on the other hand, all of that data has
already been collected, and the process of analysis has begun. The curriculum analysis is divided into four major components, as follows:

- **Scope and sequence analysis.**
  Each participating country has provided information about the extent to which each topic in the TIMSS mathematics and science frameworks forms part of their intended curriculum. In particular, for each topic, countries have indicated at what age or grade level the topic is introduced, when it ceases to be part of the curriculum, and in what grades or levels that topic is especially emphasized. In TIMSS circles this aspect of the study is referred to as the “modified topic tracing.”

- **In-depth topic analysis.**
  A small number of topics—-for example, solution of linear equations and measurement—have been selected for in-depth treatment at the intended, implemented, and attained levels. As part of the curriculum analysis, countries have provided detailed descriptions of the coverage and treatment of those topics throughout the elementary and secondary school curricula.

- **Document analysis.**
  At each population level, countries have provided a highly detailed analysis of representative textbooks in mathematics and science. The process involved partitioning each page of a given textbook into a number of “blocks,” and labelling the nature of each of those blocks. Several categories of blocks were defined, and coders from each country were trained in identifying and coding them according to an internationally defined standard.

  All of the curriculum analysis data is currently housed at the United States National Center for TIMSS at Michigan State University. Some preliminary analyses have been done, and they give a sense of the kind of analysis that will be possible. For example, the scope-and-sequence data can be used to provide a “snapshot” of a given country’s intended coverage of the topics included in the TIMSS curriculum framework.

  The scope-and-sequence data will enable researchers to compare the treatment of a given topic across countries and to compare the numbers of focal points as well as their placement. This analysis will provide a useful overview of differences in the way mathematics curricula are organized and presented to students.

**Conclusion**

Measuring educational achievement is difficult from both a conceptual and a practical perspective. What counts as achievement is not always easy to discern and even when a concept of achievement has been clearly explicated, ways and means for assessing it are not easily devised. The ongoing debate about educational measurement and the increasing number of alternative assessment approaches proposed in educational circles attest to this problem. Understanding or explaining causes of, or influences on, achievement is even more difficult. It is one thing to be able to describe what a student knows or is able to do in a given subject; however, it is quite another thing to explain what might account for that attainment. We know that environmental factors play a large role; yet we are not clear about how that role is played out. The educational context is a complex one, with a myriad of variables interacting with one another in complex ways. In spite of these kinds of difficulties, there are obvious reasons for wanting to assess educational achievement, not the least of which is to try to improve the educational enterprise.

The problems of describing and explaining educational achievement are compounded when considered across international settings. Curricular goals vary as do notions of achievement. Educational environments vary immensely. At the same time, an international context is a particularly valuable one for considering the importance of variables that might account for achievement. Studies that cross national boundaries provide participating countries with a broader context within which to examine their own implicit theories, values and practices. As well, comparative studies provide an opportunity to examine a variety of teaching practices, curriculum goals and structures, school organizational patterns, and other arrangements for education that might not exist in a single jurisdiction.

Being able to describe and explain achievement across countries that represent different stages of development, different cultures, and different educational systems is dependent upon detailed knowledge of the range of differences. In other words, if comparisons of achievement between and among countries are to be meaningful, a thorough description of a complex set of environmental conditions is crucial for at least two different purposes. The first is to provide a rich detailed backdrop to assist with an understanding of an education system in its particular context. The second is to provide enough detail to permit the isolation of variables that may account for differences in achievement. The task facing TIMSS is to describe, appropriately and adequately, different contexts in both the plans for assessment and in the analysis of results.

The challenge for TIMSS is to be a research activity that is useful to practitioners as well as
researchers. We believe this challenge has been met, and hope that teachers will find participation in the study as exciting as the research community does. More importantly, we hope that the teacher audience will find the results presented in a meaningful and useful way.

SCIENCE IN SPACE

Science in Space is a project of the Association for Science Education (ASE), funded by charity and by industry.

Space, and, in particular, the human view of space and space exploration, can provide an exciting context for students studying science. The book contains a series of units designed as a resource for science teachers who wish to present a variety of aspects of school science within the context of space.

The units were designed specially for use in science lessons with 14-16 year olds in the United Kingdom. However, in trials, they have been shown to be of use with younger and older students, in General Studies, PSE, geography and other lessons, as the basis of science club activities. Some units have been successfully trialled in schools outside the UK.

Teachers who are familiar with the Science and Technology in Society (SATIS) projects of the ASE will recognise the style of these materials.

In selecting units for their own use, teachers will be conscious of the need to take account of the language level and the assumed level of pupils' understanding. Some units are more demanding than others. Many of the units are subdivided into sections which can be tackled separately.

SCIENCE ACROSS EUROPE

Many scientific issues, such as energy supply and water quality are of common concern yet perspectives as to their causes and resolution are different. This area of science, where common ground and different perspectives meet, provides schools with an excellent opportunity to stimulate teaching by taking the European dimension into account.

Join Science across Europe and your students can compare their findings with others all over Europe. Science across Europe
• is a new way to help teach science, languages, and economics in an environmental context
• is easy to use
• is interesting and relevant to students' concerns
• provokes discussion
• is flexible—will complement any curriculum
• allows you to join a network of schools in over 20 European countries

TEACHING AND LEARNING THROUGH INTERACTIVE MEDIA EXHIBITION

Joël de Rosnay
Director Development and International Relations
Cité des Sciences et de l'Industrie
La Villette, Paris

Training and information in modern societies requires the transfer of knowledge in the form of interdependent messages, signs, codes and symbols. These messages concern various publics and represent different levels of abstraction.

The traditional media complement one another to reinforce such communications: books, graphics, photos, slides, videos, films, interactive software - all are used in varying degrees and with their own specific features to provide the essential elements necessary for the acquisition of knowledge.

The multimedia exhibition has a particular role to fulfill in such system of educational media. Its role is to increase our sensitivities and to deepen our awareness. This type of exhibition integrates in the same space, text panels, photographs, drawings and graphics audiovisual presentations, mock-ups, and interactive equipment ranging from simple computer simulation game to complex mechanical or electronic devices. Often expensive, these exhibitions are nevertheless becoming more and more popular.

How effective are these exhibitions compared to available modern communications systems? What is their specific contribution, and how do they complement other media such as books, courses, conferences, television broadcasts, or simulation software? How will they evolve in the future in order to integrate the complexity of scientific and technical information? And, above all, how to use them efficiently in order to let visitors benefit from the presentations provided as part of a personalized knowledge route? These questions give rise to a new approach to exhibitions. It needs to be considered as an integrated communications system providing adapted and tailor-made interfaces.

The first scientific and technical exhibitions were inspired by encyclopedias: putting up texts and photographs on stands, backed up by mock-ups of real objects: instruments, machines, or heavy equipment, testimony of passed technical development. Architects and scenographers were asked to fill a space, to provide it with a coherence and a style likely to attract a visitor's attention and to keep them on the spot. The person responsible for the exhibition became literally a "producer" in spatial terms, much as we might speak of a "producer" for a film, having in this context responsibility for and control of the quality of the content of the messages intended for the visitors.

This style of exhibition (in the form of a "book on the walls") has given way, (thanks to technical progress,) to interactive exhibitions in which audiovisual techniques, computer, video disk, animated screens, and sketches performed by roboticized figures play an ever more important role.

Evaluation studies tell us that visitors are no longer satisfied reading texts or watching audiovisuals: they want to participate in experiences, do something active, answer questions, initiate new sequences of hands-on experiments. This means that exhibition planners progressively become "systems engineers" in multimedia communications. Scenographers, designers, and graphic artists have continued to play their part, but conflicts have arisen between museographic designers and animators over styles or methods of space implementation, giving preference to spectacular shows over the deep meaning of the messages.

Three types of exhibition could be described today in which the new communications technologies are used on a broad scale. The first is the "linear" exhibition, which presents a subject in a sequential manner, dividing it arbitrarily into periods (such as chronological sequences), into disciplines, or even by following a progression from the "simple" to the "complex".
The second is the “matrix” exhibition, in which no sequence as such is imposed, but where closely related sectors are presented. The interactive elements are located at the cross roads of visitor’s pathways. The third is the “discovery” exhibition, a kind of labyrinth of knowledge intended to stimulate the visitor’s curiosity by presenting elements which attracts the attention as the visitor passes down the aisle, and create a desire to learn more.

Unfortunately, these three types of exhibition only partially meet the constraints imposed by the complexity of the messages and their contents. If the elements of the museographic presentations are too detailed, there is a risk of losing the lead of the whole. An exhibition which is too analytical no longer brings about a global vision. At the opposite, an approach which is too general deprives visitors of the precise details necessary to set their imagination to work and increase the depth of their knowledge.

Added to these inconveniences are the frequent restrictions imposed by the space itself, with an overload of information resulting from the close packing of texts with photographs, audiovisuas, or interactive processes, which are difficult to understand. The lack of hierarchy among the themes and sub-themes and the weakness of the descriptions makes the messages even more confused.

It seems to me, therefore, that we need to go beyond the architectural vision alone, or the scenographic or graphic representation of a multimedia exhibition. We need to consider the relationship with the visitor placed at the center a “communications system”, and no longer think of a “communication space”.

We are therefore led to define and implement in an exhibition what I shall call from now on “intellectual ergonomics”. As with any interactive system, or computer with a direct interface to one or more users.

This involves a methodological and technical approach necessary to amplify the acquisition of knowledge by providing an adequate relationship between objects and subjects, by the simplicity of the modes of use, and by the ease and comfort of the user/machine interfaces.

For a computer, these ergonomics are translated into reality by the notion of user-friendliness. For a machine, office equipment, or a work station, well-designed ergonomics will allow for improvements in the efficiency of interrelations between user, tools, and equipment. An instrument panel, a receiver unit, a cockpit or a control system will all possess a type of ergonomics adapted to the needs of their users.

It seems to me appropriate to create multimedia interactive exhibitions by integrating the intellectual ergonomics approach into the museographic domain. The global exhibition must therefore be conceived and used as one single interactive system (and not only as an area of space equipped with interactive systems). The visitor interacts in such total system through eyes, ears, fingers, and by movement of the body through the area of exhibition.

Successful intellectual ergonomics help visitors to optimize their personal pathways in a system of communications within which they are active.

The ergonomic approach to an interactive multimedia exhibition must rest on a certain number of fundamental points.

First it is necessary to recognize and take into account the basic constraints imposed on a visitor to an exhibition. There are 4 major constraints: time, energy, money, and information.

The first three are rare resources on which we need to practice savings. But the abundance of the last (information) can lead to a saturation effect, preventing the visitor from getting any pleasure or motivation through his or her visit. An exhibition with successful intellectual ergonomics assists the visitor and help to optimize the use of time, energy, money and information through the visit.

To achieve such a task it is important to set up a clear hierarchy among the messages received, in order to facilitate guidance and reduce aimless wandering or queuing. Studies of the behavior of visitors show two major types of attitude when arriving in a new and unknown exhibit area: “scanning” with the eyes and “zapping” with the feet. Scanning consists of a visual sweeping of the spaces, panels, themes or sub-themes. This activity does not involve much energy but collects large amounts of superficial information.

Zapping is moving at random in search of interesting and relevant information. It is a natural response of the visitor expose to an exhibit area poor in information content, lacking guidelines or swamped with details.

In order to avoid passivity, frustration, or saturation with information, the intellectual ergonomics of an exhibition must rely on a global language, a “macro language”, immediately visible, accessible and meaningful. Such language is expressed first in the guides and plans provided before the visit. It should then be followed up in the scenography which creates a distinction between the major objects. Finally, it should appear in the details of the exhibition which lead the visitor from the general to the specific by offering several levels and degrees of abstraction or precision.

A guiding thread would then become clearly apparent. An overall message would be conveyed
which would form the systemic frame of reference in the course of the detailed and analytic acquisition of the elements of the exhibition.

When deprived of intellectual ergonomics, an exhibition can be compared to those modern electronic machines, video recorders, microcomputers or electronic watches with over complicated operating instructions and control panels packed with buttons and switches. We all know that 80 percent of whose functions are generally useless! Seeing users turn away from these machines designers are now competing in redesigning and simplifying controls and instructions.

The same must apply to a modern exhibition. An exhibition is a communications macromachine, made up of many levels of information transfer, buttons, notices, screens, panels, and animated models. And that is why its user-friendliness, just like the software and hardware of a computer, must be carefully designed and tested before being put into use.

A multimedia exhibition with good intellectual ergonomics presents a balance between in-depth messages and their format. Between the scientific and technical content of the messages and the way in which they are presented. It should also answer that dilemma of modern museology: do we need to give preference to overall understanding or detailed analysis? Do we want to emphasize the “macro” approach or “micro” understanding? How to present in a multimedia exhibition theme as complex as biology, ecology, the city, communications, services, finance or risk (all selected by the city of science for its major exhibitions)?

We need to talk in terms of systems, networks, control, flow, evolution. But at the same time, we need to specify details, stimulate reasoning, and provide the basis for action.

The golden rule from radio and television, “one idea at a time”, applies equally to the elements of an exhibition. But what we need is to know how to insert the details into a broader context which will allow a personalized “cognitive ecology” to be constructed by way of a dialogue with that global system of communications: the exhibition.

This “ecology” is a system of interdependent knowledge. This dialectic form of knowledge acquisition oscillate from the micro to the macro, from the local to the global, from the analytical to the systemic. What format should be given to an exhibition in order to favor this dialogue, this constructive dialectical interaction?

To achieve this, I propose a combinatorial approach using the new concepts of hypertext and fractal images.

Hypertext is a network of interconnected information. Thanks to guidelines provided by a computer, one can navigate in such a hypermedia like through a multidimensional graph. A button is clicked, and an illustrated section materializes on the screen. Clicking leads on to other connections, other sections, texts, graphics, images or sounds.

A modern interactive exhibition should be organized like a hypertext. Each node and link of the network must contain the representation of the whole, even if it provides details for a particular aspect.

Such structure looks like a fractal image.

A fractal image is a geometric shape which remains unchanged whatever the degree of enlargement under which it is being observed. Each micro image contains the macro structure.

An exhibition built with the intellectual ergonomics of each museographic element in mind and by reference to a fractal approach, will recreate at every node of the network the sense of coherence of the global entity. There are many examples of these approaches at la Cité des Sciences et de l'Industrie.

The fractal and hypertextual nature of an interactive multimedia exhibit will become a determinant factor in its success and user-friendliness. It becomes possible to create an equilibrium between museographic presentation and the richness of content of the scientific and technical messages intended for general publics.

**OUT OF THE PAST**

Never teach indoors what can be learned out of doors.
Never explain in the abstract what can be demonstrated in the concrete.
Never teach with books what can be perceived in objects.
Never teach by images when nature herself is at hand.
Never show dead nature when living nature is attainable.
Never require belief where seeing and understanding are possible.

(Dryer, 1888; 106 years ago)
Calendar
1994–1996

1994

December 6–10, 1994

The 9th ICASE Asian Symposium
Location: Bangkok, Thailand
Contact: Dr. Janchai Yingprayoon, Secretariat: IPST
Sukhumvit Rd. Ekamai, Bangkok 10110 E-mail:
OICST@CHULKN.CHULA.AC.TH

The theme of the symposium is “INCREASING THE EFFECTIVENESS OF SCIENCE TEACHING IN THE CLASSROOM: A CHALLENGE FOR SCIENTIFIC AND TECHNOLOGICAL LITERACY FOR ALL.”

December 15-17, 1994

NSTA Fall Convention
Location: Las Vegas, Nevada, USA

1995

January 4, 1995

ASE/ICASE International Symposium
Location: The University of Lancaster, UK

This will be held in conjunction with the ASE annual meeting.

January 5th–7th, 1995

The Association for Science Education Annual Convention
Location: The University of Lancaster, UK (which is 200+ miles north of London)
Contact: Dr. David S. Moore, General Secretary, College Lane, Hatfield, Herts. AL10 9AA

March 22–April 2, 1995

United States Science Education Tour
Location: Philadelphia, PA; Baltimore, MD; and Washington, DC.
Contact: Dr. Jack Holbrook, Executive Secretary, 72B Blue Sea House, 28th October Street, Limassol, Cyprus

The tour will feature various levels of science education, school visits and home stays with American families. Three days of the tour will be spent at the National Science Teachers’ Association Convention in Philadelphia, PA.

March 23-26, 1995

NSTA National Conference
Location: Philadelphia, PA, USA
Contact: NSTA 1994 Area Conferences, ATTN: T. Brent, 1840 Wilson Blvd., Arlington, VA 22201-3000

April 7-11, 1995

Science Education Research in Europe
Location: The University of Leeds, UK
Organised jointly by The Centre for Educational Studies, King’s College, University of London and The Centre for Studies in Science and Mathematics Education, The University of Leeds

April 22-25, 1995

NARST International Conference
Location: San Francisco, CA, USA

Late June/Early July 1995 (exact date to be announced)

Location: Johannesburg College of Education
Johannesburg, South Africa
Organised by the STEME (Science, Technology, Environmental & Mathematics) EDUCATION ASSOCIATION on behalf of the FEDERATION OF SCIENCE & MATHEMATICS TEACHERS.
Contact: Dr. Peter Glover
PO Box 32198
Braamfontein 2017, Johannesburg, South Africa
August 27th-September 1st, 1995

Partners in Chemical Education
An International Conference on Industry-Education Initiatives in Chemistry
Location: University of York, York, UK
Contact: Miranda Mapleton
Chemical Industry Education Centre, Department of Chemistry, University of York, York, YO1 5DD, UK
Co-Sponsors: International Union of Pure and Applied Chemistry (Committee on Teaching of Chemistry) and Royal Society of Chemistry (Education Division and Industrial Division)

August 29th–September 2nd, 1995

The International Conference on Industry – Education Initiatives in Chemistry
Location: University of York, York, UK
Organisers: IUPAC Committee on Teaching of Chemistry
The Royal Society of Chemistry
University of York

The first major international conference sponsored by IUPAC which specifically aims to promote links and dialogue between concerned industrialists and teachers from higher education, secondary and primary schools, and educational decision makers; and to evaluate and encourage good practice and discuss issues of industry – education collaboration. Correspondence/Conference arrangements:
Dr. J. F. Gibson
The Royal Society of Chemistry
Burlington House, Piccadilly
London W1V OBN
UK
Tel: +(44) (0) 71-437-8656
Fax: +(44) (0) 71-734-1227

September 4-15, 1995

Fourth World Conference on Women
Location: Beijing, China
Contact: Conference Secretariat: Division for the Advancement of Women, PO Box 500, A-1400 Vienna, Austria. Tel: 431/21131, Ext. 4270;
Fax: 431/237-495 Media: Department of Public Information United Nations, Room S-1040 Tel: 212/963-1262; Fax: 212/963-4556

This conference will:
1) review and appraise the advancement of women since 1985 in terms of the objectives of the
Nairobi Forward-looking Strategies for the Advancement of Women to the Year 2000.
2) mobilize women and men at both the policy-making and grass-roots levels to achieve those objectives.
3) adopt a "Platform for Action," concentrating on some of the key issues identified as representing a fundamental obstacle to the advancement of the majority of women in the world. It will include elements relating to awareness-raising, decision-making, literacy, poverty, health, violence, national machinery, refugees and technology.
4) determine the priorities to be followed in 1996-2001 for implementation of the Strategies within the United Nations system.

September 24–29, 1995

CONASTA 44
Location: University of Queensland, Brisbane, Queensland, Australia
Contact: David Tulip, Centre for Mathematics and Science Education, Locked Bag No. 2, Red Hill, Queensland, Australia. E-mail: D.Tulip@qut.edu.au
Tel: +64 7 864 3345 or Fax: +64 7 864 3985.

While the conference program is not finalised at this stage, it is envisaged that it will include theme lectures, symposia based on science education and workshops either based on current science research or science classroom practices. All symposia and workshop sessions will allow for personal choice and will cater for Primary, Secondary and Tertiary science teachers and science teacher educators. Educational tours of the Great Barrier Reef, tropical and subtropical rainforest, whale watching and other unique geographical and biological features of Queensland, will also be offered three to seven days prior to or immediately following the conference. A detailed synopsis of the speakers, a framework of the conference activities and a call for abstracts of papers will be available by July 1994.

September 25-29, 1995

3rd European Conference on Research in Chemical Education
Location: Lublin (Poland)
Contact: Department of Chemical Education, Maria Curie-Skłodowska University, Pl.M.C. Skłodowskiej 3, 20-031 Lublin, Poland, Dr Ryszard M. JANIUK
Tel: (81) 37-56-91
Fax: (81) 336-91 e-mail: JANIUK@PLUMCS11
The previous two conferences were held in Montpelier, France in 1992 and in Pisa, Italy in 1993. The next conferences are planned to be held every two years. The conference in 1997 will be held probably in UK. The organizers of the conference are the Federation of European Chemical Societies and the Chemical Society of the country in which the conference is held.

1996

March 28-31, 1996

NSTA National Conference
Location: St. Louis, MO. USA

July 14-19, 1996

14th International Conference on Chemical Education
Location: Brisbane, Australia
Contact: The ICCE Conference Secretariat
(Sally Brown), Continuing Professional Education,
The University of Queensland 4072 Australia
Tel: (07) 365 6360 Intl: +61 7 365 6360
Fax: (07) 365 7099 Intl: +61 7 365 7099
E-mail: chemed96@ceu.uq.oz.au

The 14th ICCE will be held in Brisbane from July 14-19, 1996. It is only the second time this conference has been held in the southern hemisphere. The biennial conference brings together chemistry teachers, chemists and science educators from school, industry and university settings to share ideas and learn from one another about innovation in teaching and learning and the discipline of chemistry. The theme, Chemistry: Expanding the Boundaries, acknowledges the centrality of chemistry through its expanding relationship with many facets of science and everyday life. Conference participants will be challenged to develop this theme with the view of enhancing our understanding of the important relationships which chemistry forms with the new frontiers of human endeavour. Implications for chemical education beyond 2000 which give a "science for all" perspective will be encouraged.

RESEARCH SAYS:

Students copy their teachers' behavioral patterns. If the teacher tries to dominate students, then students try to dominate each other. If the teacher accepts students, then students are accepting of each other.

Knowing an object requires acting on the object—modifying it, transforming it. Learning results from what one does to objects and the "doing" has to be both physical and mental.

Many teachers wait less than one second after asking a question before they answer or rephrase the question. Extending this to three to five seconds causes students to:
(a) responses to increase in length and number, 
(b) confidence to increase, (c) speculative thinking, questioning, and comparison to increase.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

INTERNATIONAL COUNCIL OF SCIENTIFIC UNIONS
SCIENCE, ETHICS AND EDUCATION PROJECT
TEACHING ETHICAL ASPECTS OF SCIENCE
Peter J. Kelley
Director, SEE Project
School of Education
University of Southampton, Highfield
Southampton, UK

Objectives
That scientists and those affected by science—in effect all citizens—should be concerned with the ethical aspects of science, is today perceived as a universal imperative. The Science, Ethics and Education (SEE) project aims to examine the relationships between science and ethics and to produce practical guidance on both content and method for science teachers.

More specifically the project will:
1. Define the nature and scope of ethical aspects of science relevant to general education, particularly upper secondary, early tertiary and adult community education. We will be aiming at science and non-science students and the public.
2. Define the intellectual skills and educational experiences required for understanding and decision-making related to ethical aspects of science. This entails examining the processes of ethical thinking employed by, for example, ethicists, lawyers, scientists and policy makers to see how they can be adapted for educational purposes.
3. Review the curriculum and teaching methods of relevance to the topic.

Within several developments in science education, e.g., those categorised as Issue-Science or Science-Technology-Society, there are relevant features. Other examples occur in the humanities, social studies, and newer fields such as bioethics and environmental ethics.

4. Devise curriculum units which can be adapted for a variety of educational contexts. It is intended that there should be examples which have international significance.

The uniqueness of the International Council of Scientific Unions lies in its global connections with the scientific community. Thus the emphasis of the project is on the ethics of scientific work and social issues in which scientists have a clear role. Ethical issues of gene patenting and genetic screening arising from the human genome project, and those involved when a scientist acts as an expert witness in legal cases, are examples.

Strategy and Outcomes
Phase 1 is aimed at achieving objectives 1-3. Materials and ideas are being collected from many countries. A small executive group is developing (a) policy statements on teaching ethical aspects of science and (b) a curriculum outline which could be adapted for a variety of circumstances found in different countries. Assessments will be made of human resource needs in relation to these developments. The group is also planning the work for objective 4.

Phase 2 consisted of a writing workshop in 1994 to prepare curriculum units required for objective 4.

Phase 3 entails preparation and publication of a book incorporating the materials developed in phases 1 and 2. It will consist of:
Part 1: An overview of the nature and scope of science ethics, its role in education and strategies that can be used in dealing with it. This will be written for teachers.

Part 2: Curriculum units providing teacher and student materials, in a form that can be easily photocopied.

Part 3: An annotated bibliography of some relevant materials currently available.

The basic aim of the book is to serve as a source of ideas and materials to enable teachers and programme developers to incorporate ethical aspects of science into curricula and teaching.
ICSU Overview

The International Council of Scientific Unions (ICSU) promotes international and interdisciplinary cooperation among scientists working in all natural science disciplines (ranging from astronomy and biochemistry to mathematics and pure and applied chemistry). Two distinct types of scientific organizations came together to bring ICSU into existence in 1931: national academies and research councils (such as the Royal Society and the US National Academy of Sciences), and the international scientific organizations (Scientific Unions). It is the combination of the two types—national bodies covering many disciplines, and the international bodies covering a single discipline—which make ICSU unique and help in the achievement of its objectives—to promote international interdisciplinary scientific cooperation for the benefit of humankind. Its strengths lie in the voluntary nature of the work done for ICSU by many scientists around the world, and in its determined defence of non-discrimination and independence from political considerations.

One important way in which ICSU pursues its objectives is through Scientific Committees and other interdisciplinary bodies. ICSU has Committees dealing with the environment, genetic experimentation, space and oceanic research, and many others. ICSU also launches and coordinates major international research activities (e.g., the past International Geophysical Year and the ongoing International Geosphere-Biosphere Programme: A Study of Global Change).

It also establishes committees to handle essential services and concerns that are common to the entire membership, such as the free circulation of information in developing countries. One example is the Science Education Committee, which promotes international cooperation in this important field. The Committee holds meetings and workshops world-wide. Some of its recent work includes the development of low-cost locally produced equipment for use in schools, colleges and universities of developing countries; the coordination of a worldwide programme for primary school teacher trainees; and a series of meetings to promote new science curricula with particular emphasis on national development.

REPORT ON THE 7TH ANNUAL GENERAL MEETING
GALICIAN SCIENCE TEACHERS ASSOCIATION
Xosé Mendoza Rodríguez
President, ENCIGA

Four-hundred fifty (450) Galician science teachers attended the seventh Annual General Meeting of ENCIGA, held at the “Lucus Augusti” High School in Lugo, Galicia, Spain, 17-19 November, 1994. The broad and diverse program involved more than 40 talks, workshops, and experimental demonstrations, as well as poster sessions on physics, chemistry, natural science, mathematics and integrated science. A subject which raised great interest was that of teacher training, since we are undergoing the introduction of a new educational system in Spain. Another recurring theme involved using students’ social and cultural environments to increase student motivation and to enhance the cultural aspect of Science. Other sessions included Environmental Science and Astronomy, plus eight different expositions. The meeting also attracted many mathematics teachers, and there were a number of sessions focusing on mathematics topics.

The broad program, which included social events, excursions, and visits to museums ensured that the Annual General Meeting was an enjoyable event. We’re looking forward to the next meeting.
A VISIT TO ESTONIA
Jack Holbrook

At the invitation of the Estonian Association for Chemistry Teachers (EACT), a new ICASE member association, the ICASE Executive Secretary spent a week running workshops, teaching two classes, making videotapes and giving an address to EACT teachers. The purpose of the visit was to introduce Estonian teachers to development in the teaching of chemistry and to introduce experiments linked to everyday materials that were unfamiliar.

The experiment session attracted more than 60 chemistry teachers and was set up in the school hall. The ICASE secretary was ably supported by Miia Rannikmae (secretary of EACT) and Aarne Toldsepp (president of EACT). The experiments covered the making of cosmetics (or emulsions if you prefer), distinguishing between man-made and natural fibres and the analysis of ores (dolomite, malachite). This was an ambitious programme given the surroundings, the language difficulties and the availability of equipment, but nevertheless, proved great fun. As most chemistry teachers in Estonia are female, the cosmetic experiments proved very attractive and the lack of availability of perfume on the work table did not prove an obstacle. Soon creams, shampoos, eye shadow and lipsticks were donning the tables. All creations from the ingredients provided. Production of rayon from tissue paper, using copper carbonate and ammonia proved more of a challenge, but was not hampered by the lack of safety equipment. It was, in fact very interesting to see what can be achieved with very basic equipment when enthusiasm is much in evidence.

Besides the executive secretary, both Aarne Toldsepp and Miia Rannikmae became filmstars and videotapes were made of lessons taught by all three persons. The lessons by the executive secretary were in English and the need for translation was lowered by making the lessons student-centered either by means of group discussion or by the inclusion of experiments. Student reactions, obtained in writing, to these lessons were very positive and illustrated the acceptability of student-centered lessons.

The videotapes were edited and shown to teachers in an EACT meeting. Each videotape showed a different aspect of teaching and the teachers were asked for their reactions. The videotape by Miia Rannikmae showed experimental work on the reaction of metals; simple experiments that can be easily performed to reinforce ideas on reactivity. Aarne Toldsepp gave a lesson on diffusion, again involving the students, whilst the videotapes of the executive secretary showed a lesson on the prevention of rusting of a metal bridge and the production of soap from ordinary cooking oil.

Teacher reaction was very positive, although comments were made that the approach was too time-consuming and that the amount of preparation work for the experiments was too great. The videotapes did illustrate how experimental work can be conducted and did also show how teaching can be conducted to get the students more interested and involved—areas which are of concern in Estonia. It was concluded that the visit was a success and that it had set the seeds for further developments in this area.
ICASE WORLD SCIENCE ACTIVITY WEEK
22-28 OCTOBER 1995

BRINGING PROJECT 2000+ TO SCIENCE CLASSROOMS AND COMMUNITIES
ON THE THEME OF SUSTAINABLE DEVELOPMENT
On the occasion of United Nations Day 24 October 1995

Activity Week Theme

Item 2 of the Declaration states “ . . . believe that scientific and technological literacy are essential for achieving responsible sustainable development . . . assign priority to the development and introduction of programs leading to scientific literacy and technological literacy for all with the aim of achieving responsible sustainable development.”

ICASE encourages and supports projects in science and technology education in both formal and non-formal education. To this end ICASE offers a unique opportunity for Science Teachers’ Associations to involve teachers, who in turn may involve their students in formal or informal activities in exploring, within various cultural contexts, the concept of sustainable development.

Categories
The ICASE World Activity Week aims at involving:
• Primary/elementary level students . . . ages 6-11
• Middle school/junior high students . . . ages 12-15
• Secondary/senior high students . . . ages 16-18

Activities
Student individual/group entries may be of three types:
• Poster or cartoon, paper size not to exceed 220 mm x 300 mm, in single or multiple frame format (applies to all grade/age categories). Poster or cartoon to focus on a sustainable development issue.
• Essay/paper supported by illustrations/photos focusing on a community sustainable development issue:
  • Primary (up to 250 words)
  • Junior (250-500 words)
  • Senior (1000-1500 words)
• Investigation activity which highlights a sustainable development issue. Students prepare a report focusing on the far ranging implications of the activity (applies to all levels).

Awards
Certificate awards will be available to each ICASE Regional Representative who, with an appointed panel, will evaluate the entries and recognize up to 20 individual/group entries across all categories. One special award/prize per ICASE region will also be made across all categories. A final report will highlight entries and summarize awards stimulated by ICASE World Activity Week.

ENTRIES . . . Deadline 30 December 1995
Entries may be submitted in Spanish, French, or English and are to be directed to the ICASE Representative in your region:
Africa: I. O. Ikeobi, PMB 081, Festac Town, Lagos, Nigeria
Asia: J. Yingprayoon, IPST, 924 Sukhumvit Rd, Bangkok 10110, Thailand
Australia-Pacific: M. Silis, University of South Australia, Smith Rd, Salisbury East SA 5109, Australia
Europe: A. Wojtyna-Jodko, SNPPIT, Skrytka Pocztowa 62, PL-85791, Bydgoszcz, 32, Poland
Latin America-Caribbean: J. Chamizo, Colegio Madrid AC, Calle Puente 224, 14380 Mexico DF, Mexico
North America: K. R. Roy, Glastonbury Public Schools, 330 Hubbard St., Glastonbury CT 06033, USA

Award winners will be announced in March 1996. Entries become the property of ICASE and will be displayed or put in print in ICASE publications.

For Further Information:
Mr. Bob Lepischak, Convenor, 1995 ICASE World Activity Week, PO Box 430, Neepawa Area Collegiate, Neepawa, MB, Canada R0J 1H0, Fax (204) 476-3606.
ICASE WORLD SCIENCE ACTIVITY WEEK
What is Sustainable Development? An Example.

Manitoba has always prospered through the use of our natural resources. In the past many practices for harvesting these resources were seen as being destructive to the environment. It was also recognized that our society had a great dependency on these resources and complete bans on harvesting them would be impractical. Many people separated the economy from the environment, with the belief that the two were independent from each other. Sustainable Development bridges the gap between the economy and environment.

The government recognized that responsible decision making was needed to ensure that future generations meet their needs. In 1988, the Manitoba government, in agreement with the recommendations of the National Task Force on the Environment and Economy, consented to oversee the National Task Force recommendations.

Sustainable development can be defined as a local decision making process which integrates and balances the economic, societal (health and well being of society), and environmental factors in a global context.

Philosophically, sustainable development is a grass-roots concept which requires the active involvement of all segments of society as the environment and economy are fundamental to how we live and the quality of life we have. Business, environmental representatives, labour, educators, citizens and government working together can give a balanced perspective which is not readily available to government working alone.

There are many examples of how sustainable development has affected decision making processes at all levels of our society. Manitoba Hydro provides a good example of how business is taking an active role in sustainable development. In recent years, Manitoba Hydro has adopted sustainable development as part of its corporate policy. Manitoba Hydro has implemented a plan to involve the whole corporation in implementing sustainable development policies. Projects being planned or already in progress take into consideration its effects on the economy, environment and society in whole. They have adopted a set of principles which govern how they make decisions. The principles correspond with the principles of sustainable development created by the Manitoba Round Table on the Environment and Economy.

Many governments around the world are implementing sustainable development policies that help ensure their country uses their natural resources responsibly. Sustainable development policies will continue to grow and transform with our societies changing needs.

LETTER RECEIVED
Amal Krishna Banik

Thank you very much for your excellent letter in kindly permitting us to use and translate the article ‘Teaching Science in an Artistic Way’ in Bengali language from ICASE Journal. I feel personally grateful to you for this noble gesture. I think the points Dr. Nesbitt also made are really important. I believe that much of science which seems to burden students could be better taught artistically. This is what I have come to realize through my experience of teaching for nearly two decades. So I felt inspired to bring Dr. Nesbitt’s article to my students so they could follow its inner significance as well.

Please note:
The editor would like to remind our member organizations and individual readers that all articles in Science Education International are available for reprint in your own journals. All copyrights are extended to members. This is a wonderful opportunity. Please consider starting an international section for your journal and use our fine articles to expand global awareness. All we ask is that you give credit to the author and the ICASE Journal.
GENDER ISSUES IN CARIBBEAN SCIENCE EDUCATION

Peter Whiteley
Faculty of Education
University of the West Indies

Introduction

Jamaica has about 58,000 university-age young people, of whom more than half are female. In 1992-93, forty-eight females registered for the first year introductory physics course at the University of West Indies Mona Campus. Twenty-eight completed the course successfully. By comparison there were 137 male registrations, with 76 being successful. The ratios, 2.85 male to female in registrations and 2.71 male to female in passes, are indicative of the strong male bias in physics of UWI, as elsewhere, which is further emphasized by the fact that all academic staff in the Department of Physics are male.

The imbalance, however, is evident from a much earlier stage. In Table 1 the average passes and entries in Jamaica, for 1992 and 1993, at different levels of examinations in physics are presented.

These figures make clear that physics has become a ‘male’ subject by the time students make decisions concerning their first public examinations—C.X.C. or ‘O’ Level. Decisions with regards to option choices in Jamaica are usually made during the third form of secondary school (Grade 9).

By contrast the figures for biology show a strongly female bias in Jamaica, with variation around approximate equality in chemistry although a shift towards a ‘female bias’ is noticeable at the higher levels of chemistry—Tables 2 and 3.

Working in Britain, Kelly (1987) has also noted an unequal representation of females in the physical sciences. She suggests that gender-related stereotypes place restrictions upon individuals’ development and that both the individual and society lose from this restriction of talent. She claims that science qualifications often help individuals to obtain secure and well-paid jobs which, in turn, lead to a greater degree of power and influence of such individuals in society. Science is widely held to be an important part of a general education and in the technology-based societies of today a scientific education can give people a sense of control over their environment. Kelly is of the opinion that technology is presently controlled by men, and women as a group need to be educated in science so

Notes:

1. In the Caribbean secondary school students may enter, at the fifth form, either the examinations set for the Caribbean Examinations Council (C.X.C.) or those of the Cambridge Local Examinations Syndicate (Ordinary ‘O’, level)—the figures presented here are the combined entries and ‘passes’; Grades A-C (Cambridge) and Grades 1 and 2 (C.X.C.) which are deemed equivalent and understood as passes.

2. Preliminary courses at U.W.I. are for candidates who do not have the entry qualifications for the Introductory courses—i.e., have failed or not taken Advanced (‘A’) Level in physics but have a pass at the previous level. Thus entry to introductory courses needs either an ‘A’ level pass or a pass in the preliminary examination.

that their voices may be heard in technological discussions. Kelly also feels that a greater involvement of women in science may lead to a humanization of science as “women whose socialization traditionally emphasizes people are well placed to reorientate science towards caring concerns” (p. 8). Bazler and Simonis (1991) note that women represent only 20.5% of the natural science and 5.8% of the engineering work force in the U.S. and express similar concerns.

In Jamaica published information is sparse as to the gender distribution of holders of technological and scientific posts, but at the Mona campus of the University of the West Indies in 1990, 53 of 65 academic staff in the Faculty of Natural Sciences were male (U.W.I., 1991).

There are a range of factors that can lead to the choices made by students in their school careers—choices that may result, in the long term, in unequal numbers of males and females in scientific and technological posts and careers. This article reports on the investigation of one possible factor—the 'gender fairness' of integrated science textbooks. Here the term 'gender fairness' is interpreted (following Bazler & Simonis, 1991) as being that the textbook contains a balanced and comprehensive portrayal of both men and women.

**Textbooks in Science Education**

Potter and Rosser (1992) suggest that teachers' reliance on textbooks results in the books playing a decisive role in determining classroom events. In Jamaica textbooks are an important part of the classroom experiences of children studying science and the textbook may effectively become a detailed syllabus for a course—thus constraining the teaching methodologies and the ideas discussed. Elsewhere, Powell and Garcia (1985) cite Stake and Easley as showing that students are very reliant upon textbooks.

Powell and Garcia (1985) argue that publishers of science textbooks should depict society 'as it was, is and should be' (p. 520) when describing scientific ideas and theories. In their view, learners should be provided with illustrations and accounts of individuals from all walks of life as being involved in science and thus provide female students with female examples of those directly involved in scientific professions and activities. This may result in less distortion and stereotyping, a more positive view of females in science and greater numbers of women aspiring to science-related professions.
Peterson and Lach (1990) note that the current recognition of the constructive nature of reading points to the importance of the prior ideas for the reader’s interpretation of the material. If readers possess gender-related stereotypes they are unlikely to question printed support for such stereotypes. These authors suggest that texts should challenge stereotypes and cite evidence that exposure to non-sexist material can reduce the prevalence of sex-role stereotyping.

Brush (1985) argues that we can reasonably assume that girls derive some kind of message from the way women scientists are mentioned (or otherwise) in textbooks and that this message has some effect on their future career decisions. Brush notes that in the rare cases of women being mentioned they are often portrayed in ways that would not be considered models of success by students reading the material.

Most of the science books used in high schools in Jamaica are published in Britain although they are usually authored or co-authored by Caribbean writers. Books written specifically for the Caribbean first became generally available in the latter half of the 1970s. Research elsewhere at that time was demonstrating that many science textbooks had a clear bias towards males. Taylor (1979) looked at three popular physics texts in Britain and found many references to males (youth and adult) with very few references to females and when girls or women were shown they were not depicted in activities of a scientific nature. Historically, references were made almost exclusively to male scientists and the technological examples chosen were those of greater interest to boys than to girls. Recent work (Jones & Kirk, 1990) has shown the considerable differences which can exist between the examples of applied science that are of interest to boys or girls. Throughout the texts that Taylor studied, the image of a woman as a passive, domestic being was promoted with the references to females largely confined to domestic situations.

Heikkinen (1978) looked at American chemistry textbooks from the 1940s to the 1970s and demonstrated the all-pervasive nature of the sex-stereotyping and bias. Male figures were shown to dominate all the textbooks including the most up-to-date revisions. Named and unnamed adult figures were on average 83% male in the 1970s textbooks with the illustrations of youths or students being in the male to female ratio of two to one in the same textbooks. Bazler and Simonis (1991) followed Heikkinen’s methodology and used later editions to look for changes between the early 1970s and the late 1980s. Overall, they found significant differences in the male to female ratio in the later texts compared with earlier editions in relation to gender fairness. Only in one text was a balance between male and female illustrations found.

Powell and Garcia (1985) analysed elementary level books and found that although females were depicted throughout the illustrations in a variety of occupations they were represented in these roles less often than males. On the other hand female children were found to be represented more frequently than male children in both scientific and non-scientific activities suggesting that publishers have made progress in improving the image of young females in science texts. Recent work by Potter and Rosser (1992) has indicated that most texts now use gender neutral language and depict women in illustrations. They claim, however, that more subtle forms of sexism may still be detected, the contributions of women scientists are often omitted and topics of interest to women are overlooked. They found a significant sexist bias in science textbooks (all published in 1983 or 1984) and argue that the omission of women’s contributions and interests supports a stereotype in which only male interests are worthy of recognition and study.

Methodology

This study had the objective of analysing a popular two volume integrated science textbook series published for use in the Caribbean (Books A and B, see appendix) and comparing the results with those from sample volumes of each of four other series of integrated science textbooks (Books C-F, see appendix). One volume from each of three integrated science textbook series published for use in Britain were also analysed. (Books G-I, see appendix.) The intent was to determine the gender fairness of the textbooks being used in Jamaica, to draw relevant comparisons with the British textbooks and to attempt to identify possible changes that might be considered desirable.

The following aspects of the textbooks were considered:

(i) the number of illustrations of males and females, both youth and adult and the total number of illustrations;

(ii) the number and gender of named scientists in the text or illustrations; and,

(iii) the prevalence of the depiction, in words or illustrations, or ‘gender stereotypes.’

The selection of the textbooks for the study posed certain problems. Teachers in Jamaican high schools enjoy a considerable degree of autonomy and the Ministry of Education does not prescribe the textbooks to be used for the teaching of a given
discipline or year group. This leads to an uncertainty as to current practice and firm data as to which textbooks are used and to what extent textbooks are not available. It is, however, reported that the Books A and B are commonly recommended on school book lists for the first three years in Jamaican high schools. It is hoped that the exercise reported here will at least give pointers for further investigation and research.

**Results**

The figures in Table 4 show that a clear bias exists towards the representation of adult males as opposed to adult females in the illustrations in the two books (A and B) of the main series as adult scientists, technologists and in related occupations. On the other hand, young people of either gender, who are usually shown engaged in the laboratory activities described in the text, are depicted in approximately equal numbers. It could be suggested that the image given is one in which all students, independent of gender, are expected to play an equal role in school science but that in adult life science is a province more appropriate for males. The large percentage of illustrations without humans in both editions should also be noted.

Key: Named—Named Scientists

10
Science Education International, Vol. 6, No. 1 March 1995
Both books of the series include no named examples of female scientists. The argument might be put forward that female scientists were not involved in the development of any of the content in these textbooks but perhaps a lack of knowledge of such contributions, on the part of the authors, may be a factor.

All the other Caribbean and British textbooks considered have greater proportions of male figures than female figures in illustrations. The ratio in favour of males is generally greater for the illustrations of adults than for the illustrations of young people where an essential numerical equality is achieved in five out of seven textbooks. Thus generally, perhaps, "Science is for all school students but for male adults" may be the message being received.

The figures do not suggest that any of the textbook series is clearly preferable to the others from the point of view of equality of representation of the genders. It should be noted that the percentage of illustrations in the Caribbean textbooks without a human depicted varies from 69.2% to 85.9%; the British textbooks surveyed had a substantially lower percentage of this type of illustration—49.1% to 66.4%. An impersonal view of science may well be conveyed by such a large number of 'human-free' illustrations which may have implications for gender perception and preferences. The textbooks for British students also had considerably greater numbers of illustrations per page on average. The Caribbean textbooks had between 1.14 and 1.90 illustrations per page with an average of 1.47 while the British textbooks had between 2.33 and 3.23 illustrations per page with an average of 2.81. This may reflect an effort to reduce costs for the Caribbean textbooks and also difficulties that the British publishers may have in obtaining illustrations suitable for the Caribbean.

Figures alone, however, do not adequately describe the textbooks' treatment of gender-related issues. Although the Caribbean textbooks do not use the masculine pronoun in references to scientists and are generally neutral in language use, neither do they actively challenge gender stereotypes. The potential for such a challenge is well exemplified by Book I—a book intended for British lower school students. In this textbook a decision appears to have been made to deliberately present examples which avoid implicit gender stereotyping. The illustrations in this book include persons shown engaged in the following activities:

<table>

</table>

The list above indicates that there can be a range of opportunities in a science textbook to provide alternative perspectives to common gender stereotypes. Further, most, if not all, of the activities or occupations listed are, or contain, examples of technological applications of the physical sciences—given the low numbers, noted earlier in this article, of women in the physical sciences the emphasis in these illustrations could be seen as important. (The only other book with similar 'challenging' illustrations was Book H which is also a book for British students.)

The near total lack of named female scientists in the Caribbean textbooks (two, both in Book D) is clearly an element in the production of such textbooks that authors and publishers may wish to address. Textbook D has mention of two female scientists—the well-known Marie Curie and June Roach, the latter a Barbadian microbiologist who works in the veterinary field. This text also names three male Caribbean scientists and outlines their work—in the writer's view the utilisation of Caribbean examples of practising scientists should be encouraged with a further need for gender equality.

Work into images in Caribbean social studies textbooks (King & Morrissey, 1988) found that females, along with their achievements and contributions, tended to be ignored or underrepresented. Nearly fifty percent of the textbooks reviewed were found to use masculine nouns and pronouns to include women as well as men. Thus the general problem identified in this paper in Caribbean science textbooks appears to be found in other disciplines as well.

**Conclusion**

Overall most of the integrated science textbooks used in Jamaican high schools exhibit a male bias although authors and publishers now appear to be more aware of the need to check textbooks for gender balance. In the production of science textbooks
decisions regarding the illustrations may often be
made by the publishers with a tendency to use
material they already possess for convenience—this
may go some way in explaining the relatively slow
rate of change. It is also possible that there has not
been as much societal pressure in the Caribbean as in
England aimed at ensuring a strict equality of
representation of the genders and attempting to
challenge gender stereotypes.

It has been suggested that when historical
examples are being discussed the social context
should be explored to ‘explain the predominance of
men in science at the time’ (A.S.E., 1990, p. 6).
Further, the ‘hidden’ contributions of women
scientists in history might be good starting points for
discussion (see Alic, 1986).

It is to be hoped that a consideration of these
issues will guide decisions made by authors and
publishers in their continuing revisions of current
Caribbean science textbooks and the development of
new materials.

CHEMICAL EDUCATION IN JORDAN

Dr. A. M. I. Abdalla
Faculty of Education, Yarmouk University
Irbid, Jordan

Teaching chemistry in Jordan started in the early 1950s. At that time there were no laboratory experiments. Only lectures were given to students and they had to learn by rote. Later (1964) laboratories were set up and chemical reactions were occasionally demonstrated to the students.

A. Pre-school & Lower Basic Stage
Chemistry teaching in schools begins at the primary levels as a part of the integrated Science curriculum which begins formally from primary 3 onwards. From the first year at school (age 6 years old) students are exposed to studies on “Matter” which includes studying about the properties of water, air and other materials, elements, magnets, and changes in specific properties as a result of interactions with other matter or energy, or both.

Another important consideration is that in Jordan practically all children have at least one year of pre-school experience. Even in the kindergarten they are exposed to various materials and their properties. Concepts of color, weight, hardness, texture and even density are experienced through play and related learning experiences in a pleasant way.

One can thus appreciate the early start these young children have in Science.

B. Middle Basic Stage
Chemistry is given more prominence at the Lower Basic stage, age 10-14 years. It is offered as an integrated part of General Science which is taken by all students. Topics in General Science include:
- Laboratory set-up, arrangement, rules and safety in the laboratory.
- Measurements—SI units and use of common laboratory apparatus are introduced.
- Matter—classification of matter, states of matter and changes in matter.
- A simple introduction to elements, mixtures and compounds.
- Simple concepts of atoms and molecules in terms of the distinction between atoms and molecules.
- A brief study of air and its components.
- A brief study of water and solutions.
- An introduction to hydrogen, acid, bases and salts.

C. Upper Basic Stage
At the Upper Basic Stage, age 14-16 years, while at the 10th grade (16 years old) chemistry and earth sciences are taught as separate subjects. At the end of this stage students are divided into different streams, scientific and literature (academic education) and professional education such as agriculture, nursing, and industrial stream.

D. Secondary Level
Chemistry is available as an elective subject at secondary level. Unlike in the basic stage, 11th grade and 12 grade chemistry is a separate subject. It has its separate books, separate laboratory and more advanced chemical subjects start to be taught such as polymers, transition metals, organic chemistry, and some industrial subjects. Only specialists in chemistry teach these courses.

E. Junior College
The colleges and polytechnic, which are under the Ministry of Higher Education, offer chemistry programmes at the diploma level (two years) after the national secondary school examination (Tawijihi).

The Junior College core syllabus represents 80% of the entire course with 20% drawing option topics. The core syllabus comprises the theoretical and established concepts of Chemistry while the option topics are geared towards applications of Chemistry. The topics include:
1. Phase Equilibria
2. Further Transition elements
3. Biochemistry
4. Chemical Engineering
5. Food Chemistry
6. Polymer Science
7. Soil Chemistry
8. Spectroscopy

The syllabus is still focused on the core areas, and the questions are more demanding requiring higher levels of thinking skills on the part of the students.

F. Chemical Education at Universities

Undergraduate Study in Chemistry
In 1964 the first faculty of science in Jordan was established at Jordan University. The first chemistry building at this university was ready to function in
Since then, the chemistry building has expanded according to the increasing need. The Department of Chemistry at Jordan University, under the leadership of qualified and enthusiastic professors has made a great contribution to the development of chemical education in Jordan. It has been their graduates who have been involved in establishing most of the chemistry departments in other universities. The number of chemistry departments is gradually increasing. Out of the six state universities, there are three departments of chemistry and a department of applied chemistry has been started at Jordan University of Science and Technology (JUST). Besides state universities private universities started four chemistry departments, but have fewer students.

All the programmes offered lead to bachelors degrees and require a minimum of 132 credit hours spread over a four year study period. For a programme with a single major in chemistry, the chemistry units are 99 units minimum requirement. In the double major programme the load of chemistry is slightly reduced to 29-30 units. Jordan Universities are practicing the cumulative Average system. Under the system, those who obtain: 84% and more excellent; 76%-84% very good; 68%-76% good; 50%-68% poor; less than 50% fail.

In the first and second years the curriculum covers basic chemistry to strengthen the understanding of chemical concepts in physical, inorganic and organic chemistry. Practical classes, which account for about 25% of the total chemistry loads, are compulsory. Chemistry normally attracts large numbers of students and this usually gives rise to logistic problems to the department. The third and fourth year chemistry subjects are considered as core courses with possibilities of taking some elective subjects from chemistry or other disciplines. In the fourth year some specializations are offered in the field of analytical chemistry, physical chemistry, inorganic chemistry, material, polymer and environmental chemistry.

In the fourth year some students are required to carry out research projects. These research projects provide students with the opportunity to choose their field of interest and to work independently with close supervision by their supervisors. However, as these projects create great demands on facilities and academic staff, some universities provide option for students to skip the research project and replace it with course work.

Every year, all Jordanian universities produce about 280 chemistry graduates. Most of the chemists are employed as teachers in secondary schools, some are in the institutions and industries while others are in administrative lines. The demand for chemists is great as many new industries require chemists in their operation. This is the reason few chemist graduates pursue higher degree studies.

Postgraduate Studies in Chemistry

At Jordan University and Yarmouk University, the enrollment of chemistry postgraduate students is around 5% of the total undergraduate students enrolled. Efforts are being made to increase the graduate student population to around 20-30%. This is not an impossible figure to achieve in the near future as the country moves towards higher education industrialization. This process requires indigenous research and this will naturally push local industries to demand highly trained research chemists. In many industrialist countries it isn’t uncommon to find higher proportion of post-graduate chemistry students than their undergraduate counterpart.

Under normal circumstances only chemistry graduates with at least a good average (70% up) who have an interest and an attitude for research can be eligible to do post-graduate studies which lead to Masters (M.Sc.). Graduates with lesser qualifications who have enough working experience as school teachers can be eligible to do postgraduate studies in science education. Master degrees are for those who would like to solve a minor research problem and at the same time gain some experience in research activities.

All of the postgraduate chemistry programmes are conducted through full time research. Only occasionally are some candidates required to take a few credits of course work to strengthen their background in a particular field of chemistry.

Most of the post-graduate research in chemistry evolves around primary commodities with emphasis on pollution, water treatment, drugs, etc. Apart from these applied oriented research projects, fundamental research on pure chemistry is also offered.

Problems of Chemistry Education

This universal problem of teachers who are not fully qualified, inexperienced, and underpaid applies also to the teaching of chemistry, as in the other subjects, but here the problem is accentuated by other factors applicable to chemistry.

High school chemistry combines all the exacting topics of an exact science and the dullness of factual knowledge. With an inexperienced teacher chemistry can become extremely boring, uninteresting and unchallenging.

Students learn chemistry just because it is a part of the curriculum, not because of the subject itself.

We all know that experimentation could evoke much more interest and make chemistry more
attractive, enticing students to study chemistry for itself and opening their minds to the challenges of chemistry. Unfortunately experiments are not utilized by most teachers for the simple reason that they were not exposed to it in their own senior high experience.

Most schools lack laboratory facilities, but books on chemistry are readily available. There is a book packet written by a team of the Ministry of Education and Universities and there are many others by individual writers, many of which are quite good and up to standards. This learning material is not the biggest constraint as proven in many schools where a resourceful teacher can do a lot of experimenting with "nothing," using only discarded empty bottles, drinking glasses, vinegar borrowed from the kitchen, hibiscus flowers from the garden and so on. It is true that these teachers are exceptions, but they do exist and one can imagine what they could accomplish when given adequate facilities. But even with such teachers and facilities, we all are familiar with chemistry experiments in high-school, which in Jordan are usually carried out as lecture demonstrations. These, even when performed perfectly, can be observed clearly from front seats only. Still, when properly organized, lecture demonstrations can go far in at least making chemistry eye catching, interesting and attractive. It would be far more effective if the students could carry out experiments individually; unfortunately very few schools are in a position to do that and even in these few schools the students work in groups. The cost is still prohibitive for students to carry out experiments individually.

If possible, individual experiments would force the students to think and make them remember facts much more easily. When they actually see an indicator changing color they will remember it much more easily than just by reading it.

Besides this material constraint, it should be realized that most teachers are not able to face the challenge of organizing individual student's practical work and maybe do not fully realize its importance, for the simple reason that it was not emphasized in their previous teacher training. This constitutes a challenge to the IKI's as the source teachers, and indeed the Ministry of Education are not in the process of revising the curriculum.

Another, much more serious constrain to promoting practical work is the system of examinations. In the system of examination, the final examination (Tawjih) gives no weight to practical work. It is more important for the student to find the correct answer rather than to really understand concepts.

It is true that experimenting does help in finding the correct answer but because teaching time is limited, so much to teach in so little time and experiments certainly can be very time consuming, a teacher (especially inexperienced) will be inclined to sacrifice practical work and put emphasis on the teaching itself.

Should he spend one lecture hour to set up a lecture demonstration of the dissociation of nitrogentetroxyde or would it be more useful to use that one hour to train the students in how to calculate the concentrations of a certain solution. For the average teacher, harassed and pressed for time, the choice will be obvious.

### Attempts to Improve Chemical Education in Jordan

Some programmes are organized very pragmatically and are school-based so as to interfere as little as possible with the teacher's regular activities. A cluster of schools located not too far from each other are selected and one (usually the best equipped and staffed) is chosen as a meeting point where the teachers meet with the acting members of the Jordanian Chemical Society. The meetings are not so much a one-way course, but more like an open discussion and thus can be very productive. Each teacher can bring forward his own particular problem and the topic for the next meeting is decided.

To extend the Jordanian Chemical Society services, new branches of the society were established in other districts of the country, and some members of the Ministry of Education joined the society to act as instructors.

It should be noted that the progress of chemical education in Jordan is not accomplished by the formal educational system solely.

Other activities organized by The Jordanian Chemical Society also play an important role. Further activities include the following:

1. Meetings and workshops of the Jordanian Chemical Society.
2. Chemistry training by the Institute for the Promotion of Teaching Science and Technology.
3. Activities of the Chemistry departments which have received the kind attention and support of universities and the Ministry of Education.
4. Activities of the Department of Curriculum and Instruction in preparing teachers to get their diplomas in Science Education (two years after B.Sc.) also have been introduced.

“A WORLD IN MOTION:” PHYSICS FOR PRIMARY SCHOOL CHILDREN

More than 100 corporations have joined forces to create and fund a program to teach physics concepts to grade school children (The Engineering Society for Advancing Mobility Land Sea Air and Space International press release).

“We’re losing an entire generation of children because they’re being turned off by science,” said Lloyd Reuss, retired president of General Motors and one of the brain trusts supporting “A World in Motion.” “Our public schools don’t have the resources themselves to reverse this trend,” he added. “A World in Motion is proving to be a particular successful response to this challenge.”

The program centers on a hands-on physics and math curriculum “featuring carefully researched practical experiments” and the involvement of professional engineers and scientists. According to the release, more than 10,000 engineers and scientists have volunteered 50,000 hours of time assisting teachers and students. A recent survey of teachers using the program in their classrooms found that 90% said their students had strengthened their physical science skills and another 70% stated that student math skills had improved, writes the release.

“A World in Motion” was launched by a $1M gift from General Motors, and SAE has raised $7M from corporations including Allied-Signal, American Honda, Siemens Automotive, Toyota, Rockwell, Nissan, Chrysler, GTE, Caterpillar and the Eaton Corp. And a National Science Foundation grant of $1.8M will help expand the initiative to middle schools nationwide, reports the release. SAE also intends to raise an additional $16M during the next six years to expand the initiative and support the middle school program.

“A World in Motion” kits are distributed free-of-charge to elementary school teachers. Already 20,000 kits have been sent to 10% of public schools nationwide. SAE’s goal is to make the program available to 80% of the nation’s elementary schools, writes the release.

An Idea for Educating STS Literate Teachers

Science-Technology-Society (STS) education is distinctly different from traditional schooling. Educating science teachers to be STS literate can be achieved with strategies that help them construct appropriate beliefs, values, and professional practices. This paper proposes one teacher education strategy.

This strategy makes three assumptions: (1) Citizens literate in STS must be cultivated through STS related social issues. (2) STS literate students can be cultivated only by STS literate teachers. (3) STS pedagogical content knowledge (PCK) can be constructed only through actually participation in STS learning.

In our plan, preservice teachers engage in a problem centered STS activity using role playing, small group cooperative learning, and class sharing. The entire process is videotaped. The videotapes provide opportunities for articulation and reflection among the peers. In the process they confront inconsistencies between the traditional one and the STS instructions and come to construct more appropriate beliefs, values, and science teaching practices.

Our beliefs, in designing the strategy, are:
1. Learners as designers of instruction and learning by doing in authentic contexts are powerful tools for educating science teachers.
2. PCK can be developed through a problem centered STS activity.
3. Small group cooperative learning triggers natural instincts to construct PCK.
4. Role playing is useful in facilitating brainstorming, arousing issue awareness, finding questions, seeing multiple perspectives, and assuming relative positions.
5. Students learn better when given intellectual autonomy, which encourage them to negotiate differences and work toward consensus.
6. Videotaping activities provides opportunities for articulation and reflection. In conclusion, teachers training institutions should provide formal STS courses so that preservice teachers can have opportunities to design and use their own STS activities to construct PCK. They should be encouraged to maintain efforts along this line to assure that the college training would be far more than just cosmetic.

The Role of the National Science Council

Teaching and learning in Taiwan has been strongly affected by the national curriculum standards and the joint entrance examinations. As a result, it has been difficult to implement STS as a teaching/learning strategy in the schools, although many educators realize its importance. To encourage STS efforts, the National Science Council Division of Science Education launched the STS movement by promoting science education research. This research effort is headed by Division Director Dr. Rong-Fu Hsu.

They began with a workshop, planned by Senior Research Fellow Yung-Wen Kuo and jointly organized by National Science Council Division of Science Education, National Taiwan Normal University Institute of Science Education, and National Taipei Normal College Department of Science and Mathematics.

Held at NTNU, August 23rd-27th, 1994, more than one hundred science educators attended the workshop. Dr. Robert E. Yager, of the University of Iowa, was the keynote speaker in the workshop. Lectures and discussions were conducted on the following topics.

Day 1: The meaning of STS
The constructivist learning model
Constructing a model for student learning in science
Historical review of science education reform

Day 2: The Iowa Chautauqua Program
Assessment of changes in teacher and student learning
STS and the national standards and curriculum frameworks
Structuring STS modules (Examples)
Day 3: Teaching strategies needed for STS
   Video-tape analysis/review
   Action research and changes in teaching approach
Day 4: Assessment instruments and strategies for implementing STS in schools
   Practices in formulating researchable questions
   Relating quantitative and qualitative techniques
   Matching goals with assessment
   Strategies/instruments
Day 5: Identifying research projects for each participant team

Reporting and communicating
   Instructional modules
   Research questions and approaches
After the workshops educators are organizing collaborative STS research projects and seminars to facilitate information exchange. A cordial invitation is hereby extended to STS experts worldwide who are interested in international cooperation; please write the author at:

SCIENCE EDUCATION IN THE EASTERN CAPE, SOUTH AFRICA

Paul Webb,
Centre for Continuing Education
University of Port Elizabeth, South Africa

Introduction
The Eastern Cape is one of the nine recently proclaimed provinces of the “new” South Africa. It is the second largest province in the country, covering an area greater than countries such as Lesotho, Malawi, Austria or England and caters for nearly two million pupils, i.e., 25% of the South African school-going population.

Eighty percent of the population speak Xhosa, 10% Afrikaans and 5% English. However the medium of instruction in the vast majority of schools is English, starting in the third year.

Although the Eastern Cape has 25% of South African pupils, it produces only 6% of the country’s matriculants. Nearly 70% of all teachers in this region are considered under or unqualified. These data are indicative of general problems plaguing education in the province. The position of Science Education is even more parlous as only one out of every 10,000 black pupils who begin formal schooling leave the system with a passing grade in Physical Science and Mathematics.

- lack of support mechanisms, e.g., science societies, groups, committees, etc.
- overcrowded classrooms
- lack of facilities in general, e.g., many schools do not have electricity and some farm schools do not even have access to water.

This situation prompted a number of private-sector sponsored initiatives in science education. These programmes usually took the form of in-service training and classroom support, both at elementary and secondary level. One such programme is the Primary Science Programme (PSP) which is a national initiative with management structures in five provinces. This programme has operated for over ten years in the Eastern Province in collaboration with the University of Port Elizabeth’s Centre for Continuing Education (CENCE). Since its inception in 1984 the programme has grown more than twenty-fold from 58 teachers at 32 schools to the current figure of well over a thousand teachers in 800 schools.

Problems and Intervention
The problems encountered when teaching science in the new South Africa remain the same. These are:
- lack of training in Science Education
- lack of apparatus and supporting materials
- teaching Science in a second language

Materials and Methods
The initial intent of the Primary Science Programme (PSP) was to provide elementary schools with science apparatus and to train teachers to implement practical work. Currently apparatus is still provided to schools in kit form. The kits provide all the prescribed experiments in years 5, 6 and 7. Enough apparatus is provided in each kit for ten
groups of pupils, but smaller, five-group kits are also produced for farm schools. These kits are currently assembled at CENCE and distributed to schools via PSP in-service training workshops. The cost of the apparatus to schools is 20% of the cost of production. Over 500 schools in the Eastern Cape have been provided with at least one kit.

International trends and developments have had, and continue to have, effects on science education in the Eastern Cape and a great deal of curriculum development has taken place in the Primary Science Programme since its early days. Currently the programme’s in-service training focuses on teacher development through integrated concept-methodology workshops which attempt to create a change in attitude from valuing content to valuing skills and concepts. Activities emphasize the constructivist learning model.

As the programme is presented over an area equivalent to the size of England implementors are drawn whenever possible from local communities. These include lecturers from universities and colleges, science advisors, school teachers, farm school managers plus “home managers” who are qualified to teach science at school level. Staff development of these implementors is promoted by quarterly seminars during which the content, methodology and philosophy of the programme is discussed. These seminars, which are held at central venues, also facilitate coordination and administration.

Lack of materials per se, as well as the perception that the materials that are available do not support the programme’s aims and philosophy, prompted the development of materials for teachers and pupils. Worksheets, which include numerous cartoons and illustrations to stimulate interest and promote understanding, were tested on teachers during workshops, as well as by teachers in the classroom. Over 250,000 copies of worksheets were made available to schools for testing and teachers became part of the development process through editing and putting forward new ideas. After this process was complete, workbooks were made available to schools at a price less than the cost of production.

Another problem experienced in the classrooms of the Eastern Cape is the authoritarian methods used by many teachers. This probably reflects on their own experiences as pupils and subsequent training at College. This authoritarian approach remains a problem despite strenuous attempts at remediation during workshops. In response to this a series of “prompt posters” were developed to promote teachers questioning skills and encourage pupil participation in lessons. The prompt posters, which are draped over “holdall lecterns,” have a series of lesson prompts on the side facing the teacher. These prompts are almost entirely in the form of pupil directed questions. Examples of acceptable answers are included with the prompts.

The posters, worksheets and in-service training workshops all follow the prescribed elementary school syllabus and, wherever possible, promote the use of the apparatus provided in the kit supplied by the Primary Science Programme (PSP).

Rationale

The underlying rationale which directed the development of materials was shaped by the belief that they should:

- present concepts as visually and concretely as possible
- allow concepts to be built up in a logical way
- be pleasurable, challenging and interactive
- allow mastery of small steps with opportunity for demonstrable achievement, leading to confidence building and more complex skills
- emphasize oral, written and other communicative skills
- allow pupils with restricted language competency to demonstrate their skills and understandings
- create a change in attitude from valuing content to valuing skills and concepts

Apart from the above, the thinking which directed the development of the prompt posters in particular was they should:

- make explicit the intent underlying the lesson as this leads the teacher to security and focus
- enable learners to easily grasp what is intended through pictorial aids and verbal prompts
- allow users to become part of the development process through pupil and teacher input during testing and trialing
- be able to be put into immediate practice in the classroom
- be a model which is transferable to other subjects and which allows teacher to produce posters by themselves.

The cartoons on the worksheets and posters are meant to make the activities fun, reading more pleasant, help pupils make sense of new words and provide visual stimulation for concept formation. Varied worksheet layouts allow pupils to experience different ways of presenting and recording information.

The Future

Although cooperation between the PSP, Shell Education Service and the university has enabled the
development of a synergistic programme for both the in-service training of science teachers and the development and production of apparatus and materials for schools, there are a number of issues which require attention. One is research into the effect of these efforts in the classroom. Another is the issue of accreditation of the upgrading efforts of underqualified teachers, particularly those in remote rural areas who have little opportunity to interact with formal training institutions. Both these issues are currently receiving serious attention.

It is hoped that on-going research will provide a sound framework for further developments and that accredited in-service training, integrating science, mathematics and the medium of instruction, and which focuses on classroom competencies, will provide an incentive for teachers to develop themselves into effective science/mathematics educators while using their second language as the medium of instruction.

Stem Link: AN INTERNATIONAL EXPERIMENT

Lynn W. Glass
Iowa State University, Ames, Iowa
Eugenia Etkina
Southwest High School 1543, Moscow, Russia

When we think of international exchanges among high school students most of us think about exchanges involving foreign language, humanities, or social studies classes. It doesn't have to be that way. We want to share with you an unique experiment called Stem Link; an exchange that involves high school students of science in three Iowa high schools and three Moscow high schools.

During the summer of 1991, the National Science Teachers Association (NSTA) and the Soviet Academy of Science jointly sponsored a conference in Moscow designed to bring together science educators from the U.S.A. and the U.S.S.R. An outgrowth of the conference was the firm conviction that many mutual benefits would be obtained from an open exchange of ideas and materials between Russian and United States science educators. An exchange of subsequent visits by the co-authors of this article led to the development and funding of the Science Linkages Project (Stem Link); a project with the goal of improving the level of student achievement in science and cultural understanding.

Stem Link begins in September each year when students and teachers in Iowa and Moscow are linked via the Internet for the purpose of the daily sharing of teaching ideas and materials, student generated science data, and information about school life, values, and interests. Students and teachers are paired for the purposes of exchanging communication and home-stay visits. In February, the participating Russian students and teachers stay in the homes of their Iowa hosts. Teachers share teaching duties and students attend a full load of classes. In April, the participating Iowa students and teachers spend a month in Russian home-stays. Because few Iowans speak Russian the Iowans tend to assist in the teaching of English rather than of science and do not take a full load of courses.

Internet, our linkage, is a world-wide electronic data and communications network established by the National Science Foundation. The over one million daily users communicate via the same language, TCP/IP protocol. Teachers and students in Stem Link use modems and low technology computers, either Macintosh or MS-DOS based, to connect with Internet.

The utilization of Internet for daily correspondence allowed the project co-directors to watch the interactions of Stem Link teachers and students as they became familiar with one another and commenced the development of shared teaching and learning activities.

The average number of messages per week was 54.75. The 30 Iowa students and three teachers generated 25.03 messages per week while the 30 Moscow students and three teachers generated 23.28 messages per week. The administrative staff generated 6.44 messages per week.

While there were 54.75 messages during an average week, there were approximately 125 “conversations” during an average week. Each message contained 2.3 topics. A content analysis of one-third of the messages indicates that nearly one-half, 48.8%, of the conversations were cultural in nature; one-third, 32.1%, were academic in nature, and one-fifth, 19.1%, were technical/administrative in nature. Our sampling for content analysis was done for the September through January time period.

Improving our level of science achievement and gaining a cultural understanding of one another begin with a firm foundation of communication. Internet proved to be an inexpensive, practical way to communicate across nine time zones. Messages sent from Moscow on Tuesday were received in Iowa on Tuesday. The language used for communication was English.
Our teachers shared many ideas over the Internet. They shared philosophy, goals, lesson plans, teaching techniques, and student evaluation materials. While on the two one-month home stay visits they shared teaching materials and equipment, led class discussions, and helped write new science lessons. Follow up activities this year indicate that teachers are still utilizing texts, computer disks, laboratory activities, and teaching ideas that were shared during the exchange program last year.

The science project initiated by two physics teachers illustrates the cooperation that took place in SciLink. Each of the 20 students (10 from Moscow and 10 from Iowa) was responsible for a quantitative investigation of a topic in physics. Investigations were started in the fall of 1993 and were completed in the spring of 1994. Teachers and students helped one another regardless of country of residence.

During the last week of February, 1994, a physics demonstration program was held at Ames High School for parents and friends of the participating students. During this program, participating students gave oral presentations and visual demonstrations describing the results of their research. A video tape was made for viewing in Moscow by parents and friends.

A SciLink Physics Booklet was published. This booklet contained individual summaries written by each student describing his or her laboratory investigations. Summaries contained quantitative data, including graphs and mathematical equations. Conclusions were written including ideas for further investigation.

Topics investigated included:
1. The effect of air friction on the motion of falling coffee filters
2. Superball collisions
3. Home-made electric guitar
4. The frictional effects on a hover-craft
5. The effect of atmospheric pressure on a coke can
6. Potato battery
7. Bernoulli effect on a garbage bag
8. Cheap electric motor
9. Standing waves in a flaming pipe
10. Measurement of force exerted by strings
11. Photoelectric effect
12. Pendulum with vibrating support
13. Total internal reflection of a laser beam
14. Properties of sound waves using a vibrating thread
15. Convection currents caused by rotating cylinders
16. Visual effects caused by rotating colored discs
17. Alternating current demonstration using reversed diodes
18. Visual demonstration of standing waves in a vibrating metal plate

Students learned to work together during this project. Each of the physics teachers had the opportunity to work with small groups of students throughout the project. Justifying the many hours of work involved in this project was the strong sense of accomplishment and pride felt when the project was completed.

Another project was initiated by a chemistry teacher in Iowa and a chemistry teacher in Moscow. Because of the historical significance, they decided to study Dmitri Ivanovich Mendeleev, a Russian chemist who is credited with creation of the periodic table of the elements. Students in Moscow and in Iowa researched Mendeleev's life and contributions to science. When Russian students visited Iowa reports were given and differences were noted and discussed. Students from both countries learned a new perspective to chemistry. In addition, the Russian students had an opportunity to practice their English language skills.

Because Iowa students lacked Russian language skills the Iowa chemistry students devoted much of their time while in Moscow to assisting with chemical experiments, an area in which they possessed much expertise. A lot of chemistry was learned during these activities in addition to gaining in cultural and language understanding.

Perhaps student comments are the best way to summarize the cultural value of a project like SciLink. The following are verbatim student comments to the question, "Please identify what you feel will have the most lasting value from your SciLink experience?" The comments were part of a final written evaluation. Can you tell which statements were made by Iowa students and which ones were made by Russian students?

The most important thing that this exchange has given me is a better understanding and appreciation for the differences between our two cultures and countries. I have a much better perspective of my own home now, and am very glad to have gained this. I believe this experience will be one of the most benefiting to me of my entire life.

I think the most lasting value for me is that Russian and American families have more similarities than differences and people of both countries have very similar moral principles and goals of life.

The way my family took me in and treated me as their own will probably be the most lasting value from my trip. I didn't feel shut out or anything. I was a part of the family from beginning to end.
I now understand that people from different parts of the world are pretty much the same. I could communicate with them and they could understand me! We don’t need any conflict between us.

The long lasting relationship between another person and another culture. I learned the differences and similarities between our two cultures because of this trip. I value most the friendship between me and my host.

Thanks for this great opportunity. We have a lot of new friends, impressions, and knowledge. All the people whom we met were very nice to us, so I have very warm feelings about this project. And also, the science part of this project was very interesting and useful for me.

It is clear to the 71 persons (62 high school students and nine adults) involved in SciLink that international exchanges and cultural understanding can be accomplished through science classes. Science is an international language. We study the same concepts and utilize many of the same classroom strategies to achieve student learning. Science provided us with a common language to achieve true international understanding.

Internet proved to be an effective means to link science students and teachers from widely differing cultures. We urge you to continue our “international experiment” and bring the young people of the world together to explore science. Remember, students in our classes today are the scientists of tomorrow. If we foster better international scientific understanding today, we have a better world tomorrow.

Key to student quotes (first to last): Iowa, Russia, Iowa, Russia, Iowa, Russia

Lynn W. Glass is a past president of the National Science Teachers Association and a professor of science education at Iowa State University. Eugenia Etkina is a physics teacher and methodologist at Moscow High School 1543. Dr. Glass and Ms. Etkina presently are directing SciLink II, involving over 100 students and teachers during the 1994-1995 school year.

8TH INTERNATIONAL ORGANIZATION OF SCIENCE AND TECHNOLOGY EDUCATION (IOSTE) SYMPOSIUM EDMONTON, ALBERTA, CANADA

Alberta Education will be hosting hundreds of international participants at the 8th International Organization for Science and Technology Education (IOSTE) Symposium in August 1996.

What is IOSTE?
IOSTE is an organization committed to advancing the cause of science and technology education as a vital part of the general education of all people in all countries of the world. As well, IOSTE identifies the changing science and technology education needs of humankind and nations. The members of IOSTE are approximately 600 science and technology education policy and decision makers in regions that include the Arab States, Australia and Oceania, South and East Asia, Africa, North and South America, and Eastern and Western Europe.

What is the 8th Symposium Theme?
The symposium’s theme is Science and Technology Education for Responsible Citizenship and Economic Development: Evidence, Policy and Practices. One of the intents is to acknowledge fundamental changes in the economic climate, and make the connection between education and the workplace. This topic is becoming increasingly important to people in Alberta, Canada and other parts of the world.

The theme also addresses two emerging demands of science and technology education worldwide; preparing students to:

- make appropriate decisions regarding local and global environmental issues, and make wise use of natural resources.
- contribute toward responsible economic development in a highly competitive and integrated global economy.

Inquiries and calls for proposal forms can be directed to:

Teaching Materials and Strategies

This section focuses on the education of science teachers, and aims to communicate ideas and strategies which will assist science teachers to enhance and enrich their programs.

THINK AND DO: ACTIVITY BASED SCIENCE TEACHING FOR PRIMARY SCHOOLS

J. O. E. Otuka

The central theme of the ‘Think and Do’ approach is that of creating a challenge, thereby, conforming to the current constructivist philosophy. The program develops young pupils abilities to plan, effect, interpret, draw inferences and communicate the outcome of their experiments. Critical thinking skills are applied in interpreting the challenge, recalling relevant experiences and designing a solution. This involves negotiations with others as well as clearly sorting out what procedures will be followed and what items of equipment will be used. In the ‘Think and Do’ approach, pupils in small groups are expected to follow the sequence in the circular chart as shown in Figure 1.

The initial stimulus is provided by a bright photograph presented in an activity card. The activity cards are designed either to be popped up or held by a child as a group plans the activities to meet the challenge. Each card has an extension activity for further investigation, again through the trigger of a photograph. For example in the sample activity structure 6 - ‘Wobbly animals,’ there is such an extension activity: Investigation further; Do long legs or short legs make it easier for animals to stand up? This activity is an extension. Each card also has a list of words (vocabulary) that are discussed with relevant examples and suggestions for “before” and “after” dialogue to stimulate discussion.

The group members can talk, make suggestions and plan a strategy to meet the proposed outcome. The questions for discussion are designed to assist the teacher working alongside with children to initiate dialogue after the preliminary identification of items and associated recall and observations.

During the Harare Generator, an event held at the University of Zimbabwe in 1991, African Science educators shared experiences and generated new ideas for science teaching and teacher education. This was after a variety of specialized inputs by Science Educators and other resource persons mainly from Britain and a few from the United States of America. The Think and Do approach was pilot tested by a group of African Science Educators under the supervision of Sue Dale Tunicliffe. The African educators made the following modifications to the approach:

- the glossy work cards were replaced with locally produced sheets to reduce cost.
- the teacher used intervention questions to assist the pupils during activity sessions to avoid inactivity.
- locally available materials were used as much as possible.

A Sample Activity

One of the activities carried out under this approach was: Working with Magnets. The details are as briefly described below:

Objectives: The pupils should be able to:
- group a given set of materials into magnetic and non-magnetic substances.
- compare the strength of magnets.
- determine whether two identical magnets used together are twice as strong as one.
- play some games using the power of attraction of magnets.

Materials Provided

Piece of stone, biro, pencil, paper clips, drawing pins, piece of paper, copper wire, scissors, straw, a nail, leaf, rubber band, ruler, plain sheet of paper, circular and rectangular magnets, two puppets with magnets attached, two magnets mounted on long sticks and a carton cut open at both ends.

Probing Questions

The following questions were posed to the pupils to encourage them to discuss among themselves and determine the tasks as well as challenge them:

- Do magnets attract all objects?
- How can you show this?
- How can you tell how strong a magnet is?
• Would a strong magnet pull a magnetic material from further away than a weak magnet or the other way round?
• Can you play a game with magnets?

The pupils used the Think and Do process as in Figure I to carry out the activity.

The evaluation questions were as follows:
• Did the magnet attract all the materials?
• What general statement can you make from your findings?
• Which magnet attracted material from further away than the other?
• Did putting two magnets together improve their strength to attract objects from further away?
• What game did you play with the magnets and puppets?

Results: The pupils followed Figure I and reported their findings under ‘we discovered’ . . . The summary of their findings is as follows:
• Magnets attracted paper clips nails and drawing pins but did not attract biros, pencils, leaves, copper wire and rubber bands. Magnets do not attract all objects.
• The larger and stronger magnet attracted materials from further away than the smaller and weaker magnet.
• The two magnets put together attracted materials from further away than the other magnets which shows that they are stronger.
• The puppets were moved about and collided with each other at times.

The pupils negotiated among themselves through trial and error processes. They rotated responsibilities and tried out new and different possibilities. There was curiosity as well as anxiety to find solutions to the task. However, as the activity progressed the clever pupils tried to dominate the others in participation. The discussions became very hot arguments at the end when results were to be argued and agreed upon.

Like all teaching methods, the ‘Think and Do’ approach has its merits and demerits. Some of these are stated below.

**Merits**

The approach is easily adaptable to local demands. Pupils develop competence in reporting the outcome of their activities.
• Pupils use evidence impartially
• Pupils cultivate the habit of working successfully with others in groups
• Pupils manipulate materials using their own plans and initiative and
• Pupils are able to raise questions among themselves and search for answers.

While some of the demerits are:
• The approach consumes time. A lesson can hardly be accommodated by the time schedule on the time table. It requires a lot of extra work from the teacher.
• It makes the class noisy.

In recent times, many teaching approaches have emerged in which the pupil takes responsibility of constructing knowledge by himself/herself.

‘Think and Do’ approach is a tested constructivist approach to primary science teaching. You may like to try it.

The originator and author of the ‘Think and Do’ cards is Sue Dale Tunnicliffe, the Coordinator of ICASE STEPPING INTO SCIENCE WORLDWIDE. Prof. J. O. E. Otuka led the ‘Think & Do’ trial team during the Harare Generator.

The Think and Do series, 5 titles, is available from Simon and Schuster Young Books, Campus 400, Maylands Avenue, Hemel Hempstead Herts, UK and were originally published by Basil Blackwell, Oxford. The titles are: Materials, Living Things, Energy, Soul & Shy, Ourselves and the Environment.

**ICASE Award Scheme**

For outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below.

**ICASE Distinguished Service Award**

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local regional and global science education organisations

**ICASE Regional Service Award**

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

**ICASE Association Award**

This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Contact Dr. Jack Holbrook, Executive Secretary
ICASE, PO Box 6138, Limassol, Cyprus

Science Education International, Vol. 6, No. 1 March 1995
POPULAR SOURCES OF SCIENCE RESOURCE MATERIALS AND TEACHING STRATEGIES

Ken R. Mechling Ph.D.
Professor of Biology and Science Education
Clarion University, Pennsylvania

For more than thirty years I have presented staff development programs in science to elementary teachers all over the world. All during that time—from Iceland to Samoa, from Kenya to Malaysia, and from the United Kingdom to Russia—I have found one need expressed time and again; the need for high-interest, hands-on activities teachers can do in their classrooms tomorrow. Teachers want easy-to-do science activities they can do with children.

This universal need seems to be sparked by several circumstances. First, good teachers know that children respond favorably when they are actively involved in topics which interest them. Children are interested in animals so classroom visitors such as ants, snakes, worms, or small mammals can be wonderful resources for science. Children can learn much about sound by making and playing their own musical instruments. And they can begin building ideas about density by predicting and testing objects to observe if they sink or float. Children are highly interested in such activities and are, in fact, following the tenets of modern constructivist theory by constructing their own meaning from real experiences. Teachers like to do such activities because they are fun and exciting for the students.

The second reason that teachers want high interest, hands-on activities is to spic up the science textbook that usually forms the basis of their curriculum. Texts are for reading and the few activities included in them too often tell the answer before the children do the activities—taking away the surprise and much of the fun. Or text activities require specialized equipment that is not available. Teachers become bored and frustrated. They seek alternative experiences to interest children. They search for activities that require simple, easily-accessible materials, for example paper strips that can be transformed into neat helicopters for studying air pressure and gravity or seeds found...
locally that can be used for classification or flashlight
cells, bulbs and aluminum foil strips that make
wonderful electrical circuits. Teachers are forever on
the look-out for high-interest activities to enhance
text-based curricula.

A third reason teachers desire ideas for neat
hands-on activities is that they are either saddled with
a dull, boring, or inappropriate science curriculum or
they lack a science curriculum altogether. In such
circumstances a rich source of science activities can
become the spine of a home-made science
curriculum. Anyone familiar with the National
Wildlife Federation series of NatureScope books will
be delighted with the easy-to-use, interest-grabbing
activities in books such as Trees are Terrific, Wild
About Weather, and Astronomy Adventures. Such
references are full of high-interest science activities
and content information. They could easily form the
backbone of an exciting science curriculum.

One of the richest sources of teaching ideas is a
group of references generally called supplemental
curricula. Supplemental curricula are those resources
which include ideas for teaching materials and
instructional strategies but are seldom viewed as a
traditional, comprehensive, textbook-based
curriculum. Rather, they are resources which provide
teachers with interesting, easy-to-use activities—the
kind they can use tomorrow, the kind that could fit
any science curriculum.

Based on experiences in hundreds of science
teacher staff development programs throughout the
United States and at least fifteen countries around the
world, there are clearly some supplemental science
curricula which are very popular among teachers.
These are the teaching materials that teachers
gravitate toward, the ones they want copies of, the
ones they use for enhancing the science learning
experiences of the children in their classrooms.

The following sections will describe briefly only
seven of the most popular supplemental science
curricula. Included is the title, curricular area, grade
levels, cost in U.S. dollars, publisher and order
information and a brief description. Readers desiring
a more comprehensive but selective list of resources
for science materials and instructional strategies can
request in writing, by telephone or FAX the Guide to
Supplemental Science Curricula and Resources:
Elementary through High School Levels. Requests
should be sent to the Pennsylvania Center for Science
and Technology Education, Main Street, Box 330,
Shippenville, PA 16254; telephone 814-782-6301; FAX 814-782-6453.

**Title:** Kaleidoscope

**Curricular Area(s):** Science & Children’s Literature

**Grade Levels:** K-3

**Cost:** $15.00/year for 10 issues

**Back issues available**

**Publisher & Ordering:**

Kaleidoscope
Wisconsin Academy of Science, Arts & Letters
1922 University Avenue
Madison, WI 53705
Tel: 608-263-1692

**Description:**

Kaleidoscope is printed in a 6-page newsletter
format, focusing on a wide variety of science topics.
The uniqueness of this publication is the way it
introduces each science topic by using a children’s
book. Through the book, science concepts are
presented, along with other integrating activities for
language arts, math, art, drama, music and social
studies. Bulletin board ideas, bibliographies,
interesting facts and hands-on science activities and
science activity pages are also included. Focuses of
some of the more recent issues include The Arctic,
Camouflage, Marsupials, Snakes, Bats, The Senses,
Soil and Temperature.

***

**Title:** NatureScope

**Curricular Area(s):** Life, Earth, Environmental
Science

**Grade Levels:** K-7

**Cost:** $7.95/guide or $99.00/18 volume library

**# Guides/Books:** 18

**Publisher & Ordering:**

National Wildlife Federation
Dept 337
1400 16th Street, NW
Washington, DC
20036-2266

**Description:**

Each NatureScope issue contains teacher background
information and hands-on student activities around
that issue’s theme. Titles include Astronomy
Adventures, Incredible Insects, Wading Into Wetlands,
Endangered Species, Wild About Weather, Rain
Forests: Tropical Treasures, Amazing Mammals and
Geology—The Active Earth, Trees are Terrific and
Digging into Dinosaurs. Activities use inexpensive,
easily accessible materials and are accompanied by
“Copy Cat” pages for student record keeping or
make-and-take materials.

Science Education International, Vol. 6, No. 1 March 1995
Title: Activities Integrating Mathematics and Science (AIMS)
Curricular Area(s): Science and Math
Grade Levels: K-9
Cost: $14.95/book
# Guides/Books: Approximately 30
Publisher & Ordering:
AIMS Education Foundation
PO Box 8120
Fresno, CA 93747-8120
Tel: 209-255-4094 FAX: 209-255-6396

Description:
The AIMS curricular materials consist of teacher-written classroom-tested activities using a hands-on approach to interrelate science and mathematics. The books are grouped by concept area, grade level or theme that promotes science and math experiences kids will find in the real world. Most AIMS activities can be done with easily-obtainable materials including school supplies like paper clips, note cards and scissors and grocery store items such as cereal, candy, gum, fruits and vegetables. Sample titles include Critters, Sinkers and Floaters, Budding Botanist, The Sky's the Limit, Find Your Bearings, From Head to Toe, Mostly Magnets and Primarily Physics.

* * *
Title: Great Explorations in Math & Science (GEMS)
Curricular Area(s): Science and Math
Grade Levels: Pre K-10
Cost: $7.50 - $15.00/book
# Guides/Books: 33
Publisher & Ordering:
GEMS
Lawrence Hall of Science
University of California
Berkeley, CA 94720
Tel: 510-642-7771 FAX: 510-642-1055

Description:
GEMS teacher guides focus on science concepts in the life, earth and physical sciences. GEMS activities reflect the use of guided discovery and cooperative and collaborative learning using easy-to-obtain materials. Each guide is organized around a science or math concept/process such as chromatography, bubble-ology, consumer science, electricity, predicting, probability, etc. Titles include Acid Rain, Liquid Explorations, Mapping Animal Movement, Cabbages and Chemistry, Ladybugs, Height-o-Meters, Fingerprints, Oobleck, Hide a Butterfly, Magnifiers and others.

* * *
Title: SuperScience (Red & Blue editions)
(Subscription edition published Sept-May)
Curricular Area(s): Science and Science activities
Grade Levels: 1-6
Cost: $5.75/yr/student (Red edition)
$6.50/yr/student (Blue edition)
Publisher & Ordering:
Scholastic SuperScience Magazine
PO Box 3710, Dept 6001
2931 E. McCarty Street
Jefferson City, MO 65102-3710
Tel: 212-505-3000

Description:
SuperScience is a monthly magazine for elementary students and teachers. Published as two different editions (Red for Primary, Blue for Intermediate) it brings into the classroom meaningful hands-on science activities, take-home science, and science information relevant to children's interests. Each issue is filled with challenging activities stressing the connections of science with other elementary curricular areas and the real world. Recent themes include Creepy Crawly Bugs, Our Mom, Whales, Things We Can't See, Muscles "N" Bones, Seed Needs, Measuring Memory, Color De-Coding, Satellites in Orbit and Deep Sea "Flight".

* * *
Title: Elementary Science Olympiad Fun Day
Curricular Area(s): Science activities
Grade Levels: K-3
Cost: $15.00/book (3rd ed)
Publisher & Ordering:
Science Olympiad
864 Schoolhouse Lane
Dover, DE 19901

Description:
The Elementary Science Olympiad Fun Day book includes 31 activities which involve primary children in non-competitive, hands-on experiences in science which emphasize participation, teamwork and cooperation. Fun Day events include Barge Building, Bubble Trouble, Airplane Throw, Rock Hunt, Life Cycles, Tin Can Race and Pattern Blocks. Olympiad experiences in life, earth and physical science will heighten students' and teachers' enthusiasm for science thinking skills, science content and application of science to the real world. Olympiad guides are also available for the elementary, middle and high school levels.
* * *

**Title:** Brown Paper School Book Series

**Curricular Area(s):** Elementary/Middle level subjects

**Grade Levels:** K-9

**Cost:** $9.50/book

**Publisher & Ordering:**
Delta Education
Box 950
Hudson, NH 03051
Tel: 800-442-5444  FAX: 603-595-8580

**Description:**
This series of activity books is written about a variety of subject areas and designed for kids and grownups together. Presented in a humorous fashion they are full of information and activities. Titles in the series include Blood and Guts, Gee Whiz, The Reasons for Seasons, Big Beast Book, Good for Me, My Backyard History Book, The Book of Where, Only Human, Mathematics for Smarty Pants, The I Hate Mathematics Book, The Book of Think, The Night Sky Book and others.

**Section Editor's Comments:**
One of the roles of ICASE is to facilitate the exchange of ideas and resources for teaching science around the world.

The following paper suggests sources available within the USA that have been used by elementary teachers around the world to interest pupils, to spice up textbooks and to be the focus of a home-made curriculum.

We would welcome information from colleagues who have used the sources referred to here or others.

We are anxious to identify sources of science materials produced in other countries and to learn of their use. Please send information to the Section Editor at CES, King’s College, London, Cornwall House, Waterloo Rd., London SE187X, UK

Please note: All rights for reprinting articles in Science Education International are extended to all ICASE member organizations. Please plan to pull articles for your own publications. Why not add an international section for your readers?

Science Teacher Education and Leadership

This section focuses on the education of science teachers, and aims to communicate ideas and strategies which will assist science teacher educators to enhance and enrich their programs.

IMPROVING SCIENCE AND MATHEMATICS TEACHER EDUCATION IN INDONESIA

Dr. Robert K. Sembiring

Editor’s note: There are many approaches to improving pre-service and in-service teacher education. In the December issue Dr. Mehru from Karachi wrote about a Teacher Resource Centre which was founded by teachers for teachers: a grassroots approach. In this issue Dr. Sembiring describes the efforts of the Indonesian Basic Science Team which is involved in improving pre-service teacher education on a national scale. The team started as a curriculum team, scientists trying to design a new curriculum for science and mathematics teacher education. However, the team did not stop after producing the curriculum, but got actively involved in implementation. The team learned much about grassroots level problems, developed more complex views on teacher education and evolved into a semi-permanent committee initiating and coordinating a wide range of activities to improve teacher education.

Summary

Indonesia teacher education was created in 1954. Initially there were only four institutes. Now there are 33 state institutions and 201 private ones. Their curricula have changed several times: from stress on science content to stress on teaching and back to science content. The Basic Sciences Team was created in 1989 to improve and develop the science teacher education faculty. The team has revised the curricula, produced textbooks, upgraded 50% of the lecturers and is currently working to develop five growth centers.

Historical Background

Indonesia is a vast country, consisting of more than 3000 inhabited islands with a population of more than 180 million people distributed very unevenly, more than one-half in Java. The age distribution of the population is young, the rate of growth is decreasing rapidly, currently around 2%.

In the early years of its independence, Indonesia had no ready-made model of an educational system. The school system was fashioned to Indonesia's own needs and aspirations rather than modelled on the practice of a highly developed commercial and industrial nations. The growth of schools and universities in Indonesia has been extraordinary, particularly from 1956-1965. Political pressure from each province to have a university was very high. From 1966-1971 the rate of expansion, though still high, dropped markedly (Beeby, 1979).

The central government for very good reason emphasizes equity in education. According to the latest data, in the course of the First Period of the Long Term Development, 1969/1970-1993/1994, there was an increase in participation rate (the ratio of enrollment to the total number of school age children) of 280% for the primary school, 320% for the junior secondary school, 390% for the senior secondary school, and 690% for the tertiary level (Education Consortium, 1994).

A student can choose to enroll in a state school or a private one. All the schools have to follow the state guidelines determined by the Government in Jakarta. Except for some local content, a curriculum is decided in Jakarta. In the early periods of educational development, central planning and control were used effectively to direct efforts toward quantitative expansion as well as establishing quality standards. The system has since grown too complex for central planning to be efficient, resulting in the Government and the public becoming increasingly critical of the nature and quality of the education being given.

Secondary Teacher Education

Before 1954 Indonesia took its secondary teachers from the regular academic departments of the universities on the assumption that knowledge of subject-matter was the essential thing and that teaching methods could be picked up in practice. Thus, the training in pedagogic theory and practice began from nothing (Beeby, 1979).

In 1954 the teacher education institution was created giving bachelor’s and master’s degrees. There were four of them at that time, all of them state institutions. Two years later they were attached to universities as faculties of education under the title of FKIP (Faculty of teacher training and educational science). Due to great demand for teachers many FKIPs were created afterwards. In 1963, four of them were removed from the universities and established as separate institutes under the name IKIP (Institute of
teacher training and educational science). Currently there are 10 state IKIPs and 21 state FKIPs in the country. In addition, there are 201 private teacher education institutions (IKIPs and FKIPs). The state LPTKs (IKIP and FKIP) enroll about 240,000 students with about 28,000 S1 (equivalent to a BA degree) graduates a year, and the private institutions enroll 166,500 students with about 13,000 S1 graduates per year (Balitbang Dikbud, 1993). Since inception the LPTKs have shown themselves to be inefficient, unable to attract the brightest students to teaching and a considerable part of their graduates fail to enter the teaching profession.

In the mid-seventies criticisms were leveled at LPTKs that the courses they offered were not very relevant to future teachers’ interests and many experts suggested the need for better teacher training, meaning more emphasis on preparation for teaching. Before 1979 the curricula of FKIPs and IKIPs put heavy stress on content-subject compared to teaching content.

From 1975 to 1979 a great effort was made by the Director General of Higher Education (DGHE) to establish curricula that stress teaching competencies (10 competencies). A team of experts was created, with consultants from the World Bank, to write the curricula and all LPTKs were then required to adopt them. In practice many did not adopt. Again, less than 20 years after the use of these curricula, there were many public outcry leveled at the LPTKs. Many observations indicated that the average achievement of high school graduates over the years, especially in mathematics and natural sciences was decreasing (LAPI, 1985). It was unfair, of course, to level all the criticisms at the LPTKs, but they were the most easy scape-goat. Quantitative achievements such as the tremendous growth in enrollments, do not go hand-in-hand with qualitative achievements. One is usually achieved at the expense of the other. However, the public usually does not want to hear of this excuse.

A curriculum committee was set up in 1983 and proposed new curricula for IKIP. These curricula stressed heavily on subject matters. However, these curricula were never implemented. The six IKIPs in Java took steps in devising their own curricula in Science and Mathematics Education in line with those of 1983. About 75% of the total semester credits was allocated for subject matters. At this juncture the morale of the academic staff of LPTKs was low. Public pressure was very high, at one stage there was even talk of closing the LPTKs and moving the teacher education to universities. DGHE decided to find ways to improve the LPTKs.

One logical way of improving the quality of education at the secondary level, though long range in nature, is to improve the pre-service training of teachers. Due to budgetary constraints, the DGHE felt that it should give priority to the basic sciences (mathematics, physics, chemistry, and biology) in pre-service training. In 1988 the DGHE created the Basic Sciences Team (will be called the BS Team hereafter) with the main task to improve the science and mathematics teaching at the LPTKs. The BS Team comprises of four members from the Institute Teknologi Bandung (pure science background) and five from the IKIP Bandung including one expert in curriculum development. I am from the Mathematics Department of ITB and the team leader. The major source of funds to finance the BS Team’s activities is a World Bank loan.

**Development of the Basic Sciences Teaching**

As mentioned above the members of the BS Team come from different backgrounds. It took a while for the Team to establish a common platform and much longer to recognize the dimensions of the whole problem of science teacher education. Because four members of the Team are from outside of LPTK, acceptance of the Team, at least in the first year, was quite problematic. Many prominent staff of the LPTKs felt the existence of the Team as an intrusion on their territory.

There were many factors which contributed to the low achievements of high school graduates in mathematics and natural sciences in the middle of the eighties. One of them was the surge of secondary school enrollment due to quantitative expansion at the primary level so that the LPTKs as the main suppliers of high school teachers had to increase their input and output levels. Also the Government created crash-programs to meet the increasing demand for high school teachers. LPTKs do not attract the best high school graduates. This is even more true for science and mathematics teacher education at the LPTKs. A study conducted in 1985 by LAPI ITB, commissioned by the DGHE showed that the graduates of LPTKs in the field of mathematics and natural sciences took, on the average, more years of study than those in other fields in the same institution.

Almost all of the LPTKs suffer from a shortage of qualified teaching staff. Most of the existing staff have poor academic capabilities. Inbreeding is a common way of recruiting staff. In 1985, more than three-quarters of the existing staff only had a BA (or S1) degree. They also showed very poor command of English. Several years of observations indicated that the performance of the graduates of LPTKs who took a graduate program at ITB, was much lower than expected. Now they are required to take a one-year Pre-S2 program before being allowed to take S2 (masters) study at ITB.
There is a widely shared perception that LPTKs tend to be ‘closed’ societies, inadequately linked to the universities, to the schools, and to the broader community. Very few of the senior teacher educators have ever worked as classroom teachers, though many of the juniors moonlighted as classroom teachers to supplement their low income.

**Curriculum**

After intensive review of the present and all the previous science curricula of the LPTKs, the BS Team decided to make major revision of the current ones. In other words, the team decided to choose curriculum as an entry point to the very complex problem, many parts of it not academic in nature.

There were two reasons for selecting this entry point. Firstly, it was considered easier and secondly, to give more time for the Team to be more acquainted with the problems. This adjustment period, it turned out, was very crucial.

Since none of the members of BS Team had any bureaucratic experience the team approached the problem diametrically different from the previous curriculum committees. We realized that the efficacy of a new curriculum depends in some measure on the method adopted for setting it up. The people who work under it have to feel in some way responsible for it. On the other hand, in a country as huge as Indonesia, the school system should be regarded as an instrument of national unification. The implication is that the curricula have to have a common core of subject content for every field of study. Also, we believe that whether science is to be taught to future scientists, or to future citizens, there is a pressing need to ensure that the secondary science teacher, whose role is so crucial, has the educational background necessary to rise to both challenges.

With help from several experts from each field of study (mathematics, physics, chemistry, and biology) the BS Team wrote a first draft of the curriculum for each field of study. We wrote it in terms of core-topics and called it the core curriculum (see Annex). Another new feature of the curriculum is that it has what we called the First Common Year. All first-year students in mathematics, physics, chemistry, and biology are required to take the same general courses. The courses consist of calculus, general physics, general chemistry, and general biology and environment.

Between 144-160 semester credits are needed for a S1 degree, the BS Team recommends 144 but most LPTKs take around 150-154 semester credits. The following table gives general descriptions of the curriculum for each of the four fields of study. The unit is semester credit.

<table>
<thead>
<tr>
<th>General courses</th>
<th>Semester Credits</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 Science and Mathematics (including 24-28 semester credits for the First Common Year)</td>
<td>95-104</td>
</tr>
<tr>
<td>Educational theory, teaching and learning courses</td>
<td>28-35</td>
</tr>
<tr>
<td>Subjects to be determined at the local LPTK</td>
<td>6</td>
</tr>
</tbody>
</table>

We invited criticisms from several concerned groups, visited 10 IKIPs for the same purpose and then invited representatives of all LPTKs. After some modifications all LPTKs accepted the proposed curricula and then the DGHE made them official.

It is worth mentioning that in each core-curriculum, the BS Team appended also a complete curriculum as an example or reference. Every LPTK was supposed to write its own curriculum using the core-curriculum as a guideline. This approach, however, was entirely new. The BS Team persuaded the Director General of Higher Education to accept this approach. The previous curriculum committees stressed uniformity and produced ready-for-use curricula. However, one year later, to our dismay, the BS Team discovered that almost all LPTKs adopted the example.

**Staff Upgrading**

The BS Team soon discovered that most of the staff of LPTKs were not able to teach the science and mathematics courses in the new curricula. More than 75% of the academic staff were only S1 (B.A.) graduates where inbreeding was a common practice of recruitment. Thus upgrading the academic staff was imperative if the new curriculum had to be implemented. The BS Team persuaded two of the top universities in the country, ITB and UGM, to do the training. The training was only in subject matter and each lasted for three months. It was organized per course of the new curriculum. For example, LPTK calculus lecturers would study with ITB calculus lecturers, the former usually were also requested to attend ITB calculus lecture. By the end of 1994 about 2100, that is about 64% of all science and mathematics teacher educators of LPTKs, had been trained. About 830 young staff of LPTKs have been sent to one-year Pre-S2 Programs at ITB and UGM and about 65% of them managed to be accepted into S2 programs, of which about 90% managed to graduate. Some of them continued to S3 (Ph.D.) programs. In addition the BS Team has sent 110 senior staff of LPTKs for a three-month visit to overseas institutions to study mathematics and science teaching.
Textbooks and Lab Equipment.

Textbooks are just not available in many parts of the country and when available they almost are in English. Very few of the academic staff of LPTKs can make use of them, let alone LPTK students.

The BS Team has commissioned several scientists to write textbooks in the Indonesian language. The first draft of the books (17) are now being field tested and are expected to be published next year. Several textbooks have been translated from English to the Indonesian language. A complete list of needed lab equipment for all LPTKs has been forwarded to the DGHE to be purchased. About 100 lab technicians have been trained and many more will be trained in the near future.

Future Programs

The long term goal which the project eventually would like to pursue is the improvement of teaching-learning processes and outcomes in secondary school mathematics and science. This, in turn, necessitates the improvement in the quality of the prospective science and mathematics teachers produced by the LPTKs, and this becomes the intermediate target that the project would like to attain. The BS Team has managed to instill self-confidence in many academic staff of LPTKs. When they returned from training at ITB or UGM they brought home with them textbooks and lecture-notes, linkages amongst the trainees and their former trainers at ITB and UGM have been created. A national standard of academic qualifications of teacher educators in science and mathematics is expected to be achieved in the near future.

Problems and Programs in the Coming Years:

1. With regard to the new curriculum, there is a growing opinion that more emphasis should be given to pedagogical contents than the existing teacher education curriculum requires. In conjunction with the policy of curriculum flexibility, educator and administrators tend to suggest that all LPTK graduates should be able to teach two high school subjects, while subject matter specialists, especially those of mathematics and science, insist that it is difficult to prepare teachers with good content mastery to teach more than one subject. Furthermore, in the light of the 1994 curriculum for Junior Secondary School (SMP), there has been no clear policy on types and number of mathematics and science teachers required for SMP. Enrollments are expected to increase due to the introduction of compulsory junior secondary education. However, the zero growth policy for the number of civil servants creates uncertainty about the number of teachers that can be appointed.

2. In conjunction with curriculum implementation, there is strong evidence regarding the insufficient quality of instruction occurring in some LPTKs due to their lack of qualified staff. Staff accepted in the pre-S2 programs are unevenly distributed. They mostly come from LPTKs in Java while of those that come from further away only a few can pass the pre-S2 entrance tests. Besides, due to the slow process of facilities and equipment provisions, at present, there is a considerable number of LPTKs which do not have sufficient textbooks and facilities/equipment to support the implementation of the new curriculum. In addition to that, most of the LPTKs suffer from lack of qualified laboratory workers and technicians required to manage and support labs and workshop activities.

3. Revision/development of LPTK curricula for preparing junior secondary mathematics and science teachers.

4. Monitoring and evaluation of curriculum implementation in various LPTKs.

5. As many as possible academic staff of LPTKs should be encouraged to take graduate programs, either in subject matter or teaching. Crash programs such as short-term training in science and mathematics, lab. instructors, and lab technicians will be continued.

6. In spite of the large quantity of research on teaching mathematics and science that has been undertaken, these researches do not seem to have been well planned and implemented by the staff. Besides, almost none of the staff have any experience in conducting research in science and mathematics. More academic-staff should be sent broad to study research on teaching.

7. The BS Team is currently preparing five IKIPs to become growth centres which, after being further strengthened, will assist other LPTKs to improve their own programs. Two of the centres will have graduate programs in science and mathematics education in the future.

THE STRUCTURAL ATTRIBUTES OF ANIMALS
COMMENTED UPON BY PRIMARY SCHOOL CHILDREN AT THE ZOO

Sue Dale Tunnicliffe
Formerly Head of Education Zoological Society of London

Zoologists use criterial attributes to identify animal specimens and allocate them to their appropriate taxonomic category. Do school children spontaneously notice the same attributes when they observe animals and do their teachers focus the children's attention on such features?

Natazde (1963) found that Russian Children, between seven and ten years, had difficulty in classifying common animals while Ryman (1974a) showed that twelve year old children studying biology could identify and provide an acceptable name for animals that they had been taught, but could not classify animals into a taxonomic group, suggesting that they had no grasp of the criterial attributes required to perform such a task. A number of studies have identified what attributes of animals children use as distinguishing features in classroom exercises (Lucas, Linke, & Sedgwick, 1979; Mintzes, 1989; Sherwood, 1986; Sherwood, Rallis, & Stone, 1989; Tamir & Sever, 1980; Trowbridge & Mintzes, 1985). Older primary children list locomotory; appendages, the body coverings and attributes associated with the front end of the animals as the distinguishing feature (Bell, 1981; Braund, 1991, Mintzes, Trowbridge, Arnaudin, & Wandrese 1991; Trowbridge & Mintzes, 1985; Trowbridge & Mintzes, 1988). Locomotory organs, i.e. limbs or wings, are the parts referred to most often by children, (Bell, 1981; Braund, 1991). Twelve year old school children cited head/limbs/body covering as critical attributes for identifying a vertebrate member (Ryman, 1974). However, do the children focus on locomotory organs, body coverings and the front end of the animal when they look at live animals? The purpose of the study reported in this paper was to find out about which parts of the bodies of live zoo animals children noticed and commented spontaneously.

School groups are ostensibly taken to the zoo to learn about a particular relevant topic from the curriculum (Marshdoyle, Bowman, & Mullins, 1982; Tunnicliffe, 1994). Criterial attributes of the major taxonomic groups are a focus of many primary/elementary curricula, for example the English and Welsh National Curriculum in Science (DES, 1991), which is organised in ten levels, which children begin to study in the academic year in which they are six years old, requires that at Level 2, 'pupils should be able to sort familiar living things into broad groups according to easily observed features'. Level 3 states that children should:

- know the basic life processes common to humans and other animals.
- know that human activity in the environment can affect changes in plants and animals.'

At Level 4 children should:

- be able to assign plants and animals to their major group using observable features, through first hand observation.'

However, the content of the spontaneous conversations of primary school children and their accompanying adults was unknown.

The type of conversations heard were short. The following conversation between seven year olds, at the Bearded Lizards in the Reptile House at London Zoo, is typical of the exchanges that occur within school groups.

Boy: 'There’s one and there’s one and there’s one!
Boy 2: 'See that buffalo skull over there? That’s from America and there’s a light bulb too!
Teacher: 'Can you see the animals clearly?
Boy: 'No! They blend in.
Teacher: 'What do you call that?
Boy: 'Camouflage!

I needed to find a method by which I could capture the spontaneous conversations and then analyze these exchanges for their content.

Method

The results presented in this paper are part of a large study in which broad categories of topics of conversations became apparent. The comments about the parts of the animal’s body were identified using a systemic network (Bliss, Ogborn, & Monk, 1983; Tunnicliffe, 1993).

There were 74 categories in the network. The parts concerning structures of the body are shown in Figure 1.
A bracket, '[]', indicates one of a number of categories which an animal may have. Each conversation unit was categorised with the appropriate number from the networks. Hence the above conversation, at the Beaded Lizards, was represented in the following way.

Boy: There's one and there's one and there's one
50/ 74/ 55/ 18/ 40/

Boy two: See that buffalo skull over there? That's 20/ 16/ 17 from America and there's a light bulb too'
13/ 69/ 23

Teacher: Can you see the animals clearly?
3/ 20/ 31

Boy: No they blend in!
13

Teacher: What do you call that?
31

Boy: Camouflage!

The teacher in charge of each school party was approached and permission requested from them to record the conversations of the children and their accompanying adult. Following the visit the tapes were transcribed, coded and entered into a worksheet of Minitab (Minitab, 1991).

Conversations were recorded wherever the groups went. The majority of the conversations were at vertebrates, in particular mammals reptiles or birds.

Discussion

The content of the conversations reveals that these visitors notice predominantly the dimensions of the animal (size, shape, body covering). When a feature was obvious, or was drawn to the attention of the visitor through unusual behaviour in front of the visitor, it was commented about, e.g. excretory organs. Unexpectedly, there does not appear to be an active seeking out and mentioning of particular parts of the anatomy of the animals.

The psychological research of (Tversky, 1985) shows that the shape and colour of objects are the dimensions preferred by young children when they group inanimate objects so it should not be surprising that it is this type of attribute children notice about the animals. Furthermore, Tversky (1989) showed that children notice the salient parts of objects first of all, hence the shape, the head, the legs and the tail, are the most salient features of animals and are those that children notice.

The data from this study provides a base line upon which zoos and their education departments can construct meaningful interpretation within the zoo and for the school visitors before and after their visit. The results suggest the visitors do not embark knowing nothing of animals but use their everyday
knowledge and experiences in interpreting the exhibits.

Primary school groups embark upon their visit with an everyday knowledge and vocabulary about animals which they apply to the specimens which they view in the zoo. The dimensions of the animal form the largest category of observational comments followed by remarks associated with the front end of the body. It is not surprising because human beings seek eye contact and usually look at the face of the human to whom they are communicating and it seems likely this habit of seeking the face is carried into the observations the children and their accompanying adults make when observing animals.

Trowbridge and Mintzes (1985) reflect that 
'. . . students consider ambiguous and often conflicting pieces of information when classifying animals, ultimately arriving at a decision based on relative size or perceived importance of body parts.' Furthermore, Mintzes, Trowbridge, Arnaudin and Wandersee, (1991), suggest that children would be taught classification most effectively by the teachers using live or preserved specimens and offering immediate feedback to their pupils. The visit to the zoo provides an opportunity to do just this. The teachers can help the children learn the criterial attributes for the major taxonomic groups that children are expected to know and understand by using the children's tendencies to notice particular attributes. These first hand observations can be developed so that the children recognise and using the key features used in the taxonomy of the animals viewed and the main groups to which they belong such as mammal or reptile, cats or snakes.

This data suggests that the children and their teachers, and the educational material provided by the zoos do not take the opportunity of a visit to live animals to develop the children's knowledge of the features necessary for practicing taxonomy.

This study shows that groups of primary school children do not focus spontaneously on critical attributes that are required by zoologists in classifying animals. However, there are certain features that the children and their accompanying adults do notice and these could be used as the basis of developing the knowledge about taxonomic classification required for science courses.

This conference will:
1) review and appraise the advancement of women since 1985 in terms of the objectives of the Nairobi Forward-looking Strategies for the
Advancement of Women to the Year 2000.

2) mobilize women and men at both the policy-making and grass-roots levels to achieve those objectives.

3) adopt a “Platform for Action,” concentrating on some of the key issues identified as representing a fundamental obstacle to the advancement of the majority of women in the world. It will include elements relating to awareness-raising, decision-making, literacy, poverty, health, violence, national machinery, refugees and technology.

4) determine the priorities to be followed in 1996-2001 for implementation of the Strategies within the United Nations system.

The 14th ICCE will be held in Brisbane from July 14-19, 1996. It is only the second time this conference has been held in the southern hemisphere. The biennial conference brings together chemistry teachers, chemists and science educators from school, industry and university settings to share ideas and learn from one another about innovation in teaching and learning and the discipline of chemistry. The theme, Chemistry: Expanding the Boundaries, acknowledges the centrality of chemistry through its expanding relationship with many facets of science and everyday life. Conference participants will be challenged to develop this theme with the view of enhancing our understanding of the important relationships which chemistry forms with the new frontiers of human endeavour. Implications for chemical education beyond 2000 which give a “science for all” perspective will be encouraged.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

TRIBUTE TO SHEILA HAGGIS

The “mother” of ICASE died in Paris on 5 April 1995.

The name Sheila Haggis is synonymous with science education worldwide. Her work in UNESCO Paris as Head of the Science Education Section, and latterly as a consultant to UNESCO, brought her into contact with literally hundreds, and perhaps thousands, of science educators, including science teachers throughout the world.

But, it is with science teachers’ associations that we, in ICASE, will best remember her. She was instrumental in the setting up of the Ghana Science Teachers’ Association (GAST) in the 1960s, whilst she was a science teacher in that country. Then, when she joined UNESCO in the late 1960s she worked hard to support the development of science teachers’ associations. With UNESCO support Sheila convened a regional meeting of representatives of science teachers’ associations in Asia in 1972, which prepared the way for the establishment of ICASE in April 1973 at a meeting in Maryland, USA. Her guidance during this inaugural meeting endeared her to all who were the founder members of ICASE; hence she was affectionately known as the “mother” of ICASE.

For the 20+ years since that time Sheila strongly supported the work of ICASE and provided, on many occasions, invaluable advice on strategy and development programmes for ICASE. She was, for instance, instrumental in supporting an important international conference on integrated science held under ICASE auspices in Nijmegen, Netherlands in 1978. And, more recently, in helping ICASE and UNESCO to launch Project 2000+ on scientific and technological literacy.

Much can be written about Sheila Haggis as a teacher and author of science books for students, her ability as an administrator of international education programmes through the UN organisation, UNESCO, and her gift for writing clear reports and proposals for international organisations. Much, also, could be written to describe Sheila as a charming and elegant lady who conducted her professional and private life with dignity and with understanding of the needs of others. And, all of us who knew Sheila will have special memories of speeches, lectures, committee meetings, working groups, and social occasions at which we have been privileged to listen to or meet her. Certainly, we, in the ICASE family, deeply mourn the loss of an outstanding figurehead in the international science education community - a person whom we honoured with the ICASE Distinguished Service to Science Education Award in 1989.

EUROPEAN CHEMICAL INDUSTRY COUNCIL (CEFIC) JOINS ICASE

CEFIC has become an institutional member of ICASE. The correspondent is Dr. David Bricknell. A copy of the proceedings from the November 1994 CEFIC-ICASE Conference can be obtained from Dr. Bricknell at the following address.

ICASE STEPPING INTO SCIENCE AND THE GREEK PUPILS’ PRESENTATION

Dr. Zoe Zoni Kavogi
Greek School of London

Participants enjoyed all the activities shared at the popular ICASE Come and Share session at the January 1995 ASE Annual Meeting at the University of Lancaster. Pupils from the Greek School of London presented activities entitled “Science Recipes from Greece” to science teachers. Teachers also had a hands-on experience with them. These activities were events from a science project which is in progress in the Greek School of London. The project is entitled “Stepping into Science in the Form of Discrepant Events” and is carried out by Dr. Zoe Zoni Kavogi.

In this session, pupils introduced to teachers an alternative way of teaching physics, as some participants claimed that “these activities were thought-provoking,” “these were minds-on and hands-on activities,” and “they stimulated curiosity and motivation to comprehend the science topics.” Among the participants who shared the Greek pupils’ activities were Mrs. Sue Dale Tunicliffe, Section Editor of the ICASE Science International Journal and Mrs. Anna Garner, President Elect, ICASE and Representative of Iceland.

Pupils would welcome an opportunity to share their activities. Do not hesitate to contact:

“Oxygen in the Air.” Can you make the coloured water rise in the jar and come alive?
CHALLENGES TO SCIENCE TEACHER ASSOCIATIONS

Mary Ratcliffe
School of Education
University of Southampton

The roles of science teacher associations in the relationships between “researchers” and “practitioners” was a focus for an international gathering under the auspices of ICASE and ASE. Sixty-five educators, many representing their country’s science education association, met for a day prior to the ASE 1995 annual meeting to consider the relationship between research and practice.

Four keynote speakers set the scene by outlining a particular perspective on education research and classroom practice relationships. John Penick, from the University of Iowa, illustrated how established research findings can have a positive or negative impact in the classroom depending on the attention given by teachers. A research finding which he considers most important is “students copy their teachers’ behavioral patterns.” He stressed the importance of self-evaluation by teachers (and researchers) in promoting active learning.

Dissemination of research outcomes was discussed by Maria Saez from the University of Valladolid, Spain. She highlighted some key features which may assist dissemination.

- Decide the method of dissemination at the outset of research and actively involve practitioners in the planning for dissemination.
- Use case studies which are based on qualitative, holistic methodologies.

Many teachers are pragmatic in their approach to teaching and do not seek a theoretical stance to inform their practice. This was a view proposed by Jonathan Osborne from King’s College, London. He argued that classroom-based research, involving teachers in both implementation and dissemination, can promote the use of active learning strategies.

The perspective of the classroom practitioner was represented by Adrian Pickles, an experienced English science teacher. He explained the difficulties of making use of research findings even among those willing and able to access these. He highlighted his own experience in using some research publications and in the lack of positive action by colleagues. Lack of time, coping with curriculum change, and lack of mechanisms for active dialogue between researchers and teachers can all contribute to resistance to reflection on and change in classroom practice.

These presentations set the scene for active discussion involving all participants.

Participants were anxious to change this relationship between researchers and practitioners. As researchers and teachers, we must:

- plan, implement and disseminate research in collaboration.
- listen to each other’s perspectives and problems.
- produce readable, well-publicised articles which have direct classroom relevance.
- use multidisciplinary approaches and involve a wide range of people with differing expertise.
- view our joint relationship as important in preservice and through continuing professional development.

Role of Associations

Participants concluded that there were important roles for science education associations in assisting the development of this positive relationship. Participants were keen to see these acted upon. Science education associations should:

- develop explicit policies and structures which recognise the diversity of the association’s membership and which enable a constructive dialogue to take place.
- publish, in an accessible form, short, readable articles which have direct meaning and impact for science teachers. This should include all types of relevant research.
- deliberately organise meetings in which teachers and researchers can discuss research issues.
- plan and disseminate research and support research-based initiatives in preservice and inservice training.

The discussions also raised a number of issues, which were left unaddressed:

- What of policy makers in this relationship?
- More active involvement in the relationship outlines would be beneficial?
- What counts as research and who undertakes it?
- How do those involved in examination, curriculum development and assessment, and the educational media fit into this relationship?
- What are the implications for associations’ structures and procedures?

These unanswered questions should not be ignored. They should be part of an ongoing debate.
for action by associations. To quote from the outcomes of one discussion group, “Teachers are not necessarily resistant to change. They like well-informed, well-researched, timely and inspirational changes.”

Note: ICASE is very indebted to Mary for organising and chairing this meeting and wishes to express its sincere gratitude. ICASE hopes that readers will find much to consider in this report and be willing to contact ICASE giving reactions, concerns, and suggestions for their country in this important area. Science education research is growing at a fast pace, but so much of this is restricted to so few countries and published in journals that are expensive to purchase (even for libraries). How far is the transference of research findings applicable across country boundaries and how can research findings be made more accessible to the practitioners?

—Jack Holbrook, Executive Secretary, ICASE

Editorial Note: Member organisations are encouraged to reprint this or any other ICASE-SEI article.

MODEL 1 AN EXTREME PESSIMISTIC VIEW OF THE RELATIONSHIP

We decide the areas to be researched

RESEARCHER

We have the answers

We decide and organise dissemination

If you do as we say, learning will improve

PRACTITIONERS

We do not have time to reflect

We are not prepared to read long complex research reports

We do not wish to do your bidding

MODEL 2 A MORE CONSTRUCTIVE, DYNAMIC RELATIONSHIP WOULD ASSIST ALL CONCERNED.

EDUCATIONAL SCIENCE CENTRE IS UNDER THE SUPERVISION OF NON-FORMAL EDUCATION DEPARTMENT, THE MINISTRY OF EDUCATION

Dr. Kla Somtrakool
Educational Science Centre
Bangkok, THAILAND

Educational Science Centre, Bangkok is a new name in the global science centre community. Nevertheless, they have been providing science education via exhibitions and educational activities since 1980. It is aimed at promoting the awareness and the role of science and technology among the youth and the public in the fast growing society of Thailand.

Until late 1994 the organization was called Centre for Educational Museums, but has since been changed to Educational Science Centre. This is a part of the national project on Educational Science Centre and its Network to acknowledge the increasing importance of science and technology in the development of the country. And auspiciously, it is to celebrate the Golden Jubilee of His Majesty the King’s Accession to the throne in 1995.

In addition to the primary Educational Science Centre at the Ekamai site a new campus will be established at Rangsit, the northern outskirt of Bangkok. In addition, 76 Provincial Educational Science Centres will be established in all provinces throughout the country within the next 5-7 years. To name a few remarkable centres nearing completion: The King Mongkut Memorial Park of Science and Technology at Wa Koh, Prachuap Khiri Khan province will be completed in 1997; and the pilot project at Nakornsritammarat ang Trang Provincial Educational Science Centres just recently opened.

A wide range of educational activities and services are offered to school children and the public the whole year round. It also plans to cooperate with the science centres around the world in the exchange of ideas and personnel, including exhibitions.

Contact: Dr. Kla Somtrakool, Director, Educational Science Centre, 928 Sukhumvit Road, Klong-Toey, Bangkok 10110, THAILAND.

8TH INTERNATIONAL ORGANIZATION OF SCIENCE AND TECHNOLOGY EDUCATION (IOSTE) SYMPOSIUM
EDMONTON, ALBERTA, CANADA

Alberta Education will be hosting hundreds of international participants at the 8th International Organization for Science and Technology Education (IOSTE) Symposium in August 1996.

IOSTE is an organization committed to advancing the cause of science and technology education as a vital part of the general education of all people in all countries of the world. As well, IOSTE identifies the changing science and technology education needs of humankind and nations. The members of IOSTE are approximately 600 science and technology education policy and decision makers in regions that include the Arab States, Australia and Oceania, South and East Asia, Africa, North and South America, and Eastern and Western Europe.

The symposium’s theme is Science and Technology Education for Responsible Citizenship and Economic Development: Evidence, Policy and Practices. The theme also addresses two emerging demands of science and technology education worldwide; preparing students to:

- make appropriate decisions regarding local and global environmental issues, and make wise use of natural resources.
- contribute toward responsible economic development in a highly competitive and integrated global economy.

Inquiries and calls for proposal forms can be directed to:

"The Earth is our common home. Let’s all look after it," is the message students from the Kosygin school in Arkhangelskoye (a village on the edge of Moscow), want to pass on to everyone involved in "Science across Europe."

This is just one of the many comments received at the headquarters of the Association for Science Education (ASE), home of the Science across Europe project. The project, which is a joint venture between ASE and British Petroleum (BP), was set up to introduce a European dimension into science education. The science curriculum provides common ground between schools in all the countries of Europe (and the world) and, thus, provides a forum in which students can exchange ideas and opinions about science-related issues.

Background
A grant from BP enabled ASE to set up a pilot project in 1990. A team of science teachers from six countries got together to plan two units: one on Acid Rain, the other on Energy Use. The basic idea is simple. Take a topic related to the science curriculum and get students in different countries to exchange information and opinions. Thus, in the Acid Rain unit, students from Britain learn from students in, say, Sweden or Switzerland, about the problems caused by acid rain in their country, asking who is to blame and, most importantly, what they think can and should be done about it.

Continuing support from BP has enabled the project to grow to the point that there are now six units in publication dealing with Drinking Water, Food, Renewable Energy and Global Warming, along with Acid Rain and Energy Use covered in the two original units. At first, each unit was translated into 10 languages, but the project is presently expanding to include more languages such as Russian and Greek. Schools all over Europe can purchase the books.

Participation
There is currently a network of schools in more than 20 European countries involved in the project. Details of each school taking part are held on a computerized database. Each participating school receives a list of all the other schools around Europe that are also using that unit. They can then select one or more schools from the list with which to exchange information. The information exchange can take place by mail, fax, or e-mail.

Opportunities for Cross-curricular Work and Cultural Exchanges
Clearly, the project is not limited to science. There are many opportunities to include economics, languages, geography and social science.

As students receive information about a topic from schools in other countries, they also begin to learn about the cultural similarities and differences that exist from country to country. For example, information received from students in France working on the Food unit suggests that between meal snacks such as crisps and chocolate are rarely eaten in their country.

Indeed, once received, the uses to which the information can be put are endless. One school in Slovenia has used the Using Energy at Home unit to make a cross-curricular study which lasted several weeks and included English, technology and geography, as well as science. Moreover, schools are not limited to the schools listed on the database for their information exchange. A British school used the Acid Rain unit as the basis for a residential week shared with their existing partner schools across Europe. Students from other countries arrived armed with the results of their work on acid rain.

The Drinking Water unit led the Kosygin school, near Moscow, to seek external information for the first time. At first, the water authority of ficials were most surprised by the students asking questions, but, after persistent efforts, they obtained the details they wanted. The results led to follow-up work on environmental pollution and water quality and also raised the issue that water was not a free commodity. This led them to think about some of the costs and benefits regarding economic development and the environment.

Industry/Education Partnership
The involvement of BP has been crucial in the development of the project, not only from the
viewpoint of funding, but also because the company’s presence in most European countries has provided additional links to ASE’s existing network of members across the continent. BP’s activities in countries beyond Europe have enabled the project to develop a network in the Asia Pacific region involving around 300 schools from Indonesia, Malaysia, Singapore, Thailand, New Zealand and Australia. During 1995, this network will expand to include Korea, Brunei Darussalam and Japan. In addition, a small group of schools in the USA has joined the project, supported by Community and Educational Relations staff at BP’s Cleveland, Ohio site. Now, a new network is planned for Africa. These new networks will provide even greater opportunities for information exchange between students as Science Across Europe becomes part of a global network, Science Across the World.

If you would like more information about Science Across Europe and the World, please contact: Evelyn Van Dyk, ASE, College Lane, Hatfield, AL10 9AA, UK Fax: +44 (0)707 266532

Two students from Stanborough School, UK, test the acidity of rain water

ICASE

NURTURING THE CHILD’S ECOLOGICAL MIND: A PROPOSED MODEL BEYOND STS

Kat Hudson, Ruamrudee International School
John Stiles, University of Northern Iowa

Looking over our notes from the ICASE Asian Symposium in Bangkok in December, one term kept recurring: sustainable development. Speakers repeatedly trotted out this “buzz word” as they called again and again for educational curricula to incorporate the STS (Science Technology Society) or STL (Science and Technology Literacy) models, so that we may teach students how science and technology must move toward a global perspective of sustainable development.

Science educators with various points of view and from diverse cultures and nations gathered to share ideas in environmental education with the goal of helping to reach an economic and ecological balance to preserve natural resources and further human development. The idea which seemed central to the theme was that educators must teach students how technology can help correct the ecological disasters which humans have caused. In other words,
technology has played a major role in creating large-scale environmental problems since the advent of the industrial revolution, and society must now use current technology to stop this trend and/or heal the scars.

We question the use of technology as a tool to move toward “development” if it is purely economic in nature. The quality of human life is not always improved or “developed” because of technology. Science and technology void of ecological consciousness and without regard for interdependence of organisms and their environment will result in long-term disaster. In addition, without this ecological consciousness, the human spirit of every individual is weakened.

Many at the ICASE Symposium suggested that environmental education issues should be studied after ecological disasters have occurred, and then teaching what should be done to correct the problem. However, we suggest that it is more reasonable and effective to strengthen the innate ecological mind in children before introducing issues in STS or STL.

The STS message is that the power to heal the earth comes from technology and the responsibility of decision-making in the wise use of that technology. However, this does not empower students enough to believe that the individual has the ability to make wise decisions based on a personal relationship which is developed between them and nature. This process is developmental, beginning with the individual, exploring the self (sensory), then his/her environment and finally the child’s societal position. Educators rarely provide students opportunity to explore that connection to nature. Not only are students isolated from the environment (sequestered in a classroom) in order to occasionally—if ever—teach about it, but we do it through use of technology! Decision making is based on group actions in response to some technological issue. Rarely is there the opportunity to first develop a sense of stewardship on which to base environmentally sound decisions.

We can develop technology that is motivated by an environmental focus, rather than the reverse, which is what occurs in our society now. The result will be an environmental technology consciousness which is individually based and which blossoms into a societal pursuit. Thus, by strengthening the human bond with nature, and then introducing the role of science and technology, the investment in conservation and environmental education is many times greater for future generations.

Economic growth based on ecological considerations is the only way to create long-term sustainable development, if indeed sustainable development is possible. If it is based on anything else, there can be only ecological failure. It is apparent that the “top down” bureaucratic approach to problem-solving is ineffective. It is idealistic to call for cooperation between societal sectors, but we believe that it will only be through education that this ecologically-centered vehicle will be able to affect long-term change based on environmental consciousness. We need action, not mottoes or political rhetoric. Therefore, education of and by our teachers is key.

We propose a new model based on development of the child’s ecological mind, thus moving beyond STS to EMST (Environmentally Motivated Science and Technology). This model is based on the following premises:

Premise 1: We are all born with an ecological mind which governs interactions with our environment. Primarily, these interactions are through the senses, allowing the individual to act in a basic, sustainable way in order to survive.

Premise 2: All children have a natural sense of curiosity and unrefined observation skills. As the child grows and is introduced to aspects of our technological world, s/he uses these skills less and less, and loses touch with the natural environment.

Premise 3: Institutionalized education removes the child from his/her natural environment. The result is that the ecological mind is stifled, and students are introduced to the idea that technology is the primary means by which environmental problems can be addressed. An analogy would be one in which a person is put on a boat and asked to understand what the ocean is without ever having learned to swim in it.

A Proposed Model to Nurture the Child’s Ecological Mind

In the primary grades (ages 5-8), environmental education should be central to the curriculum, providing ample opportunity for students to individually explore nature in the natural environment. This developmental approach is appropriate for the primary years, allowing children to develop their own ecological understanding, and at their own individual rates. The teacher’s role is to enthusiastically reserve time, perhaps in an interdisciplinary approach, for activities which give children time alone in nature.
The students must be encouraged to express their ideas and feelings and describe experiences which are not evaluated, and which build unique ways of looking at the natural world. The focus is on children learning that nature is not separate from them, but that they are part of it.

At this age, children should be given many ongoing opportunities to role play in order to gain a perspective of various components of the natural world. For example, young children love pretending to be plants or animals or wind, moving their bodies to perceived natural rhythms, thus developing an awareness and sensitivity to those particular members of nature.

During the upper elementary years (ages 9-12), children may learn about consequences (cause and effect) from an individual point of view based on their developing environmental consciousness ("My actions cause this."). Students learn that there are choices, and certain responsible actions can be practiced at the individual level which promote a healthier environment. This type of opportunity is often lacking in education, where decision-making is now done almost entirely by groups.

The use of technology and science equipment may be introduced as assisting us in the decision-making. It should be noted that they are tools only, not the answer (or primary force) themselves. Children learn that the true power lies in the individual’s ecological mind and its ability to reason, and to act responsibly for the self, as well as for society. All this is done through an environmental focus.

In the middle school (ages 13-15), students continue direct exploration of the natural world, spending time in nature in different natural settings at various times of the year. This also helps them distinguish and explore their changing maturity and how their relationship with nature is affected.

This is an appropriate time to develop the group decision-making process through simulated problem-solving and awareness of environmental issues. Local guest speakers may be invited to visit the class and discuss current concerns which directly affect the students. Students learn that they can affect the decisions made by others.

In high school (ages 16-18), introduction of the role of government and ways it implements policy builds upon the foundations laid in the earlier years. Students do not simply role play: they take action at the school or community level, involved in resolving some local environmental issue of their choice. This type of application must be supported by the community and local government. Expanding to more regional or global issues may take place once students act locally.

Technology continues to be emphasized as an effective tool for examining current environmental problems and correcting past mistakes, and perhaps most importantly, predicting and thus preventing future environmental disasters.

As a result of this approach, high school graduates do not just enter the adult world with knowledge of the environment, but understanding that it is a part of them, and that they have the power to affect change. The schools thus produce competent, confident citizens, aware of their entire development from a historical perspective. They can then continue to teach others by example, particularly their own children, thus creating a type of cultural wisdom handed down generation by generation, such as those traditions integral to most “primitive” societies.

Schools must develop this environmentally centered model as an integrated approach which all teachers and administrators support. The model is sequential, but also revisits and strengthens skills and concepts, and nurtures attitudes of environmental concern as students progress through school. It cannot be the primary responsibility of any one person or subject area if it is to succeed as being a frame of mind by which one makes decisions. It must be reinforced at all levels and in all disciplines.

The environment may be thought of as connected to the human spirit or soul, just as it is connected to everything else. This is evident in spiritual teachings and cultural histories of almost every non-industrialized society. It is no accident that industrialized and “developing” nations, which base their economies on technology and economic growth, show little—if any—environmental consciousness.

The ecological mind is simplicity: how to survive and exist among the resources available. We’ve moved further from the answers which lie within us, toward a technological substitute created by the human mind, not by the human spirit. STS is missing that spirit-mind connection.

There is a great sense of security and confidence when one knows that others are also thinking from an environmental perspective. If our society can move toward that environmentally motivated model, we will take giant strides toward elimination of what has been termed “eco-phobia” which so many children have in today’s society. It is this phobia which prevents one from taking responsible actions to protect the environment. The EMST model can give children the confidence to take action from a very early age, and as a result, have a well-developed ecological mind as they enter adult society.
MICROCOSMOS: AN INTERNATIONALLY-ORIENTED, TEAM-BASED MODEL FOR SCIENCE EDUCATION REFORM

Dr. Douglas Zook,
Assistant Professor of Education
Boston University School of Education
605 Commonwealth Avenue
Boston, MA 02215
Fax: + (617)-353-4170

The most common and arguably the most influential life forms on the planet are precisely the ones which have been ignored the most in both history and education. The millions of organisms that together fit into areas no bigger than the period at the end of this sentence are not only crucial to earth systems (Schopf, 1992; Margulis & Sagan, 1993) but have played a key role in the evolution of a unique science education reform effort based in Boston, Microcosmos (Travis, 1992).

As citizens we all admire the antique hutch restorer, this artisan who busily scrapes away the layers of abused paint, who creates a sudden blizzard of flakes from the cringing sounds of a blade. As the surface breaks apart into so many million bits and pieces, a new wooden monument is gradually revealed. The dustbin collects the paint chips while this knotted resurrection stands front and center. In our search for understanding of ourselves and the planet, we as educators have not even remotely shared that all the surfaces of the globe are antique layers, vast communities of life like thick invisible paint. There is barely a surface that is bare of microorganisms! The Microcosmos science education program has been developing the right tools such that educators can both discover and peel away this surface. But the ever-reproducing “dust” scraped away is hardly discarded. Rather, it becomes a centerpiece, part of the resurrection of life science education and a model for science education reform.

Since its initiation in 1988, the Microcosmos program based at Boston University’s School of Education has focused on showing that life too small to be seen with the naked eye can be a vehicle for stimulating enthusiasm for science among students, as well as bringing us all closer to an understanding of how the earth works. Through these “inner space” classroom travels, the program’s first intent was to help fill a massive crater in science education with a blend of new life discovery and a revitalized emphasis on how to motivate and stimulate the vast numbers of pre-college classroom non-learners. More than 2500 teachers around the United States and another several hundred from New Zealand, Canada, Spain, and Denmark have been directly trained in the inquiry and constructivist-based pedagogy of Microcosmos. Many of these teachers have not only successfully integrated the explorations into their curricula, but have shared what they have learned through regional mini-workshops. They have become enthused and empowered. Through Microcosmos, they have discovered that important science educational reform can be built around a specialty subject area and expanded in various creative directions.

Microcosmos, as an internationally-founded project can teach us lessons about how to promulgate healthy science educational reform. The program’s evolution suggests that building systemic change for science improvement may depend in large part on how teacher training and curriculum development efforts are socially structured and maintained. What are the components that we need to value in science education reform that are inherent in Microcosmos? *Microcosmos evolved through a team concept.*

Approximately 20 individuals at any given time over the past seven years have primarily volunteered their time to meet once a month and work on creative approaches to classroom learning utilizing microbial themes. Too often, educators attempt to tackle curriculum and educational change within a broad topic framework. The team approach has worked in part because we have stayed focused on microorganisms, not as a microbiology curriculum creation, but as a theme for learning about many aspects of science and other disciplines. “Less is more” as a curriculum concept has become highly valued in standards-based designs (AAAS Benchmarks, 1994), but Microcosmos shows that the concept may not only be needed directly in the classroom curriculum but in the actual structuring of science educational reform groups around topic areas.

A constructivist approach based on some of Vygotsky’s principles (1978) of the social construction of knowledge and refined by recent educators (Driver & Oldham, 1986; Yager, 1991) needs to be applied to students entering a university education program. Who these education students are—their ideas, feelings, preconceptions, changing personal meanings—must be recognized, and their
involvement can be ignited simultaneously with peer-centered, reform-oriented course work so as to immediately begin to be connected to change in the real world of education.

Thus, many of the Team members today began their contributions in the program while they were students in the Master of Arts in Teaching Science Education program. Their course schedules were heavy, but even minimal involvement in the Microcosmos program brought these individuals early on in contact with currently practicing teachers and other professionals. Moreover, it helped to establish a mission, an identity in which university education was not divorced from the school districts, the everyday middle school classroom problems, the communities of parents and workers who care about their children's education. Rather, university education students could immediately begin a connection and even a contribution, not out of arrogance but out of an evolving self-realization that players need not start by being only spectators.

The Team concept brought together these graduate students with experienced, creative professional teachers from area schools, writers, artists, and scientists. Scientists were mostly represented by members of an International Advisory Committee. We asked selected individuals from various countries who were specialists in aspects of ecology, microbiology, education, genetics, and industry to be a part of the Committee and of our advice as well as scientific review and credibility. Currently, scientists from nine different countries are represented. Moreover, my principal background was in biology research; I could see the great need for translating science concepts and everyday research into classroom expressions, and thereby I was someone with whom noted scientists interested in education could connect.

Today the Team is represented by nine full-time teachers, including two from middle school, six in the secondary level and one in a small college who previously taught at the high school. Of these nine teachers, three are currently enrolled in science education doctoral programs. Two others took an early Microcosmos workshop and became so involved that they were invited to regularly be a part of the Team. One of these teachers specializes in bilingual education, teaching science to mostly Spanish speaking students. Two other Team members are within the informal education domain, having had extensive experience over many years in zoological and botanical garden settings, working on exhibits, animal and plant care, and education, and another successfully took on the role of education coordinator at a children's science museum. Two Team members work full-time as curriculum developers with well-known educational consultant firms, although in both cases their involvement in the Team predated these positions. Three undergraduates are currently involved, including one who is experienced in environmental education, another in music education, and a third in social studies education. Another is a former undergraduate in science education and now works in biomedical research. Two others are primarily artists, but both teach as well. One teaches art part-time in a public school along with her studio work in woodcuts, bookbinding, and oils, while the other does free lance drawings and teaches an intensive computer graphics course. Another is a director of a hands-on biotechnology education program where he teaches, designs curriculum, and conducts workshops for teachers. Of the 21 current Team members, 10 became involved in the program during or near the conclusion of their Masters studies in science education while two others later enrolled in the Master's program, after extensive involvement in the Team. While such a descriptive listing may seem tedious, it is important because it illustrates the great diversity, creativity, and developmental evolution of the collective. This diversity appears to be crucial to the success of an educational reform group.

Nevertheless, the Team has evolved as an informal, volunteer-centered body. There has been an informal, camaraderie spirit to the program since its inception that seems to be key to fostering creativity as well as going on unity. This minimalist structure appeals to many creative teachers and students, for it is an alternative to the constraints they see in their own daily education professions and endeavors. Microcosmos work represents freedom of expression and innovation for these individuals.

Microcosmos also helps fulfill social peer learning and professional interaction needs. Teachers are traditionally operating in isolated frameworks. Even students at the graduate and undergraduate levels frequently feel alienated from their roommates or other students whose interests are elsewhere or who are not seriously embracing studies. The Team offers a non-competitive, non-threatening social structure. Occasionally subcommittees or partnerships are proposed to work on a certain task. These individuals meet on their own and periodically report back their work and receive feedback.

There is an ongoing open management style to the program. Team members recognize that all ideas are welcome, that new explorations (we have pretty much abandoned the use of the word "lesson") can be proposed and supported. In many group of forts, money in some form or fashion frequently gets in the way of the program effort and the ultimate goals of
positively impacting classroom learning. Within the Team, “money friction” has been avoided by an openness in which the Director discusses use of funds and makes clear that whenever grant moneys allow, consultant fees for teaching or direct workshop preparation and follow-up will be shared. All members of the current staff, which includes two full-time and three part-time workers along with the part-time Director, are members of the Team.

Beside these features of the Team and its evolution, Microcosmos was not a program created by money, grants. The University allowed some space to be used in science education due to the need enliven the facility. The space was allotted, an international advisory board formed, and initial exploration ideas discussed prior to any funding. Indeed, the first four years of the program featured the development of the nearly 500-page Microcosmos Curriculum Guide to Exploring Microbial Space by the Microcosmos Team and now in its third printing with Kendall/Hunt; the creation of a viable workshop format for in-service teacher training that resulted in not only a score of intensive workshops at the University Microcosmos facilities but over 250 mini-workshops and presentations of f-campus at school districts, museums, and science education conferences around the United States as well as other countries—reaching initially hundreds of teachers and eventually thousands of classroom students; and, the gradual building of a small museum for educators that features low-tech, hands-on representations of many of the ideas and explorations expressed in the Curriculum Guide. These vast, time-consuming activities which helped build momentum for the program’s objectives all were initiated prior to any funding and were brought to success levels with minimal funds. Small grants and some copayment for workshops by teachers and school districts totaled less than $75,000 over the initial four years! University support was key, but it was clear that this kind of program could bring in additional quality students and bring broad recognition to the school’s science education program as an innovative learning center, both of which have happened.

But the essence of the program was based on the people-centeredness of the effort from the outset. It was “grassroots” in the sense that it was not top heavy with professional program developers and administrators, but instead blossomed from hard-working students and teachers. Remarkably, many of the Team meetings over the first year or two seldom brought up the topic of funds, as most of the participants wanted to discuss exploration ideas. When we received major funding from the National Science Foundation in 1992, the Team felt that we had truly earned it, and this funding would allow Microcosmos to build on its already established curriculum, workshop, and exhibit center base.

Another model aspect of the program has been the way in which our in-service workshops have been organized and conducted. With a Team approach, we are able to consistently bring in a variety and diversity of faces, styles, personalities, and approaches that help to make the daily presentations dynamic. Teachers taking our workshops consistently remark in feedback that the variety of presenters and their informal but respecting manner makes the workshop click. Furthermore, the workshops have evolved to where the Team both directly models how explorations from the curriculum can be conducted in the middle and secondary classrooms, and allows for idea circles and discussion formats on overarching and frequently cutting edge pedagogical topics such as authentic assessment, integration of constructivist teaching, building systemic change, reflective learning, heterogeneous classrooms, and integrative curriculum.

Workshops introduce and model new ideas or additions for science classroom use. For example, Microcosmos proposes a learning cycle model that evolves from Karpilus (1977) and a constructivist base, centers around inquiry oriented explorations (Schwab, 1962), and consistently features the actual creation of a physical outcome, usually in small sub-groups. The outcome can be an exhibit, ongoing experimental apparatus, a model, a poster display, art or writing samples, or some combination of these. Nearly all of the explorations in the Microcosmos Curriculum Guide feature such outcomes: Microbial cylinders, mold displays, micro-discovery boards, Microbingo game boards, marbling art microbial simulations, flasks of root beer and so on. These creations are discussed, interpreted and are often referred to and directly used throughout the teacher’s curriculum during the school year. Thus, the students have a direct part in building a personalized, stimulating learning environment that is truly “theirs,” and they are directly contributing to the teacher’s stimulating, albeit flexible, curriculum. The creations, while directly involved with microbial themes, connect to a wide variety of topics in a science curriculum, which further reinforces our central concept of using microbial life as a vehicle for science enthusiasm and learning. This same physical outcomes approach that contributes to the students’ building a learning environment can be applied to any classroom discipline design and thereby become a central strategy in general education reform.

From the start we have worked to build bridges linking cultures, knowledge, and attitudes in America.
with other countries. Even today, the Microcosmos International Advisory Committee has representatives from nine countries. This approach has grown beyond our expectations, as we have through direct workshop presentations and our follow-up network forged solid linkages to teachers in Spain, Canada, Denmark, and New Zealand. A long-range goal is to have each American alumni teacher in our network “paired” with an alumni teacher from another country for an ongoing, personalized, more structured exchange of ideas and methods among professionals. Being linked internationally while working regionally enhances educational reform structures, even when those linkages are mostly informational.

Lastly, teachers both here and abroad who take our workshops or purchase the curriculum or visit our small museum facilities are not simply left on their own. They become part of a science education network, now broadly seen as important to teacher enhancement. Through the network, they receive occasional articles on microbial or educational themes of particular importance, the periodic Microcosmos newsletter, and workshop announcements for alumni—i.e., special courses that teachers who have been using the Microcosmos explorations in their classrooms can take. It is not unusual for us to receive photographs from past workshop participants showing their students working with the Microcosmos materials or to receive occasional notes letting us know how they are doing in their work. Moreover, our current NSF grant allows for stronger network development and further dissemination of the Microcosmos ideas by requiring that all workshop participants later conduct regional mini-workshops with specific guidelines. A unique feature of this effort is that Microcosmos Team members visit some of these regional workshop sites in follow-up. Through face-to-face contact the Team can build stronger, quality alliances among teachers and administrators.

In summary, while Microcosmos has many shortcomings and a great deal to learn, it has evolved as a model for teacher professional development and science curriculum enhancement, particularly at the middle and secondary school levels. Key features include: the establishment of an informal, committed, diverse, and teacher-centered group of people; the reliance on a people-power approach rather than building from a heavily funded idea; linkage to a specific theme or topic around which experts in the form of an advisory board can be created; the actual modeling of innovative and reflective learning within the workshop formats; the boldness to promote new learning models and ideas; the ongoing internationalist base which fosters healthy exchanges and respect; and the fostering of a growing network of teachers who are permanently linked to the project.

Microcosmos is seen today as somewhat unique. We feel that major inroads in science educational reform will take place across the United States and in other countries when Microcosmos is not so special, when there are scores and even hundreds of similar decentralized, informal working collectives in regions around the globe—indeed when different groups discover and peel away their own “paints.”

HETHERSETT OLD HALL LINK
WITH WULUGU, NORTHERN GHANA

Lynne Symonds
Head of Science, Hethersett Old Hall School

Hethersett Old Hall is an independent school for girls age 8-18. It is a day and boarding school and is situated in East Anglia, Britain. Students from the school have established a strong link with students in remote Northern Ghana and the project has been extremely beneficial to both schools as well as to the whole area of Ghana surrounding the school.

In the autumn of 1993 the Head of Science from Hethersett Old Hall, Lynne Symonds, was selected to be part of the British team visiting Japan on an education/industry study tour of international educators. (Tour organised by the Japan Foundation.) Mrs. Symonds was able to form links with many parts of the world as a result of this tour, but to date the most fruitful has been that with Northern Ghana. The project began after a discussion between Karimu Nachina, Head of Wulugu School, and Lynne Symonds, which actually took place while waiting to meet the Minister for Cultural Affairs in Tokyo. Mr. Nachina told Mrs. Symonds that he had enormous problems in his school, largely associated with the education of girls. The Ghanaian school is too far away for students to walk each day from their homes so many have to board in local houses. Not only is this expensive, so deterring families from paying, but also it is hazardous. This is a polygamous society and girls can be treated as extra wives, becoming pregnant, dying from abortion, etc.

Mr. Nachina and Mrs. Symonds decided to try a trans-continental peer group education scheme, involving girls from the VIth form in Hethersett writing to similar age girls in Ghana.

Students at Hethersett were intensely interested in the lives of the Wulugu girls. They learned first hand about issues which can soon become ‘boring’ if taught in the normal way. If you hear that your friend in Ghana has malaria, has 23 living in her grass-roofed house, has not been to school because she has to work on the farm, then interest and real hunger for knowledge about wide ranging scientific and sociological issues is guaranteed. The English students are so very aware of alternative energy, appropriate technology, medical issues, etc. that they can speak with more authority than the majority of people who have read second hand accounts. They also developed real appreciation of their own school, well equipped, with books, desks, electricity and teachers (all often lacking in Northern Ghana).

The exchange of ideas and information has extended and is proving invaluable in the music, art, home science and geography departments in both schools. Also we are currently developing the student-student link to involve younger students.

The Wulugu students became keener to learn. They knew that their English friends were genuinely interested in them and the school reported quite dramatic improvements in attitude despite a gross lack of equipment and some measure of hunger. Within six months the number of pregnancies began to fall but of course no conclusions can be drawn from this.

One of the many fascinating letters from the school in Ghana revealed that they had a great need for books—in fact they asked for ‘anything you are going to throw away.’ This prompted the Old Hall students to collect 5 tonnes of books from friends, publishers, shops and other schools. A local businessman, Barry Brooks, volunteered to help organise and to pay for the transport but things were far from easy. The government in Ghana was keen to accept the books but wanted to distribute them as they wished possibly to high status schools in the south.

Wulugu is a long difficult journey from Accra, but Philip Parfitt, working for Barry, organised the whole trip successfully. When the books had arrived in Wulugu, Mrs. Symonds had an ecstatic phone call late one night from a Ghanaian who announced—

“I’m Francis and I did it—I got your books there. Everyone is amazed—they cannot believe it.”

Francis has now become a regular phone caller and friend.

Science Education International, Vol. 6, No. 2 June 1995
The books were received as gold, again the whole area celebrated they were completely overcome and set to work sorting, labelling and establishing a library. This library became a centre of attraction and the whole of Ghana seemed to learn about it. They named it the ‘Lynne Symonds Library’ and the opening was shown on national T.V. in Ghana. It seems very sad that these wonderful people should celebrate receiving our left-overs in such a fashion. However the high status of this library aids retention of teachers as well as encouraging parents and children in their education.

The headmaster at Wulugu has said he does not want to become an ‘African Oliver Twist.’ However the students in Old Hall are collecting now to build a boarding house where girls can live safely—they are: aiming for £8,000 but obviously the school will use whatever they send. During the progress of their fundraising the Hethersett girls have contacted Ghanaian students at the University of East Anglia who have helped to encourage their projects.

This link between two schools seems to be providing real aid to an area where the average lifespan is falling. Ghanaians are being encouraged to learn, particularly in the important areas of home science and agricultural science. The girls will become more aware of hygiene, nutrition and simple medicine, as well as able to read instructions on contraceptive packets. These skills will help them to take decisions about their lives and those of their children. Agricultural science lessons will enable better use of resources and perhaps improve living standards. The people in this area are mainly subsistence farmers but they are very aware that the high degree of illiteracy in the north is largely due to political decisions to concentrate resources in the south. The Northern Ghanaians have a more difficult climate and fewer natural resources so it is important that they are aware of possible solutions to their problems. Baroness Chalker representing Overseas Development Administration said in a recent interview (T.E.S. 6.1.95):

We are trying to help people to help themselves. We cannot get good governments in developing countries unless people are literate and numerate; likewise we cannot help people who are unable to read instructions on something as simple as a packet of seeds. One of the major thrusts in development policy is to promote literacy particularly amongst girls.

The girls at Hethersett Old Hall are endeavoring to provide sustainable assistance to Wulugu. At the same time their own education is being greatly enriched. The project has done a great deal for the self esteem of students and teachers in both schools and it is an idea which is worth repeating. Other British schools could link with other schools in English speaking Africa. French schools could link with French speaking Africa. The scope for development is enormous and, from our experience, rewarding for all concerned.

A SCIENCE EDUCATION CENTER AT UNIVERSIDAD DE LOS ANDES

Jose Mauro Briceño-Valero
Universidad de los Andes
Merida, Venezuela

John E. Penick
University of Iowa

This short paper is a proposal for a new Science Education Center in Venezuela. The authors would like comments, criticism, and indications of interest and involvement from science educators world-wide. Please contact them at the address shown at the end of the article.

Human resource development is at the very heart of the developing process.

Frederico Mayor
Director General, UNESCO

Rationale

Throughout the world, leaders are recognizing that full participation in democracy and growth requires science literate citizens (Bowyer, 1990). At the UNESCO World Conference on Education for All (1990), the ministers of education from virtually every country in the world affirmed the notion of “science education for all,” meaning every person, not just the elite preparing for careers in science, mathematics, and technology. The current UNESCO/ICASE Project 2000+ endeavor affirms that this grand goal is being sought in many ways in many
places. Project 2000+ recognizes that a science education for all necessitates different goals for students and a very different approach to schooling than is traditional, especially in many countries of Latin America. We strongly support Project 2000+ and wish to be a part of its growing international momentum by creating a Latin American and Caribbean Center for Science Education at Universidad de los Andes (ULA) in Merida, Venezuela.

The Latin America and Caribbean region contains vast resources and potential which, for development, demand a population well-educated in science, mathematics, and technology (SM&T). Currently, many of these countries rely for innovation on either local initiatives or ideas imported, typically, from North America or Europe. While these provide for needed growth, a truly sustainable educational development requires that Latin America and the Caribbean be more than passive recipients of ideas. A Center for Science Education at Universidad de los Andes could both provide for the indigenous development of Latin American and Caribbean ideas and be a nucleus for their dissemination. ULA is a natural setting because of its relatively central location, its heritage (established in 1785), administrative support, and its well-established position as a leading center for research and education.

Our Mission Statement

The Science Education Center of Universidad de los Andes is dedicated to the promotion and improvement of the teaching and learning of science, mathematics, and technology for all persons at all levels throughout Latin America and the Caribbean.

The Vision

We see the Center for Science Education as fulfilling a variety of functions including:

1. Designing and conducting research related to the teaching and learning of SM&T at all levels.

The body of literature related to effective teaching is growing quite rapidly. While much of the present literature pertains to Latin America and the Caribbean, we have our own unique heritage, situations, perspectives, and problems which require investigation and analysis in the unique context of the region. In addition, we must move ahead to be producers of research, curriculum, and new ideas rather than waiting, passively, for ideas to filter down from more developed nations. This research would also serve to link faculties of science, humanities and education in joint ventures to improve schools and schooling.

2. Designing and delivering pre- and in-service teacher education in SM&T, including methods of teaching, the content to be taught, and new technologies.

At the core of a science literate citizenry is education, especially in the pre-university years. Leaders world-wide acknowledge that, currently, only elite students receive an adequate education in SM&T. To remedy this, we need the best possible teachers we can produce. Rather than passively accepting teaching as an untrainable art, we must design and implement the most effective programs to change how teachers teach and think about teaching. Powerful models exist; if we add to these models our own research and the thinking of the best minds, we can create a teaching force which is second to none and students who truly understand and can apply SM&T.

3. Providing consultation, leadership, and training in the development, and instruction for education in science, mathematics, and technology.

Many academic departments, schools, industrial training groups, and government bodies need seminars, workshops, and advice aimed at improving the educational development or knowledge of their constituents. Affiliated with our Center will be a variety of scholars and professionals from many disciplines and nations, each ready and prepared to offer such advice. The Center will maintain a professional data bank and promote linkages and relations with such persons in order to facilitate this process.

4. Developing appropriate assessment techniques and technologies.

Society’s goals for citizens includes attitude, performance, creativity, and communication in addition to mere learning of the content and skills. If we are to meet these additional goals effectively, we must both teach for them as well as evaluate them in the classroom and beyond. As few assessment instruments are available, especially in a Latin American-Caribbean context, we need to adapt, modify, design, and test until we have techniques and instruments which meet our needs.

5. Developing policy statements related to the teaching and learning of SM&T.

Education is more than a teacher and students in a classroom. Unless national standards, attitudes, and policies reflect the overall goals of SM&T, little innovation or progress will occur in the classrooms of
our nations. Overcoming this requires working with policy-makers to develop position statements, documents, procedures, and even institutions which affirm the goals, research, and directions which truly support and encourage SM&T literacy.

6. Establishing and maintaining cooperative links with science education centers, science teacher associations, established groups of SM&T researchers, and science teacher educators worldwide.

Communication is the essence of research in science. So, too, communication is a vital ingredient in research, development, and implementation of educational ideas. We will serve as a center for such communication among scholars and professionals world-wide, bringing science and education professionals together. Each year, the Center will house visiting scholars, both students and professors, and, at the same time, will facilitate mechanisms for regional scholars to work at similar centers in other nations. Both of these will add to the richness of our knowledge base while enhancing our regional capacity for educational research and development.

7. Establishing and housing a library for materials and educational technology useful for SM&T education.

Our library will contain the usual books and journals and provide for interlibrary loans but will go considerably further, taking advantage of new technologies. We will provide educators and researchers with access to international data-bases and other students and scholars via computer linkages. Our materials will include computer software, courseware, simulations, and laboratory interfacing and other instructional technology so that teachers and researchers may evaluate their potential value and learn to use them.

8. Disseminating, world-wide, information and ideas related to SM&T.

Through newsletters and a periodic journal, the Center will communicate with numerous individuals and provide a forum for intellectual discussion. These media will also provide ideas of practical importance and new knowledge directly to teachers and others. Just as with the scientific enterprise, we will communicate with all science educators worldwide and be active partners with associations and groups dedicated to enhancing the SM&T literacy of all citizens.

9. Creating and coordinating SM&T activities for pre-university students.

Pre-university students often become university students and, eventually, enter science careers or teach at various levels. We must ensure that they have available appropriate opportunities to fully participate in SM&T activities. At the same time, those students who terminate their formal education earlier must have multiple opportunities to participate in learning experiences which help them understand and appreciate science. Thus, the Center will encourage and sponsor a variety of field trips, short courses, research experiences, science fairs, publications, associations, and competitions for pre-university students, beginning with the very young.

10. Encouraging the development of SM&T professional associations.

At the heart of an effective SM&T education lies the teacher. Sharing of ideas in a public forum is a key to enhancing the knowledge, skills, and professionalism of our teachers at every level. Professional organizations provide such a forum as well as opportunities for collegiality, communication, leadership, and debate. The Center will assist in the development of associations and will, itself, be an active member of the International Council of Associations for Science Education (ICASE) and the World Council of Associations for Technology Education (WOCATE).

Organization of the Center

The Center for Science Education will be an independent unit of Universidad de los Andes, reporting to the Vice-Rector. While basic funding (facilities, the Director’s salary, a secretary) will be provided by ULA, the Center will seek grants from national, regional, and international agencies for operations and specific projects. The Center will include a physical facility with offices, classrooms, a library, and a laboratory for development and testing of laboratory activities. Development of relationships with schools will allow field-testing of curriculum and instructional materials in real settings. Permanent staff will include a Director, clerical staff, and various assistants. Faculty members from a number of academic departments, universities, and nations will be invited to join the center for varying lengths of time. Sometimes they will be housed at the Center and other times they will be intellectually involved without being physically present.

In addition to guidance from the Vice-Rector, oversight will be provided by an International Advisory Board (IAB) consisting of eminent scholars from education, science, mathematics, medicine, engineering, and technology. The director will communicate frequently with the IAB and they will advise the Director, probably via an electronic conference, on a regular basis. The IAB will also be charged with keeping the Director and faculty cognizant of current trends and work in science education.

Current Educational Problems in Japan
As many scholars in education have discovered, the Japanese educational model, since World War II has developed ties to U.S. education. In turn the Japanese educational system has become a model for many other countries. But, in actuality, there are many problems with science education in Japan. The development of science and technology brings new problems to the present Japanese society, including lack of confidence, as well as a failure to humanize the subject.

Even with these problems, there is a consensus that more and better science and technology are needed in Japan to promote a better life. In 1989, the reform of the Course of Study, called National Standard Curriculum included a re-examination of the interrelationships among science, technology and society. However, critical deficiencies in the Japanese approach to assimilation attempts were noted when compared to the Science/Technology/Society (STS) movement in the U.S. (Kumano, 1991).

One of the major features of Japanese science education relates to how the system of education is organized. The National Standard Curriculum identifies what every school should teach at each grade. It is generally revised every ten years. Recently, the science content for each discipline has been decreased (MESCNC, 1982, 1989). The Ministry of Education also dictates the number of instructional hours each course will have as stated in the official Course of Study. From 1971 to 1979, 698 hours of science were designated for grades one to six. This number was dramatically decreased to 546 hours for the 1980-1991 interim. It was again decreased to 420 hours for 1992 and beyond. Similarly, the time for junior high school science was shortened from 420 hours (1972-1980) to 350 hours (1981-1992) and 315-350 hours for 1993 and beyond. Such decreases in the time allocated for science lessons illustrate that science education is becoming less important in Japanese society.

Another reason that some call the current situation ‘one of crisis’ is the changes in individual life styles that are occurring as well as general changes in Japanese society, caused by the rapid development of science and technology. It is not an exaggeration to identify the major problems today as having come from the interrelationships among science, technology, and society. Many citizens believe that too much development of science and technology may be harmful to Japanese society. People are being inundated with too much information in too short a time. People are becoming
more focused on individual priorities and materialistic goods. Time and space among people is becoming smaller and smaller. Physical changes in the environment produced by modern human beings cannot be predicted. The development of science and technology in the context of a changing society requires an attitude change on the part of teachers and students. Most of the teachers say that students are becoming more self-interested and desirous of an easy life. Communication between teachers and students is changing; respect for teachers is decreasing; some students look at teachers as teaching machines. Younger teachers have changed and, like their students, they long for the easy life.

Standardized examinations for college or university entrance pose still another reason for designating the current situation as one of crisis for science education in Japan. For many the main goal is merely to get better scores on standardized examinations during the senior year of high school. The major purpose, then, is drill and practice in order to learn many science concepts by rote memorization and to review questions likely to appear on the examination.

In reflecting on all of the current problems in science education in the Japan, it is easy to argue that the situation is likely to worsen within the next 10 years. To resolve the deepening crisis, new corrective efforts must be undertaken now. Grayson (1984) examined and analyzed Japanese science and technology education and he proposed interesting ideas. He observed, “For the first time, Japan is in the position of having to advance the state of knowledge, do advanced research, and create its own technologies. Japan must develop a creative, more knowledge intensive industrial structure” (p. 298).

**STS Instruction in Japan**

Before Nagasu’s work (1987) there were almost no studies reported which focused on STS instruction in Japan. Nagasu (1993) has summarized the studies reporting on STS efforts in Japan between 1983 to 1993. About 30 studies have been completed which illustrate the emerging STS efforts in Japan. Twenty-six studies concerning STS in foreign countries have been reviewed for special relevance in Japan. At the time of the first National Convention for the Society of Japan Science Teaching (SJST) in 1992, a special session on STS was scheduled at the Joetsu University of Education. The 1993 National Convention at Fukuoka University of Education established a new area of study in science education called “STS/Environmental Education.” Eleven presentations dealt with STS, 16 presentations were concerning constructivism and six presentations discussed this new philosophy. So all together 33 presentations (about 20%) out of 174 had strong connections to STS. Another major association in Japanese science education is the Japan Society for Science Education (JSSE). The National Convention of JSSE was held at Okayama University of Science in 1993. During this convention seven presentations were directed toward STS, and 18 presentations discussed constructivism representing about 20% of the convention presentations.

At least five governmental institutions in education are doing active research on STS for science education: The University of Tsukuba, Kobe University, Shizuoka University, Osaka University of Education and Ibaraki University. Many institutions have developed STS courses based upon their own departmental or institutional interests. In most cases, those STS courses are called ‘integrated or synthesized.’ There are also some institutions or departments whose main research is targeted on STS including the University of Tokyo.

Two important researchers in STS visited Japan from the U.S. so far. They were Professor Robert E. Yager, of the University of Iowa and Professor Rustum Roy, of Pennsylvania State University. They were invited by the Ministry of Education with university funding to an international conference and had a great influence on STS for Japanese audiences.

More and more researchers in science education, government researchers in science education, administrative researchers, and science teachers are getting involved with STS in Japan. However, the swiftly changing situation is complicated by many biases of academic scientists and science teachers. The definition of STS is not stable in Japan. University scholars frequently search for a solid theory to explain their actions and advocacy positions. However, there is a difference between understanding STS in an academic sense and using STS in a science class. STS has not only become the target for research in science education and other fields; it also provides practical learning activities for future citizens who prepare for life long learning.

**Future of Japanese Science Education with STS**

STS has a great potential in the development of science education in Japan. Data from STS classes showed great increases in creativity and other important domains (Yager, 1993). STS asks not only students but also science teachers and whole schools to have a major paradigm shift toward constructivism, the new philosophy of teaching. STS calls for major changes for preservice education and in-service
education in Japan. Only one dissertation on STS for Japanese science education written about the Iowa Chautauqua Model was completed by Kumano (1993) showing many interesting findings between the two cultures.

Japan has a national standard curriculum in every subject approved by the Ministry of Education, called Course of Study; 'Gakusyu Shido Yoryo' in Japanese. Also, the Ministry of Education is keenly focusing on in-service science teacher training to meet the national standard. We need a two step approach for the implementation of STS in science education. At first a short term strategy can provide understanding, performance of the goals, and evaluation of STS. We need to promote development of STS modules as a new paradigm of science education during pre-service teacher training for elementary and secondary levels. As a consequence, STS teachers will greatly increase in number. Secondly, the long term strategy must involve a systematic and long-term approach. Lead universities such as the University of Tsukuba and Shizuoka University, are trying to conduct the in- and preservice training program based upon STS education as a new paradigm for science education. We also will need more communication concerning STS with other countries. We need more detailed evidence concerning STS in the Japanese setting and we need to develop Japanese STS models. Government grants and private funding will be needed to support continued STS research in Japan.

With all those process mentioned above, both lead teachers and lead universities will be able to cooperate and synthesize a Japanese STS education model, based on philosophical and practical studies. As the results of this synthesis, our society will have a new direction with a wider and deeper philosophy and practical studies. Eventually, STS education shall be adopted by the Ministry of Education in Japan.

FROM OBJECT, THROUGH WORD TO UNDERSTANDING: LANGUAGE DEVELOPMENT THROUGH SCIENCE ACTIVITY

Mitch O’Toole
School of Teacher Education
University of New South Wales

Science activities are interesting, practical and shared, so science activities are an ideal context for language development. This should not surprise us, as people learn language best when they are motivated, and interesting things motivate. They learn language best when they are engaged, and practical activities engage. They learn language best when they work together, and shared tasks involve this.

The mesh between the considerations which underlie both conceptual and language development at the Primary school level provides an opportunity for an integrated response which is too good to miss.

Many activities can be devised which build towards the acquisition of science skills and concepts at the same time as encouraging the general language development of the children. Shared activities demand a certain degree of language competence. However, the immediacy of science activities means that the language requirements are usually very modest. Students with very little command of English can often share with native speakers in practical activities. This is also true of groups whose members are closer in language competence. An activity approach allows children who are operating at different levels to benefit from time spent together, as they take from each activity, and from the surrounding talk, those things which they can assimilate. Properly structured activities will encourage the use of particular areas of language, and the less adept children will take up the language used by the more confident. In fact, the range of experiences and abilities possessed by different children can be a real asset, as groups come to grips with novel relationships between familiar objects and situations. Science activities are one of the few places that an otherwise silent student can make a real contribution. This helps both the more adept, who may come to see the new participant in a new light as they accept their help, and the other, who assumes a more active role in the class. The activity base of primary science makes it possible to draw on the whole wealth of experience which children bring to class.

One example of a language rich activity follows, accompanied by a discussion of the areas of language which could be developed through it. The activity itself is an adaptation of a fairly common children’s game.

1.2 Memory Chain
Objectives
The children will be:
- observing features of a natural object
- describing a natural object

Materials
For the class:
- any fairly large natural object with interesting features such as a twisted, gnarled piece of driftwood, an animal’s skull, a spiky, intricate, patterned shell, a piece of marble.
- a list of about ten words describing the object including words you suspect your class will not think of (these do not have to be ‘big’ or ‘technical’)

Activity
In this lesson you will be working with one group of children at a time. Make sure that you have work for the other children to go on with.

1. Hold up the object and ask the class to suggest words to describe it and record the suggestions on the blackboard. If appropriate, show how phrases such as ‘it
has zig-zags’ can be changed to ‘zig-zagged.’ Add some of the words from your own list.

2. Sit a group of around 10 to 12 children in a circle (while the remainder carry out other work). Let the children take turns at looking at and handling the object. Place the object in the middle of the circle or have it passed around the group as the chain develops.

3. Start the chain with a sentence like, ‘Here we have a large piece of driftwood.’ The first child then says, for instance, ‘Here we have a large, honeycombed piece of driftwood.’ The next child says, ‘Here we have a large, honeycombed, knobbly piece of driftwood.’ Continue in this way around the circle, with each child trying to recall the sequence of descriptive words and adding a new one to the chain. Let the children use words from the blackboard if they cannot think of their own. Jot down the words as the chain grows and see how long the group can keep the chain going.

4. Repeat the memory chain game with the remaining groups of children in the class.

5. After everyone has had a turn, write each group’s chain on the blackboard so that groups can compare their work.

(Freer & O’Toole, 1990 pp 5,6)

This activity never fails to interest children, as they work together, expanding their repertoire of words and practising precision in description, a skill which is appropriate to both science and language. The sophistication of the description produced will depend on the object used and the experience and imagination of the children. Students from a wide range of language backgrounds can fruitfully share in this activity. The more adept provide more sophisticated describing words, and the less adept participate actively while being exposed to new words. Further, the activity leads all of the children towards those chains of words which are a feature of mature scientific writing.

This is probably a good place to discuss the issue of specialist language styles in the primary school. Science has a distinctive style of language, of which word chains are a part. The style provides a significant barrier to learning in the secondary school and beyond. I do not believe that it should be introduced into the primary school. Primary science is about exploring, investigating, understanding and refining. We should be concerned with these things, and not with the introduction of specialist language styles which will only impede the successful acquisition of those skills and understandings which are our proper concern. The specialist styles of English can await a later day in our children’s lives. However, sometimes, as in the activity above, an opportunity presents itself to deal with the precursors to aspects of specialist English. Such opportunities should be recognized, but how far they are explored will depend on the interests and abilities of the particular class.

The simple example presented here is drawn from a resource which had language development as one of its major aims (Freer & O’Toole, 1990). However, many of the activities making up other published primary science resources can also develop students’ language. “Look!” (Gilbert, Matthews, & Monaghan, 1990) is a mine of activities, “Cracking Up!” (Jakab, Keystone, & Lambert, 1989) illustrates the potential of thematic work based on science, and “Informazing” (Clyne & Griffiths, 1990) integrates language, science, mathematics and information skills in a highly motivating group discussion context.

Take Hold of the Opportunity!

Good primary science involves children working together, on shared tasks involving the manipulation of everyday objects, towards refined understandings of the world around them. This is an ideal context for the development of language skills. Science activities can allow groups of students from a range of language backgrounds to work together, learning more about their world while expanding their language repertoires. Primary children do not need to produce the specialist scientific style of English, but the activities of science, and the directed talk and writing which happen around them, provide a rich context for the development of general language skills.

PRIMARY SCIENCE EDUCATION IN GREECE

Dr. Zoe Zoni Kavogi
Research Associate
University of Glasgow

Introduction

Educational changes in Greece have been limited to the “extrinsic rearrangement” of education (legislation, establishment of new types of schools, structures of schools, etc.). They have not concentrated on the core of educational reality (intrinsic rearrangement) methodology, curriculum, books, teacher training, etc. (Terzis, 1981).

It was in 1964-65 that the first steps were taken by George Papandreou’s government to change educational policy and impose a new national curriculum (Kazamias, 1983), only to be stopped by the 1967 dictatorship. Years later, a new attempt to change educational policy created the “Educational Renaissance of 1976.” However, it was not until 1982 that this policy was implemented in schools through a new national curriculum and new textbooks.

The new Greek national curriculum includes four basic structural elements (Xohellis, 1981):

- Objective didactic targets
- Content
- Methods of teaching
- Testing

Changes in all the above elements have already influenced the qualitative results of classwork.

The new national curriculum was introduced gradually, starting in 1982, by modifying new textbooks. The new textbooks, which have been gradually introduced for the first time in primary education, cover areas of Greek language, mathematics, study of environment, discovering the natural world, and social and political education. The new national curriculum was written by the Department of Primary Education of the Pedagogic Institute—an important department of the Ministry of Education.

Schools and School Science

In a primary school, which caters children age 6 to 12, there is science instruction starting in the first grade. There is very little science instruction in nursery school (children age four to six). From the ages of 12 to 15, children attend middle school (compulsory education) and science is taught in separated subjects such as biology, physics, chemistry, etc., by science teachers; some of them with varying amounts of training in science. From age 15 to 18, children attend secondary school and science is also taught as before but at an advanced level.

Primary School

In a primary school class, the average number of pupils is around 30 to 35. There are two other types of primary schools found in remote rural areas:

1) primary schools with all six grades in one classroom;

2) primary schools of six grades in three classes where each class includes pupils of two grade levels.

For pupils of the 5th and 6th grades, the assessment for primary school pupils is the average of two marks:

1) an oral grade which comes from tests, oral exams and homework;

2) a written mark from written exams in each of the taught subjects at the end of the school year.

There are three terms in a school year. At the end of each term, parents receive the oral record of achievement.

The 1982 National Curriculum and Primary Science

This curriculum was based on a pupil-centered approach to learning rather than the old teacher-centered approach. It was based on Bruner’s
theory for the structure of knowledge. However, the constructivist theory of learning science is also applied by considering pupils as active learners and taking into account their previous ideas about the natural world.

The methodology for organizing the knowledge in the national curriculum and new textbooks follows the prototypes of the USA and European countries, with the exception of the amount of time spent in schools—25 to 30 hours per week—because of the lack of buildings.

Most of the science teaching was focused on the content of science. Nowadays, national programmes in science education have shifted the emphasis away from content towards process. Process is how a scientist works, thinks and investigates. In other words, it is a method of investigating.

**Discrepant Events: An Alternative Teaching Process in Science**

As in most countries of the world, our typical primary teacher is responsible for many different subjects. Science is not the only concern and it is often the teacher’s greatest weakness. As a result, success in primary science is not easy to achieve. Within these teaching limitations they try to teach as much science as possible by taking away the complexity so often built into science teaching. Discrepant events provide teachers with many simple, concrete and easy-to-use examples of science concepts.

Discrepant events are events which are unexpected or surprising to the viewer. They are used because of:

a) the lack of suitable equipment in schools (very few instruments, or laboratory halls for physics, chemistry or biology) and they usually require inexpensive, everyday materials, and

b) the fact that discrepant events are often described as paradoxical, unexpected, and surprising. Thus, they tend to produce a rather strong feeling in the observer. Generally, he/she will have an inner feeling of wanting to know, wishing to resolve the discrepancy in his/her mind. Adults and children will display a desire to resolve the unexpected. Certainly, the enthusiasm of the latter will be even greater. Children will simply not rest until they find out why certain events occurred as they did.

It is obvious that when pupils are strongly motivated, conditions are favourable for learning. Therefore, any method which helps generate this motivation is worthy of investigation. Thus, discrepant events capitalize on the pupils’ own curiosity, helping him/her gain a better understanding of science.

Discrepant events have been used to teach the characteristics of matter, heat energy, static electricity, magnetism, current electricity, sound, light, lenses and colour, air and air pressure, weather and climate, just to name a few. At the same time, this approach develops many specific skills such as observing carefully, recording data, predicting, graphing (a form of recording data, estimating, formulating hypotheses, classifying information, comparing, measuring, inferring, generalizing, and controlling variables). All the above mentioned are methods of investigating which is the core target of the Greek national primary science curriculum. The methodology of teaching a discrepant event has the same framework and procedure used by “Stepping Into Science” activities (Tunniclefife, 1989).

**The New Textbooks for Primary Science Education**

These include programmed material for learning and methods of teaching in detail (quality, quantity, didactic actions and student activities, available time, evaluation of the success of learning targets, etc.).

There is also a teacher’s textbook for each subject and grade—a resource which all teachers had been waiting for. Each teacher’s and pupil’s textbook is the result of the work of groups of specialists—members of the Pedagogic Institute—or canonical under the guidance of the Ministry of Education. The new textbooks include what teachers need to know and what pupils need to learn. For instance, the pupils’ textbook contains all pupils’ activities, exercises and questions in a predefined format. Demaras (1979) contends that national control is needed to improve the textbook and protect pupils and parents from the high-handed acts of some editors. Hence, a common and compulsory book is imposed on all students at no cost to them. Teachers’ opinions are reflected in the research of Daniilidou (1984:87). He found that to a certain extent the textbooks help teachers save time in preparing to teach. However, they have found themselves incompletely prepared or lacking in knowledge, time or confidence to handle many new subjects. Members of the Pedagogic Institute who have designed and written these textbooks claim that “they aim to protect the teacher from sketchy improvisation and insecurity” (Pedagogic Institute, 1983:6).

**Results on the New National Curriculum and Textbooks**

The content renewal of the subjects “Study of Environment” and “Discovering the Natural World” has produced the following results in school practice:
1. Positive

The new national curriculum and textbooks in science has opened another horizon for science teaching and learning. Providing all learners with motivating experiential activities is an important didactic strategy, especially when teaching abstract science concepts and principles. Experiential activities, which may be thought-provoking or hands-on activities, have the ability to stimulate curiosity and motivation. The more contradictory the phenomenon appears to their strongly-held notions of the event, the better.

2. Negative

a) The time for teaching has not increased in proportion to the increased amount of content. A trial period has already proceeded the wide application of the new national curriculum. The benefits of pilot studies have included improving the content of daily lessons, methodology, and number of exercises, and have indicated the need of additional hour of teaching time in order to complete the content in each lesson.

A first proposal is the use of some time from other activities (music, athletics, arts) to complete the lesson. A second proposal is also in progress for additional teaching hours for both science courses. However, the teaching rhythm of the two subjects is intensive, producing anxiety in teachers and pupils, according to teachers' reports. Further research and evaluation of the new national curriculum in primary science education must be undertaken.

b) Specific attention must be paid to the professional needs and problems of primary teachers' education programmes in science.

AIDS IS NO GAME: AN INTERACTIVE ROLE PLAY

E. M. M. van Rens (Vrije Universiteit, Amsterdam)
G.R. de Wildt, MD, MSc (West Heath Hospital, Birmingham, England)

Editor's note: Students carry a glass with a mixture of water and milk, one student (unknowingly) with some starch in his/her glass. The students simulate sexual activity by mixing fluids in unsafe encounters, by just toasting (safe sex) or just chatting (no sex). In the end the test...... iodine (fluids which contain starch turn blue). This role play, with help of some simple chemicals, makes for a powerful simulation of the spread of STDs (sexually transmitted diseases). The activity has been used in several African and European countries and at several levels of education.

Abstract

The complexity of factors which influence sexual health led to the development of a health promotion tool which emphasizes not only individual risk-characteristics, but also the importance and unpredictability of interactions between individuals. This resulted in a role play which links knowledge with emotions in a non-threatening way. The play facilitates discussion and creates awareness of individual risk-behaviour, of power relations and of the ability to negotiate safe sex. Furthermore, it has the advantage of being fun, thus overcoming the obstacle which arises when sexual behaviour is associated with a predominantly negative context of illness and doom. The roles can easily be adapted to different cultures. Field tests in Botswana, Lesotho and the Netherlands proved the value of the role play in schools and other groups. The play can be meaningfully integrated into the curriculum (human biology or sex education).

Introduction

In countries such as Botswana, Lesotho and the Netherlands, HIV and AIDS are included in the science curricula for secondary schools. The aim is to develop knowledge, understanding and attitudes and to promote safe behaviour. There are many factors which influence behaviour. These include individual characteristics, peer group pressures, media messages, examples of role models and other persons in authority. Also gender issues play a role, for instance where cultural and social patterns encourage boys to be hunters and girls to submit to boys' wishes. These factors interact in a complex, virtually unmeasurable manner. Factors may combine and lead to higher risk situations, e.g., when passion or pressure gain the upper hand over knowledge or self-protective efforts in an encounter between partners.

The role play focuses on the importance and unpredictability of risk situations and promotes awareness of individual risk behaviour, the interaction between partners and negotiating safe sex. It facilitates talking about the sensitive issue of sexual behaviour. First the role play is described with suggestions and strategies for the facilitator. This is followed by findings in field tests in three countries with further suggestions for use.

The Role Play

The role play can be used for groups of 15 or more people aged 15 years and above. Prior to using the role play participants need some basic knowledge of HIV/AIDS. For instance: HIV is a virus that can cause AIDS; one can be infected without knowing or
being ill for a long time; one can be infected and infect others sexually; and an infection can be shown by a test. In other words, the play is not meant to teach the basic knowledge concerning the HIV virus and AIDS. This should have been taught beforehand.

Editorial comment: Role plays of this kind can also be used first, with little or no previous knowledge to provide experience with a concept so students have a common base from which to develop further understanding. Constructivism suggest that we build knowledge on experiences.

**Description and Materials**

All participants receive a glass of water with a bit of milk to make it turbid, symbolising “body fluids”. One participant also carries invisible starch in his or her glass—symbolising the “seropositive” starter. The participants meet each other, simulating encounters whereby safe sex, unsafe sex or no sex takes place. This depends on the role which each participant has been given and on the interaction between two partners. Safe sex or no sex is symbolized by toasting glasses - no body fluid is exchanged. In unsafe sex the partners mix the content of their glasses, thus spreading the invisible starch from “infected” to uninfected partners. At the end of the play the starch will be made visible by a iodine solution, as in real life where the infection with HIV is established by a test.

The materials for this play include a saturated starch solution, an iodine solution, preferably transparent beakers or glasses and a set of role cards. Each role card carries a name and a description of the characteristics of the person (Figure 1).

**Figure 1. Examples of Role cards.**

1. You are Bernard. You have three regular girlfriends and use a condom if asked to. Exchange and mix body fluids if you have sex without a condom.

2. You are Alexander. You have Christia as your partner with whom you have sex regularly. You are faithful to her.

3. You are John/Sarah, you do not believe in sex before marriage. You are attractive though and like company. You are a keen racing cyclist. You want to learn how to drive as soon as possible.

4. You are Edward/Virginia. You have as many sexual partners as you wish, since you are a star and very popular. But you never use a condom.

5. You are Sarah and want to become a doctor or nurse and you are a vegetarian. You are outgoing and fond of boys. Condoms seem a lot of fuss when the pill is so easy.

6. At last weekend’s pop festival you met a girl you fancy but you think you are too young to be tied down yet. You have not really thought about contraception, it is something up to the girl. You never wear white sox, you are a supporter of Greenpeace.

7. You are Alina and have Bernard as your partner with whom you have sex regularly. You are faithful to him.

8. You are Robert. You do not have sex at all, because you are not really interested in it. Besides that, your faith tells you not to have sex before marriage.

The set contains a mix of roles: some encourage to take risks and others to avoid risks. There are also some roles which leave it very much to the individual. The participants keep track of their encounters by writing down their respective partners on a contact card and noting whether they had no, safe or unsafe sex. There is a manual for the facilitator, usually the science teacher. The following describes what the facilitator may do.

**Suggestions and Strategies for the Facilitator**

The Introduction (5-10 minutes): Briefly explain the play and handout to all participants: (a) a role card, (b) a contact card, and (c) a beaker with “body fluid.” Carefully select the “seropositive” starter, who is not likely to be upset by a high risk role and is very well able to play the role of making passes. (S)he does not need to know that (s)he is the “seropositive” starter. Other roles should be assigned randomly to avoid stereotyping of students by the teacher. Allow the participants time to get themselves into their roles. Tell the participants to stick to their glasses all the time and to fill in their contact cards after each encounter.

**Encounters (15-20 minutes):** Give the go-ahead for the participants to start meeting each other. They will usually take some time to get to
know their partners. Do they choose sexual contact, then they have the choice of either safe or unsafe sex. Toasting their beakers with safe sex, exchanging fluids with unsafe sex. If they do not want sexual contact then they go their own way. After each encounter they fill in their contact card.

Testing (5 minutes): Stop the play and ask e.g.: Who thinks (s)he has been infected? And Why? Who thinks (s)he has not been infected? And why? Each participant’s beaker is now tested by one or two drops of iodine solution. The beakers with starch turn bluish, indicating infection.

Discussion (20 minutes): The facilitator discloses who the “seropositive” starter was, and facilitates the discussion by posing questions such as: Who had contact with this person? Who got infected? Who got infected, but did not have contact with the “seropositive” starter? How did participants manage to avoid infection? Do you go about it differently in your own life than in the play? It might also be interesting to try to trace the infection back to the seropositive starter.

The facilitator must feel at ease with the group as well as with discussions of sexual issues. The facilitator must be able to capitalize on the opportunities which the participants present in the group discussion. These opportunities may lie in further exploring issues such as power relations between the sexes, the role of persuasion, pressure and passion. Facilitators may want to make the classroom attractive by rearranging tables and chairs and by playing music from a cassette player.

Field Test Comparisons of Process and Content Between Different Countries and Subgroups

The role play was field tested in three countries. In Lesotho, the participants were from the post graduate certificate of education programme. In Botswana, the participants were secondary school pupils and members of the “Brigades,” teenagers and adolescents who combine work and vocational training for various trades. In the Netherlands, the participants were pupils from different levels in secondary education and trainees in Public Health Nursing.

Process

The process of the role play was remarkably similar in all countries and groups. Participants would initially be anxious or reticent. However, the ice was always broken within minutes and participants would actively engage in meeting partners. Participants joined the role play without exception, including students who, according to their teachers, were thought to be shy and withdrawn. This underscores that the role play was found non-threatening. Participants experienced the play as captivating and as great fun. They did not become disrespectful or vulgar. It was found that participants or groups who were younger and thought to have less sexual experience tended to spend less time on “chatting up” and courtship, while older students tended to spend a lot more time and effort on these aspects. In the group discussions, younger and less experienced groups, tended to discuss more their intentions about what they would like to do in future situations, while more experienced groups highlighted the difficulties in controlling situations in real life.

Content

As far as the content of the group discussion is concerned, some differences were observed. In the Netherlands, a number of participants pointed to the fact that they engaged in serial monogamous sexual relations. The play had made them realize, more than before, that partners may have their own sexual histories and that there is a risk of being infected. In all three countries, some boys received girls roles and vice versa (this is also a nice solution to the problem of having a rather unequal balance of boys and girls in a class). This raised a sharp awareness of gender issues. In a number of occasions in Botswana and Lesotho, women pointed out that, in real life as in the role play, they often felt that they could not refuse sexual advances, even if they did not really want to submit. At the same time, a number of men stated that they had never before so clearly felt the potential force of male pressure and its negative effects upon women.

In most groups, the potential for safe behaviour was discussed in some detail, both in terms of its practicalities (e.g., access to condoms at odd times of the night) and in terms of interpersonal dynamics. The latter included the importance of feeling self-confident, of trying to stay in control and of negotiating with your partner. In school classes participants often continued the discussions outside class hour and without the facilitator, sometimes off and on for a number of days.

Further possibilities for use of the role play

In science education, the role play may have additional value in highlighting mathematical issues,
such as simulations, risk and probability. In health care, the role play can also be used to illustrate epidemiological concepts, including the spread of disease, individual risk behaviour, interpersonal dynamics and risk situations.

Additional Note: The role play with a facilitator’s guide plus a few examples of role cards can be ordered from Rutgers Stichting, Postbus 17430, 2502 CK Den Haag, The Netherlands.

Students role playing in AIDS activity.

The International Conference
THE STANDARDS IN EDUCATION:
PROBLEMS AND PERSPECTIVES (SE-95)
9 - 13 October, 1995
Moscow, Russia

The Conference will be held on 9-13 October, 1995, at the International Center for Scientific and Technical Information in Moscow, Russia. The Conference is hosted by the Institute for General Secondary School (the Russian Academy of Education) and the International Center for Scientific and Technical Information.

The main topics of the conference include:

I. Standards of education (general topics):
   - standards and state policy on education;
   - purpose of educational standards;
   - functions of standards in educational process;
   - role of educational standards in democratization and humanization of education;
   - standards and certification of students and teachers.

II. Standards in mathematics and science education.

III. Standards in social studies and humanitarian subjects.

IV. Standards and assessment of the educational achievements:
   - methodology and technique of assessing the achievement of educational standards;
   - system of indicator and instruments.

Registration fee for participant, US $280; for student, US $140; for accompanier, US $100
For further information, you may contact by E-mail or phone to T.B. Zakharova: E-mail: zakh@inftech.iesi.rus Fax: +7-095-943-00-89 Phone: +7-095-198-7481 or +7-095-198-7320
LEARNING TO TEACH AND THE SCIENCE MUSEUM

Nancy Nagel, Ed.D
Charles Ault, Jr., Ph.D
Lewis and Clark College

Marion Rice, M.A.T.
Oregon Museum of Science and Industry

Beginning Our Collaboration
Lewis and Clark College and the Oregon Museum of Science and Industry (OMSI), in Portland, Oregon, have collaborated on numerous education projects since the early 1980's. The success of these projects, principally in support of experienced teachers, led staff at OMSI and Lewis and Clark College to think about developing an elementary level program for preservice teachers. Given the resources and reputation of OMSI, we chose to focus the program on science, mathematics, and technology education. Both institutions felt that developing and implementing a shared program for students preparing for an initial teaching position matched their goals and mission. We were interested in exploring new territory through utilizing museum experiences in the preparation of new teachers. This was a different venture than our prior experiences focusing on enrichment and enhancement for experienced teachers. A preservice teacher education program would provide a unique opportunity for each institution to share our collective strengths in the development of new teachers.

The existing elementary education program at Lewis and Clark College has a strong and well deserved reputation for a focus on "whole language" and thematic inquiry learning. Our goal in adding a new program or cohort (group of twenty students) was to preserve this model, yet modify the curriculum and experiences to capture the benefits from learning to teach in conjunction with science museum experiences and perspectives.

In the fall of 1991, Lewis and Clark College decided to hire an assistant professor of education to serve as coordinator of the new program. Staff from Lewis and Clark College and OMSI contributed to the job description and the interview process. All salary and benefits for this position are provided by Lewis and Clark College, and the College designated collaborating with OMSI staff in designing and coordinating the new teacher education program as a principle responsibility of this position.

During this same period, OMSI was expanding their role in teacher education. Over a ten year period, OMSI supported collaborative education projects with Lewis and Clark College in a variety of configurations. Murdock funding was obtained to support a half-time position at OMSI, with responsibility for coordinating graduate level science education courses and inservice teacher projects. When the funding cycle ended, OMSI continued the position, with funding obtained from NSF to implement a Teachers in Residence Program based at OMSI. The coordinator's position was advanced to Director of Teacher Education and, as a result of additional grant funding for technology and science education projects, a specialist position was added to assist the Director.

The program coordinator at Lewis and Clark College began her position in August 1992, working both at Lewis and Clark College and in an office space at OMSI shared with the Director of Teacher Education. Frequent discussions about goals and visions for teacher education helped clarify our
thoughts about education and set the stage for developing the new elementary preservice program. We knew we wanted to strengthen mathematics, science, and technology education, and we also knew we wanted students to be involved in an informal learning environment through the museum experience.

Lewis and Clark/Oregon Museum of Science and Industry Teacher Education Program

From these premises, planning began in earnest. We conducted interviews with teachers, administrators, and newly certified teachers. We read and discussed current educational reform agendas (American 2000, 1991; Holmes Group, 1986; SCANS Report, 1992). Frequent conversations reinforced our original thoughts about the need to improve mathematics and science education in the elementary grades. The program coordinator worked with college faculty, staff at OMSI, and local educators to develop and implement a sequence of coursework, network of school sites, utilization of museum resources and space, and shaping the role of the museum practica. By the early months of 1993 we had developed a 15-month graduate level teacher education program with an interdisciplinary approach to teaching and learning. The curriculum for the elementary education program, which began in June 1993, includes a 10-month practicum at a school site with a mentor teacher, a six-month practicum (one-half day per week) at OMSI, and education coursework.

The program was named the Lewis and Clark/OMSI Elementary Teacher Education Program and admits 20 students each June in a cohort format, with students moving through coursework and practica together. Many candidates hold undergraduate degrees in areas of science or mathematics or have had some experiences with outdoor schools, environmental programs, or summer science camps. Following completion of four consecutive semesters of coursework and practica (15-month program), students receive an initial teaching license and their Master of Arts in Teaching Degree.

OMSI Practicum

The focus on teaching and learning in the museum setting is a distinctive component of the program. We developed the OMSI practicum guided by the belief that sustained, first-hand experiences in informal science education at the museum would lead students to transfer this experience and create active, engaging learning environments in their classrooms. Science museums provide a unique setting, with children following their personal interests as they interact with an exhibit. Future teachers are well advised to pay close attention to the features of an informal setting that provoke and sustain interest as well as stimulate direct encounters with "the things of science" (Falk, Koran, & Dierking, 1986). From this perspective, the museum becomes a rich resource of teaching and learning models for transfer to the classroom setting.

During the first summer of the program, students enrolled in a Child Development course, located both in a classroom and on the floor at OMSI. Throughout the course, students observed child initiated interactions and following these observations on the museum floor, returned to the classroom and discussed their observations of how children were learning and what might be guiding their learning. This provided an extraordinary opportunity to immediately integrate theory and readings with practice, through observations and discussions. For example, when discussing Piaget’s theory of conservation, the students observed children investigating water and structures that move through water at OMSI’s “Engineer It” exhibit. Students watched the children gain new knowledge as the children manipulated objects in the water and explored density, speed, and maneuverability.

Because the science museum is a rich, informal learning environment, students have the opportunity to watch children in self-directed activities, with the freedom to explore, experiment, and interact among themselves. Discussions also focused on implementing lessons in classrooms that would enable children to be actively involved in learning as they construct their own meaning from the world around them. The purpose of these discussions was to facilitate the transfer of observations of informal learning made at OMSI to the classroom setting.

Additional summer practicum experiences included involvement in summer classes, Outreach programs, Whale Watch Adventure, and the OMSI Boys and Girls Clubs. Students were able to sample a wide range of science oriented activities and interact with children in these settings.

For the Fall semester OMSI practicum experience, students work in a science hall on a project for one-half day per week over a six month period. During the summer, students spent the first four weeks exploring the different halls at OMSI, beginning with an orientation to the museum and an introduction to each hall provided by the Hall Specialist. The Director of Teacher Education serves as coordinator of the practicum, working closely with the LC/OMSI Program Coordinator, the Lewis and
Clark Science Educator, and the Hall Specialists in designing optimal informal museum learning experiences for the LC/OMSI students.

Following orientation, students select a hall to work in and discuss project possibilities with the Hall Specialist. For example, several students chose to become involved in the Busytown Exhibit. The Hall Specialist asked them to observe children as they explored the exhibit and provide feedback about which activities seemed to be used most frequently and which activities needed revision. After several weeks of observing and note-taking, the students met with the Hall Specialist and discussed their observations. Changes were made to the exhibit based on the findings and information gathered by the students. Their next step was to work with OMSI’s Child Development Specialist to design curriculum that teachers could use prior to and following a visit to the Busytown exhibit. The curriculum was field tested in one of the student’s classes and was then incorporated as part of the materials accompanying this traveling exhibit.

The practicum experiences supported our original belief, that informal learning at the museum could be translated into classrooms. The students observed children interacting with the exhibit, discussed their observations with the Hall Specialist, designed curriculum for classrooms that was based on a museum experience, and implemented the curriculum with the children in their classroom. Indeed, these students experienced and created a strong connection between classroom-based instruction and informal learning at a museum.

Throughout the fall semester, students continue with their coursework, OMSI practicum, and begin their school practicum. As the OMSI practicum and school experiences are concurrent, students are able to relate their observations of learning in two different settings and discuss influences on children’s learning. The science and math education courses are held at OMSI, with OMSI staff participating in some of the sessions and students using the science museum to collect data or make observations related to the course topics. During a weekly seminar, students discuss their observations and experiences with teaching and learning and are encouraged to explore best practices in education, in both formal and informal settings.

**A New Dimension For The OMSI Practicum**

As we examine the OMSI practicum experience, we asked teachers, past graduates, and staff from OMSI and Lewis and Clark College to evaluate the practicum and make recommendations for next year.

The general consensus finds the LC/OMSI connection does support our initial belief: learning to teach while concurrently “learning about learning” in the science museum leads students to understand the importance of informal learning and how to construct a classroom environment that allows children to experience informal learning. All students in the first graduating class who were seeking teaching positions were hired. The number and quality of our admission applications have risen significantly, demonstrating a strong interest from students looking for a program with an emphasis on science, mathematics, and technology education through a museum connection.

One of the major OMSI practicum changes we plan is to hold a one-week special event at OMSI as a culminating outcome of the practicum experiences. In early December, the students will present their projects and interact with children from local schools. OMSI will advertise this event to the local schools as an opportunity for classes to be involved in science experiments, demonstrations, and short tours with future teachers. The students will share their knowledge about specific exhibits with the children along with designing and developing interactive activities for this special week. Revenue generated from the admission fees will cover costs for the Hall Specialists’ time with the interns, equipment, and materials needed for exhibits developed by the students, and other related expenses.

**Prospects for the Collaborative Journey**

We remain committed to working together to improve both education and teacher education by emphasizing the value and importance of informal learning and student-directed learning, as seen in science museums. For the past two years, we received Eisenhower funding to support the science, mathematics, and technology emphasis within the collaborative program. Financial concerns raise challenges, as the cost of accessing limited resources at both institutions must be paid. We anticipate that the admission fees for the “special event” week will raise sufficient revenue to pay for expenditures related to the OMSI practicum.

**School Collaborations**

The institutions involved in the LC/OMSI Elementary Education Program include public and independent schools, a college, and a science museum. Five schools representing inner city schools, suburban schools and an independent school continue to work with us in program design and student teacher (intern) placement. Staff from these schools assisted in the planning and continue to
provide input in ongoing evaluation of the program, along with participating in seminars for mentor teachers. We find the expertise of the mentors and the school administrators to be a critical program component and welcome the interactions and conversations about learning to teach. Their input has guided changes in the schedule, courses, and program requirements.

Parting Thoughts
If children learn best when constructing their own meaning from their experiences, then indeed informal learning such as that occurring in science museums is an important model to become immersed in while learning to teach. The rich, varied experiences that surround both children and the LC/OMSI elementary education students in the science museum encourage and promote the creation of classroom environments where children are actively involved in hands-on, meaningful learning on a daily basis.

**ICASE AWARD SCHEME**

for outstanding contributions to international science education

Nominations for these awards must be forwarded by member associations of ICASE. For full details of how to forward nominations, contact the Executive Secretary below

**ICASE Distinguished Service Award**

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local regional and global science education organisations

**ICASE Regional Service Award**

This award honours individuals who have made a significant contribution to international science education through their involvement in international activities at the local and regional levels

**ICASE Association Award**

This award recognises individuals who, within their science teacher association, have made a significant contribution to the international activity of their association

Contact Dr. Jack Holbrook, Executive Secretary ICASE
72B Blue Sea House, 28th October Street, Limassol, Cyprus
Resources

RECENT ICASE PUBLICATIONS

1. *The Status of Science-Technology-Society Education Worldwide*
   This 1992 ICASE Yearbook (140 pages), edited by Professor Bob Yager, University of Iowa, USA, has four sections: STS definition and rationale; Examples of STS initiatives; Evaluation of STS efforts; and STS in various countries.
   Price - £5.00 or $8.00

2. *Empirical research in chemistry and physics education*
   This book (195 pages) contains the papers presented in English at the biennial seminar on research in science education held in Dortmund, Germany, organized by Professor Dr. Hans-Jurgen Schmidt, in June 1992.
   Price - £5.00 or $8.00

3. *Problem-solving and misconceptions in chemistry and physics education*
   This is the latest in the series of biennial seminars on research in science education held in Dortmund, Germany in June 1994. The book (280 pages, in English) contains the papers presented at the seminar.
   Price - £8.00 or $12.00

4. *Sustainable development for a new world agenda*
   The World Environment, Energy and Economic Conference held in October 1990 in Winnipeg, Canada had as its main theme *Sustainable development strategies and the new world order*. The report of that meeting, with the main papers and discussion reports is now available as a major ICASE publication (250 pages), edited on behalf of ICASE by Professor John Penick, University of Iowa, USA. It contains a variety of viewpoints presented by specialists from many countries on the nature and complexity of problems associated with sustainable development and on educational strategies for introducing aspects of sustainable development into science curricula.
   Price - £10.00 or $16.00

5. *Education-Industry Partnerships*
   This is the report (125 pages) of the second ICASE European symposium, held in Arnhem, Netherlands in November 1992, on approaches to science education and industry liaison partnerships. The objective of the symposium was to strengthen the network of organizations and associations involved in industry-education links and to review the contribution of media and science centers toward the public understanding of industry and science.
   Price - £5.00 or $8.00

6. *Education in science and technology for development*
   This is a report (260 pages) of a conference held in Trinidad in 1991 on the theme of science and technology education for development—perspectives for the 21st century. There are three sections: Issues in education; Curriculum and educational strategies; and Science and technology and education.
   Price - £7.00 or $10.00

7. *Pasteur and Microbes*
   A teacher resource book commemorating the 100th anniversary of the Pasteur Institute 1888-1988.
   Price - £5.00 or $8.00

8. *Apollo 11*
   Price - £6.00 or $9.00

9. *History of ICASE*
   The 1993 Yearbook commemorating the first 20 years of ICASE.
   Price - £5.00 or $8.00

10. *Primary Science Source Book 1*
    This is the latest ICASE publication—for primary science teachers. It contains 50 photocopiable sheets of primary science activities from around the world with teachers' notes. There is a foreword by Wynne Harlen, Director of the Scottish Research Council.
    Price - £12.00 or $20.00
11. *Science in Space*
This book produced on behalf of ICASE by the Association for Science Education in the UK contains 10 units as resource notes for teachers who wish to present a variety of aspects of schools science within the context of space. The units are designed for students in secondary schools (age range 14-16 years), but trials in several countries have shown them to be of use with younger and older students as well as in general studies and social studies courses. Space and in particular the human view of space and space exploration can provide an exciting context for students studying science.
Price - £8.00 or $12.00

12. *ICASE Journal—Science Education International*
Published quarterly, the ICASE Journal is available at Price - £10.00 ($17.50) per year for individual subscribers. Postage is included. The Journal has sections devoted to Science Technology and Society, Science Teacher Education, Primary Science and Research in Science Education, as well as feature articles and general news items.

---

**SCIENCE ACROSS EUROPE**

Many scientific issues, such as energy supply and water quality are of common concern yet perspectives as to their causes and resolution are different. This area of science, where common ground and different perspectives meet, provides schools with an excellent opportunity to stimulate teaching by taking the European dimension into account.

Join Science across Europe and your students can compare their findings with others all over Europe.

Science across Europe
- is a new way to help teach science, languages, and economics in an environmental context
- is easy to use
- is interesting and relevant to students' concerns
- provokes discussion
- is flexible—will complement any curriculum
- allows you to join a network of schools in over 20 European countries

For information contact Evelyn Van Dyk, The Association for Science Education, College Lane, Hatfield, Herts AL10 9AA, UK

(See article in this issue)
1995

August 27th-September 1st, 1995

Partners in Chemical Education
An International Conference on Industry-Education Initiatives in Chemistry
Location: University of York, York, UK
Contact: Miranda Mapleton
Chemical Industry Education Centre, Department of Chemistry, University of York, York, YO1 5DD, UK
Co-Sponsors: International Union of Pure and Applied Chemistry (Committee on Teaching of Chemistry) and Royal Society of Chemistry (Education Division and Industrial Division)

August 29th–September 2nd, 1995

The International Conference on Industry–Education Initiatives in Chemistry
Location: University of York, York, UK
Organisers: IUPAC Committee on Teaching of Chemistry
The Royal Society of Chemistry, University of York

The first major international conference sponsored by IUPAC which specifically aims to promote links and dialogue between concerned industrialists and teachers from higher education, secondary and primary schools, and educational decision makers; and to evaluate and encourage good practice and discuss issues of industry–education collaboration.

Correspondence/Conference arrangements:
Dr. J. F. Gibson
The Royal Society of Chemistry
Burlington House, Piccadilly
London W1V OBN
UK
Tel: +(44) (0) 71-437-8656
Fax: +(44) (0) 71-734-1227

September 4-15, 1995

Fourth World Conference on Women
Location: Beijing, China
Contact: Conference Secretariat: Division for the Advancement of Women, PO Box 500, A-1400 Vienna, Australia Tel: 431/21131, Ext. 4270;
Fax: 431/237-495 Media: Department of Public Information United Nations, Room S-1040 Tel: 212/963-1262; Fax: 212/963-4556

This conference will:
1) review and appraise the advancement of women since 1985 in terms of the objectives of the Nairobi Forward-looking Strategies for the Advancement of Women to the Year 2000.
2) mobilize women and men at both the policy-making and grass-roots levels to achieve those objectives.
3) adopt a “Platform for Action,” concentrating on some of the key issues identified as representing a fundamental obstacle to the advancement of the majority of women in the world. It will include elements relating to awareness-raising, decision-making, literacy, poverty, health, violence, national machinery, refugees and technology.
4) determine the priorities to be followed in 1996-2001 for implementation of the Strategies within the United Nations system.

September 24–29, 1995

CONASTA 44
Location: University of Queensland, Brisbane, Queensland, Australia
Contact: David Tulip, Centre for Mathematics and Science Education, Locked Bag No. 2, Red Hill, Queensland, Australia. E-mail: D.Tulip@qut.edu.au Tel: +64 7 864 3345 or Fax: +64 7 864 3985.

While the conference program is not finalised at this stage, it is envisaged that it will include thematic lectures, symposia based on science education and workshops either based on current science research or science classroom practices. All symposia and workshop sessions will allow for personal choice and will cater for Primary, Secondary and Tertiary science teachers and science teacher educators. Educational tours of the Great Barrier Reef, tropical and subtropical rainforest, whale watching and other unique geographical and biological features of Queensland, will also be offered three to seven days prior to or immediately following the conference. A detailed synopsis of the speakers, a framework of the conference activities and a call for abstracts of papers will be available by July 1994.
September 25-29, 1995

3rd European Conference on Research in Chemical Education
Location: Lublin (Poland)
Contact: Department of Chemical Education, Maria Curie-Sklodowska University, Pl.M.C. Sklodowskiej 3, 20-031 Lublin, Poland, dr Ryszard M. JANIUJK Tel: (81) 37-56-91 Fax: (81) 336-91 e-mail: JANIUJK@PLUMCS1

The previous two conferences were held in Montpelier, France in 1992 and in Pisa, Italy in 1993. The next conferences are planned to be held every two years. The conference in 1997 will be held probably in UK. The organizers of the conference are the Federation of European Chemical Societies and the Chemical Society of the country in which the conference is held.

October 9-13, 1995

Location: St. Louis, MO, USA

May 28-31, 1996

14th Dortmund Summer Symposium
Theme: Educational Research in Chemistry and Physics Education
Contact: Dr. Hans-Jürgen Schmidt
University of Dortmund, Dept. of Chemistry
Otto-Hahn-Str. 6
43221 Dortmund
Germany

The main aim of this conference is to discuss the methodology of empirical research in this field.

June 14-18, 1996

Science Centre Conference
Location: Finland
Contact: Ms. Helena von Troil, Secretary General Heureka, The Finnish Science Centre
PO Box 166
FIN-01301 Vantaa, Finland
Tel: +358 0 85799
Fax: +358 0 873 4142

The Association of Science-Technology Centres (ASTC) and the European Collaborative for Science, Industry and Technology Exhibitions (ECSITE) invite science centre professionals from all over the world to the FIRST SCIENCE CENTRE WORLD CONGRESS to be held at Heureka the Finnish Science Centre in Vantaa (Helsinki), Finland. The congress will give opportunities to learn and share the experience of colleagues from all over the world.
Internationally recognized experts will be invited to
give their views on education, science centres and
global issues. The programme will consist of several
parallel sessions. Sessions will be on aspects relevant
to the overall congress theme, such as:
- Providing memorable exhibits
- Influencing motivation in audiences
- Knowing your visitors
- Educational aspects of exhibits
- Catching the new wave technology
- Marketing an educational product

July 14-19, 1996

14th International Conference on Chemical
Education
Location: Brisbane, Australia
Contact: The ICCE Conference Secretariat
(Sally Brown), Continuing Professional Education,
The University of Queensland 4072 Australia
Tel: (07) 365 6360 Intl: +61 7 365 6360
Fax: (07) 365 7099 Intl: +61 7 365 7099
E-mail: chemed96@ceu.uq.oz.au

The 14th ICCE will be held in Brisbane from
July 14-19, 1996. It is only the second time this
conference has been held in the southern hemisphere.
The biennial conference brings together chemistry
teachers, chemists and science educators from school,
industry and university settings to share ideas and
learn from one another about innovation in teaching
and learning and the discipline of chemistry. The
theme, Chemistry: Expanding the Boundaries,
acknowledges the centrality of chemistry through its
expanding relationship with many facets of science
and everyday life. Conference participants will be
challenged to develop this theme with the view of
enhancing our understanding of the important
relationships which chemistry forms with the new
frontiers of human endeavour. Implications for
chemical education beyond 2000 which give a
"science for all" perspective will be encouraged.

December 27-30, 1996

NSTA International Convention
Location: San Francisco, CA
The convention, to be chaired by NSTA Executive
Director Bill G. Aldridge, will bring together
scientists and K-college science educators from
dozens of science and science education societies and
organizations worldwide. Invitations have already
been sent to societies in more than 30 countries.
Holding the event in San Francisco, it is hoped, will
especially encourage participation from Pacific Rim
countries.

At this convention, participating teachers and science
educators will present sessions in their areas of
expertise (interdisciplinary approaches are
encouraged) to scientists who are not as familiar with
the classroom. In turn, scientists will present sessions
about their work to nonspecialist scientists and to
educators less familiar with the latest news from the
research laboratory.

1997

South African Conference
Eastern Europe Conference
10th ICASE-Asian Conference
Location: Lahore, Pakistan

FOOD FOR THOUGHT

Why is it that scientific research uses
induction to create generalizable
rules while many teachers employ
deduction to teach it?

Ron Bonnstetter

OPPORTUNITY FOR STUDENTS WORLDWIDE
ICASE WORLD SCIENCE ACTIVITY WEEK
22-28 OCTOBER 1995

SUSTAINABLE DEVELOPMENT

Activity Week Theme

The ICASE Project 2000+ Declaration states “...believe that scientific and technological literacy are essential for achieving responsible sustainable development”...assign priority to the development and introduction of programs leading to scientific literacy and technological literacy for all with the aim of achieving responsible sustainable development.”

ICASE encourages and supports projects in science and technology education in both formal and non-formal education. To this end ICASE offers a unique opportunity for Science Teachers’ Associations to involve teachers, who in turn may involve their students in formal or informal activities in exploring, within various cultural contexts, the concept of sustainable development.

Categories

The ICASE World Activity Week aims at involving:

• Primary/elementary level students ... ages 6-11 years
• Middle school/junior high students ... ages 12-15 years
• Secondary/senior high students ... ages 16-18 years

Activities

Student individual/group entries may be of three types:

1) Poster or cartoon, paper size not to exceed 220 mm x 300 mm, in single or multiple frame format (applies to all grade/age categories). Poster or cartoon to focus on a sustainable development issue.

2) Essay/paper supported by illustrations/photos focusing on a community sustainable development issue:
• Primary (up to 250 words)
• Junior (250-500 words)
• Senior (1000-1500 words)

3) Investigation activity which highlights a sustainable development issue. Students prepare a report focusing on the far ranging implications of the activity (applies to all levels).

Awards

Certificate awards will be available to each ICASE Regional Representative who, with an appointed panel, will evaluate the entries and recognize up to 20 individual/group entries across all categories. One special award/prize per ICASE region will also be made across all categories. A final report will highlight entries and summarize awards stimulated by ICASE World Activity Week.

ENTRIES . . . Deadline 30 December 1995

Entries may be submitted in Spanish, French, or English and are to be directed to the ICASE Representative in your region:

Africa: I O Ikeobi, PMB 081, Festac Town, Lagos, Nigeria
Asia: J. Yingprayoon, IPST, 924 Sukhumvit Rd, Bangkok 10110, Thailand
Australia-Pacific: M. Silis, University of South Australia, Smith Rd, Salisbury East SA 5109, Australia
Europe: A. Wojtyn-Jodko, SNPPIT, Skrytka Poczta 62, PL-85791, Bydgoszcz, 32, Poland
Latin America-Caribbean: J. Chamizo, Colegio Madrid AC, Calle Puente 224, 14380 Mexico DF, Mexico
North America: K. R. Roy, Glastonbury Public Schools, 330 Hubbard St., Glastonbury CT 06033, USA

. . . award winners will be announced in March 1996 . . . entries become the property of ICASE and will be displayed or put in print in ICASE publications.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

ICASE DISTINGUISHED SERVICE AWARD

The ICASE Distinguished Service Award was presented to Professor Dr. Hans-Jurgen Schmidt of the University of Dortmund Germany by ICASE Honorary Treasurer, Dennis Chisman, during the German Science Teachers' Association (MNU) annual meeting in Nuremberg on 10 April 1995.

Hans-Jurgen Schmidt was the European Regional Representative on the ICASE Executive Committee from 1981 to 1985 and has been the organiser, since 1981, of the Dortmund Summer Symposia on research in science education held, in cooperating with ICASE, every two years. He has represented MNU at many international science education meetings and has particularly encouraged the development of science teachers' associations in Europe. He has contributed papers at many international conferences on the role of research in science education and has written many articles in science education journals on the role of research in promoting more effective classroom practice in the teaching of science.

The proceedings of the most recent Dortmund Symposium, in 1994, edited by Hans-Jurgen Schmidt is entitled Problem-solving and misconceptions in the teaching of chemistry and physics (available from ICASE at $12 or £8). The next symposium is scheduled for 28-31 May 1996.

THE INTERNATIONAL BACCALAUREATE ORGANISATION

Overview prepared by: Andy Williams
Subject Area Manager—Science/Technology
IB Offices, Pascal Close, St. Mellons, Cardiff
Wales CF3 0YP, UK

What It Is

The IBO provides a Diploma programme, primarily for 16-18 year old students, which is an internationally recognised university entry qualification. The IBO also offers the Middle Years Programme (MYP) for students aged 11-16 years.

The IB Diploma is gained by examination following two years of study in the final years of secondary education. The IB organisation does not seek to compete with national systems of education, but rather to run parallel with them, offering a curriculum which is international, innovative and balanced. It is offered in nearly 600 schools in over 80 countries around the world. Students holding the IB Diploma are accepted by universities and other institutions of higher education in these countries.
The IB Diploma provides a well-regarded alternative to many national requirements. There are three working languages: English, Spanish and French.

Administration
The main headquarters of the IBO is in Geneva. Curriculum and Assessment activities, including curriculum development work, examination paper preparation and grade awarding, are carried out in Cardiff, South Wales. There are Regional Offices for North America and the Caribbean (New York), Europe/Africa/Middle East (Geneva), Asia Pacific (Singapore) and Latin America (Buenos Aires). These are complemented by sub-regional offices in Sweden, Australia, Mexico, India and Japan. Further basic information about the IB Diploma or the Middle Years Programme can be obtained from the IBO by writing to:

15 Route des Morillons,
1218 Grand-Saconnex
Geneva, Switzerland.

PROJECT 2000+ – REPORT OF A VISIT TO VANUATU

by Dr David Slimming
Science Education Consultant
15 Macknight Place, Canberra 2904, Australia

Introduction
The aim of Project 2000+ is to promote scientific and technological literacy (STL) for all people in all countries. The Republic of Vanuatu (formerly the New Hebrides) is a group of about 80 islands some 400 km north-east of New Caledonia and some 800 km west of Fiji. The islands are mostly volcanic in origin and the population of about 150,000 is largely Melanesian. Before gaining independence in 1980, the islands were administered as an Anglo–French condominium. As a result of this, approximately half the schools use English as the medium of instruction, and half use French.

My brief for the visit, from 30 June to 7 July 1995, was to:

• promote awareness of Project 2000+ amongst appropriate personnel in the formal and non-formal sectors in Vanuatu.
• promote debate of STL in Vanuatu, and stimulate initial discussions aimed at identifying desirable projects/activities and the means to implement them.
• identify appropriate institutions and individuals with whom international organisations such as UNESCO and ICASE might communicate regarding, for example, regional activities under the auspices of Project 2000+.
• participate with teachers in a short workshop to develop examples of teaching and learning materials for STL.

This brief is in line with ICASE’s policy of promoting Project 2000+ and, in particular, of helping to facilitate the training of science educators in the development of STL resource materials which are appropriate to local needs and circumstances. ICASE therefore saw the Vanuatu visit as a useful pilot exercise and were successful in obtaining financial assistance from the Commonwealth Secretariat on this basis. The teachers’ workshop was organised by the Vanuatu Ministry of Education with financial support from the New Zealand Educational Assistance Programme. Some of the materials used at the workshop were provided by Questacon, Australia’s National Science and Technology Centre.

Pre-Workshop Discussions
In the two days before the workshop, I tried to meet as many as possible of those concerned with education in both the formal and non–formal sectors. All of my contacts were supplied with documents relating to Project 2000+ in either French or English, including the Project 2000+ Declaration. They were also advised of the role of ICASE, both generally and in promoting the project.

In both sectors, the most interesting discussions centred around the interaction between local cultures and those aspects of science and technology which increasingly affect the lives of island communities. Three barriers to the successful integration to the two cultures became apparent:
the need for, or desirability of, the changes introduced was not always truly accepted by the community decision makers;

- communities often felt no sense of ownership for new technologies (especially when these were introduced by outsiders);
- lack of relevant understanding, skills and attitudes often prevented communities from making effective use of, and from properly maintaining, new technologies.

The introduction of pumps to supply water in isolated island communities provides a good illustration. In similar small island communities in Britain, for example, if the pump breaks down almost anyone in the community will immediately try to fix it – and will usually succeed. If not, the professionals will be called in and the matter rectified without delay. In Vanuatu, on the contrary, nothing at all may be done for some considerable time! Eventually “Public Works” may be informed. After only a few years, the pump may become defunct. The British community places a high priority on the clean water provided by the pump. It is perceived as part of their own technology and even someone with no particular training in its maintenance probably has sufficient know-how, confidence and initiative to try repairing it. In the culture of Vanuatu, the decision makers are the senior men of the community and they may not greatly value the pump at all. After all, they can obtain the water they need by simply sending the women to fetch it in buckets, as they did in the past! They may not appreciate the difference which the pump makes to the quality of the water and the quality of life of the women, nor fully understand the importance of both to the health of the community. They may see the pump as not really belonging to their own way of life and therefore feel unwilling to do anything about it when it breaks down. In any case, their culture has not prepared them with the understanding, skills and attitudes which would give them the confidence to try fixing it, so they are dependent on outside help.

In the Ministry of Education, my discussions focussed mainly on the implications of Project 2000+ for Basic Education. In Vanuatu this covers both primary and junior secondary schooling. Almost all children attend primary school (years 1 – 6) but only about 20% at present proceed to junior secondary (years 7 – 10). Of these, again only about 20% go on to senior secondary schools, where about half will specialise in science. It was encouraging that all concerned accepted the notion that the science and technology included in basic education should arise naturally out of the actual needs and interests of island communities, and should not be dictated by the demands of higher education for a small minority. However, it was conceded that the needs of future science students could not be neglected in the junior secondary curriculum.

Those responsible for administration and finance within the Ministry were also contacted and were very supportive. They pointed out the importance of involving them at the earliest possible stage when particular activities were being proposed under Project 2000+. This would greatly facilitate their efforts to obtain the administrative and budgetary resources needed.

Although Vanuatu is a small country, it proved difficult in the short time available to get a good overview of what was happening in the area of non-formal education. Quite a number of church and community groups, as well as NGOs and Regional Organisations, are engaged in projects which include rural or community education. In the case of the Presbyterian church, many of these projects are associated with vocational training and appropriate technology. They have, for example, worked with local communities to develop water pumps, water tanks and more than one kind of cooking stove. In addition to more local efforts of this kind, the Federation for the South Pacific is involved in community education, and the UNESCO Regional Office have programmes promoting basic education and life skills in the community as well as the training of primary school teachers in the formal sector. The Environmental Education Awareness Project of the South Pacific Regional Environmental Programme (SPREP) is another regional initiative which involves training activities in both the formal and informal sectors. With so many organisations involved, there would be obvious advantages in mutual co-ordination and the sharing of experiences. This may already happen to some extent, but it was clear that only a minority of those I met were well informed regarding the activities of other programmes and groups. In this situation it was not immediately clear how Project 2000+ might best become engaged in the non-formal sector.

I also called at the Vanuatu Cultural Centre where I met the Director. He expressed great interest in the ways in which science and technology are already interacting with local cultures in Vanuatu. He also drew attention to the importance, when planning curricula for both non-formal and formal sectors, of considering the place of traditional medicine and “magic” alongside modern scientific notions. He was already aware of the work of Questacon and of their hopes to bring their popular “Fascinating Science” programme to Vanuatu. Although such a visit would probably be coordinated
through the Ministry of Education, I expressed the hope that it might act as both inspiration and opportunity for the Cultural Centre to develop interactive exhibits consistent with its own mandate.

**The Basic Science Teachers’ Workshop**

The workshop lasted four days and was attended by 40 full-time participants. These were mainly junior secondary science teachers who represented 19 schools on 10 different islands. There were also two staff each from the Curriculum Development Centre and the Vanuatu Teachers’ College. In addition to these, various interested people attended selected sessions.

The objectives of the workshop were to –

* raise participants’ awareness of Project 2000+ and promote active discussion of STL for all;
* familiarise participants with a hands-on, interactive approach to learning science;
* give participants experience of developing teaching and learning materials consistent with such an approach and appropriate to local circumstances;
* enable participants to contribute to on-going renewal of the science curriculum.

The workshop was opened by the Honourable Minister of Education who expressed his strong support for the notion of STL for all in Vanuatu. The opening was reported on Radio Vanuatu.

After a short session to deal with administrative matters, the workshop moved into top gear with a major presentation regarding Project 2000+. This was delivered in the local pidgin, Bislama, one of the official languages of Vanuatu and well understood by both the English and French speaking teachers. It was supported by a large number of slides which were projected simultaneously in French and English. The origins and aims of the project were discussed and the proceedings of the International Forum on STL for All, held at UNESCO, Paris in July 1993, were reviewed. The importance of gender issues in the context of STL for all was particularly stressed. This rather lengthy presentation was broken up by two short interludes which attempted to bring home to participants the drastic nature of the world population explosion. It was followed by a short video illustrating the sorts of environmental degradation that can result from the unwise importation of inappropriate technologies and the over-exploitation of natural resources.

On the second day, the participants broke up into small groups to discuss the meaning and implications of STL for all in Vanuatu. These sessions evoked some very animated and fruitful discussions. The need to make science and technology more relevant and more accessible to women and girls was particularly highlighted. In the afternoon, the groups tried out and evaluated six different "Exciter Packs," developed at, and kindly donated by, Questacon. These packs contain hands-on science activities suitable for use with children up to the age of about 12 years. The teachers all had plenty of fun with the packs which clearly generated a lot of enthusiasm. A short video about the work of Questacon completed the day's work.

The third day started with a discussion of some ways in which Vanuatu might start to become involved in Project 2000+. One francophone and two anglophone groups produced short written reports which were then consolidated as a basis for further discussion during a plenary session on the final day. The remainder of the day was devoted to developing, again in small groups, hands-on activities suitable for Vanuatu children using the "Exciter Packs" as a model. Themes selected by different groups included Heat, Air Pressure, Water, Environment, and Tins! Within each theme, groups developed two to five activities using cheap, locally available materials. Each activity had to include simple instructions for the children and an explanation of the science underlying the activity. On the morning of the final day, each group displayed its activities on a separate table and then moved around trying out those produced by other groups. Although most of the activities still required further development, this generated so much enthusiasm that teachers and pupils from a nearby primary school were invited to come and see an impromptu exhibition during the tea break. This was enjoyed by all, and indeed a few of the participants were so busy demonstrating their activities to groups of children that they missed their tea altogether!

Perhaps inevitably, not many of the activities were particularly original, although the materials used and the presentation often were. One or two, however, are briefly described below as examples. Two ladies in one group produced a working model of a cooking stove using discarded materials. This used only sawdust packed into an old tin. A hole was cut into the side of the tin near the base. A short stick of sugar cane was inserted through this hole and a longer one was held vertically in the centre of the tin while it was packed fairly tightly with the sawdust. The two sugar canes were then removed, leaving a passage from the air inlet at the base leading to a vertical flue through the packed sawdust. After lighting a few twigs inside the inlet, the sawdust catches fire and burns slowly in the air draft created by the flue. Several tins of water were boiled on this during the workshop. In addition to exemplifying the
local appropriate technology on which it is based, the stove provides an excellent illustration of convection and various aspects of combustion; for example, it quickly goes out when the air inlet is blocked!

Another interesting idea, also designed to show convection, took advantage of pupils’ natural interest in the volcanoes which are a feature of the landscape on many islands. It was based on a hollow “volcano”, made of plasticine or clay, in a container of cold water. This was placed on top of a container of hot water which had been coloured by ink. The inky water was intended to rise through the hole in the top of the plasticine volcano. Because of the short time available during the workshop, the model produced still had some problems at the interface between the hot and cold water and in reliably establishing the convectonal circulation in the required direction! Given more time, however, these would surely be overcome to produce an attractive, instructive and appropriate demonstration.

The last session of the workshop was devoted to a plenary discussion of proposals drawn up following the group discussions on the third morning. Final recommendations, which were forwarded to the Ministry of Education, included:

- Review of curricula at basic education level (to include technology as well as science, to be based on the experiences, needs and interests of the community and not on the demands of secondary education, and to employ flexibly many hands-on activities for pupils);
- Training and use of junior secondary science teachers to run in-service courses and materials development workshops for primary school teachers in the islands;
- Coordination of overlapping efforts involving various regional and local groups as well as the Ministry of Education, and the non-formal as well as the formal sector;
- Appointment of a permanent science education adviser (with appropriate qualifications and experience in both science and basic-level education) to spearhead the above efforts;
- Formalisation of the Science Teachers’ Panel (by appointing a committee and drawing up a constitution) so as to facilitate interaction with overseas science education organisations including ICASE.

Before leaving, participants were asked to complete a short evaluation form which contained both closed and open-ended questions. About two-thirds of the respondents said that the workshop had been very successful in achieving all of its objectives, while the remaining one-third said that it had been moderately successful. They also expressed particular enthusiasm for doing and developing hands-on activities, for all the sessions which involved discussing and working together in small groups and for the final plenary session at which recommendations for further action were drawn up. My own impression too, was that the workshop went well and that most of the participants were interested and involved throughout. Although many had little previous experience of working together in small groups, this appeared to be an effective, as well as popular, strategy. Opportunities for individual contributions were maximised and participants clearly enjoyed and benefited from the sharing of ideas which took place. Perhaps more time might have been allowed for the presentations and discussions which followed most of the group work, however I regarded the process of thinking about and discussing the implications of STL for all, as more important than reaching any particular and final conclusions at this early stage of the project.

**Some Reflections on the Visit**

As mentioned in the introduction, ICASE regarded this visit to Vanuatu as a pilot exercise. It therefore seems appropriate to reflect on what might be learnt. First, then, I would like to emphasise the value of the pre-workshop discussions. Not only did these provide excellent opportunities to promote Project 2000+ in the appropriate quarters, and identify those most likely to become involved in implementing it, they also proved a valuable source of ideas and inspiration for the workshop itself. Perhaps the most interesting aspect of this, was the way in which the idea of helping communities to bring relevant scientific and technological ideas within their own cultures, gradually took over from the notion of scientific and technological literacy as such.

In regards to the workshop, the number attending was well in excess of expectation. This had both positive and negative outcomes. On the positive side, the presentations and discussions involved more people in thinking about Project 2000+ and its implications for Vanuatu. However, during the sessions devoted to the development of teaching and learning resources, it was difficult for so many participants to receive the individual help they needed. Thus, although many promising activities were certainly produced, all but a few still required further improvement to make them suitable for classroom use. In particular, greater individual help might have succeeded in encouraging greater originality and improving the quality of the written materials which accompanied each activity.

Generally speaking, the instructions to pupils were
adequate, but the explanations of the underlying science were less so.

As regards the planning of future workshops, I believe that the numbers attending should be limited to about 20 of the best and most committed teachers. A few additional staff from the curriculum development and teacher training establishments could also be involved and could have a dual role, assisting the team leader as well as participating. The next workshop should also be more sharply focused and more product oriented. It might, for example, be directed towards the revision of the primary school curriculum, or the production of hands-on activities to cover particular topics or process skills, or the intensive training of selected teachers to run courses for primary school teachers or rural communities. Indeed, all of these activities would be worthwhile and are likely to be needed at some stage before the year 2000.

A particularly valuable feature of the workshop was the decision to put forward recommendations regarding the implementation of Project 2000+. The importance of curriculum review at the basic education level, and for this to reflect community needs in technology as well as science, was accepted by all I met. If one also accepts the notion of fostering the adoption of appropriate science and technology into local cultures, and the fact that as many as 80% of pupils do not at present progress beyond class six, it may be that the formal sector should borrow curricula ideas from the non-formal, rather than vice versa! Indeed much could be gained through improving communication between the formal and non-formal sectors, and between the many different groups which are making significant inputs to both. The SPREP Environmental Education Awareness Project, for example, has budgeted for two extended teachers' workshops to carry out, in the more limited field of the environment, almost exactly the same training and tasks as those just undertaken at our own basic science workshop. Teachers told me that, in the past, lack of adequate liaison at the professional level has led to confusion in the minds of those who have attended workshops or gained by different bodies. These have sometimes presented very different messages and it would obviously be desirable to avoid this sort of confusion in the future. Certainly the idea of training junior secondary school teachers as resource persons has much to commend it. Their schools are well scattered throughout the main islands and, with suitable support, they are well placed to liaise with those working in community education projects and to help primary school teachers to develop and use locally appropriate learning activities with their pupils.

Any new initiative requires leadership from the right person in the right place. Probably in common with many small countries, Vanuatu does not at present have anyone well placed to pursue the challenge of implementing Project 2000+. There are no professional science educationists in the Ministry of Education itself, and those having nominal responsibility for science in the curriculum development and teacher training institutions, have primary responsibilities in other subject areas which take up most of their time. Unless the importance of science and technology in basic education is recognised by the appointment of at least one suitable person to a suitable post, it is difficult to see where either the drive or the expertise necessary to achieve the aims of Project 2000+ is likely to come from. Similarly, science teachers need to open channels for professional communication if they are to benefit by exchanging ideas and information with those engaged in the same enterprise all over the world. The formalisation of the structure of Vanuatu's science teaching panel was recommended by the workshop explicitly to facilitate such communication with appropriate international organisations.

In conclusion, I would like to take this opportunity to express my thanks to ICASE for their help and encouragement in arranging for the visit and to the Commonwealth Secretariat in London for paying for my travel and my subsistence. I would also like to thank the Ministry of Education for inviting me, all those in Vanuatu who gave their time to organise everything, to meet me, and to share their views with me, and finally all the participants in the workshop for their good humour and hard work.

David Slimming was a Science Education Adviser with the British Council for more than 20 years and has worked in many different countries in Africa, Asia and the Pacific. He now undertakes consultancy work from his home base in Canberra.

CONSTRUCTIVISM FOR SCIENCE TEACHERS

William W. Cobern, Ph.D.
Arizona State University West
Associate Professor of Science Education

Constructivism is a concept that in recent years has garnered considerable attention among science education researchers. Essentially, it is a model or metaphor of how learning takes place. Prominent science educators have called it a most promising model and a theoretical shift that may lead to a coalescing of current thought as well as the stimulation of new ideas. I do not believe this is hyperbole. The potential significance of constructivism has already extended beyond research and into the science classroom. References to constructivism appear ever more frequently in the literature, however, often with little or only trivial discussion of the philosophical meaning of constructivism. My purpose in this article is to acquaint teachers with the philosophical roots of constructivist thought enabling them to better understand this expanding literature. First, however, it is necessary to offer a word or two about Piagetian cognitive development theory which has dominated educational thinking for some years now.

The Eclipse of Piagetian Theory
Piagetian cognitive development theory has precipitated enormous amounts of educational research. However, an inability to translate research findings into practice has been a chronic weakness of Piagetian theory. Joseph Novak, an eminent professor of science education, wrote that for years he had been "trying to suggest that the Piagetian paradigm for cognitive development is not the most useful paradigm to guide research in science education nor for planning instructional programs" (1978, p. 591). His arguments remain appropriate. Moreover, cognitive development theory has never quite escaped the charge that it is culturally biased. The difficulty with cognitive development theory lies in a paradoxical relationship between rationality and understanding. Piaget designed a set of clinical interviews based on formal propositions of logic. He inferred levels of cognitive development in terms of rationality from performance on interview tasks. By inference, a person who successfully completes the tasks is able to handle advanced propositions of logic, and therefore, is capable of learning advanced subject matter. To use the jargon of research on reasoning, this person is a rational, logical thinker who uses formal, abstract operations. For use in education research, educators derived from Piaget's clinical interview procedures several paper-and-pen assessments of rational development which can be used with large numbers of students at one time. This latter type of research is typically called research on cognitive development and is the focus of the next comments.

It strikes one's attention when reading the literature in education on cognitive development research that so many studies find that many secondary students and even adults have not reached abstract or formal levels of logic. The research seems to say that many secondary students and adults fail to understand science because they simply have not attained a high enough level of rational thinking. I find this problematic. Clearly the cognitive development researcher must assume that the premises of the assessment procedures are correctly understood by the person being assessed. That a person understands a task or statement, however, can only be determined by observing that the person agrees or disagrees as to (a) what statements are the same as the given one, (b) what the given statement implies, (c) what other statements are contradicted by the given statement, and (d) what is irrelevant to the given statement (Smelser, 1970). This is exactly where the difficulty lies. If a person cannot think well (if a person is not very rational) that person will not be able to recognize statements that are equivalent in meaning, statements that contradict each other, the implications of a statement, or the things that are irrelevant to the presented statement or problem. Then, if the subject fails to answer the test or interview question properly, the researcher is actually unable to determine whether the subject failed due to a lack of logical skill or due to a failure to understand
the premises of the task. The point is that in ordinary situations it is exceedingly difficult, if not impossible, to separate rationality from comprehension. The cognitive development researcher can only proceed by assuming that a subject understands what is going on in the test. But, this is a counter-intuitive and counter-factual assumption. "In conversation we always assume that the other person is logical . . . When our expectations are not fulfilled, we normally attribute it to a lack of understanding . . . but not to genuine illogically on his part . . . logic must be presupposed, since it is characteristic of any activity of any integrated system and is a part of the very notion of a person (Smidslund, 1970, p. 217-218). Smidslund's point is that the researcher is making an assumption that defies common sense. We have a very well established precedent from everyday life: when a person does not get a thing correct, we don't assume he lacks logic. We assume he has failed to understand and thus we proceed to try another approach to explaining the thing.

The question in education is why would we want to abandon an approach that has served daily life so well? The answer that people give is that children are different. Surely children are at a lower level of rational thinking than adults regardless of what is assumed about understanding. On this premise educators have written what they argue are developmentally appropriate curricula which prescribe what topics can be taught at various ages. Indeed, few would disagree, for example, that the concept "chair" is less abstract than the concept "atom," and therefore more readily understood by young children. But how is it that the concept "atom" is more abstract than the concept "chair?" In cognitive development theory the answer is that acquisition of this concept requires advanced rational thought that children have not yet attained. However, it is also true that "atom" and "chair" are not epistemologically equivalent concepts. A conceptual analysis of "atom" reveals that this concept is built up from a large number of other concepts. In other words, the concept "atom" subsumes a large number of related concepts. Grasping the concept "atom" requires a grasp of the subsumed concepts. In contrast, the concept "chair" subsumes far fewer related concepts, and thus, grasping the concept "chair" requires the grasp of fewer related concepts. Is then the concept "atom" more difficult to understand because its understanding requires an advanced level of rational thought? Or, is it difficult because of the sheer number of subsumed concepts that must be grasped before one can understand the concept "atom"? In the later case, the young child simply has not lived long enough or has not had the requisite experiences needed to build up the prior knowledge necessary for understanding a difficult concept such as "atom." It is not clear that children's thinking differs from adult thinking because children are less rational, rather than because children have less developed conceptual frameworks.

This issue of understanding versus rationality has great importance for the classroom. If the teacher assumes that (say) elementary children are rationally unable to learn certain concepts, the teacher will not teach those concepts. In first grade one teaches about animals, but not about atoms. At first glance it appears that the ability to offer teachers a developmentally appropriate curriculum is a good thing. Unfortunately, such a curriculum can easily put the brakes on teaching. In a developmentally appropriate curriculum, the tendency is to not press beyond a given topic even when that topic has been successfully taught, because the curriculum implies that the teacher should go no further than the prescribed appropriate concepts. Common sense tells us that success should be a stimulus for further efforts regardless of difficulty, and that the teacher should simply keep going as long as the children are learning. This is exactly what a competent teacher does when the teacher's focus is understanding rather than rationality and cognitive development. Thus, even if one accepts that children are at lower levels of rationality than adults, the value of the influence of cognitive development theory on curriculum is debatable at best.

Cognitive development theory is used to inform instructional practice as well as curriculum, but it is not the stage development aspects of the theory that are used. Instructional practice is informed by Piaget's concepts of accommodation and assimilation. These concepts are clearly about understanding, not rationality. David Ausubel (1968) has demonstrated that the concepts of accommodation and assimilation do not have to be linked with developmental stages. His focus has been to develop a theory of meaningful learning that extends the concepts of accommodation and assimilation rather than switching to concepts of rationality. One of Ausubel's chief ideas is that only personally meaningful learning is true learning. His recognition of the powerful influence that prior learning has on the meaning a student makes of any learning situation sets the stage for constructivism.

The focus of constructivist theory is understanding. In my view, this is one of the primary reasons that constructivism is rapidly replacing cognitive development theory as the foundation for science education research and practice. Moreover, one the attractions of constructivism is its utter simplicity. On reflection, one would almost say the
notion is patently self-evident. However, the widespread adoption of the term constructivism has actually created considerable confusion and controversy. For all its simplicity, the term seems to mean different things to different people. Constructivism for some is a rather uncomplicated, pragmatic description of learning that can be turned about and used to guide teaching. For others, constructivism is more a philosophy about knowledge. Those with the more philosophical orientation (they are known as radical constructivists) argue that it is fundamental that cognition is a biological adaptation that serves to organize experience for a person but it does lead to the discovery of how things really are (Glaserfeld, 1989). So what is constructivism?

The Uncertainty of Knowledge

In an effort to foster an intuitive grasp of this concept, I prefer not to start with a definition. Rather, what follows is a descriptive narrative. I trust that the narrative, in somewhat inductive fashion, will evoke in the reader an understanding of constructivism prior to hearing a formal definition.

We all wish to know about the world around us, whether we are speaking of the world in physical, social, or even spiritual terms. Science, of course, is the discipline that tells us about the physical world, and in science one’s senses are critical. One uses sight, hearing, feel, and taste to learn about physical phenomena. Instruments are used to extend the range of the basic human senses. These instruments can be as simple as an ordinary ruler or as complex as a radio telescope or mass spectrometer. Typically, what we have thought in science is that our senses provide authentic data about the real world. Experimentation keeps subjectivity in check. But is that really how our senses work? Consider that science uses the senses to focus only on what can be measured. For example, a scientist typically is not as interested in the color of an object as he or she is in measurable electromagnetic wavelengths emitted or reflected by the object. If you want to build a color television, knowledge of electromagnetic wavelengths is necessary. However, who can say that a wavelength of $4.0 \times 10^{-7}$ meters tells us any more about the reality of an object than does blueness? In fact, philosophers of science tell us that the question cannot be answered. Scientists focus on measurable attributes simply because they have chosen to do so—it works for what they want to do.

There is another question that confronts our attempts to understand reality, regardless of the physical attributes on which one chooses to focus. How do we know that what we perceive is what is actually there? As early as 1604, Kepler demonstrated that the physical image on the retina of the eye is actually inverted. Yet that is not how we perceive objects. We perceive them right side up. In other words, even though we see an object upside down, we nevertheless perceive it right side up. So how can we say that what we see is actually what is there? Perception appears to involve interpretation rather than simple transmission. To further illustrate the difference between sight and perception, try to image a person born without functioning sense organs. Somehow the person survives and one day after many years, the person’s eyes suddenly start functioning. His eyes would see reflected light just as ours do; but, what would he perceive? A mass confusion of light, a jumble of hues and intensities, a tumult of sensation, all signifying absolutely nothing. He would not recognize a tree in front of him because he could not have had any prior knowledge of the concept of tree. Perception is the act of one who sees, not the passive reception of light reflected by objects. To make this more personal, imagine that you have just removed the cover of your personal computer. Few of us know anything at all about the physical apparatus within a computer casing. Open one up and what we perceive is a confusion of lines, shapes, and colors—signifying nothing. On the other hand, the computer scientist perceives a computer. This illustrates what the modern developments in the philosophy of science have clearly shown, all observation is theory laden.

There are then two profound limitations on scientific knowledge. First, science is limited by its focus on selected attributes to the exclusion of others. This is a choice made by scientists, not a limitation imposed upon science by physical reality. Second, one can perceive an object only when one has preexisting knowledge of what is being examined. The result is that the scientist can never say that he or she has exact knowledge of what reality is like. Rather, the scientist drawing upon previous knowledge interprets experience following rules agreed upon by the community of scientists. A scientist constructs knowledge to fit experience. Instead of a photograph of reality, scientific knowledge is much more like an artist’s impressionistic painting of reality. The notion that knowledge is constructed leads some to conclude that all knowledge is inherently subjective. Others take the more conservative position that knowledge can be objective but that all knowledge is fallible.

This essentially means that scientific knowledge is fallible, and this has implications for education. If there were a direct link between the scientist and a physical reality independent of the scientist, one
could argue for a direct link between scientific knowledge independent of any knower and the acquisition of scientific knowledge by a learner. This is the viewpoint of naive objectivism. It implies that knowledge can have an existence independent of a knower. It thus implies that the best way to teach is by careful, methodical, detailed explication of scientific knowledge with the expectation that students will learn by receiving (i.e., memorizing) the knowledge. In fact, under the influence of positivism which taught that rationality and objectivity resided in quantitative experimental science, that is exactly how science has been taught for many years. However, if scientific knowledge is a scientist’s meaningful construction based on his or her experiences of reality, how can the learning of scientific knowledge be any different? If I cannot know reality for sure, what is it that I am learning when I learn? Essentially, there is no difference between the original derivation of scientific knowledge by a scientist and the learning of scientific knowledge by a student. Both are acts of interpretation. When I learn a science concept, I am constructing a personal understanding of the concept based on what I perceive the textbook, or activity, or teacher to be saying. Just as a scientist interprets experience in light of a personal background of knowledge, I learn by interpretation in light of my personal background of knowledge. In contrast, rote memorization involves no interpretation, is rarely meaningful; and, therefore, most of what students memorize is soon forgotten.

The concepts of construction and meaningful learning help make sense of a widespread occurrence among people. Science education research has shown that people hold many different ideas about such things as motion, force, life, and gravity. People’s ideas frequently differ considerably from accepted scientific viewpoints even when the people are students of science. After very careful explication of a concept, students frequently come away with quite different interpretations of the concept. Even graduate level physics students have been shown to have views of the concept “impetus” that vary considerably from what is considered the scientifically orthodox view. This phenomenon prompted David Hawkins to write, “reasonably patient explanation is no cure . . . we are up against something rather deep in the relation between science and common sense; we are up against a barrier to teaching in the didactic mode which has hardly been recognized, or if recognized has been seen mainly as a challenge to ingenuity in teaching rather that as a challenge to a deeper understanding of human learning” (1978, p. 5, 7). What is the barrier? You ask, how do these scientifically unorthodox ideas happen? They happen because learning does not involve photography, but impressionistic artistry. As the learning theorist David Ausubel says, the only real learning is meaningful learning. We have learned something when it makes sense to us. The advanced physics students have a particular impression of what impetus means because that impression makes sense to them. If their impression of impetus does not resemble the teacher’s, it is because their impression is a personal construction. If learning occurred by transmission, students would either have the concept or not. What they would not have are idiosyncratic versions of the concept.

Defining Constructivism

The definition of constructivism is carried in its name. Learning is the active process of constructing or putting together a conceptual framework. The philosophical basis for constructivism is epistemological fallibilism. All knowledge is fallible by virtue of lacking exactitude and comprehensiveness. Ultimately, we can never know for sure how close our knowledge actually approximates reality. Rather, knowledge is a meaningful interpretation of our experiences of reality. If the original derivation of knowledge is by meaningful interpretation, then the learning of knowledge must also involve meaningful interpretation. Thus, no one learns by transmission. No one learns in a way analogous to the copying of a computer file from floppy disk to hard drive. We learn by making sense of what is experienced.

As I mentioned at the start, constructivism is a practical idea. Consider the following simple dialogue:

Teacher: I say to you the man is tall.
Student: I hear you say that the man is tall. I think this man is also tall.
Teacher: No, that man is only 2 meters tall.
Student: Okay, I hear you saying that the first man is tall because he is over 2.4 meters
Teacher: Yes, but you are saying the second man is tall because he is over 2 meters.

We might call this dialogue “coming to an understanding” or “clearing the air,” or “seeing eye to eye.” The dialogue demonstrates three things. It demonstrates that both the teacher and the student are learners. They learn from each other. Second, the dialogue demonstrates that learning is an interpretive process. The student had to interpret the meaning of “tall.” The teacher had to interpret the student’s response. Third, in order to help the student understand the teacher’s intention, the teacher had to come to an understanding of the student’s viewpoint,
i.e., that student interpreted tall to mean over 2 meters. This, essentially, is the constructivist model of learning. It says to us that learning is always an active process of making sense out of an experience, and that this process is much influenced by what one already knows. Therefore, in any teaching/learning situation it is crucial that the teacher come to a common understanding with the student. Constructivism says to us that learning involves negotiation and interpretation. Therefore, the teacher is advised to engage students in discourse that facilitates the actions of negotiation and interpretation. The discourse may be with the teacher or among students. In this regard, cooperative learning strategies are ideal. Constructivism also implies that activity, or hands-on learning, by itself is not enough. A good inquiry lesson will fail with many students if students are not allowed to engage in negotiation and interpretation of ideas.

There is a further issue to consider. Most people have had the experience of being in a conversation where one would swear that the other person was speaking in an unknown foreign language even though that was not the case. One simply could not make oneself understood by the other person. This failure to communicate happens when the parties bring to the conversation radically different conceptual frameworks, and this is not uncommon in the science classroom. The problem is that the student has no idea what the teacher is talking about. The issue here is contextual constructivism (worldview is a related issue; Cobern, 1994). One of the clearest examples of this in science is the topic of origins. The scientific view of origins has to do with evolutionary mechanisms that speak to the question of how. For many students, however, origins is not about how but about why. Origins is a religious topic rather than a science topic, and these students construct knowledge appropriate to the context that is meaningful to them. The result is a radical schism between teacher and student, which is made only worse when the teacher assails the student’s position without ever trying to understand the student. The solution is not to tell the students they are wrong, but for teacher and students to work through the issues together.

Conclusion

In summary, constructivism is a model intended to describe learning. The model suggests:

1. The student is always active when learning takes place.
2. This active process is the process of making sense. Learning does not occur by transmission but by interpretation.

3. Interpretation is always influenced by prior knowledge.
4. Interpretation is facilitated by instructional methods that allow for the negotiation of ideas.

Inquiry activities are powerful specifically when they promote discourse. By the same reasoning, cookbook labs and demonstrations are far less effective. Thus, if students are not talking science, you will find that many are not learning science. As to the different views of constructivism, some educators are content to use the model as a basis for developing teaching strategies. However, Glaser'sfeld (1989) is right. There are at work here key issues of epistemology and ontology. The model can be used pragmatically, but I do not think that its full potential can be realized without the support of a philosophical framework.*

Suggested Reading

*This article was prepared as part of the Scientific Literacy and Cultural Studies Project funded by the National Science foundation (RED 9055834).
Hudson and Stiles in the June 1995 ICASE Journal have proposed nurturing the child's ecological mind as a model moving beyond the current reform that has been called Science-Technology-Society (STS). They advance their model while calling STS a "buzz word." Their attack illustrates a major problem with STS as a reform that is meant merely to result in change and improvement.

One problem is with a definition for STS. The National Science Teachers Association (NSTA) foresaw such a problem in 1988 which resulted in President LaMoine Motz appointing a Task Force to clarify the meaning of STS which even then had attracted many educators and researchers.

Two years later the NSTA Board of Directors unanimously accepted the Task Force recommendations which define STS. The NSTA definition is simple: STS is the teaching and learning of science/technology in the context of human experience (1990-1991). This surely is not the definition Hudson and Stiles used in their article.

The NSTA definition includes—perhaps emphasizes—that any reform needs to focus on learning. Interestingly the NSTA definition emphasizes technology (the human-made world) as well as natural science. But most importantly, it indicates that effective teaching and learning must occur in a context of human experiences—both past and current experiences of learners.

When Hudson and Stiles talk of a reform that goes beyond teaching and learning, beyond science and technology, a reform that ignores the context of human experience, what are the features of the reform? Their "new" model certainly incorporates the essence of STS.

STS is advanced as affecting instructional goals, teaching and assessment strategies, and the curriculum. Many STS reformers like to include curriculum last—just as many others can not conceptualize reform unless it emphasizes curriculum. Hudson and Stiles seem to fall within that trap.

But, Hudson and Stiles also focus on teacher (or curriculum) directiveness. They want environment topics to be central to the curriculum. They talk of teacher reserving time for environment activities that they (i.e., teachers) choose. They use such teacher-directed phrases as: "Children should be given," equipment "may be introduced," the model "can give students." Many have argued that "how" teachers teach is more important than what they teach (Yager & Lutz, 1994). But, Hudson and Stiles obviously feel that the "what" is more important if their model is followed.

Although Hudson and Stiles suggest many fine instructional outcomes as occurring if their model is used, their concerns for the human spirit or soul, their open desire to affect the spirit, their identification of the "correct" environmental ethic borders on religion and suggests again the danger of school science focusing on developing the "correct" view.

Many in environmental education seem more concerned with creating awareness of the environment and instilling wider use of this condition in reversing environmental degradation. This is a desirable goal—but is it science education?

Many around the world see the advantage of broadening a definition of school science. Most are willing to include technology as a full-partner—unlike the situation in the 60s where nearly everyone has concerned with the differences between the two and insisting that science be pure and characterized as a way of knowing by scientists.

In a democratic society it seems wise to posit—as Jefferson did as the U.S. democracy was born—that the citizenry must be literate and able to make decisions. Hudson and Stiles urge a model which will give students a broader view of the environment—and information about what humans are doing to further its degradation, especially in more advanced societies. But are Hudson and Stiles following their own philosophies of how humans learn and of the essence of the scientific enterprise?

INTEGRATED SCIENCE TEACHER EDUCATION IN NIGERIA:
HOW EFFECTIVE IS IT?
PART 2 “TRAINING TEACHERS FOR INTEGRATED SCIENCE IN
NIGERIAN SECONDARY SCHOOLS”

Dr S.N.Wuyey, Science Education, University of Jos, Plateau State, Nigeria
Dr. A.D.Turner, Science Education Department
Institute of Education, University of London, London WC1H OAL.

Abstract

In a previous paper we identified the focus of our research and the methodologies employed(Wuyey and Turner, 1994). This paper presents a summary of the findings. The research set out to establish the characteristics, quality and appropriateness of the training of teachers for integrated science in Nigerian Secondary Schools and in particular, how that experience fitted trainees for their intended teaching appointment.

The inquiry revealed that:

• many of the students in training had poor academic backgrounds in the contributing sciences; they could be described as fundamentally deficient in the subject knowledge needed to teach an integrated science course in schools;

• for many trainees, integrated science as a curriculum device was poorly understood, particularly in relation to the philosophy underpinning it;

• there was a dearth of trained integrated science teachers in the schools to act as role models;

• there was a lack of appropriately qualified and trained teacher trainers in the training institutions.

The implications of these findings, while not a surprise to us, suggests that until these deficiencies are remedied and that both trainees and trainers are adequately versed in the curriculum implications of an integrated approach to science teaching, then the successful implementation of current science courses specified for Nigerian Junior Secondary Schools is in jeopardy. An important feature of training is to understand the integrated approach to school science and to develop an appreciation of the underlying purpose and structure of the teaching programme in schools. This appreciation, too was found to be lacking in most participants to the training enterprise and is, we suggest, contributory cause to the poor image of integrated science teaching held by many of its practitioners. The strengths and weaknesses of the current teacher education system for integrated science is discussed in terms of the emphasis in the national system of education in Nigeria on a common integrated science course for junior secondary school pupils.

Introduction

This research undertook a survey of pre-service teacher training for integrated science in some Nigerian university departments of education and their affiliated colleges. The aim of the inquiry was to establish the characteristics, quality and appropriateness of the training in preparing the prospective teachers for their job. The research sought to explore the strategies employed in training these teachers in order to gain information about the course structure, the views about the training programme of the several participants in the enterprise; and the understandings held by these participants about the aims and objectives of integrated science as a school subject.

The study sought specifically to determine the

• the characteristic features of the pre-service programme of teacher training;

• the relevance and usefulness of the teacher education programme for integrated science student teachers in relation to their future role in schools;

• the perception of “integration of science” held by practising teachers already in post, by student teachers and the teacher trainers; and to compare and contrast these views. As a result of this inquiry it was expected to be able to point to the strengths and weaknesses of the current teacher education system in this specialist field; and the extent to which the training supports the supply of good quality science.
teachers into Junior Secondary Schools. The national system of education in Nigeria requires that one common integrated science course is taught to all pupils in this age group in schools. The quality of the teachers and the adequacy of their training is central to the successful implementation of this decision.

The Sample
Two university departments of education and six of their affiliate colleges were selected for this study. One criterion for selection of an institution was that they should have been running a training course of this nature for at least five consecutive years. In this way, the experiences of course tutors can be elicited, thus avoiding those colleges which have problems that could be attributed to teething troubles. Furthermore, it was hoped that by selecting institutions in this way, the views of experienced teacher trainers could be sampled.

The sample population included the coordinators of the integrated science teacher training programmes; other teaching staff in the universities or colleges; final year student teachers and practising teachers in schools. A total of 264 respondents made up the research sample.

Instrumentation
Questionnaires were the principal instruments used for the data collection supplemented with personal interviews. Four different questionnaires were designed for the various respondents, each with a common structure. The questionnaires were designed for the:
- coordinators of the integrated science courses in universities and colleges;
- teacher trainers of the integrated science courses in universities and colleges;
- student teachers;
- practising teachers in school.

The interviews were used mainly to clarify the questionnaire responses and to probe further thereby giving confidence and reliability to the data obtained through the use of the questionnaires.

Data analysis
The questionnaires sought to obtain the respondent’s views, opinions and understanding of both of the training programmes designed to train teachers of integrated science and the nature of integrated science itself.

In some instances numerical data was sought and this was analysed using straightforward quantitative summaries and tests of significance applied. The qualitative analysis made use of a Systematic Network Analysis (Bliss et al., 1983). This type of analysis is concerned with reporting results in terms of a relatively simple category scheme. It works with defined categories, but it attempts to elaborate those categories to the point where enough of the individual essence of the data are preserved and represented.

The strategy for elaborating categories uses a notation derived from systemic linguistics that sets out category names in a manner that shows their interdependencies. The analysis generates network-like structures in which descriptive categories appear linked in a structure that shows which categories belong within others, those categories which are independent and those which are conditional on the choice of other categories. The data collected in figure 2 is constructed by using these principles.

The total of 264 questionnaires were returned, as follows:

- student teachers, final year: 144 (54%)
- practising teachers: 52 (20%)
- teacher trainers: 60 (23%)
- course co-ordinators: 8 (3%)

264 (100%)

The research sought to establish some of the practices occurring in pre-service teacher education in the field of training integrated science teachers for Nigerian schools, by revealing through the eyes of the participants the characteristics and efficacy of the training programmes.

Results and discussion
1. Characteristics of teacher training
Three characteristic features of integrated science teacher training investigated in this study included the entry requirements of candidates; the selection process used by institutions; and the content of the course as taught to the student teachers.

The findings revealed that although every institution said that, in order to qualify for admission, it required all the candidates to hold credit passes in biology, chemistry and physics of the Nigerian Certificate of Education, or its equivalent qualification, their practice was very different. Of the 144 final year students responding and receiving training in the Colleges of Education the breakdown of qualifications was: Biology 63% Agricultural science 59% Chemistry 30% Physics 9%

In other words, a typical student teacher would have an academic background in biology or agricultural science. This was the case, too, with university graduate student teachers. Most students selected for training did not have the required academic qualifications for the course of study. Less than a third had a qualification in chemistry. As in
many countries, there is a severe shortage in Nigeria of applicants to teacher training with a physics background.

None of the institutions in the sample interviewed their applicants for training places. In view of the shortage of suitable applicants for training to teach integrated science, coupled with the policy drafting into integrated science surplus applicants from other sciences training courses, it appears to us that the need to interview was redundant. Nevertheless, qualities which contribute to the skills of a successful teacher but which are not visible on an application form are not relevant, therefore as selection criteria at this stage.

In addition to academic qualifications, some trainees displayed a low interest in the course of study on which they were placed. A number of the students said that their admission and placement on a course to train as integrated science teachers was not their own choice but that of the college. This situation arises when applicants' first choice course is full and, in order to stay in college, unsuccessful applicants were directed by the Institution tutors into the integrated science teacher training course. This occurs mainly when teacher training courses are full for prospective teachers of biology, chemistry and physics.

The evidence arising from this study identifies in candidates both an academic shortfall in their background and a poor attitude to the course of study. These two negative factors are, of course, connected. In drafting applicants into courses for which they are not suited either by choice or by qualifications the institutions are, by implication, downgrading the importance and value of integrated science as a course of study for teachers. By offering places to students who are not suitably qualified to train to teach integrated science the course becomes regarded as second best. In particular, this situation suggests that teachers of integrated science are identified with those who are not regarded as suitable to train as subject specialists. This position has to change if the teaching programmes in school are to properly staffed. If Integrated Science is to establish itself as the most appropriate form of school science for the Junior Secondary School then both the subject and its teachers must be given a status equal to that of other science subjects.

The position in which teachers of integrated science find themselves is exacerbated by the fact that integrated science is not a discipline in the same sense that, for example biology is a discipline. Integrated Science is not an independent field of academic study with its associated experts and literature. It is a curriculum device used to construct a course of study for school science programmed. This lack of an underpinning discipline leads to a serious problem of status for teachers who train to teach integrated science (Black, 1986).

2. Practising teachers

Part of the study focused on the type of training these teacher received and its' appropriateness for the job. Altogether 52 practising teachers were sampled. With reference to figure one below it appears that this cohort contained teachers in one of three categories of training, as follows:

Formally trained to teach Integrated Science 23%
Received no training to teach Integrated Science 46%
Informal training* 31%

In summary then, 77% of teachers in the sample had received no formal, pre-service training in Integrated Science teaching. The nature of the

Figure 1: Training received by teachers of integrated science

![Figure 1: Training received by teachers of integrated science](image)
informal training(*) included workshops or seminars of short duration amounting to days. About 58% of the practicing teachers were male showing nearly equal distribution between the sexes.

3. The Teacher Trainers

The inquiry sampled the views of co-running the course in the colleges and universities; their numbers were small compared with overall numbers in the inquiry.

This situation is inevitable and in the nature of training process. In addition, some 51 teacher trainers were sampled for their opinions.

Within this sample of 60 staff, 10% indicated that they have had some form of training to teach integrated science. The remaining 50% were engaged by the institution because of their academic qualification in a subject (science) discipline or because of their (wider) educational background. The results of this inquiry suggests that staff of the training institutions lack Other school teaching experience or academic background in the nature and practice of integrated science teaching in schools.

Whatever their knowledge and ability as scientists or their good intentions might be the finding casts doubt upon the capacity of the staff to help students in training to teach integrated science.

All staff were asked to identify the skills and abilities which they hoped to develop in their trainees. The replies were analysed and collated using the Systemic Network Analysis. The response of the eight course coordinators is described first in figure 2.

The network summarises closely the expectations of the course coordinators and thereby the experience intended for the integrated science teachers during their course. For knowledge acquisition, the course co-ordinators specified that attempts were made to equip student teachers with sufficient broad based factual knowledge in the basic sciences and any other scientific fields relevant to the syllabus. In terms of skills to be developed by the student teachers, these were grouped into two domains, the psychomotor and the cognitive; see figure 2.

Although the list of abilities and skills represented in the Network can be said to be comprehensive and capable of imparting the necessary expertise to produce effective integrated science teachers, the ideas expressed in the summary Network are only those of the course Co-ordinators. Other staff, the teacher trainers responded less coherently to the invitation to identify the skills and abilities which they hoped to develop in their trainees.

We were forced, reluctantly, to the conclusion that the network of abilities and skills gives at best, a theoretical picture of what the course is intended to achieve. In terms of what is happening in the training classroom the picture is confused. None of the co-ordinators held views consistent with the whole network, which was not surprising; however, whereas most teacher trainers were able to identify for themselves some of the aims embedded in the network(Figure 2) few held any coherent picture. There was no holistic view of the intended outcomes of initial teacher training held in common by all staff committed to the programmes in the several institutions.

Another feature of the training programme was the expressed intention of the course coordinators to develop motivation in the students towards the course, towards the idea of integrated science and to bring about a change in attitude towards integrated science. Bearing in mind the attitudes engendered in some students by their enforced placement into integrated science teacher training course this clearly is an important feature to identify and nurture.

4. Perception and understanding of Integrated Science Education

The research attempted to obtain the participants views about their perception and understanding of integrated science as it takes place in schools. The participants included practicing teachers, student teachers and the staff running and teaching the training programmed

Participants were asked to give a definition of integrated science; these definitions were analysed and categorised. The summary of this analysis is shown in figure 3.

The most popular definition was "a subject which teaches a combination of contents from the biological and physical sciences as well as a measure of some of other related scientific fields". This response, Category 1 in Figure 3, was given by many respondents drawn from all three categories of participants; in addition, factors as qualification, training and experience of the participants did not materially alter the response. Clearly integrated science is seen mainly by most teachers associated with the programs in terms of breadth of content. This finding is further confirmation of earlier researches undertaken in Nigeria to find out how pre-service and in-service teachers of integrated science teach and understand their school curriculum (Olawaraju, 1983; Jegede, 1983; Akinmade, 1988; Madubum, 1990; Nkpa, 1991).

After a decade of teaching and research into integrated science teaching in Nigerian schools, there
is very little change in the perception by teachers of the underlying purpose of school integrated science teaching. It is of concern that, even in those teachers who claimed to have been trained, or to have benefited from some type of training in teaching integrated science, most respondents did not show any wider understanding of integrated science beyond a teaching of "combined biology, chemistry and physics."

However, participants who did have some training to teach integrated science, or who were professional school science teachers and with many years of experience did offer responses that generated category 2 (Figure 3). Such respondents reflected an appreciation of the broad range of possibilities opened up by an integrated approach to science teaching and reflected in the Nigerian Integrated Science course aims (Federal Ministry of Education, 1985).

Discussion

One powerful message given to the researchers by the many course participants was that, as a school subject, integrated science was a second best subject compared with the traditional subjects of biology, chemistry and physics. Furthermore, that those teachers who taught the subject in schools and in addition, those who were being trained to teach integrated science, were second best teachers. This message was clearly relayed to us, not only in the follow up interviews with teachers responding to the questionnaires, but by staff in colleges of education and university departments of education not least by the manner in which they recruit students to their courses. It was our impression, too that the status of teachers in the field reflected a hierarchy in which integrated science teachers in secondary school were at the bottom and was reflected in the pay and limited movement of staff between the Junior Secondary Schools and High Schools. The High Schools in Nigeria recruit subject specialists to teach biology, chemistry and physics and do not generally teach integrated science.

Overall there was a strong negative attitude towards integrated science teachers. This effect must be transmitted to the pupils, making the teaching of the subject that much more difficult.

If progress is to be achieved towards a broad based science education for all Junior Secondary School pupils through the means of an integrated science curriculum, then clearly this powerful negative influence must be reversed. The courses in schools have the potential to offer a sound stepping stone and reliable base for those who go on to further study while to those whose education-finishes at the Junior Secondary School stage it gives pupils a rounded course of study in the sciences and the opportunity to understand aspects of science and technology relevant to their daily lives.

If circumstances permit, the admission procedures of the institutions offering training in integrated science teaching need to be overhauled by
developing a clear policy of entry with transparent and achievable selection procedures. If the admission of suitably qualified candidates cannot be guaranteed within this process then perhaps the policy of requiring an integrated science curriculum to be taught in schools by dedicated trained specialists might be re-examined.

The teaching of integrated science in schools need not demand one teacher teaching all the course. For example, a team of teachers might be envisaged in which the best way to deliver the curriculum is arrived at in the light of the teaching force available, e.g. single subject specialists may be deployed to teach those aspects within their compass. However it would be necessary for all teachers in such a team to understand the aims and objectives of the whole course, to ensure coherence and common purpose.

This lead us to a final point. There is an urgent need in the training of teachers to give priority to the meaning and purposes of integrated courses. If the purpose of the course and the knowledge, skills and attitudes it hopes to engender in the pupils is understood then the effectiveness of teachers is enhanced. In this way a team approach to school science teaching could be developed. This objective requires that the teacher training institutions give attention to this aspect of their programme; and that assessment of trainee teachers on a teaching practice placement has this objective in mind.

The Nigerian Integrated Science Teacher Education Project (NISTEP) has been the only enterprise directed at upgrading the teacher training institutions. At present it is based in one centre and there is clearly a need to spread the influence of this Project more widely. Such a move might be co-ordinated by the National Commission for Colleges of Education, the Science Teachers Association of Nigeria and the National University Commission.

The proper and adequate training of science teachers at both the initial and in-service stages are a fundamental requirement for the delivery of National Curriculum aspirations. Well qualified teachers are the sine-qua-non of successful curriculum implementation. Experience has shown that no matter how well an education programme has been written and developed the success finally rests on the enthusiasm, commitment and quality of the classroom teachers (Wuyep, 1986).

HOW CAN WE COMMUNICATE THE RESULTS OF EDUCATIONAL RESEARCH TO PRACTITIONERS?

Maria J. Saez
Valladolid University, Spain

Introduction

This paper discusses how the teacher community can become aware of an eventually use the results and information produced by educational research. The essence of this paper was presented by request at the last ICASE meeting in Lancaster, England, in January, 1995.

For many researchers the main goal of the research enterprise has been to produce knowledge and make the findings available to the scientific community. For that purpose, introducing the outcomes and the procedures used was a matter of delivering the product to libraries, information centers and the data bases. However, for successful dissemination, the information must be put into the system and users (teachers) must become aware of it. Placement of information in the database does not guarantee dissemination.

For this reason, the use of research findings is one of the important issues of our decade and the educational field must close the gap between researchers and practitioners. The research findings must research the practitioner communities and be used for more accurate and successful implementation.

For a long time, researchers in the social sciences aligned themselves with engineers (Huberman and Ely 94). The idea was that rational research and the development process would be sufficient for the job (Research—Development—Dissemination).

Let us analyze in more detail the main issues of dissemination when the purpose of it is only spreading or exchanging information:

1. If the focus of the dissemination effort is the spread of information, the goal is to reach the large number of people using a variety of media formats, e.g. audio, video or text, usually using more than one vehicle.

2. If the exchange of information is the goal, this occurs when information, products or observations are shared. Exchange involves interactive communication through face to face visits, e-mail messages and informal conversations at professional meetings. The audience is usually small; individuals or small groups who sometimes form networks for the purpose of sharing findings about new information.

It is necessary to work on the reception side to have a message that virtually no one listens to, much less acts on. As it turned out, what is needed in the social and behavioral sciences is a more complex and less linear model for transferring knowledge from developers and researchers to users then either of the above approaches allow. Here is a definition that more accurately reflects the complexity of the process:

Dissemination is the process of communicating information to specific audiences for the purpose of extending knowledge and, in some cases, with a view to modify policies and practices.

(Huberman & Ely)

Two new ideas have been introduced in this definition, i.e. first, the receptor perspective which needs to be taken into account and second, the idea that the goal of the message is not only to deal with information (spread or exchange) but to take action.

When the action perspective is included in the purpose of dissemination, then implementation or the use of information by practitioners is the goal, and direct assistance to the user should be planned.

Innovation and Dissemination

Since innovations have become an important aim of educational practices, it is assumed that dissemination does not occur simply because information has been sent. Some authors point out
that improving school practice should include policies that clearly define and validate practices when linked with in-person assistance from experienced developers, implementors, and facilitators. In this respect, dissemination is context dependent. People in various settings often act on the basis of the traditions and values of the organization. There are general procedures or guidelines for discussion that are useful but absolute rules do not exist (Huberman and Ely, 1994).

To involve teachers in the use of research findings, several things must occur. The process cannot be seen as a technical process. There are no reasons why teachers must act and work as if they were part of the research community when they are not. The boundaries between professional practices are in a constant process of redefinition and there is increasing pressure on different professional groups to collaborate in the provision of services (Elliott, 1980). For practitioners to use research findings a new conception of professionalism including permanent learning must be developed (Saez, 1987).

If change is interpreted as an evolutionary progression in society, it can be steered by the state (Handy, 1989). Human needs under this type of change remain fairly constant as do the forms of their provision. The "infallible expert" image matches a society conceived as a stable and unchanging state.

In the "infalible expert" model of professionalism, the acquisition of knowledge and the development of competence are two rather different processes. Propositional knowledge (knowing that) can be acquired off the job, while competence may only be developed through direct experience. According to this point of view, competence is the ability to apply knowledge in ways which generate correct practical responses to a situation. This ability is acquired by learning through experience to recognize applications of knowledge drawing on common sense stereotypes that have evolved as part of the professional culture and which are mediated by its guardians. "Knowing that" is the foundation on which competent "know how" is built, because one does not test knowledge directly in assessing competence, but in terms of pre-specified performance outcomes and inferring adequate knowledge from such evidence. Direct testing for "knowing that" and assessing competence or "know how" are quite different activities.

**Reflective Practitioner Model**

Other authors (Schön, 1982, Elliott, 1980, Ebbutt, 1986) proposed another model of professionalism years ago, the "reflective practitioner," grounded in a different understanding of the nature of social change than mentioned above. If change is seen as discontinuous and unpredictable, human and social problems have unstable definitions and explanations; understanding becomes situated, personal, controversial and negotiable through dialogue with others. The role of the practitioner, rather than operating as an infallible source of relevant knowledge, should be to participate in a process of collaborative problem-solving through which the relevance and usefulness of his/her specialist knowledge can be determined and new knowledge acquired. Knowledge acquisition becomes an integral dimension of situational problem-solving. The practice itself is a form of learning which some used to call action/research (Elliott, 1980). Professional learning in this context is a dimension of practice, rather than a segregated activity.

From the perspective of the "reflective practitioner" model, professional competence is different from the "infallible expert" and consists of the ability to act intelligently in novel and unique situations that require what constitutes an appropriate response to be learned in situ. Competence cannot be defined simply in terms of an ability to apply pre-ordained categories of specialist knowledge to produce correct behavioral responses.

Within this model of professionalism, stereotypical applications of knowledge are to be avoided because any attempt to pre-specify correct responses or performance indicators constrains intelligent practice (Martineck, 1988; Shavelson, 1986). Instead they need to focus on the qualities of judgment and decision-making which are indicative of capacity for understanding situations holistically, for looking at it from a variety of perspectives allowing wise and intelligent responses in novel and unpredictable situations.

For the "reflective practitioner," the acquisition of relevant and useful knowledge cannot be separated from the development of competent intelligent action in unpredictable and complex social situations. The viewpoint must be its relevance and usefulness, determined by one's own competence in reflecting about such situations and how to act wisely on them.

The professional knowledge of the reflective practitioner, as (Schön, 1982) has pointed out, consists of reflective situational understanding, stored in the long-term memory. When confronted with a new situation, the practitioner selects cases from experience and contrasts them. This eclectic use of past experience illuminates aspects which may be significant for clarifying the new situation and determining the appropriate response; constructing new meaning.
Of course, the professional knowledge of the "infallible expert" is contextualized by being associated in the memory with stereotypical cases of its application. But the infallible expert does not use these cases as a basis for reflective comparison. Rather they are not used reflectively as a basis for intuitively subsuming the new situation under pre-existing categories of knowledge.

Elliott (1980) argued that intelligent practice, e.g., knowing how to perform educational activities like teaching, curriculum development and evaluation, cannot directly spring from knowledge of theoretical principles about practice, since these principles themselves derive from the analysis of practice. The principles are abstractions from practical knowledge embodied in concrete performances. One does not first understand a theoretical principle about education and then apply it to an analysis of practice. Understanding emerges from the analysis. Thirdly, theories about concrete practice rather than generalizable features, are bound to a particular substantive context.

**Collaboration for Dissemination**

For all these reasons dissemination of research can no longer be produced for a group of people (researchers) completely separate from the practitioners. From this point forward, it must be regarded as a collaborative work (Saez, 1991), where the focus and goals of research are decided on as a negotiation among the different concerns.

According to the methodological point of view, the requirements for collaboration include:

1. To use qualitative methods which can overcome the reductionism of positivist sciences and their paradigms (Hopmann & Riquart, 1995), because it is recognized that educational research does not hold to causal effect but to a more complex network of elements that are often impossible to isolate as single variables. The holistic perspective of the situations should be emphasized and the research must be described within the context where it takes place.

2. That the focus of the research will be on problems and issues emerging from practice and therefore must be defined and formulated by the collaboration between practitioners and researchers.

3. The need for a conversation of practice among researchers, practitioners and policy-makers that extends the knowledge about educational processes, institutions and phenomena. We need to understand issues of implementation to overcome the existent gap among policy, theory and practice. For discussion purposes, implementation will be situated within a cycle of inquiry. The cycle of inquiry, referred to as a holistic process, begins with establishing an inquiry purpose. The view of inquiry (Guba, 1994) is based on cycles of activities where people are engaged in a variety of actions to achieve particular purposes. Practitioners, researchers and policy-makers are all seen as inquirers who are engaged in activities driven by particular purposes.

To establish a common base for exploring implementation within a cycle of inquiry (Guba, 1990), it is necessary to consider the term in a decontextualized form, and returning to the context of use to construct a situational definition and alternative ways of knowing. These definitions form an important base for conversation of practice. Working in such a way, all members of the educational enterprise are seen as potential inquirers. Inquiry is viewed as a conceptually based process that depends on the person, the purpose of the study, the way people view the phenomena, the background knowledge of the inquirers, and the way in which they conceptualize and implement the inquiry process. Underlying this perspective is knowledge generation of a constructivist nature. Knowledge is interpreted and then integrated into the audience’s perceiving, believing, acting and evaluating everyday life in the context of practice.

**Doing Research**

When doing case studies, describing educational events within their context becomes extremely important. The description should be so realistic that, for the readers, the school is recognizable. The reader should be able to note the aspects that are particular to the setting and those that seem similar to the broader array of educational phenomena. The data in this descriptive narration must focus on groups or their activities, e.g. teachers, pupils, teaching and learning strategies, and the changes. The narration is a story of the events, based on the common sense explanations of the participants who reflect the reasons of the events as they occurred. The level of abstraction resembles that of investigative reporting. The study contributes to knowledge by preserving a record of a past event compiled by an expert observer.

The initial case study description is followed by analysis and interpretation. The researchers analyze selective aspects of human actions and events in order to construct explanations. The complexity and the interrelationships of the events and in human lives is emphasized. The study contributes to knowledge by
providing an understanding of the phenomena studied. This type of case study potentially enables others to recognize and anticipate what may occur in similar situations. These studies focus on how schools differ in terms of the innovation and the limits within the school’s context.

Research problems originate in the field, but theoretical literature is essential for recognizing and exploring the problems more closely. The researchers begin with preconceived problems that may change to fit the reality of events. The data base is extensive, including direct on-site observation, having a holistic emphasis on multiple data sources and skills in noninterfering observation, listening and recording, as well as the selection of a research role. The description of the context includes field notes as data and is written at a level of abstraction appropriate for the purpose of the study. It is a record of a natural even which provides an understanding of the complexities of an educational phenomenon.

The case study researchers must emphasize the holistic view of the setting. The researcher provides a sense of totality by representing the social, temporal and overall relationship in the field. It is clear that it is impossible to observe everything, but sufficient data can be obtained for a holistic emphasis by using multiple data sources. The essence of this lies in obtaining different types of data from different persons in different organizational positions in different situations at different times. Multiple data sources can best be illustrated by listing the methods, participants, situations and organizations in the study to show the different perspectives and views. In constructing explanations, the group of researchers looks for convergence of their data sources and develops sequential, phase-like explanations, assuming that none of the events has a single cause.

**Summary**

The educational practitioner must be regarded as an equal partner in the research enterprise, otherwise our efforts in improving educational practice will be in vain.

When to Use Overhead Transparencies
Chemistry teachers can use various teaching methods to increase student cognitive activity: demonstration and laboratory experiments, group work, role plays, or work on local and international projects, just to name a few. Another way to animate chemistry classes is to use overhead transparencies, especially for complicated theoretical concepts, e.g., atomic mass and chemical bonding. Overhead transparencies can provide students with visual models for these abstract concepts. Pedagogical process research (P. Leppik, 1993) has shown that a teacher who uses only verbal teaching methods works resultively with less than half the class.

Overhead Transparencies Students Prefer
Students are not fond of “dry” descriptions of facts or phenomena. They prefer overhead transparencies that set problems and problem situations, give puzzles, or represent the surrounding world in a humorous way. The author’s experiences confirm that vivid and fascinating problem presentations mentally excite pupils. All this promotes knowledge acquisition and greater concept understanding.

Some Examples
We have composed 20 overhead transparencies in above mentioned style. They reflect the diversity of the surrounding world (atoms, molecules, crystals, substances, solutions) or are used to develop students’ skills, including safety. These overhead transparencies were designed to be used in our first chemistry classes (in grade 8 in Estonian schools) or in an integrated science course. This article shows several examples of how transparencies can help students make connections and enhance mental operations.

For example, students analyze the situation shown in Figure 1, draw conclusions, count the mistakes, and discuss proper laboratory techniques.

Figure 2 deals with an extremely complex but important chemical concept: “How are atoms weighed?” The concept “atomic mass” can be made more understandable if we use analogy and a comparison with daily life situation. For example, “an atom is like an orange divided into 12 equal pieces.” Students conclude that atoms are “weighed” by comparing their masses with atom mass similar to buying sugar in a shop.

In Figure 3 students must identify the attribute or idea that ties these pairs of objects together, i.e., that they are connected by their masses. In other words, ratio of a proton’s and electron’s masses is the same as the ratio of a fox’s and a mouse’s masses.

Chemical bonding is explained by using a “chemical fairy tale.” Here the formation of the ionic compound sodium chloride (NaCl) from sodium and chlorine is presented. First we model the periodic table of elements as a big house for 111 inhabitants (Figure 4). Our fairy tale begins with the words: “Once there lived...” let’s say: among 111 inhabitants there lived a young man Sodium and a girl Chlorine. There was a strong attraction between them. One day Sodium begged Chlorine to go for a walk (Figure 5). However, Chlorine was not warmly dressed and felt cold so Sodium gave her his coat. “What did Sodium give away?” (= a valence electron).

Conclusion
Having students analyze problems, make decisions, draw conclusions, and use models allows a teacher to stimulate cognitive activity and expand understanding. Based on the author’s experience, comparing and connecting invisible objects and phenomena of the microworld with those of the macroworld leads to better understanding of these complex concepts.

Introduction

The Secondary Education Development Program in the Republic of the Philippines, begun in 1988, has involved major curriculum change and consequent whole-country inservice teacher education for all components of the secondary (Grades 7-10) curriculum. Within this context the Philippines-Australia Science and Mathematics Project (PASMEP) has contributed to chemistry, physics and mathematics in Grades 9 and 10 (the last two years of Filipino schooling) through equipment provision, “Training the Trainers” programs for those who were to conduct the inservice teacher education programs (INSET). In this article we consider one of the two Monash involvements in PASMEP. This was focused on the Grade 10 subject “Science and Technology”, referred to here as S&T4. This is a physics subject. Our brief was to provide a special purpose, 10 month, full-time program in Australia in 1990 for 34 selected trainers, and to work in four follow-up workshops in the Philippines in 1991 and 1992 for these and 28 further trainers. These experiences addressed physics content, teaching and learning strategies, nature of INSET, designing INSET, etc. Below we give some background to the Philippine context and to this Monash component of PASMEP. We then consider the features of the Monash program, discuss the consequences of the program, and address some general issues arising from the work. Before this we very briefly consider some past approaches to teacher development for major curriculum change in order to give relevant context for the significant processes and outcomes of the PASMEP S&T4 program.

An Outline of Some Past Practices in Inset for Major Curriculum Change

When a country embarks on a major reform of its school science curricula it is also faced with the very substantial issue of professional development. This INSET of those who are to teach the new curricula, and who have been with varying degrees of success and experience teaching previous curricula, is probably the most critical factor for successful implementation (e.g., Zoller & Watson, 1974; Fullan, 1982).

However affluent the country or however poor, however developed or however developing, the problems of persuading, informing, and equipping the existing teachers to change in the ways required by the new curricula are similar. Changes required by new curricula can include new content emphases, new laboratory intentions, new forms of assessment, new pedagogics and new teaching roles. Often these are required of teachers who have been accustomed to and, in many cases, successful in teaching science in other ways.

In general, it is true that the richer countries have more resources for tackling these problems than do
the poorer countries. However, richer countries can have considerable difficulty in bringing these resources to bear on the problems in an effective and coordinated manner. Because education for development is an international aid and loan priority, it does sometimes occur that a less developed country with the capacity to plan and organize also has access to the substantial resources needed to implement its plans. Quite remarkable results can then emerge.

Thailand in the 1970s is an example of this phenomenon (Fensham, 1986). Given the ways the above problems and their solutions were conceptualized at that time, and using the dual criteria of extent of coverage of the teaching force and the thoroughness of the induction into the intended curriculum changes, then Thailand achieved professional development of its science and mathematics teaching force which was at that time without parallel. Wongthonglour (1979) has documented and evaluated this professional development in the specific case of a new Physical Science curriculum.

In this present paper we describe a similarly remarkable success story from the 1990s, in which professional development occurred in the Philippines on a scale and of quality that far exceeds anything that has been yet possible in the cooperating donor country, Australia. The nature of the approaches contributing to this success reflect current conceptualizations of the problems of professional development and curriculum implementation, and current ideas of how to tackle the problems. These differ from the conceptualizations and approaches of the 1960s and 1970s, differences that result from research in the intervening years. In brief, the differences of importance in the S&T4 program involved our greater understanding and the participants’ eventual acceptance of: learning and conceptual change, including the need for time; the recognition of the importance of role models and sustained support; seeing incremental degrees of change; embracing conceptual change in content and pedagogy; accepting the need for networks to support change; and accepting that the translation of ideas into the local context has to be the responsibility of those who work in that context. We elaborate and justify these after giving an outline of the relevant contexts of participants and of the structure of the S&T4 PASMEP program.

The Philippines Context and PASMEP

Formal education in the Philippines, an archipelago of 7000 islands with a population of over 60 million, is modeled on the U.S. system. Six years of free compulsory elementary (primary) education are followed by four years of secondary schooling. A policy of free public secondary education was included in the 1986 constitution, and the consequent abolition of tuition fees at this level began in 1988. The Philippines takes pride in being one of the Asian countries with high rates of adult literacy (about 86 per cent in 1988). It has relatively high participation rates at all levels of education (over 45% of each age cohort was completing secondary schooling in the late 1980s, and of the 17-24 age group, about 16% were enrolled in post-secondary education). The organization of and policy for school education derives centrally from the national government and is supported by 14 administrative regions, each of which has a Regional Science and Mathematics Teaching Centre attached to a Teachers College or University. There are, in total about 3.4 million secondary students. The private sector is strong—about 40% of secondary and 80% of tertiary students are in private institutions.

The secondary science curriculum reflects the US influence already noted. The Grade 7 curriculum ("Science and Technology 1") is general science, Grade 8 ("S&T2") focuses on biology, Grade 9 ("S&T3") on chemistry and Grade 10 ("S&T4") on physics. Officially, the language of high school science instruction is English (Filipino is used for some other subjects). In practice, local dialects are sometimes used by science teachers in rural areas and areas remote from Manila. English language proficiency varies across science teachers.

The contexts for science teaching are variable. Public schools, on which PASMEP focussed, are either nationally funded ("National High Schools") or locally funded with partial national funding for teacher salaries ("Barangay, i.e., village High Schools"). Although only 22% of the 3,400 of public high schools are national, these employ two-thirds of high school teachers and enroll about the same proportion of students. Locally funded schools thus are very often small, and often very poorly resourced. National high schools can be very large (enrollments of several thousand). A few National High Schools are designated Science High Schools. These are generally well resourced and staffed—S&T4 classes of under 30 occur here. In other National High Schools, S&T4 classes of 45+ are the norm and equipment is often lacking. There is also a substantial shortage of physics teachers with less than 10 per cent of S&T4 teachers being physics majors. The total number of S&T4 teachers in the country is between 6,000 and 7,000, many of whom have backgrounds in biology, mathematics, social sciences on language.
Each region has a designated Regional Leader School in science. This school has frequently served as the location for whole region INSET, and was the site in each region for the S&T4 whole country INSET with which we were concerned.

The PASMEEP project came from negotiations between Philippine government agencies and a small group of Australian experts (including one of us) late in 1986. It involved provision of equipment for Grades 9 and 10 to about 380 schools (largely focused in three regions), a program for teacher educators, trainer programs for INSET of Grade 9 and 10 mathematics teachers and Grade 9 S&T3 (Chemistry) teachers, and a supplementary materials development project for Barangay school teachers. The two programs for Grade 9 ran a year ahead of the programs for S&T4 and Grade 10 mathematics.

From 1989 to the end of 1992, Australian co-ordinating staff in the Philippines worked closely with the local PASMEEP staff and the Philippine government agencies charged with overseeing the implementation of new educational programs.

The S&T4 PASMEEP Program

The stated basic purpose of the S&T4 PASMEEP program was to develop the participants ("fellows") to be trainers who would carry out in 1992 the INSET of all government high school physics teacher for the new S&T4 curriculum ("mass training"). The fellows who came to Monash were selected by the Philippine authorities who used a variety of tests (including one of physics knowledge). They were current S&T4 high school physics teachers, not physics academics or physics teacher educators—an unusual choice, given the traditions of science INSET in the Philippines and the inversion it represented of where the expertise in INSET was seen to lie. It was, however, a choice of great significance, particularly in relation to the importance of role models.

In 1989 one of us visited the Philippines to see schools, to talk with teachers, and to negotiate the broad structure of the 1990 program with staff from the Bureau of Secondary Education (the relevant National Government agency), ISMED (The Institute for Science and Mathematics Education Development at University of the Philippines, a body that for many years has led innovative curriculum development and INSET activities), and those involved with implementation of PASMEEP and the new curricula.

There was clear agreement that the major influence of the fellows in their eventual roles as change agents would, in reality, be in contexts other than mass training: in their own schools, in ongoing local INSET, etc. This did not diminish the importance of the mass training role, but placed that role in a broader and longer term INSET context. This issue was of major importance to our approach.

Thirty four trainers spent February to November 1990 at Monash: 2 teachers from each of the 14 regions in the Philippines; a third teacher from each of the three regions on which PASMEEP had a particularly strong focus; one physics educator from Bureau of Secondary Education; and 2 physics educators from ISMED. Subsequent follow up workshops in the Philippines were held in January 1991 (1 week), May 1991 (4 weeks), October 1991 (2 weeks), and January 1992 (2 weeks). In the May 1991 and later workshops a further two physics teachers from each region joined the group to become trainers, and in the last two workshops, teacher educators (who had undertaken another year-long PASMEEP program) and some selected school administrators were present for part of the workshop. All these personnel made contributions to the 12 day mass training programs, in April or May 1992. An intended presence of Monash staff as observers at mass training was canceled because of its concurrence with national elections. A subset of the fellows was also involved in 1991-2 in a series of curriculum writing and equipment use workshops organized by the PASMEEP staff in the Philippines. We were not involved in these. A number of local and regional INSET programs were, as intended, conducted by the fellows through 1991-2 (and, of course, subsequently).

In outline, the 1990 program focused on physics content, on issues of curriculum, learning and teaching, and on the nature and provision of INSET. The culmination of the program was the production of resource material for use in INSET or classroom teaching, and explorations of varieties of these resources. (Other components of the 1990 program, such as the Australian context and learning word processing, are not considered here.) The follow-up workshops in 1991-2 were a mix of additional materials production, further planning for mass training, training the new fellows, and trial of approaches and considerations of other INSET (both what the teachers had attempted on return to the Philippines and what they might attempt).

The Rationale For the S&T4 Program

In an earlier section we listed some features of the approach to our work with the S&T4 trainers (understanding of learning and change, time, role models, networks and sustained support, accepting responsibility for adapting ideas). Here we describe these more fully, indicate our justifications and give some sense of how the features played out in the program. One obvious difficulty in this need to
discuss the features somewhat separately is that in the real situation they were interrelated in a complex whole. A further difficulty is the presence of another complex interaction, that of teacher, learner and subject matter, or, in the terms of Hawkins (1973), the interactions in a three term communications relation-teacher, learner and subject matter. The importance of this second complexity is embedded in some of the features of the program.

At the heart of the program was a constructivist view of learning (e.g., White, 1988) and a recognition that what was known about conceptual change in school students had appropriate parallels in conceptual change in teachers (Gunstone and Northfield, 1986). Of particular importance in these parallels is the scheme advanced by Posner, Strike, Hewson and Gertzog (1982) for considering conceptual change: there must first be dissatisfaction with the existing conception, and the new conception must be intelligible, plausible and fruitful. Concern with the fruitfulness of new conceptions was a pervasive theme throughout the program. Collaborative work with teachers, for example, the Project for Enhancing Effective Learning (Baird and Mitchell, 1986; Baird and Northfield, 1992), has shown clearly the fundamental importance of time and of collaborative, sustained support (a “network” of support) in fostering teacher change in conceptions of learning and of appropriate pedagogies. We thus had no illusions that we could expect too much early in the 10 month program and considerable personal support, including much peer support, was built into our approaches. PEEL and other projects have also pointed to the importance of role models. These are significant not only for the obvious reason of providing an exemplar to learn from but also for the more profound reason of the “learner” seeing that the “teacher” values ideas sufficiently to use them him/herself. In other words, part of the value of role models is intertwined with the fundamental importance of teachers of teachers practicing what they preach (Gunstone, et al., 1993). One other theme running through the above, and described in detail in a number of the associated references, is metacognition. In the context of the S&T4 program, it was necessary for the fellows to become aware of, to understand and, in due course to accept the approaches we used, particularly in terms of the contributions these approaches could make to their own learning. Time once again is a major issue for such metacognition, indeed even just for arriving at a state of dissatisfaction with current conceptions of teaching and learning.

The above outline is relevant to the approaches we made to both physics and to learning and teaching. The large bulk (75%) of the first half of the 1990 program was devoted to physics content, and most of that to fostering a genuine understanding of fundamental concepts through the consistent use of a range of teaching approaches congruent with the conceptual changes this goal required (e.g., concept maps, predict observe-explain, interpretive discussion; see White and Gunstone, 1992).

In the physics content component the Monash staff (who included Australian school Physics teachers) were role models for the fellows as subsequent users of the same strategies for the same learning goals with their students. Through this time the fellows were encouraged to keep diaries about their learning which were used, inter alia, for later considerations of learning and change. Sessions were gradually introduced for the consideration of teaching and learning via these physics learning experiences. Dual agenda (i.e., in this case, learn physics and at the same time consider learning and teaching) were a common feature of the program. For example, as part of our focus on INSET later in the year, the fellows had two separate experiences of INSET workshops of relevance to the program (one focused on an Australian curriculum development, the other on the physics PLON project from the Netherlands). As well as being of value as experiences, these two INSETS were also analyzed by the fellows as examples.

In the second half of the 1990 the program was increasingly concerned with learning, teaching, INSET and professional development (85%) and physics learning focused on more specialized aspects—frontiers of physics, STS, nature of science. As fellows’ understanding of professional development grew they related this to a 4 x 3 matrix which had on one axis your classroom”, “your school”, “local schools”, “regional/national” and on the other “physics”, “learning and teaching”, “change”. Each cell of the matrix contained questions and issues of relevance.

In the latter part of 1990 modular materials were generated by groups of 5 or 6 fellows. Each had a structure for up to one hour of INSET, and each was required to focus on one physics concept from the new S&T4 curriculum and one teaching strategy. The concepts were determined by a simplistic form of Delphi technique as likely to be the more difficult ones for the teachers who would be undertaking the mass training. The teaching strategies were selected from the experiences in the program. A total of 103 modules (which we called “components”) were produced, and 53 different teaching strategies were used. In the last few weeks of the Monash program we focused on seeing the set of modules as a resource.
to be selected from. We used a building metaphor to emphasize the need to include a linkage between selected modules ("cementing") that would be different for each new purpose. A wide variety of purposes was explored by taking cells from the 4 x 3 matrix (e.g., use the modules to generate a teaching sequence for your S&T4 class, generate a 1/2 day INSET about different teaching strategies for local physics teachers). "Selecting and cementing for mass training was largely left for the 1991-2 follow up workshops.

The same broad approaches were used in the follow-up workshops in the Philippines. Clearly time was much shorter with the 28 new fellows who joined in May 1992. However the power of role models was evident here. In the 1990 program, acceptance and then valuing of our purposes and approaches by the first group of fellows was a long and demanding process. For some it took months. In May 1991, some of the new trainers had embraced much of our approach before the end of week 1. They informed us that this was due to the presence of the group who had been at Monash, and the ease with which the new fellows could check with these peers the likely value of what Monash staff were doing and asking them to do.

**Some Outcomes**

Here we give account of common outcomes among the fellows, both in terms of the 1990 program per se and in terms of subsequent actions in the Philippines. The outcomes were not, of course, common across all fellows.

Evidence of change during 1990 was strong: change in physics conceptions, in conceptions of pedagogy, and in awareness of the conditions appropriate for fostering change. While much "conventional" data (e.g., test performance) supports this assertion of considerable change, more powerful evidence is found in fellows' diaries and other manifestations of their changing perceptions. The planned absence of a detailed yearlong program when the fellows arrived is a good example of this. This absence was very distressing to them all. Some months later most had changed to the point where they could argue why such a year-long timetable would have been inappropriate, and indeed often made suggestions to change the plans for the current few weeks. Most also accepted and could articulate the position that experiencing the flexibility of our program was a necessary part of understanding the absence of a detailed timetable. Our choice of physics content for our starting point—teaching of mechanics and heat—was also an initial problem. We began with this content as about 50% of the weekly program for two related reasons: while it was seen as familiar content by the fellows, as both areas were central to both the existing Grade 10 physics curriculum and to S&T4, we were aware both from the extensive research literature and from the physics tests done by the fellows during the selection of participants that their understanding of these content areas was not always deep; and we intended to teach this partially understood content via the new pedagogies we were anxious to have the fellows experience. The early focus on these content areas however caused considerable unrest among the fellows who expected to be learning those topics which were new in S&T4, and hence unfamiliar to them. We had also planned early sessions (about 25% of the program) on the general Science, Technology, Society (STS) curriculum movement to which the new S&T1-4 programs were a Filipino response. At this early stage of the Monash program this strand had no resonance with the fellows' conceptions of and expectations about the Monash program. We hastily deferred considerations of STS until later in the year and began to consider physics topics which were new to S&T4—radioactivity then nuclear energy. In this way we did attempt to be responsive to where the fellows were in their thinking about the program and in their initial ideas and beliefs of what it was going to mean to be a trainer of other teachers.

In terms of the fundamental purposes of the project our data about fellows' activities on their return to the Philippines, and subsequently the activities of the group who joined in May 1991, are more important. At the first follow up in January 1991 we asked the 31 high school teacher members of the group to describe anything they had attempted to do since returning from Monash two months before. All but one gave convincing accounts of the trials and successes of their use of alternative teaching strategies in their own S&T4 classrooms. A significant number had already run informal INSET sessions for local physics teachers. One had initiated lunch time seminars on alternative teaching strategies for pre-service students on teaching practice in his school with the student teachers being from all school subject areas. This activity in areas other than mass training continued to grow throughout 1991-2, with the whole gamut of likely practices being evident (from individual classroom work to ongoing INSET).

As already noted we were unable to be present at the mass training. However PASMEP staff based in the Philippines were, and we have their reports, feedback from the trainers, and an occasional evaluation from a teacher being trained. These data point to a consistent feature which separated this mass training from the more usual approach to
INSET in the Philippines. The trainers had indeed accepted the need for them to be pedagogical role models for their trainees, and the fundamental importance of this to the trainees at least considering adopting the new teaching strategies included in mass training for their own classrooms.

The whole program can be characterized, in an aquatic metaphor, as a long soak followed by repeats of intensive swims. Between the swims (the follow up workshops) there were other significant events and aspects with which Monash was not directly involved. These aspects provided temporary but very important opportunities for the fellows and the Philippines-based staff to experience ownership of and responsibility for the future of a physics curriculum that was always theirs and never some Australian imposition. Each of these aspects also contributed to the support and network issues we have addressed above. They included curriculum and equipment workshops conducted by PASMEP staff in the Philippines, fellows collaborating in the provision of regional and local INSET programs, and, most importantly, the strong support for PASMEP and the trainers given by staff at ISMED and by the Director of the Bureau of Secondary Education. The active support of these significant local educational agents has encouraged trainers to pursue their INSET work beyond mass training, and has led also to the formation of a PASMEP alumni. This body provides a structure for maintaining the network in the absence of PASMEP which has now formally concluded. We have, indeed, learnt a great deal about how co-operative action, in which the initiatives shift from one partner to the other until the intended consequences of the action are established and ongoing, can be mutually rewarding.

ACKNOWLEDGEMENTS: Many outstanding professionals contributed to the success of the PASMEP S&T4 program. We particularly acknowledge Mrs. Mary Brown, Ms. Helen For gasz, Mr. John Gipps, Ms. Christina Hart, Dr. Ian Mitchell, Ms. Joan Szalman (Monash University): Mr. Geoff Sanderson, Mr. Garry White and other PASMEP staff; Ms. Nenita Crisologo and staff of EDPI-TAF, Department of Education, Culture and Sports, Republic of the Philippines; Ms. Jo Pabilio and the other physics staff of ISMED; Dr. Avelina Ilagas, Director of the Bureau of Secondary Educations, Department of Education, Culture and Sports, Republic of the Philippines, who not only provided all the bureaucratic support which only her of fice could give but did so in a most insightful and inspiring manner.

Editor Note: Science safety concerns are not unique to one country. The goal of this paper is to describe the findings from the United States so other organizations and countries consider examining their own situation. The author may be contacted directly for copies of the survey instrument.

Methodology

The author became very concerned about how this lack of safety knowledge might translate into safe teaching and learning in our nation’s school science environments. He decided to try more formal assessment techniques to verify suspicions. In early 1994 written survey questionnaires were prepared addressing three major aspects of science safety:

- Safety Management
- Chemical Management
- Legal Aspects

It was anticipated that these questionnaires would be administered at the beginning of all safety training programs conducted by the author over a year’s time. Table 1 outlines the specific items addressed within the three major safety components. In many instances, the participants could not relate to the items at all. In extreme cases, they were totally unaware of even the need to know.

In a one-year period, 300 science educators were surveyed at the beginning of each workshop conducted in the states of California, Illinois, Louisiana, Mississippi, New Jersey, Oklahoma, Pennsylvania, Tennessee, Texas, and Utah. These workshops included NSTA conventions, State Department of Education hosted seminars, and local district training programs. All participants were volunteers.

Background

During the past 10 years there has been a great deal of federal, state, and professional or organizational activity surrounding safety in science settings. Thousands of orientation and training programs for professional science educators (supervisors, teachers, preservice professionals) were offered. This author has conducted safety programs at national and regional meetings of the National Science Teachers Association (NSTA) as well as state and local settings for the past 15 years. In the last year, however, he became concerned about the effectiveness of such efforts and decided to attempt to assess participant understanding of safety issues. At first the inquiries were limited to informal inquiries of the participants, however, when it became clear that there was a problem with teacher understanding of vital issues, he decided to probe into the issue in a more formal manner.
Table 1

Science Safety Survey Items

Legal Issues
Tort law
Sovereign immunity
Save harmless provision
Negligence
Due care teaching duties

Safety Management Issues
Equipment
Ground fault interrupters
Fire extinguishers
Eye protective equipment

Facilities
Entrances & exits
Exhaust hoods
Drench showers

Procedures
Placement of safety equipment items
Class size limitations

Chemical Management Issues
Storage
Right-to-Know legislation
Chemical Hygiene Plan legislation
NFPA Hazard rating system
MSDS

Safety Management Issues

This component of the assessment focused on performing safety assessments of teaching techniques, equipment used in teaching, and the teaching environments used.

Only 16% (48 of 300) of participants assessed knew the function of ground fault interrupters (GFI’s). This strategic piece of safety equipment helps prevent electrocution due primarily to faulty grounds in electrical wiring. They are typically placed on electrical outlets in close proximity to faucets, where the reliability of electrical grounds is uncertain—as in older buildings, or where other potential electrical problems exist.

Fourteen percent (41 of 300) of participants knew the best type of fire extinguisher to place in science labs. For most general labs, ABC tri-class dry chemical extinguishers are generally recommended, unless there are other unusual circumstances which exist. Where computers, or other sensitive electronic equipment items are a regular part of the lab, halon extinguishers are generally recommended. The author, a commercial airplane pilot, knows that halon has been used in the aviation community for more than a decade because of its effectiveness in extinguishing all three classes of combustible materials (paper, grease/alcohol, electrical). Halon also provides “reasonable” pilot health protection when used in the confines of a closed cockpit.

Only 4% (12 of 300) of participants knew the American National Standards Institute (ANSI) symbol for compliance with breakage and burn standards for eye protective equipment items such as goggles. ANSI, an independent testing agency, tests many types of safety equipment and then certifies them for government regulations. The Z87 symbol, reflecting compliance with this ANSI clause, is generally placed on the faceplate and/or molding of the goggle along with the manufacturer’s trademark. Compliance with this standard guarantees that the goggles will not burn under normal conditions. In addition, they will not break, shatter, splinter, or fall backwards into the user’s face, when subject to the impact of a 1” ball bearing dropped from 50” or when impacted by a quantity of 1/4” ball bearings traveling at 150 feet per second.

Nineteen percent (58 of 300) of participants knew that, unless other circumstances dictate, chemical exhaust hoods should be placed as far away from primary lab entrances/exits as possible. Air would be drawn from the primary entrance across the room and exhausted through the hood. This placement also prevents explosions, or other complications in the hood, from blocking the primary exit to the lab.

Seventy-one percent (212 of 300) of participants knew that science labs should have at least two entrances/exits and that these should accommodate various human handicaps (wheel chair, crutches, etc.). Doors to these entrances/exits should also open outward in order to facilitate rapid egress during emergencies. Such portals should also be kept clear of clutter. All laboratories should be designed with efficient, safe egress as a priority. Subpart E of 29 Occupational Safety and Health Association (OSHA) 1910, contains specific minimum requirements for exits and egress in case of general emergencies and fires. The 1988 Uniform Building Code requires educational laboratories using hazardous chemicals to have two exits from any room larger than 500 square feet. The doors from a high hazard area, such as a lab, should swing out in the direction of travel (outward opening doors). They should be clearly marked to assure safe egress in the event of an emergency in which one doorway becomes impassable.

Twenty-one percent (63 of 300) of participants knew that, in the event of a chemical splash to the eye, that medical experts recommend flushing with temperate, aerated water for 15 minutes. This time frame helps assure dilution of the damaging chemical until the victim can reach medical help. Application
of neutralizing chemicals is not generally recommended without specific directions from qualified medical personnel.

Eighteen percent (55 of 300) of participants knew the recommendation of the National Science Teachers Association (NSTA), and now supported by numerous other science education professional science organizations, for class/lab size limitations. The NSTA suggests a minimum of 5.5 square meters per student in a combined classroom/laboratory and four square meters per student in a separate lab area. Because of safety considerations and the individual attention needed by students in laboratories, science classes should be limited to 24 students in elementary, middle level, and high school science labs unless a team of teachers is available. In addition, “a minimum of one square meter of laboratory space per student” is recommended.

The Council of State Science Supervisors in its Exeter III report recommended 24 students as a limit. The Texas Education Agency recommends 60 sq. ft. of floor space per student (includes teacher prep areas, store rooms) and a maximum class size of 24 in the high school science labs.

Jay Young, safety expert, suggests that 25 is a maximum for the number of persons in a laboratory. In 1972, Young indicated that the accident potential for a class increases when the square feet area per student falls below 41.

Louie DiBerardinis states that experience shows that 32 ft$^2$ per student is an absolute minimum for a teaching laboratory. And this minimum assumes that other aspects of the design allow ideal placement of hoods and adequate circulation about and egress from the room during an emergency.

The architect will generally note the student capacity of the room based upon its physical dimensions. In many instances, the capacity will be premised upon the number of work stations that the plumbing, electrical outlets, and gas jets can accommodate in addition to the square footage area of the room. Teachers should be cautious not to exceed the suggested capacity of the room if laboratory activities are to be a regular part of the science courses to be taught there. Physics labs, for instance, that are capable of producing ignition sources should not, ideally, be combined with chemical laboratories that use flammable liquids and gases.

The Uniform Fire Code classifies science laboratory classes as academic subjects and specifies 20 sq. ft./student. The California Administrative Code, Title II, subchapter 4, section 18111(a) requires the state architect to design labs with 1300 sq. ft. of floor space (including preparation and storage space) for 26 students in grades 7-12 or 24 students in grades 9-12 (50 or 54 ft$^2$ or 4.5 m$^2$ or 4.9 m$^2$ per student respectively). The California Department of Education suggests that the following items be considered when making this decision: “1. the number of students that one teacher can supervise in a potentially dangerous activity, 2. the degree of personal risk, 3. the increased liability when class size exceeds 24 students, 4. the level of maturity and knowledge of safety that students bring to the science laboratory, 5. the space required for each student to perform experiments safely.”

**Chemical Management Issue**

This section of the assessment encompassed chemical labeling, storage, and hazard assessments.

Twenty five percent (74 of 300) of participants knew that chemicals are best stored by chemical family. This method helps eliminate unwanted chemical reactions in the event of container breakage, it facilitates chemical association to properties, and it helps assure compliance with “Right-to-Know” and “Chemical Hygiene Plan” requirements.

Only 1% (3 of 300) of participants could identify the major requirements of the OSHA Hazard Communication Standard or “Right-to-Know” (RTK) Legislation, pertaining to hazardous chemicals in the workplace. This legislation was originally drafted as Final Rule in 1983 and became effective November 25, 1985. The standard can be found in Title 29 of the Code of Federal Regulations in Subpart 2 of Part 1910 (Federal Register, November 25, 1989 and August 24, 1987). This OSHA regulation, similar to many others, have compliances based on national consensus standards from such organizations as the American National Standards Institute (ANSI), National Fire Protection Association (NFPA), and the Department of Transportation (DOT).

All privately financed educational institutions are covered by the federal standard as well as the Right-to-Know laws in force in their respective states. Publicly funded schools must comply with their respective state government statutes. All RTK legislation is designed to help employees recognize and eliminate the dangers associated with hazardous materials in their workplace. The legislation requires that a written program be developed and that all affected employees know it’s contents. The details of such legislation will vary from state to state. Check with your Department of Education, federal (Chemical Emergency Procedures and Right-to-Know questions 1-800-424-9346) or state OSHA office, or Department of Labor. The plan need
not be lengthy; however, it must include these components:

1. Written Hazard Assessment Procedures, including: designation of responsible individual(s) or agency, consideration of scientific evidence for health hazards, evaluation of physical hazards, consideration of regulated chemicals, and assessment of chemicals prepared on site.

2. Material Safety Data Sheets (MSDS's), including: designated person responsible for maintaining the sheets, procedures for apprising and allowing employees access to them, procedures to follow when MSDS's are not received, procedures for updating the sheets, and descriptions of alternatives to actual sheets in the work area.

3. Labels and Warnings, including: designated person responsible for ensuring proper labeling of chemicals, description of labeling system, and procedure for updating the labeling information.

4. Employee Training, including: designation of person responsible for conducting training, format of the program, documentation of training, and procedures for training new employees. The ultimate purpose is to assure a safe workplace.

A 1991 electronic survey of the 50 state departments of education, by Gerlovich, indicated that 39 states currently recognize either the federal or state versions of the RTK legislation. States with their own version of the RTK must assure that the guidelines are at least as stringent as those of the federal government in protecting employees from hazardous chemicals.

Only 1% (4 of 300) participants could identify the major components of the OSHA Chemical Hygiene Plan (29 CFR, 1910.1450). As of January 31, 1991, laboratories engaged in activities that are encompassed within the definition of “laboratory use” must have in place a written Chemical Hygiene Plan (CHP) outlining how the facility will comply. This OSHA standard applies to all employers engaged in the laboratory use of chemicals. “Laboratory use” means:

- chemicals are manipulated on a laboratory scale where the chemicals are handled in containers designed to be safely and easily manipulated by one person;
- multiple chemical procedures are used; procedures are not of a production process;
- protective laboratory equipment and practices are in common use to minimize employee exposure.”

The legislation became effective January 31, 1991. The plan requires that employers, including schools, develop a comprehensive plan for identifying and dealing with chemical hazards. The plan must include all employees who could be exposed to these chemicals and it must be updated annually.

Legal Issues

This component of the assessment focused on legal issues which educators must understand to help avoid negligence and potential liability surrounding accidents involving their teaching.

Forty-five percent (136 of 300) of the participants knew nothing about tort law and its focus upon personal physical injury cases. The remainder of the legal issues addressed all focus on components of tort law in education.

Nine percent (27 of 300) of the participants knew that “sovereign immunity doctrines” were once used effectively as legal defenses for teachers in tort negligence cases. Sovereign immunity is a carry-over of British law which states that certain parties were sovereign and thus immune from negligence suits. At one time government agencies, including schools and its employees, were covered by this immunity. It is very rare today, having been superseded by insurance and “save harmless” provisions to tort law.

Only 8% (25 of 300) of the participants knew that the “save harmless provision” is currently used as a powerful defense for educators in tort negligence cases. The save harmless provision is nearly universally applied in all states. It generally states that accidents can happen, parties can be injured by educators, and law suits can be filed against the educator. However, unless it can be proven that the educator broke the law (goggle legislation, Right-to-know legislation, etc.), or were grossly negligent (violated well accepted professional or manizational guidelines, established codes, department of education standards, etc.), they would be defended to the limits of the resources of the school district or state.

Twenty-two percent (66 of 300) of participants could explain what constituted negligence in science education. Generally speaking, negligence is defined as conduct which falls below a standard set by the law or one’s profession to protect others from injury. Lack of “due care” is another legal synonym. Educators must conform to the civil laws of society as well as applicable codes (fire, electrical, plumbing, etc.) and standards (professional standards of performance, state Right-to-Know, Chemical Hygiene, Bloodborne Pathogen legislation, etc.) in order to assure a safe teaching and learning environment.
Only 6% (19 of 300) of participants knew that “due care” was a synonym for assuring that the educator was not negligent, and that it consisted of satisfying three major duties. First, is Instruction appropriate for ALL students in one’s charge (inclusion or special education students, students with special medical needs, etc.)? Second, is Supervision adequate for the situation, surroundings, student population being served, and activities being conducted? Is the environment (equipment, instructional surroundings) properly Maintained? Satisfying these duties helps assure that the educators in charge are not negligent should an accident occur.

Conclusions

There is little doubt that moral, ethical, and now legal responsibilities of science educators have increased in the past 10 years. Education has become a recognized profession by a good part of our society. As such, the public expects certain levels of knowledge, conduct, and foreseeability on the part of those employed within this profession. They also assume that science educators will keep themselves informed concerning recent advances in their field, especially if such information relates to the safety of their children.

This study indicates that there is reason to suspect that the level of basic knowledge of many science educators is marginal at best. Is this the fault of teacher preparation programs for not requiring such education as part of their graduation requirements? Or is it the fault of inservice training programs for not making the information more readily available to professionals? Or could it be that state licensing boards are not doing their jobs by allowing licensure without such information? Or are science educators themselves at fault for not demanding such training? It appears that all of these organizations and professionals bear some of the responsibility for seeing that science is taught to students in an effective and safe manner.

There is little purpose served by pointing fingers of fault. We must recognize that safety in science teaching is a huge undertaking and requires a cooperative effort from ALL parties involved—professionals, government, the courts, parents, and even students.

For the purposes of this study, it was revealing to discover what science education professionals actually know regarding science safety. More importantly it indicated that much more research is needed in this area of safety understandings and perceptions.

**ASE ANNUAL MEETING**

**January 4-6, 1996**

**The University of Reading**

The Association for Science Education will be holding the 1996 Annual Meeting at the University of Reading next January. Reading is the most accessible of venues for those coming by air. There is a direct rail service from Gatwick Airport and a direct coach service from Heathrow.

Although the meeting officially starts on January 4th, there will be a special International Seminar organised jointly by ASE and ICASE on Wednesday, January 3rd. The subject will be "Continuing professional development of the science teacher" and contributors are very much welcomed. There will be accommodations available on Tuesday, January 2nd, for those attending.

As well as the British Council symposium and an international reception, there will be hundreds of sessions to interest and inspire, whatever the level—primary secondary, tertiary, or higher education.

E-mail: chemed96@ceu.uq.oz.au

The 14th ICCE will be held in Brisbane from July 14-19, 1996. It is only the second time this conference has been held in the southern hemisphere. The biennial conference brings together chemistry teachers, chemists and science educators from school, industry and university settings to share ideas and learn from one another about innovation in teaching and learning and the discipline of chemistry. The theme, Chemistry: Expanding the Boundaries, acknowledges the centrality of chemistry through its expanding relationship with many facets of science and everyday life. Conference participants will be challenged to develop this theme with the view of enhancing our understanding of the important relationships which chemistry forms with the new frontiers of human endeavour. Implications for chemical education beyond 2000 which give a “science for all” perspective will be encouraged.

August 4-8, 1996
14th Bicentennial Conference on Chemical Education
Location: Clemson University, Clemson, SC
Contact: DeWitt Stone, BCCE General Chair, 206 Sikes Hall, Clemson, SC 29634-5170
Fax: (803) 656-1515; e-mail: bcce@clemson.edu
WWW address: “http://tigerched.clemson.edu”

The Planning Committee has selected “Chemistry: The Challenge of Change” as the conference theme. The uses of computers and multimedia technology in chemistry teaching will be a particular focus of this conference. Another focus will be topics such as biotechnology, polymers, textiles, advanced materials, and environmental science—fields in which chemistry overlaps with the interests of other disciplines.

November 1996
Australian Model Solar Car Challenge
Location: Adelaide, Australia
Contact: Brenton Honeyman, Chair, AMSCC
The National Science and Technology Centre
King Edward Terrace, Canberra ACT 2600
Tel: (06) 270 2816
Fax: (06) 273 4346

In November 1996 students from across Australia will meet in Adelaide to compete in the Australian Model Solar Car Challenge, the culmination of state-based challenges conducted from September to November in New South Wales, Victoria, Queensland, South Australia, Western Australia, Tasmania, and the ACT.

December 27-30, 1996
NSTA International Convention
Location: San Francisco, CA
The convention, to be chaired by NSTA Executive Director Bill G. Aldridge, will bring together scientists and K-college science educators from dozens of science and science education societies and organizations worldwide. Invitations have already been sent to societies in more than 30 countries. Holding the event in San Francisco, it is hoped, will especially encourage participation from Pacific Rim countries.

At this convention, participating teachers and science educators will present sessions in their areas of expertise (interdisciplinary approaches are encouraged) to scientists who are not as familiar with the classroom. In turn, scientists will present sessions about their work to nonspecialist scientists and to educators less familiar with the latest news from the research laboratory.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

PARTNERS IN CHEMICAL EDUCATION: AN INTERNATIONAL CONFERENCE ON INDUSTRY-EDUCATION INITIATIVES IN CHEMISTRY

The Partners in Chemical Education Conference was held August 27-September 1, 1995 at the University of York, York, UK. Pictured below is Professor David Waddington, Chemistry Professor at the University of York, who hosted the conference, and Anna Garner, ICASE President Elect.

THE CHALLENGE

Jack Holbrook

ICASE continues to promote Project 2000+ to its member organisations and encourage them to undertake activities to promote scientific and technological literacy for all (STL) among its members. The 21st century is very close and the Project 2000+ Declaration, put forward as a worldwide goal, states that “appropriate structures and activities should be in place by the year 2001 to foster scientific and technological literacy.” ICASE, as a member of the Project 2000+ international steering committee, supports this declaration and recommends it to its members.

It is the meaning attached to “scientific and technological literacy” and “how this can be attained” that is at the heart of the challenge. It seems there is a big gap between “teacher-centred instruction” and “the development of skills and values in student-centred classrooms considered necessary for enhancing scientific and technological literacy for all.” And it is the “FOR ALL,” i.e., necessary for all students, that is of particular importance.

How do we get the average teacher to accept this meaning and embrace STL in their classrooms? How can we get teachers to

- realise that science education is not simply the acquisition of facts, concepts or even the process of being a scientist.
- to accept that there is a values education component to science education and this is embedded in the intended curriculum
- realise that student learning needs student involvement (involvement in homework, classroom thinking, investigating through experimentation, writing, communication in general, in solving societal problems which encompass science and in making societal decisions in which science has a part to play).
- realise that in areas where students proceed slowly and need help (planning approaches/investigations, carrying out experiments, analysing data and opinions) need more
attention not less in the teaching process, more practice is appropriate, not less.

• realise that statements by the teacher, such as “I need to finish the syllabus” have no meaning. At best it draws attention to the gap between the teacher’s teaching and students’ learning. To guide the students to complete the syllabus is much more in keeping with STL.

ICASE cannot do this. ICASE is an umbrella for its member organisations. ICASE can only encourage and support its member organisations to find ways to promote scientific and technological ideas to its members and to consider ways in which this can be made more meaningful to teachers in their day-to-day teaching.

Here are some possible ways to reflect on STL. (Does your organisation agree? Is your organisation promoting any of these? If so, how? Why not write an article in the ICASE journal?)

• make teaching more student-centred
• increase meaningful feedback from students through written, verbal, graphical, diagrammatical, manipulative, attitudinal mechanisms
• increase higher order thinking within the classroom (students need to think). It is insufficient to simply state or predict observations. This is but a small part of science education. It is certainly insufficient to follow a recipe (such as worksheet instructions)
• teach from the application or concern or issue to the concept
• teach from the familiar and from what students know of this to the unknown (don’t teach what they already know)
• teach in a logical sequence, BUT LOGICAL FOR THE STUDENT, not simply according to scientists (e.g., chemistry is not necessarily microscopic ideas. Only if it can be related directly to an area of relevance to society is a sequence recommended.).
• if a topic (or part of a topic) is too difficult for the students, leave it out. [The topic can always be revisited later.]
• teach the students. Don’t simply quote the textbook. The textbook is science ideas. It is not science education. The students need education. Science is the vehicle for this education. The textbook is an aid, not the substance.

May 1996 be a challenge and rewarding year as we each face these and many other educational challenges.

ICASE WELCOMES THE CHINESE SCIENCE EDUCATION SOCIETY

The Chinese Science Education Society has been accepted as a full member of ICASE. The society was founded in 1988 and is a nationwide academic community. The society consists of 480 members with professors, teachers, officials, and some student members. Most of their members are active leaders in the field of science education for academic research, service, and national policy formation. The activities include the annual Science Education Conference, publications of conference proceedings, and the Chinese Journal of Science Education. In the past, they have selected many outstanding young scholars to attend the international conferences and assessed science education research programs under the authority of the Ministry of Education.

NEW CHALLENGES IN SCIENCE EDUCATION:  
THE BIRTH OF "PRIME" SCIENCE

Introduction

Prime Science is a major new development in science education in the United States. It is a course for Grades 6-10 which is being designed by two groups, one at the University of California, Berkeley and the other at the University of York, UK. In this paper the history of the project is traced against the background of fundamental changes in science education which are occurring in the US and UK, pointing out the similarities in thought and delivery of national guidelines.

PRIME Science is a multidisciplinary course, encompassing astronomy, biology, chemistry, earth sciences, geology, and physics from Grades 6 to 10 which is being developed by a team of practising science teachers from universities and schools in the two countries; it is probably the first international endeavour in curriculum development in science on such a large scale. The course responds to the challenge of the AAAS Project 2061, NSTA’s Scope, Sequence and Coordination Project, and initial documents from the National Science Education Standards, both in terms of content and assessment; and it can be adapted readily to recent state frameworks.

Why should teachers from the US and UK come together to produce a science course? It is more usual to learn from each other during visits and conferences, and through the literature. What are the advantages of actually working together?

National Changes in Science Education

The US and UK are undergoing similar fundamental changes in their national educational strategies, focussed by political debate. One of the most important elements in this strategy, the enhancement of the role of science and technology education in the school curriculum, is at the core of the debate. Further, there is an extraordinary similarity in the two countries on the problems facing science education in schools.

There has also been a similarity in the way the political and educational debates in the two countries have unfolded. In the UK, James Callaghan, then Prime Minister, opened the discussions in 1976 in a speech which emphasized that the increasing complexity of modern life meant that standards in many areas, including education, needed to rise (Callaghan, 1976). It initiated a national debate, on four issues: the curriculum, the assessment of standards, the education and training of teachers and the relationship between school and working life (DES, 1977). One strand in the debate was the provision of science education for all, which would not only empower all students to live in an increasingly scientific and technological society but also enable and encourage intellectually able students to pursue careers based in these subject areas.

In England and Wales, reports on science education from the Department of Education and Science and Her Majesty's Inspectorate (HMI, 1981; DES, 1982, 1985, 1987) enhanced a wide-ranging discussion which included major contributions from the Association for Science Education (ASE, 1979, 1981) and the Royal Society (Royal Society, 1982). There was general agreement that science should be taught throughout a child’s period of statutory education (age 5-16) and that by the time the child was 11 years old, 10% of curriculum time should be devoted to science, climbing to 20% by the age of 14. From these discussions arose the National Curriculum in Science (DES, 1989a, 1991a; DfE, 1995), given statutory status in the Education Reform Act of 1988. The National Curriculum in Science is now organized around 4 attainment targets. For each attainment target, there are programmes of study which describe what the students should be taught (DES 1989b, 1991b, 1994). For assessment, each attainment target is described by statements of attainment at different levels.

Meanwhile, a similar concern was being raised in the United States. In A Nation at Risk in 1983, the

If we want America to remain a leader, a force for good in the world, we must lead the way in educational innovation. And if we want to combat crime and drug abuse, if we want to create hope and opportunity in the bleak corners of this country where there is now nothing but defeat and despair, we must dispel the darkness with the enlightenment that a sound and well-rounded education provides.

The teaching of science and mathematics were seen to be at the heart of the change needed (US DoE, 1991), echoed in other key reports (Carnegie, 1991; NCESS, 1992), all very similar to the UK debate.

Between the publication of A Nation at Risk and the Bush goals, two initiatives were getting under way. In 1985 the American Association for the Advancement of Science began Project 2061. Phase I produced Science for All Americans (Rutherford & Ahlgren, 1989) a detailed analysis of what a high school graduate should know: which deals with learning goals, what students should remember, understand and be able to do after they leave school. The second phase involves a compilation of ‘bench marks’ which may be used for creating a meaningful science curriculum. In a separate action, the National Science Teachers Association began its Scope, Sequence and Co-ordination Project, publishing The Content Core: A Guide for Curriculum Designers Volumes I and II (NSTA, 1992). Both reports were notable for advocating what in the UK is called a balanced science approach, namely teaching all the natural sciences, year by year to all students.

In 1991, the US National Research Council, through the National Academy of Sciences, formed a Committee on Science Education Standards and Assessment. Results from its preliminary work are explicit; science instruction should include biology, chemistry, earth/space science and physics every year for every student.

In contrast to the more detailed UK National Curriculum for Science, this US framework is organized simply in three grade groupings K-4, 5-8, 9-12 without levels of attainment. As in the UK, there is emphasis both on the nature of, and applications of science which include knowledge of the inquiry process, the ability to design and carry out an investigation, perspectives associated with critical thinking or ‘habits of mind,’ and other positive attitudes usually associated with learning.

Making it Happen

The University of York Science Education Group went beyond the question of what science should be taught to explore the question of what it would mean in practise to provide such a curriculum. As a result of this work, four new science courses were developed which are now being used extensively in UK schools, Science Focus: the Salters Approach (for Grades 6-8) (UYSEG, 1990, 1992, 1993), Science: the Salters Approach (for Grades 9-10) (Campbell et al., 1990; Ramsden et al., 1992), Chemistry: the Salters Approach (for Grades 8-10) (UYSEG, 1989; Hill et al., 1989a, 1989b) and Salters Advanced Chemistry (for Grades 11-12). The uptake by schools is, at present, rapidly expanding in the UK, Trials of the materials are taking place in many countries including the Netherlands, New Zealand, Spain and Russia and one of the courses has been translated for Belgian schools (Brandt, 1993, 1994).

In this paper, we first describe the Science Foods and Science: The Salters Approach programs, which, together, provide a multidisciplinary science education course from Grades 6-10. We then describe steps taken to create a program for the US: the PRIME Science program, based on the Science Focus and Science: The Salters Approach materials.

The Development of the Salters Approach

Science Focus and Science: The Salters Approach were developed over a period of nine years by school teachers, university educators, university scientists, and industrialists, in a collaborative venture based at the University of York (Campbell et al., 1994).

The starting points for lessons were different from those usually used. Traditional starting points for curriculum development are the concepts in science which textbook writers and teachers know are important to their subjects. For example the Classification of Living Things, Gravity and the Periodic Table have often been used as the titles for textbook chapters. The teacher begins a topic by introducing these ideas, and from time to time gives examples of how they can be applied. What if the order were reversed? Could not the issues and applications of science with which students are familiar, or which they can recognise will be of significance to them in the future, be made the starting points for study? Could not scientific theory arise as these issues and applications are explored through student investigations? We believed that if the students’ interest has been captured they will
work harder to understand the concepts. Thus, we considered the following criteria (Lazonby et al., 1992; Campbell et al., 1994):

(i) Relating the course material to life experience:
Base the content of the course on something from a students life that students have experienced either first-hand or through the media.

(ii) Allowing concepts to emerge from the context:
Introduce the underlying science concepts only when they are needed to help the student understand the topic;
Develop the content at a level appropriate to consider what students might bring to the course at that age;
Link concepts to a context that students perceive as important. Thus social, economic, industrial and technological aspects of science pervade the whole course.

(iii) Encouraging active learning and exploration:
Involve students in a wide range of activities which encouraged them to learn through active personal experience, rather than simple passive listening;
Keep students involved throughout the course by using a wide range of cooperative learning strategies such as: laboratory activities; small group discussions; creative writing and reporting; role-playing exercises for discussing value-related issues; exploration of various other decision-making activities.

Constructivist theories and research on the role of student talk in the learning process (Driver, 1988) encourage use of opportunities for discussion in a meaningful context. Furthermore, the students participate in a broad variety of activities. The new courses make students get involved in expressing their understanding of concepts; planning investigations; discussing implications of data; considering social and economic issues. The teachers' role is to provide and lead students through a variety of opportunities to learn about the science as much as to teach students directly.

Using these criteria, 27 units were produced for Grades 6-8 (Science Focus) and 23 for Grades 9-10 (Science; The Salters Approach) (Tables 1 and 2). Each unit revolves around a topic the students will already be familiar with, or ones which they quickly realise to be of significance to students. The scientific principles then emerge during discussions. For example, ideas about rates of reaction are introduced to develop an understanding of food decay in the unit Food and particulate theory is used in the unit Drinks to explain ideas about states of matter in the context of the drinks we consume. The use of bicycle helmets provides the context used to introduce the concept of pressure in the unit Moving On; space travel gives the opportunity in Earth in Space to examine the atmospheric composition of other planets; digital signals emerge in Sound Reproduction in the context of disc players; safety signs on trucks, an international language leads, in Transporting Chemicals, to another international language-chemical symbols and formulas; fire prevention is the context, in Fire, Friend or Foe, for a study of combustion; germination is introduced in Full of Beans in terms of supplying fresh vegetables all year round and the role of medicines which we use is a context in Keeping Healthy to study the body's reaction to microbial invasion.

The course is challenging for both student and teacher. Content is set in new contexts, and a wide range of learning strategies is used. Therefore, extensive guidance for teachers is provided in the materials to make the contexts and strategies clear.

The design of the materials involved significant participation by teachers. The most important criteria were that the published materials should accomplish the following:

- Give teachers a quick overview of the units within the course
- Provide detailed guidance and support for inexperienced teachers or those teaching outside of their master area
- Delineate common student misconceptions and safety points
- Include suggestions for introducing discussions
- Include suggestions for the extension and evaluation of activities
- Present a structure and format that encourages more experienced teachers to begin the process of continual review, renewal, and development of the course.

Teaching material is organized as unit guides for the teacher's use. Each begins with an overview of the unit and an overall lesson-by-lesson plan. These satisfy the first criterion.

An outline is given for each lesson in the unit—which identifies the activities, outcomes, and skills used—and satisfies the second criterion. More extensive notes follow each lesson giving further guidance; for example, in suggesting interesting questions for prompting discussion. Masters, with limited copyright for student activity guides and information sheets, are also included.

The third criterion is met by producing the unit guides in loose-leaf form. The unit guides provide the basis from which schools develop individualized teaching schemes. Lessons and parts of lessons can be modified and replaced by the teacher. It is not possible to provide for the needs of all students with a single set of worksheets, so advice is given for adapting activities for a variety of levels of attainment. Colorfully illustrated student books support the unit guides. Each chapter is based on one unit and contains five parts: a one-page student-level introduction, a collection of several text-related activities illustrating applications and uses of scientific ideas, a quick reference summarizing important points, an explanation of the scientific ideas and a collection of suggested activities for home, library, club or school, including sample test questions.

Written materials for activities for younger students are needed, which are much more highly illustrated and for units for Grades 6-8 (Science Focus) are in individual booklets entitled ‘Working with Science’ and ‘Looking into Science’ (UYSEG, 1993).

As described above, the National Curriculum for Science in the UK sets out in some detail the progress that students might be expected to make both in terms of their knowledge and understanding and of their investigational skills. Each of the unit guides contains detailed guidance and sample assessment items to assist teachers in monitoring their students’ progress in all of these areas. At the age of 16, students are also required to take examinations which are written, marked and graded by examination bodies external to the schools.

In spite of the radical nature of the Salters Approach, schools in the UK have been adopting the
course at a rapid rate, particularly when it must be remembered that it leads to an examination which is moderated nationally, and thus many teachers may baulk at the idea of putting students “at risk.” That they have not is a signal of confidence. Forty thousand students in the UK took the examination set at the end of Grade 10 in 1995, with more expected to take it in subsequent years.

The Development of PRIME Science

The similarities in the science education debate in the UK and US set the scene for an exciting new collaboration which will deliver a multidisciplinary course for grades 6-10. It began with a three-year feasibility study which included many discussions with leading US science educators and then with two one-week workshops in California.

Ten teachers from California schools and six from the development team at the University of York worked together on about eight of the units at each workshop to get a feel of the adaptations and additions necessary for US classrooms. The resulting materials have been tested in schools. Parallel to this, several schools in Oregon have evaluated the UK version of the materials as part of a research and development study (Borgford et al.). In July 1992, 10 US teachers went to York for a third workshop. Some participants had experience of the Californian workshops, giving valuable continuity. Having this workshop in the UK enabled the US team to watch the program in action in British classrooms and to talk to teachers experienced in the program.

Detailed criteria for the PRIME Science program were then developed. This program uses some of the best science teachers and educators in the US to rewrite, update, and localize each activity and each unit of the program in collaboration with the original UK team. This involves not only language and factual information embedded in the units, but changes in lesson duration, equipment for activities, safety regulations, support and reference materials, and matching content to state and national knowledge bases.

Adaptation workshops are being held in 1994 and 1995 in six states, California, Colorado, Iowa, Massachusetts, South Carolina, and Tennessee. Each site gave a unique perspective and orientation for the adaptation. Between workshops, teachers involved in them are trialling the materials. In 1995, teachers from all six states were brought together in Berkeley to undergo training in dissemination.

What is most significant about the program is that not only are major scientific concepts and skills developed over the five-year school period with sensitivity to the developmental level, but also starting lessons with a topic which is of immediate interest or easily recognized as being highly important to a student’s life. Teaching the science behind that topic through exciting student experiences is motivational and effective.

Acknowledgement

We wish to thank the National Science Foundation for funding to make possible the creation of PRIME Science and the hundreds of teachers in the US and UK who have given their time in writing and trialling the resources.

CONTEXT-RELATED CURRICULUM PLANNING:
USING THE OZONE PROBLEM

Professor Marilu Rioseco G.
Universidad de Concepcion
Direccion de Investigacion
Concepcion - Chile

Introduction
Since Chile is a narrow and long country, where the so called dilution effect of the ozone layer jeopardizes most of the land from Punta Arenas (53 degrees South) to La Serena (33 degrees South), it is necessary to prepare its population for possible ecological consequences of UV-B radiation increase.

Scientists in Chile assume part of this task by studying short and long term effects upon the different ecosystems. Education also plays a role since the problem requires an attitude change in population.

The Ozone/UV-Radiation Problem—
General Information
In over 20 years of reports from several sources, indications are that the ozone concentration is gradually and permanently decreasing each spring over Antarctica. The so called OZONE HOLE is increasing in size. But since ozone is the only element which effectively absorbs solar UV radiation, the observed depletion of the ozone layer might negatively affect life in that region.

Punta Arenas, located at the edge of the Antarctic ozone hole, is the southernmost major city in the world (53.3 degrees South). Production activity in Punta Arenas is related to wheat crops, forestry, fishery, cattle, and especially sheep. The increasing damage in the ozone layer over the region could, therefore, cause larger exposure to UV-radiation, and reduce food production both in the South of Chile and Argentina.

Research results with several atmospheric models suggest that the ozone layer depletion is the effect of many trace gases from human activity, such as CFCs (chlorofluorocarbons), CH4, N2O and CO2. Worrisome questions are posed with respect to the biological consequences of the combined seasonal and year round ozone depletion above Punta Arenas. Scientists are looking for an answer to these questions, such as how to reduce the problem and how big are the consequences upon the health of living organism; how does the depletion affect the photosynthesis process, how do living or ganism respond and which are their adaptive mechanisms for short and long term UV-B radiation exposure events, among others.

There are also some educational questions which we, as science educators, could and should attempt to answer.

The Task for Science Educators
In Chile, science teaching has as its main goals to contribute to a better quality of life, to allow the students to give a positive direction to their life, and to allow them to turn into constructive members of society who know themselves and their environment.

Closely related to these objectives is the ozone-UV radiation problem. Therefore, science teaching should consider this issue and curriculum developers should accordingly organize science content to include the ozone-UV radiation problem each school year.

The rapidly thinning ozone layer has created widespread concern among people living in this region. Since its discovery, several surveys have been conducted because Punta Arenas, due to its unique position within the ozone hole, is a living prototype model most likely 10 years ahead of the rest of the world regarding photobiological change.

The Ozono Group in the Universidad de Magallanes (UMAG) is presently undertaking a range of studies related to the Antarctic ozone hole and ground level UV radiation. Studies by the UMAG
ozone group have already shown an increase in ground levels of UV radiation by as much as 400% during the time that the ozone hole lies above southern Chile. The group has established an effective system to coordinate the dissemination of the information they receive to the public.

A number of satellite systems are presently able to collect data on high altitude ozone concentrations and to transmit this to receiver stations located in different places around the world.

The UMSG ozone group has been studying the movement of the Antarctic ozone hole for the past decade. Estimates from UV-B radiation measurements show that in 1992 approximately a doubling of the average daily exposure was experienced in Punta Arenas on those individual days on which the ozone depletion was greatest presently represent the time frame for greatest exposure: September and October.

Even though a decrease in stratospheric ozone does not necessarily translate into an increase in the dangerous short-wave UV-B, large increases in ground level UV-B (100% above normal) have been measured in the recent years in the south of Chile and Argentina. These increases correlate with the measured decrease in the ozone column.

UV-light passing through the ozone hole could alter the balance of the species that make up the different levels of the ecosystem. Several studies have been conducted in an attempt to measure the damage done by the extra UV-B radiation coming through the ozone hole. In addition, a net of 16 stations have been installed in different cities in Chile and Argentina. These stations have been provided with two types of sensors for solar UV radiation.

The effect of the increases in UV-B radiation has been studied in wheat crops. Sea plankton has also been studied. A survey has been conducted to evaluate the consequences of a short-term increase in UV-B radiation upon the ocean water. The effect of UV radiation on animals and human beings has also been studied. Studies to date have found no acute or immediate impact on human health. This may be due to small sample size and the lack of any long-term exposure studies. Nor do any data show convincing evidence of acute eye disease associated with the ozone hole. Findings related to eye disease rates among shepherds and fishermen, who spend most of the time outdoors, and among hospital workers, are uncertain. Although sheep from several ranches showed higher rates of eye infections, researchers state that ophthalmic findings could not be related to the ozone problem.

The above information shows that although direct stratospheric measurements of the ozone layer are being registered, few systematic or concerted effort exist to relate such measures to actual health effects. Nevertheless, human immunology, skin cancer, cataract and the effects of UV radiation in the Antarctic region have been identified as priority research areas for populations exposed to ozone depletion conditions.

Several multidisciplinary teams have been formed and have designed pilot studies, such as described above, to identify possible health effects associated with the ozone hole over southern Chile.

There is no doubt that major and more accurate information is needed to successfully confront not only the potentially dramatic Antarctic ozone hole created by our civilization, but also the unforeseen problems reserved for our future world population.

Teaching in Context

Science educators are aware of these and other related issues which affect society. For some years science education has not only been seen as that curriculum component which provides the students with scientific knowledge and prepares them for future scientific studies, but also as an important component of their personal development. Science for all is the idea. Science for the citizen, science for daily life, science for the job, science for the scientist.

One of the problems which science educators must face is the students' lack of interest in science. From the application of an interest questionnaire developed at the Institute for Science Education (IPN), in Kiel, Germany, and translated to Spanish at the University of Concepcion, it has been possible to gather information. The questionnaire was applied to a sample of about 2,000 students from grades 5 to 12 in Concepcion. Results indicate that not many students show high or very high interest in the different topics of physics. While by grade 5 around 60% of students show interest, by grade 12, less than 50% are interested. A significant decrease appears along the school years.

However, this study has also shown that some topics attract the students better than others. The contexts which arise more interest in students are those related to health, environment, and society issues.

Chilean educational authorities are concerned about the lack of student interest in science-related professions. The 1995 admission process to universities showed many careers in the science and technology area (engineering, science teachers, among others) where vacancies of fered were not filled. Compared to the situation in 1984, the above
is especially worrisome. At that time applications were close to double the number of vacancies of ered. Critical is the case of Mathematics and Physics Teachers Training and Bachelors in Physics, where for each 10 vacancies there are only 4 to 8 applicants.

In an effort to revert the situation, modern approaches to science teaching have identified five contexts under which science should be taught. These are considered as suitable for someone living in our society as it is and as it will be tomorrow. "This 'someone' is everyone, male or female, beginning with the youth who has finished his schooling and is looking for an apprenticeship, and including the retiree who goes for walks in the park and whose favorite pastime is playing pinochle with his old friends" (Haussler et al., 1988, p. 2).

The suitable science education for this 'someone' means not only passing on scientific knowledge but also understanding scientific and technological developments and their consequences, recognising dangers arising from scientific and technological developments, avoiding sources of danger and accidents in daily life, knowledge of technical systems, appliances, etc., found in the home or used in maintaining a household, using positively the leisure time, positively integrating the social and public spheres, acquiring an understanding of the work world and the basic qualifications for employment. It also means personal emotional development, subjective satisfaction from learning about the natural sciences, personal intellectual development, and enlightenment. Corresponding to this view of science education, several topics were identified as suitable curriculum content for science courses.

The Chilean school science program, although divided into biology, chemistry, and physics, allow flexibility in choosing how to organize the content. We will discuss the physics curriculum structure and how teaching in context can be applied. The curriculum traditionally consists of basic content and optional modules where different applications are analysed. The teaching in context curriculum recommends not to start from the basic contents and discuss later (if possible) some applications, but to start from a real problem (a so-called application problem) and from there on to motivate the students to seek for explanations in the structures (concepts, laws, scientific processes or procedures, etc.)

This approach has proved successful in physics. It has been applied for three years by a group of teachers who collaborate with us at the University of Concepcion. They report that pupils show more interest than when working in a more traditional way. Achievement tests also show a satisfactory level of learning. Information gathered through an opinion questionnaire given to pupils indicates that they liked this approach. It is time to consider expanding this approach to include biology and chemistry. Table 1 describes the present science Chilean curriculum for secondary school (grades 9 to 12):

Our proposal has the following main objectives:

A. To enable the person:
   - to perceive and to make judgments on the intimate connections between scientific and technological developments, on the one hand, and economic and political developments on the other;
   - to integrate scientific and technological developments with the science knowledge he/she already has;
   - to understand and to pass judgment on misdevelopments and their consequences for the environment;
   - to act with full awareness of his/her social responsibility and to reflect critically on what he/she is doing;
   - to discuss current problems and to translate one's own insights into socio-political action.

B. To make it easier for the person to meet the demands made in daily life, with knowledge and understanding of the ways in which technical objects function, in which one must deal with them so as to recognise sources of danger and to avoid accidents.

C. To enhance and guide the attitudes and feelings with which a human being confronts nature and technology and in this way furthers personal emotional development and to lead to the person's voluntary engagement with science for its own sake and in a subjectively satisfying way.

D. To pass on important parts of scientific knowledge, developing cognitive abilities as well as scientific methods of thought and conceptual schemas, providing also an accurate picture of the world and of the laws which govern it, thus contributing to the individual awareness and understanding of both the natural and the technological environment.

E. To impart the basic qualifications for many occupations and to give a glimpse into the technical work world and the occupations which are shaped by the science.

The ozone problem is a real problem in Chile and provides an excellent opportunity to help students make connections between the content of chemistry, biology, and physics. Table 2 shows the content of physics, chemistry, and biology as organized around the ozone hole problem.

---

Table 2
The Proposal: Physics, Chemistry and Biology Basic Contents
Theme: The Ozone Hole, A Menace To The Quality Of Life

9th grade
1. The sun, our main source of energy
   1.1 The light of the sun allows the life in earth: photosynthetic activity and atmospheric CO2-O2 balance
   1.2 The light of the sun is a wave
   1.3 Waves transport energy
   1.4 Energy is necessary for human activity
   1.5 Different sources of energy
   1.6 Waves elements: speed, frequency, wavelength, amplitude
   1.7 Sun light consists on different wavelengths
   1.8 UV radiation is part of the sun light
   1.9 The effect of waves depends upon their wavelength

2. Air is important for living beings
   2.1 Air is composed by different elements
   2.2 Ozone is a component of the atmosphere
   2.3 Ozone protects the quality of life in earth
   2.4 Ozone uses energy from UV radiation and absorbs it
   2.5 Air is polluted by human activity
   2.6 Some air pollutants destroy the ozone layer

3. Food is necessary for our health
   3.1 Nature provides food for all living beings
   3.2 Living beings interact among others and with the environment
   3.3 Soil, water and air contribute to ecological balance
   3.4 Fresh food is important for our health
   3.5 The sun makes life possible but heat damages fresh food
   3.6 Cold allows to preserve food

Science Education International, Vol. 6, No. 4 December 1995
3.7 Industry contributes to preserve food
3.8 Industry uses different processes to preserve food
3.9 Food is preserved in freezers
3.10 Freezers design includes the use of some products which can damage the ozone
3.11 Science and technology seek substitute products for freezers design which do not damage the ozone

10th grade
1. Food is important for mankind
   1.1 Chemical industry contributes to food production
   1.2 Food provides energy
   1.3 The sun provides heat energy
   1.4 Heat transfer is important for the atmospheric behavior
   1.5 Atmospheric pollution is affected by atmospheric thermodynamic processes
   1.6 Ozone concentration in the atmosphere is affected by climatic conditions
   1.7 Ozone filters UV radiation coming from the sun
   1.8 Much of our food comes from the ocean water
   1.9 UV radiation penetrates the water
   1.10 UV radiation alters life in water systems
2. The UV radiation and the electromagnetic spectrum
   2.1 Waves are reflected, refracted, diffracted and absorbed
   2.2 Electromagnetic waves - the electromagnetic spectrum
   2.3 Electromagnetic waves travel in space
   2.4 The atmosphere reflects, refracts, diffracts and absorbs electromagnetic waves
   2.5 UV radiation is absorbed by the ozone
   2.6 The ozone protects from UV radiation
3. The cell as basic structure and origin of living beings
   3.1 The cell structure
   3.2 Chemical components of the cell
   3.3 UV radiation affects the cells
   3.4 Diversity of living beings - phytoplankton and zooplankton
   3.5 UV radiation affects the different ecosystems
   3.6 Living beings adapt to changes in the environment
   3.7 Man activity changes the environment
   3.8 Man is responsible for preserving the environment

11th grade
1. Optical systems help man
   1.1 The microscope helps to study the cell
   1.2 Optical systems in the microscope
   1.3 Optical systems help to study the space
   1.4 Our eye, an optical system
   1.5 The eye suffers with UV radiation
   1.6 UV radiation intensity depends upon atmospheric conditions
   1.7 UV radiation changes together with ozone concentration in the atmosphere
2. Energy is necessary for chemical change
   2.1 Matter is made out of atoms
   2.2 Atoms have electric components
   2.3 Atoms emit waves
   2.4 Emission spectrum
   2.5 The study of light through its spectrum
   2.6 Energy participates in all chemical change
   2.7 UV radiation transports energy
   2.8 UV radiation provides energy for atmospheric reactions (O2 and O3)
3. The eye, as main information receptor for man and animals
   3.1 The eye structure
3.2 Vision and eye health
3.3 UV-B radiation damages the eye
3.4 How to protect the eye from UV-B radiation

12th grade
1. Carbon, an important element
   1.1 Carbon in chemical industry
   1.2 CFCs are made out of carbon
   1.3 CFCs are used in cold food preservation industry
   1.4 CFCs are used to isolate and save energy
   1.5 Cosmetic industry uses CFCs
   1.6 CFCs emission to the atmosphere
   1.7 CFCs reactions with the ozone
   1.8 CFCs destroy the ozone layer
2. Heredity and ADN
   2.1 ADN structure
   2.2 Genetic code
   2.3 Mutations and ADN
   2.4 UV radiation damages the ADN
   2.5 Skin health and UV radiation
   2.6 Cosmetic industry helps to protect the skin
   2.7 UV radiation in medicine

Closing Comments
It is important that Physics, Biology, and Chemistry teachers integrate among themselves. Students should see that each science has a role to play with respect to the ozone/UV-B radiation problem. Thus learning will turn meaningful. They will make different connections between the concepts studied in each course and the ozone problem will serve as a good organizer of knowledge.

As always, each teacher should emphasize the context which relates best to their actual school, students, and local environment conditions.

Editor's Comment:
It is important to remind readers that thematic teaching approaches, such as the Ozone theme, reorganize the content of science and ultimately help students find meaning and usefulness for this body of knowledge called science. In other words, we are not teaching Ozone, but are using themes and issues of interest to students to make the content of science and other areas come alive for students. If you wish to learn more about this extremely powerful teaching approach, consider searching the literature for: Science-Technology-Society (STS), Teaching in Context, Thematic Teaching, Inquiry-Based Teaching, Problem-Centered Learning or Constructivism.

Additional Ozone/UV-B Radiation Information
With respect to the ozone/UV-B radiation problem, reports indicate that Chile does not contribute significantly to atmospheric pollution through CFCs emission (see Table 3).

<td>0.9%</td>
</tr>
</tbody>
</table>

Considering this, students should recognize the ozone problem as a serious one which, although not caused by Chile, affects the land and the population health and quality of life. They should understand the physical and chemical concepts related to the ozone decrease in the atmosphere, those related to the characteristics of UV radiation. They should also understand the biological aspects of damage caused by UV radiation to living beings.

Students should also be made conscious of the effort done by national industries for reducing emission and use of CFCs, although knowing that their impact upon the global atmospheric pollution is very small. Thus, they will recognise how scientific development and technological progress must collaborate to maintain the quality of life. Perhaps the above knowledge will attract them to science and to the choice of science as a professional alternative.

The curriculum, although taking into account the understanding of technological progress, should place more emphasis on the knowledge of sources of
danger and of ways for health protection. Curriculum in other countries should place the emphasis on global atmospheric damage and on the need of attitudinal changes, integrating social and public spheres, and understanding of scientific and technological development and their consequences.

ASTRONOMY ACTIVITY AND RESOURCE NOTEBOOK PUBLISHED

The Universe at Your Fingertips, an 813-page astronomy activity and resource notebook for teachers in grades 3-12 (and astronomers who work with them), has just been published by the Astronomical Society of the Pacific. The loose-leaf collection includes 90 hands-on activities, dozens of annotated resource listings, featuring reading material by topic for students and teachers, and audio visual aids, computer software, and organizations that assist teachers, as well as a catalog of national astronomy education projects. In addition, the notebook contains articles on student learning, astronomy basics, and fitting astronomy into the science curriculum at various levels.

The Universe at Your Fingertips is $24.95 plus $6.00 for shipping and handling to U.S. addresses. California residents please add sales tax. Send orders to Astronomical Society of the Pacific, Notebook Order Dept., 390 Ashton Avenue, San Francisco, CA 94112; phone 1-800-335-2624.
A DISCUSSION LIST IN A SCIENCE METHODS COURSE

M. O. Thirunarayanan, Ph.D.
Elementary Education Department
Rowan College
Glassboro, NJ 08028-1701

An electronic discussion list has been used for two academic years by students who enrolled each semester in an elementary science methods course. Many students subscribed to the list and posted numerous messages during Spring 1995. This paper reports what students who subscribed to the list had to say about their experiences with the list. Some of the many messages which were posted on the list during Spring 1995 are also excerpted and reproduced in this paper.

Introduction

A recommendation made by the National Science Teachers Association (NSTA) is that science teacher preparation programs should provide preservice elementary science teachers “with experiences, materials, and skills which will enable them,” when they become classroom teachers, to “use electronic educational technology in teaching science” (NSTA, 1992-93, pp. 192-193). Incorporating an electronic discussion list into science methods courses which preservice teachers enroll in, is a good way to implement this recommendation.

Teachers of the future will have many opportunities to subscribe to electronic discussion lists and communicate with other teachers across the United States and the world. However, unless preservice teachers are provided adequate and appropriate experiences with discussion lists, they may not feel comfortable enough or knowledgeable enough to join and use discussion lists when they start teaching. This was one of the reasons why an electronic discussion list was established for use by students enrolled in an elementary science methods course.

What Are Discussion Lists?

A list is quite simply a list of electronic mail addresses. When someone wishes to subscribe to a list, he or she sends a message to the appropriate address with the request that his or her electronic mail address be added to the list of addresses. Once a person has successfully subscribed to a list, he or she will then start receiving copies of all the messages which are sent to the list.

A person who has subscribed to a list can also send messages to the list. These messages, like the messages sent by other subscribers, will be automatically copied and distributed to all the people who have subscribed to the list. In this sense, a list is an automatic mail distribution system.

Since many people use lists to share information and resources, and to exchange, argue, and “discuss” ideas on various topics of mutual interest, lists are also commonly referred to as “discussion lists.” Since these discussions are held electronically, these lists can also be called “electronic discussion lists.”

A Discussion List in a Science Methods Course

An electronic discussion list was established in Fall 1993. All students who enrolled in the science methods course were given the option of choosing, from a list consisting of a number of assignments, the assignments which they wished to complete in order to earn their grades in the course. Subscribing to the list and participating in discussions on the list was one of the assignments which students could choose. Since Fall 1993, many students have chosen to subscribe to the list and have posted hundreds of messages.

Students have used the list in many ways during the first two years of its operation. They have used it to:

• share ideas for science activities
• follow up on classroom activities
• share information about resources
• submit assignments
• ask questions and get answers
• answer instructor’s questions
• share their internship experiences with each other
• seek and receive ideas for use in the classroom
• provide feedback regarding course assignments
• provide feedback about the discussion list itself.

Sample Messages
During Spring 1995 semester, students were requested to answer the question “What are the qualities of a good science teacher?” The following are excerpts from some of the responses to the question which were posted:
• “A good science teacher must make science fun for the students, while at the same time providing them with the necessary information they need to learn the concepts.”
• “Also, enthusiasm for the subject is vital, as is an understanding of how science relates to so many areas of life and learning.”
• “. . . a science teacher needs to give the students lots of opportunities to discover things about the world around them. Hands on activities are a must.”
• “A good science teacher welcomes questions and does not discourage answers to questions. Flexibility is another quality that I think is important to have as a science teacher.”
• “A good science teacher needs to be willing to try new ideas and experiences.”
• “They should have current knowledge of science teaching methods and research. They should be willing to let students explore and discover.”

Students’ Reactions to the List
Also during the Spring semester, students were asked to answer the question “What will you tell someone if he or she asks you to describe your experiences with this list server?” All the students who took the time to respond to the question considered their experiences with the list to be beneficial. The responses posted by some of the students are excerpted and reproduced below:
• “The experience with the list was very inspiring and I have gained much from the personal input from everyone.”
• “Also, the list is a great place to share ideas and to learn about other’s experiences. I learned that I was not the only one who was frustrated by certain things or excited about certain things—my fellow students told me through E-mail about their experiences and I could compare them with mine.”
• “I like the list program but have not had the time to really enjoy it.”

• “I would strongly encourage students to take part in the list. You get plenty of encouragement and feedback on how internships are going. Not to mention all the original lesson plans you get access to! Plus, it helps many students who have not really worked with a computer to get familiar with it.”
• “I have enjoyed the communication with my “fellow” students through the list. I jot down ideas, book names, etc., for future reference. It’s been interesting to read about other people’s experiences in their field work.”

Conclusion
Students do benefit in many ways when discussion lists are incorporated into courses. As electronic communication grows in availability worldwide, it is a good idea to provide future elementary school teachers the experience of discussing ideas and exchanging information with their peers.

AN ALTERNATIVE FOR SCIENTIFIC FORMATION

Obaya, V.A. And Palacios, A. J.
Fes-Cuautitlán, Universidad Nacional Autonoma De Mexico

Introduction

Our current educational system tries to develop scientists through courses where students are basically taught to solve problems that are often unfamiliar and therefore irrelevant. The scientific attitude is buried under mountains of papers describing experiments, procedures, guidelines, etc. Nothing could be further from what science really is. Although the scientific attitude is really an attitude toward life and is present everywhere, it is in the laboratory, which is specially designed for research, where an activity like chemistry finds the best environment for its development. We set up a program, oriented toward the acquisition of knowledge where the young student can participate in a unique process: to learn how scientific research is done. Research, like any other activity, is learned by doing. With this principle in mind, we started a program that directly acquainted young students with the research presently being done in our Applied Experimental Chemistry Laboratory of the FES-Cuautitlán which is a separate campus of the Universidad Nacional Autonoma de Mexico (U.N.A.M.).

Our program goals are clear: to develop scientists through scientific research.
H. M. Cartwright (1980) and R. A. Bailey (1981) were some of the first to describe the results of integrated laboratories. Taking into account their findings and our own experiences, we offer the following recommendations for making an undergraduate research program successful:
1. Encourage student participation and initiative.
2. Stimulate the student to establish his or her own goals and the ways to achieve them.
3. Present complex problems in an integrated manner, encouraging the students to exercise their inventive and reflective capacities for solving problems.
4. Maintain scientific curiosity and a research spirit.

Implementation of the Program

In most chemistry programs, students usually do not begin research until the end of their studies (after the ninth semester). Our students dedicate more and more time to their research projects from the seventh semester on.

Our program invites students to do research, not to fulfill requirements. Because of the nature of their work many students spend long periods of time on their research projects, often years. Inevitably their daily work produces the undergraduate thesis and the social service required in Mexico to obtain a degree.

In our program neither a tight schedule nor a minimum amount of work hours is required. The students choose the amount of the time they want to dedicate to the project. Access to the lab, and equipment, is allowed all day long.

Frequently, working in a chemistry lab requires a minimum amount of work hours, for example, the time to assemble the equipment, carry out the reaction, separate certain products, and put the equipment back in place. In these cases, it is the student who decides when he or she will have enough time to carry out the experiment. A surprising result is that the students decide to spend considerable vacation time working on their projects. In fact, the spring break is the most productive period in our lab.

For a student to agree to spend many hours on his or her research project, it must be, at least, interesting, appealing, and important to him or her. At the same time, the suggested project must be feasible from the advisor’s point of view.

Four faculty members attend this program and the students are divided in small study groups. Students have choice in selecting an individual part from the main research project according to the cooperative group theory.

It is important to describe the research process in detail. Key points to be registered include: objective, experimental methodology, collected data, graphical representation of results and bibliography.
To carry out the main research as a group, it is necessary to study various subjects of different complexity. The newer students in the group start out with assignments that are relatively simple, but we consider them fundamental for the overall development of the research project.

The resulting projects are of high quality and offer importance from a scientific point of view. Sometimes a project that seems simple on paper turns out not to be so in the laboratory. The situation is not pleasant, but the students go to the lab to do research, not to get a good grade or to pass an exam, therefore it is not a depressing failure. On the contrary, these are valuable opportunities not only to go over the chemistry involved and come up with an explanation of the facts, but also to discuss the processes of science including the establishment of a hypothesis, the significance of negative evidence, and the role of experimentation in science.

The student lives the scientific method. Nevertheless, in some cases, changing the research focus is unavoidable, but nothing is lost and much has been learned.

As a result of structuring a research group as described, the communication level between its members is very high. During the weekly seminar where different techniques, procedures, the use of equipment and specific safety precautions are reviewed, newer students may discuss doubts or problems with their contemporaries, more advanced students or supervisors. They are all equally interested in what these students are doing and whatever advances develop or obstacles appear, because much of the group's future work depends on their results. It is hard to establish clearly what it is that motivates the student to commit himself or herself so seriously to a research project. No doubt it is a mixture of circumstances that are different for each person.

Many of the students that worked with us while completing their studies decided to continue with graduates studies. A total of 204 students have been enrolled in this program of which 30% have obtained a Master’s degree or Ph.D. degree. This reflects their individual commitments to scientific work.

We also think it proves, as we expected, the possibility of forming scientists by getting young students excited about research. Our students have participated in research seminars, presentations at national and at international chemistry congresses, and their results have been published or accepted in national and international scientific journals.

The richness of this experience is invaluable. All the papers are the result of teamwork. The students and advisors are directly involved, but we insist that the oral presentation should be done by the student, no matter how advanced they are in their major field. This is a useful practice because, among other reasons, the students get into the habit of presenting their work each time with more clarity, order, and even elegance. At the end they are convinced that their research is not completed until they have discussed it and have motivated their colleagues with their findings.

Something similar happens with papers for publication. In general, it is the student who has all the information and who, along with his or her advisor, prepares the manuscript with its tables, drawings, etc. They know that in these cases the examination of their work will be more gratifying. At F.E.S.-Cuautitlan our experience with this program has been positive. The laboratory does indeed connect and unify the chemistry curriculum.

Sample project topics include: Organic Chemistry, Food Chemistry, Polymer Synthesis, Physical Chemistry, Natural Products, Analytical Chemistry and Electrochemical Analyses.

Some comments that the students have given about the program are:

"With the purpose of solving real problems, the integration of different areas of chemistry is necessary".

"We learned to approach chemistry problems solving in a mature and independent way".

"We have used a new approach to chemistry work bases on research and independent work".

1081 HV Amsterdam

This section focuses on the education of science teachers, and aims to communicate ideas and strategies which will assist science teacher educators to enhance and enrich their programs.

HOW DO YOU KNOW THAT: AN EPISTEMOLOGICAL CHALLENGE?
Dr. Martin Monk & Dr. Sally Johnson
Centre for Educational Studies
King’s College, University of London
Cornwall House Annex
Waterloo Road, London SE1 8TX United Kingdom

Activities for Students

In working with science teachers from a wide range of countries—India, Belize, Indonesia, Pakistan, Nigeria—we have had to think carefully about:
- how we can help students learn science;
- what epistemological justifications there might be for scientific knowledge;
- what activities students might carry out to create epistemological justification.

We have come to address these questions more through our work with groups of teachers from overseas than from our interaction with UK science teachers. The reason for this is that we have worked with teachers who are keen to do more practical work with their students but who feel themselves frustrated by the usual litany of lack of equipment, chemicals and glassware, no technical support, textbooks that concentrate on facts, examinations that test recall and old fashioned syllabuses that pay little or no attention to the processes of science. We have therefore been trying to formulate alternatives that address the epistemological question of, “How do you know that?”.

In attempting to provide teachers with alternative strategies we have devised a generic approach that makes use of worksheets focusing in turn on each of the processes of science (Monk, Fairbrother and Dillon 1993). We have presented the processes of science as providing a framework for developing activities for students. So we encourage our science teachers in our short courses to think more carefully about:
- observing patterns in the real world
- making hypotheses
- designing experiments, surveys or data searches
- manipulating apparatus
- taking readings
- recording data

- transforming data and finding patterns in data
- building theories
- communicating ideas.

Then we point out that information comes in one of a limited number of forms,
- diagrams, photographs and pictures
- words in text
- tables of data
- graphs
- algebraic formulations.

Science teachers in our short courses spend time constructing activities for students that involve the students changing data given in one form, into another form, whilst engaging in one of the processes of science. The science teachers put together a package of these activities focused on one particular topic, e.g. the photo-electric effect, electrode potentials or gas exchange in humans, etc. The finished product should provide students with activities where they translate information whilst using the processes of science to develop an epistemological justification for the standard predictions that modern scientists make about natural phenomena. We try to create activities that take the students from a position of not knowing, to a position of both knowing what and knowing why. We try to hand them the opportunity to say how they know what they know.

Typically:
- a first sheet might show a flash-photograph of a falling ball. In groups, students can be asked to interpret such photographs and discuss their interpretations. Then representatives from groups can be called upon to explain their group’s ideas on what is happening and, more importantly from the point of view of turning empiricism into science, why they think it is happening.
• a second sheet might give a written description of some apparatus and the students are asked to draw the apparatus and then discuss their diagrams. A class display of diagrams can be used to preface a whole class discussion on what the definitive version might be and how it might be used.

• a third sheet may be rather sparse in simply asking students to design an experiment to test an hypothesis previously discussed by the whole class. Help and guidance can be given in getting the groups of students to be systematic in thinking about variables, controls, estimates of effects, suitable equipment, step-by-step procedures, and what confirming or falsifying results might look like.

• a fourth sheet might show some recorded trace of the movement of a falling ball alongside a standard rule. Students are asked to take readings from the sheet and to tabulate the data for themselves. A display of different tabulations can lead to a whole class discussion of the advantages and disadvantages of different tabulations.

• a fifth sheet can display data already tabulated. The students are required to find patterns in the data by transforming the data and analyzing the patterns. They would be encouraged to draw graphs to illustrate their results.

• next, the students might be presented with a graph or set of graphs and asked to write out in their own words what can be "read" from the graph. Students can be asked to decide on a group response which can then be used to formulate a whole class description.

• to take this pencil and paper activity beyond empiricism it is necessary to ask students to devise some theory that explains why the pattern they have deduced is as it is. This takes us back to the first sheet and questions about what is happening and why is it happening.

Working with Teachers

This brief outline example shows how part of our task, as teacher trainers, is to get the science teachers to take on board a pedagogy appropriate for use with these rather different materials for students. We endorse group work. We want science teachers to use the materials they have produced with students working in small groups, say four to a group. With a class of sixty students it is possible to run 15 groups of four. It is necessary to show teachers how to organize groups of students in a class. All too often, without explicit direction, our science teachers have four people in a line as a discussion group. When we see this we get the whole group of teachers to think about the management issues of grouping students in classes with a variety of furniture arrangements and different ways of seating. Usually we can do this with a great deal of good humor.

Each group works on the tasks on the sheet and then the teacher calls the group to order and collects feedback from the groups. The mistake that beginners make is to go through all 15 groups in turn. This is tedious beyond belief. We advise teachers to take feedback from two groups, three at the most, and then to open up the discussion for general comments. Good teachers finish each section of work with a general summary before starting on the next task.

Recently we have been working with groups of teachers from Korea. The issue for them is not one of doing practical work. Generally Korean schools are well equipped and they have enough for all their students. Rather, we find the teachers to be wedded to a strong teacher-centered pedagogy. We use this worksheet approach to try to pry them away from their blackboards and to hand control of students' learning over to the students working in small groups. They resist our efforts by commenting that our methods will:

(a) take too long;
(b) not be acceptable to students themselves;
(c) not be suitable for their syllabuses.

We counter with the arguments that:

(a) students speed up when they are familiar with the pedagogic strategy and that their learning is more effective in being active rather than passive learning;

(b) students are surprisingly enthusiastic about working this way but, like all things, doing only this will lead to boredom (variety is important);

(c) the method is more flexible than they think if they know their science.

Some of our science teachers find the materials production itself a hard task. There are several interesting things that can go wrong. Sometimes the science teachers try to use the activities as tests. That is, the students cannot reasonably be asked to do anything for which they are not handed the necessary information in the activity. Teachers who start on the production of these materials often create questions that are recall questions rather than processing tasks. Sometimes we have to go through each of the activities in turn and help the teachers to pull out all the recall and replace it with hypothesizing, designing, transforming, pattern finding and theory building activities.

Some science teachers do not actually know how or why modern scientists think what they do. This is a deep seated systemic problem that has to do with the way many textbooks, examinations and syllabi focus on the knowledge that is the product of science
rather than the processes of science. So, for instance, how do we know that DNA has a helical structure? How do we know that the atom has a nucleus? How do we know that alkanes are saturated? After working with us, a few of our science teachers spend a good deal of time brushing up on their own scientific knowledge and finding out, sometimes for the first time, why scientists think what they do.

A third problem has to do with layout and design. It is curious that teachers who come from countries that have flourishing traditions of graphic art and design often produce the most appalling products in terms of layout and design. Here the daily grind of coping with limited resources, such as poor chalkboards and very limited paper stocks, reduces the horizons beyond which the teachers look for alternatives. We try to get them to produce bold, clear, clean, graphics and text. We encourage good draughtsmanship. We actively press them to "spread their wings" across the page rather than cramming their work down into small overcrowded spaces. When they do take this on, and we must say the biologists generally have a head start, they can produce the most wonderful pages that make you want to get going on the activities straightaway. We expect them to carry the products back into their classrooms and motivate their own students with the same graphic skills.

The worksheets that focus on the processes of science and ask students to translate information from one form to another can help students focus their attention on the small scale detail that contributes to science’s success. The stepwise approach of the worksheets can help students gain confidence in their evidence in order to make legitimate claims. This can be more challenging for our teachers than for their students. Teachers who devise and use their own worksheets gradually come to appreciate this approach.

In order to make accurate predictions, ones that other people will take seriously, it is necessary to have some way of generating predictions. How do scientists do this? They study the properties of the natural world as it now is and as it was. They have a methodology. That methodology is contained in a set of processes and the iteration between processes allows critics to complain that there is no single way of going about the task. Two well known texts questioning the very notion of a scientific method are Feyerabend’s, “Against method” (1975) and more recently Woolger’s, “Science: the very idea” (1988). The generic set of processes used in our worksheets introduce students to the notion that there is a method to science. The flexible use of the worksheets by science teachers allows them to stress different processes for different topics. This can help students appreciate that success in science comes, in part, from the flair of knowing which processes to use at which stage.

However, the defining features of the methodology are not to be found in a specific chain of procedural operations but rather in a set of underlying beliefs about the nature of the tasks scientists set themselves when they use these processes. Dixon (1989) makes the point that the scientific method is distinguished from the messianic-prophetich-shamanistic method more by its axiology than its actions. Most scientists subscribe to the belief that the world is explicable and not mysterious, that cause-and-effect operate through direct linkages, that evidence needs to be set in the context of its plausibility and that conclusions need to be made with caution. The last two often involve some care over stating exact conditions, taking pains over repeated measurements and being skilled enough to use statistical methods to estimate errors and probabilities. By isolating the processes in the worksheets teachers can ask students to stand back and inspect those processes for their internal dynamic. The meta-question is, “What are we doing here?”

Finding patterns is not enough for the study of the natural world to become science rather than for it to get stuck at empiricism. Scientists also need to
build models of how the world might be in order to come to understand how the world is. The ancient Egyptians and Babylonians were skilled observers of the heavens. But without a model of the heavens that was mechanical, rather than mythological, all the Egyptian empiricism in astronomy trickled into the sands of astrological mysticism. Darwin’s ideas on evolution were viewed skeptically by many of his negligently knowledgeable critics as much for his inability to describe any mechanism for the evolutionary process as for anything else. No mechanism, no model, no theory - no science. How do we raise this issue, if at all, with our students? How do we help students to build their mental models so they have some theoretical, as well as empirical, justification for what they claim to know? Teachers need to be aware of this issue in the nature of science. The worksheets created under our direction and generated by our generic model do not directly address this issue. Instead, we need time with our teachers, and, in turn, they need time with their students, to discuss what sort of thing science is and how it works.

It has taken the past twelve years for us to reach this point where we, ourselves, can articulate what it is we are trying to achieve. We have reached this position because we have had the great privilege of working with a large number of patient and dedicated science teachers. We salute them for having helped us to help them. Without them, we ourselves would not know what we now know.

CONCEPT MAPPING: A GHANAIAN SECONDARY SCHOOL STUDENT’S EXPERIENCE

Jophus Anamuah-Mensah
James Otuka
and
Ngaman-Wara Ernest
Department of Science Education, University of Cape Coast: Ghana

Concept mapping is often seen as a technique for evaluation of teaching programmes, assessing knowledge and understanding of a topic, and for examination purposes, etc. But concept mapping also can be used as a technique for teaching and learning of science.

The present action research was designed to find out how students reacted to concept mapping as a teaching/learning technique. Twenty-two form two senior secondary biology students were involved in the study. The class was divided into four groups. The groups were introduced to concept mapping by means of a common topic in Biology.

The concept of fern reproduction was generated by the class through a brainstorming session and then used to create concept maps. Each group had two attempts at concept mapping. Students were positive towards concept mapping as a teaching and learning technique.

Introduction
Sizmur (1994) described concept mapping as a simple but flexible activity that can be integrated in science as well as other curriculum areas. Concept mapping show relationships between areas of knowledge. Sizmur (1994) referred to concept mapping as reflection in action since it creates a more reflective, constructivist and hence less transmissive, learning environment.

Concept mapping is described by Adamczzyk et al. (1994) as a multipurpose and multi-level tool. In other words, it can be used for many educational programmes including evaluation of a learning unit after instruction, measurement of longer-term
retention, or cooperative learning. It also can be used at any level of the learning process, from primary to tertiary.

The framework of a concept map, according to Adamczyk et al. (1994) is defined by prime descriptors and linked by propositions. The prime descriptors are the key words or components of the topic to be studied. The propositions are statements, or phrases that describe the relationship between the concepts. These relational comments are linked to the lines connecting the concepts. The lines have arrows at the end to indicate the direction of the relationship between any two concepts.

White and Gunstone (1992) describe concept mapping as a means of eliciting the relationships each student perceives concerning a concept. Concept maps can quickly reveal a complex structure of ideas about sophisticated concepts.

These descriptions and definitions reveal a number of applications or uses of concept mapping some of which include:

i) organization and consolidation of the learners' knowledge base;
ii) measurement of longer-term knowledge retention;
iii) promotion of cooperative learning in class as students talk over ideas, identify problems and share knowledge;
iv) evaluation of whole teaching programmes; and
v) assessment of knowledge and understanding.

These uses of concept maps indicate different types of concept map. Five of these have been described by Adamczyk et al. (1994) namely, free range, object only, the 'link only', prepositional and the picture map. Each of these are briefly described below.

Free Range—The students are given the opportunity to demonstrate what they know. The teacher provides a list of prime descriptors, which may be defined by the teacher or provided by an initial brainstorming session with students.

Object only—The teacher provides the concepts and the students to supply the propositions and the direction of arrows.

Link only—The students are to supply descriptors only

Propositional—Descriptors and propositions are provided and the student is expected to choose appropriate connections in order to build the pre-defined concepts.

Picture map—The students work in groups and link pictures representing the prime descriptors either verbally or by various written or pictorial methods.

A number of concept mapping research studies have been carried out for various purposes. Roth and Roychoudhury (1993) reported that concept maps resulted in meaningful learning of science concepts. This meaningful learning is thought to arise from at least two concept mapping features. First, concept maps assist learners to become aware of and control the cognitive processes of the task. Second, they assist learners to develop more integrated conceptual frameworks. Jegede, Alaiyemola and Okebukola (1990) showed that besides higher achievement, concept mapping was also associated with reduced anxiety. In addition, Okebukola and Jegede (1988) found that students who collaborate in concept map construction "attain meaningful learning better than students working individually."

Concept maps are ideal for helping students to examine and reflect on knowledge. They also help students to become more reflective, thus emphasizing the constructive nature of learning (Beyerbach & Smith, 1990).

Sizmur (1994) experimented with concept mapping as a group activity to examine the critical sharing of knowledge and whether new understandings emerge.

The study involved two groups of fifth and sixth grade children. Both groups used concept mapping as a learning tool. The first group was engaged in constructing habitats and food chains. The second group considered the relationship between the process of photosynthesis in plants and respiration in animals. He gathered recordings of the children's discussion as they engaged in concept mapping tasks. These were transcribed and analyzed.

Sizmur (1994) concluded that concept mapping is a valuable discussion task. It introduces idea in a tentative manner which invites differing interpretations. It provides opportunities to see and deepen the level of students' understanding. New ideas emerge as children engage in discussions.

Trowbridge and Wandersee (1993) studied concept mapping in a college course on evolution. The study examined how concept mapping could be used as an integral instructional strategy for teaching evolution, assess the impact of concept mapping on students' study practices, and on students' understanding of course content. They found that students who made concept maps spent an average of 37% more study time on this college biology course than on their previous biology courses. They also felt that the use of "seed concepts," "micromapping," a standard concept map format, and a standard concept map checklist made the strategy easy for the instructor to implement and for the student to adopt.

Huang (1993) designed an experimental study to investigate a relationship between concept mapping and science achievement at the elementary school.
level. The study involved sixth grade Taiwanese children. The experimental group received instructions in concept mapping prior to the study. A content pretest was then administered to both experimental and control groups followed by regular course instruction for all students. The teachers gave the students a list of concepts covered during instruction before the end of the class period. The experimental groups were asked to form concept maps and the control groups were to simply define the concepts.

A post test was administered to the groups after the end of the course units. Based on data analysis, science achievement was higher for students who had learned how to make concept maps than those who completed concept definitions. The researchers concluded that concept mapping techniques may be an appropriate method for sixth grade students to learn science.

The literature reviewed gives evidence to support concept mapping as a teaching and learning technique. Group concept mapping creates a friendly environment that promotes cooperative-learning. The individual in the group shares his/her ideas with others and through dialogue and trading ideas, the learner reconstructs or rejects his/her own ideas about issues discussed.

The present action research study was designed to find out whether concept mapping could be a useful technique for teaching biology at the senior secondary school level in Ghana. Presently, biological concepts are often defined for students to memorize. Little or no effort is given to help students make connections between concepts or to form a unit whole.

**Methodology**

**Sample**

An intact class was used for the action research. Twenty-two biology students of University Practice Secondary School, near the University of Cape Coast, were involved in the research. The group consisted of equal number of female and male students. Biology is one of the elective science subjects at the senior secondary level. The class has studied diversity of organisms and general principles of reproduction in different groups of organisms. The group had never been engaged in concept mapping.

**Procedure**

The ‘free range’ concept mapping technique was used because it exposes more of the student’s understanding of the subject content and their prior knowledge of the topic. The group approach also provides a better environment for sharing of ideas among students.

The topic used for this study was fern reproduction. The students had been introduced to the topic while studying diversity of organisms.

The class was divided into four groups of at least five students. Each group chose a leader to coordinate the discussion and a secretary to write what the group agreed upon.

The class was introduced to concept mapping by the researcher. A familiar topic, Living Things, was used to facilitate students’ understanding of the concept mapping process.

The prime descriptors of the topic were generated through a brainstorming session with the students. These included sporophyte, gametophyte, antheridia, archegonia, antherozoids/sperms, egg/ovum, prothallus, sorus, spores, zygote and sporangia.

The groups were then instructed to arrange the concepts on a sheet of paper to form a concept map. Pencils were used in the exercise to ease changes when necessary. While the groups were engaged in the exercise the researcher moved around to observe and to offer help to groups having difficulties. The researcher also noted the learning activities being carried out by the groups. When all groups were satisfied with the map produced, each group’s secretary represented their concept map on the chalkboard. Each group then presented their concept map and the whole class discussed each map.

After the discussion two new concepts were introduced by the researcher for a second attempt at concept mapping. The new concepts, “haploid” and “diploid,” were explained to the class. The second attempt was to perfect the groups’ concept mapping ability. The groups again represented their concept maps on the chalkboard for further discussion.

A short questionnaire was administered to the students to find out their impressions of the new technique. Some of the questions were:

1. What was the attitude of your friend during the activity?
2. Will you want to do more of concept mapping? Why?
3. Compare concept mapping technique to the normal teaching you experience in your biology class. Which one do you prefer? Give reasons for your answer.

**Results and Discussion**

Figures 1a, 1b, 2a, and 2b are examples of concept maps constructed by two groups. The examples are presented for the purpose of illustrating the progress of the students through the activities. The concept maps labeled A were the first attempts
by the groups and the label B indicates the second
attempts by the groups.

The groups presented concept maps of similar
pattern. The maps had a cyclical nature with one or
two branched inter connections. The patterns are
similar to what is presented in their textbooks where
the life cycle of Ferns is discussed. The concepts
were arranged hierarchically by all groups. All
groups except group 4 used all the concepts/prime
descriptors generated during the brain storming
session in their first maps.

A number of anomalies were noticed in the first
maps. Some links did not show the direction of the
relationship between the concepts connected (Figure
1b). Only group 4 showed the directions of the
relationship between the concepts linked (Figure 1b).
Groups 2 and 5 registered five errors respectively
while group 3 registered one error.

Propositions to indicate the type of relationship
between some concept were not stated. Group 4 did
not provide propositions for any of the links on the
map (Figure 1a). The group had a problem agreeing
on propositions.

The general discussion that followed the first
attempt at concept mapping improved the concept
maps in the second attempt

All groups improved upon the links between
concepts regarding the direction of their relationship.
Groups used the appropriate proportions to show the
relation between linked concepts. However, some
groups had a problem using the appropriate words.
For instance, instead of the gametophyte develops
antheridia and archegonia the students substituted the
word develops with produce (Figure 2a).

The new concepts introduced during the second
attempt were used by all groups except group 4. The
groups that used the new concepts however used
them as descriptive words, e.g. haploid sperms,
diploid zygote (see Figure 2b).

The students were expected to use them to form
links between concepts or stages of the cycle which
share these characteristics. This would have
increased the net work of their maps. The inability
of the groups to use the concepts haploid and diploid,
was an indication of poor concept understanding.
The concepts were discussed in detail with the
students. The level of interaction is in agreement
with Sizmur (1994) who also found concept mapping
to be a discussion activator.

The individual ideas proposed by group
members generated a discussion that moved personal
knowledge, held by the individual, to public
knowledge. Each student had to reconstruct his/her
ideas in the light of the discussion.

There was a sense of competition among the
groups during the first presentations made by each
group. Although this could have destroyed the
friendly learning environment concept mappings
provides, it actually motivated the groups to work as
teams to perfect the second maps. Group members
maintained a friendly environment and active
participation throughout the activity.

The concept maps of the groups revealed the
students understanding of the topic. The
improvement of their second maps indicated that
learning took place during the presentation and
discussion of the first maps. Hence concept mapping
can be an effective tool for teaching and learning in
the classroom.

The students also stated a positive attitude
toward concept mapping. This is in agreement with
the findings by Trowbridge and Wandersee (1993) as
well as Huang (1993).

---

**THE LIFE CYCLE OF FERNS**

- **Prothallus**
  - produces
  - Germinates into Sporangia

- **Gametophyte**
  - produces Antheridia
  - produces Archegonia

- **Sporangia** (fer plant)
  - develops into Sporophyte

**LIFE CYCLE OF FERNS**

- **Gametophyte**
  - Produces Sporophyte

- **Sporophyte**
  - Produces Spores
  - Spores burst to release Sporangia

- **Archegeonia**
  - Produces Egg

- **Sperm**
  - Fused to form Zygote

**Figure 1a.** First concept map of Group 2

**Figure 1b.** First concept map of Group 4
The students answers to the questionnaire after the activities confirmed the use of the concept mapping as a teaching and learning technique with one or two precautionary comments made by some of the students concerning its use as a sole learning tool. The students preferred concept mapping as a teaching technique to the normal teaching of concepts. The concept map presents at a glance, the main concepts of the topic and how they are related and the topic is seen as a whole instead of as set of disjointed concepts.

The students saw the discussions that followed the presentations as integral for learning. The discussion improved the students' understanding of the topic as they shared and learned new ideas from their friends.

They also found the process useful for review before examinations.

However they expressed a concern for the time necessary to use concept mapping and felt that it should not be the sole technique for teaching. They voice concern that the biology syllabus could not be completed and they would not be prepared adequately for the final examinations. They suggested that it could be used sparingly to generate or sustain the interests of the students and to improve their understanding of difficult topics.

Though the action research was carried out with a class not representative of Ghanaian Senior Secondary school Biology students, a number of valuable conclusions were reached.

Concept mapping can be used as a pre-instructional and post-instructional tool in biology. The first instance will inform the teacher the level of student understanding. This will enable him/her to better prepare the lesson to meet student needs. The second provides insight into how well the students learned the material and their ability to connect information.

INVESTING IN PROFESSIONAL DEVELOPMENT
SERVING THE INFORMAL SCIENCE EDUCATOR

Andrea V. Anderson

"Somehow the experience changes you and challenges you to grow outward as you search inward.", project participant

If you had $1,000 to pursue a professional growth experience, what would you do? Would you look for a course or a workshop that interests you? Most educators find there is an abundance of learning opportunities. Advertisements for workshops arrive weekly, covering virtually every discipline and every curricular or instructional approach. One can simply choose among the options.

But what if you are the person who typically gives the courses or workshops attended by others under the rubric of professional development? What does a professional development provider do for his or her own personal growth and development? Teachers are expected to continue their education; shouldn't teacher educators follow suit?

In university settings, which are home to most teacher educators, conducting and reviewing research, taking sabbaticals, or attending conferences continues the intellectual growth and development of the individual. When the teacher educator works in an informal learning setting, such as a science center, how is the challenge of continued professional growth answered?

This report describes the activities undertaken by 33 informal science educators who designed professional development opportunities for themselves and their colleagues. The findings from their individual reports submitted at the conclusion of the experience, permit a brief glimpse at outcomes from various investments in professional growth. They suggest the value of investing in staff development and the amazing financial leverage achieved by educators who must make the most of every dollar.

Creating Professional Growth Opportunities

As part of a grant to the Association of Science-Technology Centers (ASTC), the Carnegie Corporation of New York provided $30,000 for a Small Grants for Professional Development program for museum-based science educators. The overall goal of the Carnegie project was to "strengthen the capacity of science museums to support school science programs." The solicitation for the small grants required alignment with that goal, permitting individual educators to request support for personal growth experiences, or to fund programs for museum colleagues and teachers.

The guidelines described the types of professional development activities appropriate for funding including but not limited to the following:

- visits to observe teacher education programs or school-museum partnerships in action
- participation in programs sponsored by other museums
- staff exchanges between two or more museums
- participation in NSF-sponsored summer institutes, accredited teacher education programs, or other workshops to improve skills necessary for teacher education

The procedure for applying was simple: the educator needed to "make the case" for their participation in the chosen activities. In addition to giving their own educational and experiential background, and a brief description about programs they offer, they had to answer questions about what they wanted the funds for; when, where, how, and with whom they would undertake the proposed activities; how proposed activities would benefit the participant and his or her institution; and why particular experiences would be valuable. Each application had to be accompanied by a letter of commitment from the participant's institutional leader, a budget, and a timeline. The proposals were reviewed by a committee that made the final recommendations.

While the solicitation was open to all museum-based teacher educators, half of the funds were reserved for educators who had attended the ASTC...
Inquiry Institutes. This was a deliberate strategy, building on the momentum of the prior workshops, which encouraged museum educators to become change agents in the reform of science teaching and learning. At the heart of the current science education reform effort is inquiry learning and teaching. These reforms require practitioners to know how to inquire and to facilitate others in inquiry. Shifting from a traditional science pedagogy to an inquiry approach requires ongoing support as individuals transform their own practice. Thus, an iterative experience with inquiry, observation or collaboration with others in trying new instructional skills, and an outsider working with one’s colleagues, were deemed the most effective approaches.

Through two rounds of proposals ASTC gave 23 grants to 33 educators from 22 institutions. The types of institutions represented included natural history museums, zoos, botanical gardens, children’s museums, and science centers. Awards ranging from $500 to $3,000 were given to institutions varying in size and in geographical location. Awards were given to individuals, to teams of individuals, and in two cases to an institution representative who invited colleagues to participate.

Choosing An Approach

Site Visits

Three approaches characterize how the museum-educators designed their experiences. Most frequently, awardees used funds for site visits to other institutions. For some, the purpose of visiting other sites was to assess programs similar to those of the participant’s own institution. For example, a mutual exchange between a museum in Minnesota and one in Saskatchewan allowed two educators to compare existing school visit programs and approaches to exhibit development.

For others, the site visit was exploratory, serving to generate new program ideas for the participant’s home institution. One team noted their museum was about to participate in a State Systemic Initiative (SSI), a multi-year program of science education reform funded by the National Science Foundation. By visiting another museum already engaged in such a program, they hoped to understand the functional relationship between the museum and the SSI effort.

Not surprisingly, given the intentional support to ASTC Inquiry Institute graduates, the site visits were used as a follow-up experience with inquiry learning. Being able to observe the implementation of others’ efforts illuminated principles that were crucial for inquiry instruction. A participating team commented on the value of follow-up experiences in observing others teach through inquiry.

The ASTC Inquiry Institutes gave us an inspiring start, and the professional development grants provided support that significantly increased our ability to move in this direction.

We [learned] a most valuable lesson—the importance of being aware of individuals and creating a feeling of familiarity and safety as people embark on learning something really new.

Hosting a Workshop

Another option was to host a workshop at the awardee’s institution for museum colleagues, teachers in the community, and educators from other institutions, including universities and other informal science institutions. Although this option was used less frequently than the site visits, it permitted many more individuals to gain from one funded experience. Indeed, one of the objectives for the institutions choosing this approach was to create a larger community of like-minded individuals.

One institution requested funds for two day-long sessions for educators in museums in North Carolina, South Carolina, and Virginia. It was expressly designed for educators who typically can’t attend national conferences by virtue of their position within the institution. The sessions were aimed at “professionalizing the museum educators engaged in teacher education at informal science institutions.” Twenty-five educators from 11 institutions attended the first session, and, as one participant noted,

I thought it was interesting when [faculty] asked how many would be at the ASTC meeting and only 2 hands out of 25 went up—you are meeting a need for staff development. There’s certainly a benefit to doing this at an “away” site; it seems more like real professional development for these folks who are working their hearts out at their jobs, and one day makes it manageable logistically. I hope we are able to continue.

Sometimes participating as an individual in professional learning opportunities is insufficient to achieve desired institutional changes. One individual, feeling isolated following his prior professional development experience at the Inquiry Institute, needed to build a community of learners around the inquiry approach to science teaching and learning. He requested funds to bring the expertise to his institution and invited museum colleagues, teachers, and peers from other institutions to participate. His purpose was specific:

I realized that I was the only staff person from my museum who had the opportunity to
explore, discuss, and reflect upon the nature of inquiry. If inquiry was to catch on at the museum, then other staff members also needed to have a meaningful experience with this approach to science education.

Attending a Formal Program

In only two cases was the money used to attend a formal professional development program offered by non-museum educators. One science center in San Francisco, well known for its teacher education programs, wanted a learning experience that would take museum staff and their Teachers In Residence to a new level. In attending a symposium on action research, the team felt

what was important was finding a way to form a network, to share observations with others, and to encourage them to consider themselves fully empowered professionals, teachers influencing other teachers.

For this team it was necessary to seek expertise outside of the traditional realm of science education to attain the professional growth they desired.

As a next step in teacher development we wanted to offer the opportunities for these Lead Teachers to become involved in teacher research, reflecting on their own learning and their teaching of science.... We feel that it is important for these teachers to learn to reflect on and articulate their teaching capabilities, and to observe more closely how their children are learning.

Noting Outcomes

While many participants reported “it was a great experience” others went into depth about changes in thinking, changes in programs, and products created as a consequence of either visiting other sites, hosting or attending workshops. What seems most productive is suggesting the range of application made by professionals as a consequence of their own learning experience.

After visiting two institutions, a museum and a nature center, one educator developed a “Protocol for Reciprocal Professional Development Experiences,” suggestions aimed at helping host sites know better how to shape an effective visit experience. This Protocol document will be published by ASTC on the World Wide Web as a service for informal science educators.

One museum reconceived its service to teachers in the community and the museum’s role as a center for inquiry as a consequence of a site visit to the Workshop Center at City College in New York. A teacher center was designed, with teaching kits, a wide variety of inquiry materials, and scientific expertise available daily for district teachers who drop in or request specific support. The education center of the museum became a home for teachers—a type of teachers’ lounge away from the school, where conversation, exploration, and professional dialogue could flourish.

The museum expecting a successful grant for a State Systemic Initiative took its lessons learned and applied for a local systemic initiative grant from the National Science Foundation. This museum is now supporting every educator in three rural school districts in developing their own abilities to do inquiry science.

The San Francisco team piloted a Teacher Research Network. In addition to the museum’s staff, nine teachers attended our Teacher Research Network meetings [the first year]; seven returned [the second year] joined by four others. They met every two weeks, and discussed articles.

Findings

Multiple Strategies

Three different strategies define the type of professional development experience chosen by participants. While most grant recipients used the money to visit other sites, some used the funds to bring in an expert and thereby extend the reach to more museum staff. A small number of the grantees used money to attend a workshop or conference. What is intriguing is that informal science educators prefer to construct and control their own learning experience. Taking formal courses was the exception, not the rule, an approach that may reflect the informal educator’s predilection for learning and teaching in nontraditional ways.

Multiple Benefactors

Also striking was the recipients’ capacity to leverage the funds and extend the investment. While the money was given directly to either individuals or to a team of two or three, the influence of the funds extended to a much larger number. In measuring outcome, either the funds supported multiple people to participate in an experience, or it fostered the formation of networks, implementation of training programs, or creation of products to be shared among educators. In all cases the awardees found money or in-kind donations to match the original grant.

The Nature of the Benefits

The value of these experiences is more often felt than catalogued. Sometimes the educator can point directly to an outcome and say, “Therein is the
benefit.” More often, the change is dynamic, internal, and difficult to grasp. It encompasses reflection, catalyzing change and innovation, an appreciation of time, and connections. It is sometimes difficult to make the case that a program has been effective. However, the following quotes suggest the nature of the benefits derived from the Carnegie small grants.

Professional development opportunities, such as the one offered through ASTC, serve a role that is sometimes difficult to measure. The opportunity to stretch and use one’s imagination as a result of reflective time in a different museum setting is invaluable. One returns to the workplace energized and filled with excitement about the potential to grow.

Having the time to reflect on the work museum educators do was the single most identified benefit. A comment by one member sums up the feelings and thoughts of many.

It’s difficult to state strongly enough the value of conversations with other educators that the grants made possible. Sharing ideas with people from other institutions made for wonderful cross fertilization, and the special circumstances justified dedicating enough time to explore topics without hurrying and without necessarily following the most direct path to making decisions and getting things done.

This kind of rejuvenating opportunity is unusual in our sped-up times.

Museum educators said being validated as a professional was a significant benefit.

The grants presented an opportunity rare in museum culture: they validated the idea that collegial contact and conversation could be a significant and worthwhile way of working as well as a model of professional development, with real value for the institutions as well as for the individual employees.... it was not just by providing funds that the grants made our experiences happen, but also by helping us to imagine them as worthwhile and possible.

Having a first-hand experience, seeing programs and ideas within context, and gaining perspective was a benefit.

As we construct our understanding of these new tools and their applications, we are facilitated by observing how others are meeting these challenges...seeing things in context is of great value.

While not all the participants described the consequences of their experiences, those that did spoke of making changes in designing new programs, attempting new instructional strategies, creating new environments, initiating inquiry institutes, and networking with others. One grantee observed that the professional development experience “led beyond acknowledgment to commitment.” In fact, most participants launched a variety of new innovations at their home institutions.

Finally, many people commented on the value of networking, of meeting others in parallel positions, of sharing ideas, practices, and materials. A team from Philadelphia wrote,

A strong outcome of this trip was the especially strong sense that we had colleagues with whom we could share problems, questions, and ideas and that we really could learn from each other.

The challenge now facing us is to build on this model and create similar professional development opportunities worldwide. As we have seen in this project, a small investment can result in tremendous professional growth.

SESSION DATA:
I. Session Title
   Brief Description (limit to 25 words)

II. Type of Session
   A. □ Hands-On Workshop
      A 60-min. presentation that actively engages everyone in the audience in a hands-on experience with materials. Work table setup.
   B. □ Demonstration □ (30 min.) □ (60 min.)
      A 30-min. or 60-min. presentation where presenter(s) demonstrate a series of experiments or a scientific phenomenon. Theater-style setup.
   C. □ Poster Session
      A 60-min. mini-exhibit of ideas displayed on corkboard(s) by one or more presenters. Flea market-style setup.
   D. □ Lecture/Discussion □ (20 min.) □ (30 min.)
      A 20-min. or 30-min. opportunity to share an innovative teaching idea or present the results of research. Theater-style setup. (Formerly called Contributed Paper.)
   E. □ Panel
      A 60-min. interactive session by two or more speakers on a topic of general or specific interest, including a question-and-answer period. Theater-style setup.
   Z. □ Other

As a reminder, a presentation that promotes a product in which the presenter has a financial interest (or is representing a company that has a financial interest) must be proposed as a commercial workshop. In order to propose a commercial workshop, the company must be exhibiting at the convention. For information, contact Paul Kuntzler, Director of Advertising and Exhibit Sales, NSTA, 1840 Wilson Blvd., Arlington, VA 22201-3000, (703) 312-9265.

(See reverse side for additional information)
III. Subject Area (Check only one for listing in Final Program)
A. ☐ Astronomy  B. ☐ Life Science  C. ☐ Chemistry  D. ☐ Computer Science  E. ☐ Elementary  F. ☐ Ecology/Environment

See the list of strands and topics on the backcover.

IV. Intended Audience
A. ☐ General  B. ☐ Minimal Math & Science Background  C. ☐ High Level Math & Science Background

V. AV Equipment Required
NSTA will provide one overhead with screen for all sessions. NSTA will also provide microphones for sessions scheduled in rooms seating 100 or more. Please note: Participants may request the equipment listed below if essential to the presentation. Please consider the necessity of this equipment. NSTA's rental expense has increased significantly.

A. ☐ Overhead (NSTA will provide)

One computer and/or VCR will be provided if necessary. (Check box below)

B. ☐ 1/2" VHS with 25" monitor
C. ☐ Macintosh (8 MB) (or equivalent model) with monitor
D. ☐ IBM or IBM-compatible 486 VGA computer with DOS (or equivalent model) with monitor
E. ☐ Slide Projector with screen

VI. How many participants do you wish to accommodate at your session?
(Room assignments based on meeting space availability)
A. ☐ 45-65  B. ☐ 66-99  C. ☐ 100 +

SAFETY (guidelines on following pages)

Identify any potential safety hazards associated with your presentation:

What precautions will be taken during the presentation to deal with these hazards and to inform the audience?

What safety equipment will be required?

I have read a copy of the "Minimum Safety Guidelines for NSTA Presenters and Workshop Leaders" and agree to comply with the guidelines during my presentation.

Signature ___________________________ Date ______________

YOU MUST SIGN THIS

VII. Abstract (150-200 words—Provide details of your session content and activities on an attached sheet)

RETURN THREE COPIES OF THIS PROPOSAL BY MARCH 1, 1996, TO:

Donna Fletcher, Conventions, National Science Teachers Association,
1840 Wilson Blvd, Arlington, VA 22201-3000, U.S.A.

34
NSTA MINIMUM SAFETY GUIDELINES
FOR PRESENTERS AND WORKSHOP LEADERS

PREAMBLE: The National Science Teachers Association, an organization of science education professionals dedicated to the stimulation, improvement, and coordination of science teaching and learning, supports scientific safety at all levels. Presenters, workshop leaders, contestants, and authors at NSTA-sponsored activities serve as role models for other science educators. As role models, these individuals must develop, encourage, and display good safety habits at all times. A good safety role model promotes positive safety in actions, words, behavior, and deeds. Science safety is an integral part of science education and serves as a preparation for life. Accordingly, NSTA encourages teachers to offer meaningful and safe science experiences both inside and outside the classroom. NSTA requires that all presentations, workshops, and related science education activities be conducted in accordance with recognized safety procedures and good common sense. The intent of the safety guidelines that follow is to promote safe science practices at all NSTA-sponsored activities.

ALL PRESENTERS AND WORKSHOP LEADERS MUST FOLLOW THE NSTA MINIMUM SAFETY GUIDELINES

THE FOLLOWING MAY NOT BE PART OF ANY PRESENTATION OR WORKSHOP AT AN NSTA CONFERENCE UNDER ANY CIRCUMSTANCES:

1. Parts of the body are not to be placed in danger, such as placing dry ice in the mouth or dipping hands or fingers into liquid nitrogen or molten lead. Demonstrations such as the following shall not be conducted: walking on broken glass or hot coals of fire with bare feet, passing an electric current through the body, and lying on a bed of nails and having a concrete block broken over the chest.
2. Live vertebrate animals may not be used in demonstrations or for experimental purposes. Such animals may be used only for observational purposes provided the animals have been lawfully acquired, are housed in proper containers, and are handled in a humane way following the NSTA’s “Guidelines for Responsible Use of Animals in the Classroom” (NSTA Position Statement).
3. Live ammunition, firearms, or acutely dangerous explosives, such as benzoyl peroxide, diethyl ether, perchloric acid, picric acid, and sodium azide, may not be used. Commercially available firecrackers and blasting caps shall never be employed.
4. Plants with poisonous oils (e.g., poison ivy), saps (e.g., oleander) or other plants known to be generally toxic to humans are not to be used. (Resource: Human Poisoning from Native and Cultivated Plants, by James W. Hardin & Jay M. Arena. The publisher is Duke University Press, Durham, NC 27708.)
5. Experiments or demonstrations with human blood/body fluids may not be conducted.
6. Radioactive powders, liquids, or solutions are not to be used in a nonlaboratory facility.

GUIDELINES FOR PREPARING YOUR PRESENTATION:

1. Practice all demonstrations or workshop procedures BEFORE presenting them to an audience or having participants try them.
2. Research and understand the properties, chemical reactions, and dangers involved in all demonstrations. Plan to use correct handling procedures for all biohazards used. Arrange to have a fire extinguisher available whenever the slightest possibility of fire exists.
3. Prepare a handout that gives participants detailed instructions about the procedures, safety precautions, hazards, and disposal methods for each demonstration.
4. Prepare photographs, slides, videotapes, and so on, that show safe science practices. When preparing these materials, safety goggles and equipment shall not be removed for aesthetic considerations.
5. In planning demonstrations and/or workshops, keep quantities of hazardous materials to a minimum. Use only those quantities that can be adequately handled by the available ventilation system. Do not carry out demonstrations that will result in the release of harmful quantities of noxious gases into the local air supply in the demonstration or other rooms. The following gases shall not be produced without using a fume hood: nitrogen dioxide, sulfur dioxide, and hydrogen sulfide. Volatile, toxic substances such as benzene, carbon tetrachloride, and formaldehyde shall not be used unless a fume hood is available.
6. Make sure your glassware and equipment are not broken or damaged. The use of chipped or cracked glassware shall be avoided. If glassware is to be heated, Pyrex™ or its equivalent shall be used.

7. Thoroughly check motor-driven discs that will be revolved at moderate or high speeds. Make sure the disc is sturdy, that it contains no parts that may come free, and that the safety nut is securely fastened.

8. Arrange to use a safety shield and/or eye protection for audience members and interpreters for any demonstration(s) in which projectiles are launched or when there is the slightest possibility of an unsafe explosion. Arrange for proper shielding and protection for demonstrations which involve radiation. Only low-level, radioactive sources shall be employed. Do not allow direct viewing of the sun, infrared, or ultraviolet sources.

9. Make sure any lasers to be used in demonstrations are helium-neon lasers with a maximum output power rating not exceeding 1.0 milliwatt. At all times, avoid direct propagation of the laser beam from the laser into the eye of an observer or from a reflected surface into the eye.

10. Secure pressurized gas cylinders by strapping or chaining them in place or by using proper supports, i.e., lecture bottles.

11. Obtain, in advance, the necessary state and/or local permits needed for the firing of model rockets. Activities involving the firing of rockets must be well planned and follow Federal Aviation Agency (FAA) regulations, state and local rules and regulations, and the National Association of Rocketry’s (NAR) Solid Propellant Model Rocketry Safety Code.

12. Arrange for appropriate waste containers and for the disposal of materials hazardous to the environment.

13. Plan to dress safely for your presentation or workshop.

14. If you have any questions concerning safety and your presentation, contact the NSTA Associate Executive Director of Conventions (703-243-7100).

**DURING THE PRESENTATION:**

1. Comply with all local fire and safety rules and regulations. Follow the “NSTA Minimum Safety Guidelines.”

2. Wear appropriate eye protection, an apron, and similar protective gear for all chemical demonstrations or when appropriate for other demonstrations. Provide eye protection, aprons, and safety equipment for participants who will be handling chemicals, hazardous substances, or working with flames.

3. Do not select “volunteers” from the audience. Assistants used in demonstrations shall be recruited and given the proper instructions beforehand.

4. Warn participants to cover their ears whenever a loud explosion is anticipated.

5. Use a safety shield for all demonstrations that involve the launching of projectiles, or whenever there is the slightest possibility that a container, its fragments, or its contents could be propelled with sufficient force to cause injury. Shield moving belts attached to motors. Use caution when motor-driven discs are revolved at moderate or high speeds. Shield or move participants to a safe distance from the plane of the rotating disc.

6. Follow proper procedures for working with pressurized gases.

7. Use appropriate gloves and shields when working with hazardous chemicals, cryogenic materials, hot materials, radioactive substances, vacuums, electromagnetic radiation, and when presenting animals for observation.

8. Do not taste or encourage participants to taste any nonfood substance. A food substance subjected to possible contamination or unsafe conditions shall never be tasted.

9. Note clearly at the beginning of the program the presence or production of allergenic materials such as “theater” smoke, lycopodium powder, or live animals.

10. Maintain clear egress during the demonstration or workshop.

11. Emphasize and demonstrate appropriate safety precautions throughout the presentation or workshop.

12. Distribute a handout that will give participants detailed instructions about the procedure, safety precautions, hazards, and disposal for each demonstration.

—Adopted by the NSTA Board of Directors, August, 1994

VOICES OF EVOLUTION: A REVIEW

Duane Jeffery
Professor of Zoology
Brigham Young University, Salt Lake City, Utah

This one-of-a-kind publication belongs in every library dealing with science and science education. Born of the continually smoldering creationist controversy in the United States, it brings together 86 formal statements addressing creationism, evolution, and their proper roles in religion, science, education, and society at large. It summarizes the six most critical court cases on the issue, and gives extended excerpts from four of them.

The 86 statements include 40 from scientific organizations (e.g., the Academy of Science of the Royal Society of Canada, the American Anthropological Association, the American Association for the Advancement of Science, the American Institute of Biological Sciences, the National Academy of Sciences [U.S.], the Geological Society of America, and various state academies of science), and 15 from religious organizations (e.g., the American Jewish Congress, Center for Theology and the Natural Sciences, a number of major Protestant groups, and Pope John Paul II for Roman Catholicism). Eleven statements derive from civil liberties organizations (e.g., Americans for Religious Liberty, Institute for First Amendment Studies, and People for the American Way). The remaining 20 come from 17 educational organizations such as the American Association of Physics Teachers, the Biological Sciences Curriculum Study, the National Association of Biology Teachers, and various state teachers' groups.

Beyond just stating formal positions, this collection supplies some of the most sensitive and sophisticated analyses available on these critical topics. The legal summaries will be especially useful for teachers and school boards facing pressure from creationist groups and individuals. Highly recommended for all persons in these fields, and a must for libraries.

Membership in the National Center for Science Education, which publishes Voices, is $25.00 per year, and that includes a subscription to the journal: Creation/Evolution. Voices, itself, sells for $10.00 to members of NCSE, $12.00 otherwise (includes postage).

1996 CEFIC SCIENCE EDUCATION AWARD

This annual Award, created by the European Chemical Industry Council, CEFIC, and it's National Federation Members, will recognise excellence in science education achieved by a teacher and a class of pupils—aged 10 to 17 years.

The Award comprises three prizes for the winning team:

- A one-week, all expenses paid, trip to another European country.
- 5.000 ECU for the purchase of scientific or teaching equipment for the school of the winning team, and
- 1.000 ECU plus a "Diploma of Excellence" for the teacher.

In addition, prizes will be awarded to other particularly meritorious entries.

Entries should be sent to your National Chemical Industry Federation by April 16, 1996. An independent international jury will select one team comprising a teacher and a class of pupils who by their innovative project have demonstrated a more effective and attractive way of teaching Chemistry or Science in general. The Award will be presented on the occasion of the CEFIC General Assembly in Amsterdam June 14, 1996.

The rules of operation and further information may be obtained from:

Science and Technology Department
Avenue E. Van Nieuwenhuysen, 4 Box 1
B - 1160 Brussels
Phone: +32 2 676 72 07
Fax: +32 2 676 73 30

Science Education International, Vol. 6, No. 4 December 1995
Calendar
1996-1997

Industry-Education (ELF Sponsored)
Location: Paris

January 4-6, 1996
ASE Annual Meeting
Location: University of Reading
Contact: Iris Sinfield
Association for Science Education
College Lane
Hatfield
Herts AL10 9AA
UK
Fax: +44 1707 266 532

Although the meeting officially starts on January 4th, there will be a special International Seminar organised jointly by ASE and ICASE on Wednesday, January 3rd. The subject will be "Continuing professional development of the science teacher" and contributors are very much welcomed. There will be accommodations available on Tuesday, January 2nd, for those attending. As well as the British Council symposium and an international reception, there will be hundreds of sessions to interest and inspire, whatever the level—primary, secondary, tertiary, or higher education.

January 5-10, 1996
GASAT 8 International Conference
Location: Ahmedabad, Gujarat, India
Contact: Jayshree A Mehta
Conference Chair/Convenor
GASAT 8 Secretariat
SATWAC Foundation
A1/22, Amarpali, Sukhipura,
New Shardamandir Road,
Paldi, Ahmedabad-380 007, INDIA
Tel: 91 79 428991, Fax: 91 79 416941

January 8-11, 1996
JISTEC '96—The Second Jerusalem International Science and Technology Education Conference
Location: Jerusalem, Israel
Theme: Technology Education for a Changing Future—Theory, Policy and Practice
Contact: Dr. Arley Tamir, Conference Chairman, or The Conference Secretariat
POB 57005, Tel Aviv 61570, Israel
Fax: +972-3-6133341

The conference expects to provide a forum for discussion on technology education, an opportunity for exchange of ideas and for reporting on achievements by experts, researchers and developers from both developed and developing countries. It is anticipated it will bring together education policy decision makers, educators, and other professionals from institutions of higher education, teacher training institutes, schools, educational authorities, etc.

January 21-26, 1996
3rd International Interactive Multimedia Symposium
Location: Perth Western Australia
Contact: Promaco Conventions Pty Ltd
ACN 008 784 585
PO Box 890, Canning Bridge, Western Australia 6153
Tel: (61) (9) 316-1453
e-mail: promaco@cleo.murdoch.edu.au

February 7-9, 1996
International Consortium for Research in Science and Mathematics Education (ICRSME) 6th Consultation
Location: Belize City, Belize
Central America
Contact: Dr. Arthur L. White or Dr. Donna F. Berlin
The National Center for Science Teaching and Learning (NCSTL)
Room 100
Ohio State University
1929 Kenny Road
Columbus, OH 43210-1015 USA
Tel: (614) 292-3339, Fax: (614) 292-1595

March 7-8, 1996
16th Triennial LMFK Nordic Congress for Math and Science Teachers and the UNESCO-INISTE Conference (being held in parallel)
Location: Linköping University, Sweden
Theme: Educating for the Future—Energy Environment Communication

March 28-31, 1996
NSTA National Conference
Location: St. Louis, MO, USA

March 28-April 5, 1996
EDUTOURS, Inc.
Location: United States
Contact: Mr. Dennis Chisman, Knapp Hill, South Harting, Petersfield, GU 31 5LR, UK.
The International Council of Associations for Science Education (ICASE) in conjunction with ICASE member associations is offering a Science Education and scenic tour in the United States.

April 1-4, 1996
XVIII International Meeting on Communication, Education and Scientific and Technological Literacy
Location: Centre Jean Franco, Chamonix, France
(This meeting will be in French.)
Theme: Sciences, Techniques and Public Understanding
Contact: Daniel Raichvarg
G.H.D.S.O.—L.I.R.E.S.T. Bat 307
Universite Paris-Sud
F-91405 Orsay Cedex, France

This meeting will explore the various modes of promoting scientific and technological literacy—the media, museums, schools, associations, etc., and consider the developments, successes, limitations and concerns that have arisen. The meeting will include lectures, presentation of research findings and discussion sessions.

May 28-31, 1996
14th Dortmund Summer Symposium
Theme: Educational Research in Chemistry and Physics Education
Contact: Dr. Hans-Jürgen Schmidt
University of Dortmund, Dept. of Chemistry
Otto-Hahn-Str. 6
43221 Dortmund, Germany

The main aim of this conference is to discuss the methodology of empirical research in this field.

June 14-18, 1996
First World Congress on Science Centres
Location: Finland
Contact: Ms. Helena von Troil, Secretary General
Heureka, The Finnish Science Centre
PO Box 166
FIN-01301 Vantaa, Finland
Tel: +358 0 85799
Fax: +358 0 873 4142

The Association of Science-Technology Centres (ASTC) and the European Collaborative for Science, Industry and Technology Exhibitions (ECSITE) invite science centre professionals from all over the world to the FIRST SCIENCE CENTRE WORLD CONGRESS to be held at Heureka the Finnish Science Centre in Vantaa (Helsinki), Finland. The congress will give opportunities to learn and share the experience of colleagues from all over the world.

June 14, 1996
1996 CEFIC Science Education Award
Location: Amsterdam
Contact: Science and Technology Department
Avenue E Van Nieuwenhuyse, 4 Box 1
B-1160 Brussels; Tel: +32 2 676 72 07
Fax: +32 2 676 73 30

This annual award, created by the European Chemical Industry Council, CEFIC and its National Federation Members will recognise excellence in science education achieved by a teacher and a class of pupils aged 10 to 17 years.

July 14-19, 1996
14th International Conference on Chemical Education
Location: Brisbane, Australia
Contact: The ICCE Conference Secretariat
(Sally Brown), Continuing Professional Education,
The University of Queensland 4072 Australia
Tel: (07) 365 6360 Intl: +61 7 365 6360
Fax: (07) 365 7099 Intl: +61 7 365 7099
E-mail: chemed96@ceu.uq.oz.au

The 14th ICCE will be held in Brisbane from July 14-19, 1996. It is only the second time this conference has been held in the southern hemisphere. The biennial conference brings together chemistry teachers, chemists and science educators from school, industry and university settings to share ideas and learn from one another about innovation in teaching and learning and the discipline of chemistry. The theme, Chemistry: Expanding the Boundaries, acknowledges the centrality of chemistry through its expanding relationship with many facets of science and everyday life. Conference participants will be challenged to develop this theme with the view of enhancing our understanding of the important relationships which chemistry forms with the new frontiers of human endeavour. Implications for chemical education beyond 2000 which give a “science for all” perspective will be encouraged.

July 22-26, 1996
EDINBURGH '96: The Fourth International Conference on School and Popular Meteorological and Oceanographic Education
Theme: Roles of meteorology and oceanography in science education
Location: Edinburgh
Contact: Mr. J. M. Walker, Dept. of Maritime Studies
PO Box 907, Cardiff CF1 3YP, UK
Tel: +44-1222-874271, ext. 6754
Fax: +44-1222-874301;
e-mail: walkerjm@cardiff.ac.uk

**July 30-August3, 1996**

16th Nordic LMFK Conference  
Location: Linkoping, Sweden  
Theme: Baltic Sea Project and the INISTE Network  
Contact: Lisbeth Ekstrom  
LMFK-Kongressen 1996  
Gia Ledbergsvagen 6  
S 58320 Linkoping  
Sweden

**August 4-8, 1996**

14th Bicentennial Conference on Chemical Education  
Location: Clemson University, Clemson, SC  
Contact: DeWitt Stone, BCCE General Chair, 206  
Sikes Hall, Clemson, SC 29634-5170  
Fax: (803) 656-1515; e-mail: bcce@clemson.edu  
WWW address: “http://tigerche.d.clemson.edu”

The Planning Committee has selected “Chemistry: The Challenge of Change” as the conference theme. The uses of computers and multimedia technology in chemistry teaching will be a particular focus of this conference. Another focus will be topics such as biotechnology, polymers, textiles, advanced materials, and environmental science—fields in which chemistry overlaps with the interests of other disciplines.

**August 23-28, 1996**

9th Annual Visitor Studies Conference  
Location: Estes Park, Colorado  
Theme: “Listening Outside”  
Contact: Marcella Wells, Conference Coordinator  
Colorado State University, Fort Collins, CO 80523  
Tel: (970) 491-5358; Fax: (970) 491-2255  
e-mail: marcella@picea.cnrr.colostate.edu OR  
Margie Marino, Workshop Coordinator  
Denver Museum of Natural History  
2001 Colorado Blvd.  
Tel: (303) 370-8342; Fax: (303) 331-6492

The intent of this conference is to foster a network among museum professionals and others concerned with visitor learning and behavior in informal settings; stimulate discussion and practice of the Excellence and Equity guidelines and principles; stimulate an awareness about the diversity of settings appropriate for visitor studies; increase the understanding about the application of visitor studies to outdoor recreation and natural resource settings; enhance higher education and public natural resource agency involvement in visitor studies research.

**November 1996**

Australian Model Solar Car Challenge  
Location: Adelaide, Australia  
Contact: Brenton Honeyman, Chair, AMSCC  
The National Science and Technology Centre  
King Edward Terrace, Canberra ACT 2600  
Tel: (06) 270 2816  
Fax: (06) 273 4346

In November 1996 students from across Australia will meet in Adelaide to compete in the Australian Model Solar Car Challenge, the culmination of state-based challenges conducted from September to November in New South Wales, Victoria, Queensland, South Australia, Western Australia, Tasmania, and the ACT.

**December 27-30, 1996**

NSTA International Convention  
Location: San Francisco, CA

The convention, to be chaired by NSTA Executive Director Bill G. Aldridge, will bring together scientists and K-college science educators from dozens of science and science education societies and organizations worldwide. Invitations have already been sent to societies in more than 30 countries. Holding the event in San Francisco, it is hoped, will especially encourage participation from Pacific Rim countries.

At this convention, participating teachers and science educators will present sessions in their areas of expertise (interdisciplinary approaches are encouraged) to scientists who are not as familiar with the classroom. In turn, scientists will present sessions about their work to nonspecialist scientists and to educators less familiar with the latest news from the research laboratory.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

The opinions expressed in this publication are those of the authors and do not necessarily represent the official position of ICASE or ICASE members.
LITHUANIAN ASSOCIATION OF CHEMISTRY TEACHERS (LACT)

LACT currently has 97 members comprising chemistry teachers from secondary schools, University lecturers and staff of the in-service teacher training institute. The corresponding person is Regina Jasiuniene based at the in-service training institute.

The Main Aims of LACT
- to develop creative and social activities for chemistry teachers;
- to collect and disseminate the latest information on research and methods of teaching;
- organise conferences, symposia, meetings, exhibitions and publications;
- propagating the best chemistry achievements;
- to build networks and professional contacts of chemistry teachers and connections with other Lithuanian organisation and associations, thus supporting cooperation;
- to provide LACT members with new teaching materials;
- to initiate nature protection problem solving;
- to promote Chemistry Teachers’ professional development;
- to support new projects on Chemistry teaching;
- to influence the Ministry of Education and Science in their decision making concerning the priorities for Chemistry teaching; and
- to defend the interests of Chemistry teachers.

ASTE '95—DURBAN, SOUTH AFRICA

During the week of December 4 1995, a group of more than 100 African science educators and scientists met at the University of Durban-Westville (UDW) in South Africa. The occasion was the African Science and Technology Education meeting titled, “Towards the Future: Practice, Policy, and Priorities.” At a time when many wonder about Africa’s place in the world—the Ugandan leader Yoweri Museveni, for example, recently published an article titled “Does Africa Count?”—many also recognize the need to improve education for African children if Africa is to take its rightful place in what has become the Global Village. Certainly science and technology must be an important part of that education.

ASTE '95 was thus held to define philosophy, practice, research, policies and priorities for science and technology education in Africa with special regard for women. Organisers also hoped that the meeting would promote collaboration amongst science education policy makers, practitioners, and donors. The conference participants also included long time friends of the continent, most notably the very distinguished Phillip Morrison of Harvard University and Professor Jerry Pines of the California Institute of Technology. The conference discussions centred on key issues: historical perspectives, science and technology for development, curriculum issues, political and hegemonic issues, equity, teacher education, resources for education, philosophy and theory, research, and media issues.

The conference organisers under the direction of Mr. Prem Naidoo (UDW) are now compiling conference papers and notes to be published as a proceedings. It is anticipated that the group will meet again in two years so that progress can be assessed. The meeting was sponsored by The African Forum for Children’s Literacy in Science & Technology, The Rockefeller Foundation, The Norwegian Agency for Development Assistance, the University of Durban-Westville (RSA), and the Foundation for Research & Development (RSA).

THE EUROPEAN SCIENCE EDUCATION RESEARCH ASSOCIATION (ESERA)

ESERA is a new association formed at the European Conference on Research in Science Education held in Leeds, England in April 1995. Participants agreed upon a draft constitution and elected an executive committee. The Aims of ESERA include:

- enhance the range and quality of research and training research in science education in Europe;
- provide a forum for collaboration in science education research between European countries;
- represent the professional interests of science education researchers in Europe;
- seek to relate research to the policy and practice of science education in Europe; foster links between science education researchers in Europe and similar communities elsewhere in the world.

Activities will include summer schools for Ph.D. students (the 1996 programme will be in Barcelona but probably restricted to European students) and a conference every two years (Rome in 1997, Kiel in 1999, open to everyone).

Membership is open to Science Education Researchers from any part of the world. As it was determined that this should be a professional association of academic standing, applications for membership should be accompanied by a brief curriculum vitae showing evidence of research in science education, and the nominations of two established science education researchers (not necessarily members of ESERA).

The subscription is currently 50 Dutch Guilders (about 22 pounds sterling or $35, but you need to add the cost of transfer).

For further details and an application form, please contact the secretary.

A VISIT TO INSTITUTO DO DESENVOLVIMENTO DA EDUCACAO (INDE) MOZAMBIQUE

Dennis Chisman and Jack Holbrook

Introduction

At the invitation of INDE, an ICASE member institute, we were able to give a number of lectures and seminars on science education development in Mozambique. The visit was made possible by a grant from the Royal Society of Chemistry.

The timing of the visit was arranged to fit in with a visit to South Africa to discuss arrangements for a major international conference on science education to be held in 1997 in collaboration with the International Council of Associations for Science Education (ICASE).

Seminars

Seminars were held in INDE and the Pedagogical University based on curriculum development in science and, in particular, on Project 2000—a joint project of UNESCO and ICASE—for the promotion of scientific and technological literacy. In addition, one seminar was given on primary science education, promoting Stepping Into Science, the ICASE project designed to encourage investigations at the primary level by giving certificates to students for taking ‘steps’ into science (for more details on this scheme, contact the ICASE Primary Science Officer—Dr. Sue Dale Tunnicliffe).

The participants in the seminars included some of the academic staff of INDE and the Pedagogical University, together with the teacher trainers and a few teachers. In addition, foreign advisers working in science education in Mozambique, including a Russian specialist (Dr. Oleg Popov) and a Dutch United Nations Volunteer (Sylvia den Hengst).

Impressions

Mozambique is a very poor country with little or no resources for education. The teachers are poorly paid and lowly qualified. Most of them have more than one job. There is very little motivation for professional development of teachers or for the formation of professional associations of teachers. Nevertheless, there are pockets of enthusiasm—one such is INDE—and the National Teachers Organisation is already organising some inservice courses. The participants at the seminars showed much enthusiasm and were very willing to be involved in activities. Many showed creative skill in putting activities into place with very little equipment. The need for this was amply illustrated on a visit to a primary school just outside Maputo.
The school, covering grades 1-5, caters to 1076 students in 23 classes with only 14 teachers. If this is difficult enough to imagine then add to this that the 7 classes need to function at any one time in a 2 classroom school. Five classes are held under trees outside the school. At the time of our visit the school was not in session and all the school equipment was packed and placed in the headteacher’s room. There was space as the room held little in the way of furniture. All the equipment for the entire school was stored in 3 cardboard boxes, each about 0.5 x 0.3 x 0.3 meters. The classrooms were sparsely equipped and besides a table and chair for the teacher, and a blackboard, there were desks that could cater to about 10-12 students (the rest sat on the floor).

Acknowledgments

We both wish to record our thanks and appreciation to the Royal Society of Chemistry for the grants which enabled this visit to Mozambique. We also wish to thank those colleagues in Mozambique who received us and who arranged our busy 3-day schedule, not least the Head of the Zimpeto Primary School for so graciously receiving us and answering our many questions and to Dr. Oleg Popov who made it all possible.

ICASE HAS A NEW HOME PAGE

ICASE is now available on World Wide Web. As we all know, communication within and among our organizations is crucial. We must explore all possible avenues for improving both the quaintly and the quality of our interactions. The World Wide Web has tremendous potential with it’s ability to provide print material, color photographs, and even short film clips from one location.

ICASE President Brenton Honeyman has been busy exploring how this latest communication tool might help all of us. His efforts may be viewed at the following location. Please add this home page site to your bookmarks and plan to visit us regularly: http://sunsite.anu.edu.au/ica.

Increase Communication

Let us know how we may help you and your organization. Send us e-mail comments, suggestions and even articles electronically. If you have access to internet, we would like very much to hear your suggestions as to how ICASE can better serve your needs. Send your comments to:

THE ROLE OF SCIENCE TEACHER ASSOCIATIONS IN PROMOTING SCIENTIFIC AND TECHNOLOGICAL LITERACY

Jack Holbrook
Executive Secretary
ICASE

Introduction

Articles in Science Education International, as illustrated in the December 1995 issue, are showing the emergence of a new direction for the teaching of science subjects. The importance of relevance in science education is beginning to shift teaching towards issues and concerns of society either by making these stated areas of study within the curriculum, where traditional academic chapter titles are maintained, orienting the teaching approach within the topic towards such issues or concerns. The former can be related to the outcomes of an ICSU CTS conference in India (Bangalore, 1985) on science and technology education for future human needs, where teaching areas were suggested as—Health; Food, Land, Water and Mineral Resources, the Environment, Energy, Industry and Technology, Information Technology, Ethics, and Social Responsibility.

With this in mind, it is time, if it is not already the case, for science teacher associations to consider the teaching directions they would wish to promote for the 21st century. This is important now. Whilst it might be fairly easy to change the curriculum, or the textbook, or even an external examination, it appears to be much more difficult to persuade teachers to change their science teaching philosophy and their approach in the classroom (or laboratory). For many teachers the move towards teaching science appropriately to all students is likely to prove very difficult. It is also likely to be difficult to interpret the meaning of scientific and technological literacy within society and implement this in the teaching of science in ways that differ from the gaining of unrelated scientific conceptual ideas and an academic foundation in the sciences which is often perceived as important by scientists.

Project 2000+

Project 2000+ (1992), initiated by ICASE and UNESCO and officially launched in 1993, calls on both government and non-governmental organisations to rethink their philosophy towards the teaching of science and technology in their own country and to begin measures to help teachers meet the challenges of teaching science to all students in a relevant and meaningful way. The Project 2000+ declaration, strongly supported by ICASE and distributed to all ICASE member organisation, calls for measures and activities to be in place by the year 2001, a mere five years from now.

Project 2000+ suggests that STAs take note of trends and developments occurring in science and technology education over the previous 20 or so years and makes attempts to bring together the considerable and growing research outcomes with the needs of teacher educators and teachers. The major message is the need to pay much more serious attention to the scientific and technological needs of society for the 21st century and the way the intentions of science education are to be implemented in practice.

Federico Mayor, Director-General of UNESCO, in addressing the Project 2000+ conference on Scientific and Technological Literacy for All (UNESCO,1993), pointed out: “In a world increasingly shaped by science and technology, scientific and technological literacy is a universal requirement. If people are not to be alienated in some degree from the society in which they live; they are not to be overwhelmed and demoralized by change. They are to have the basic knowledge and understanding to make those multifarious political, environmental, and ethical choices with which discovery and its consequences are confronting us all.”

Possible Curriculum and Teaching Implications related to the Goals of Project 2000+

To promote relevant and meaningful science education for all students obviously calls for changes in the curriculum. But simply changing the content is not enough. Below are suggested a number of fundamental changes in the curriculum structure and the manner in which teachers approach the teaching of science subjects. The suggestions try to illustrate that basing teaching time on content alone is no longer appropriate. This will have obvious implications for the manner in which textbooks are used and where teachers place emphasis in their teaching approaches.

The implications of teaching for scientific and technological literacy for all are suggested as:
a) Science and technology will no longer be taught through a 'teach the fundamentals first', concept-led syllabus (the traditional academic approach). Other approaches which stem from societal or technological concerns and build on students' prior experiences which provide a basis for constructs to be formed will be seen as more relevant (constructivist theories).

b) Syllabus units will generally be expressed with societal, rather than academic, titles. This will encourage teaching units away from the concept first, 'application as an afterthought', approach. It will promote greater consideration of which science is really relevant and hence provide the rationale for selecting topics (from the excessive and ever-growing body of scientific knowledge). The old argument 'it is fundamental' will no longer be applicable.

c) Sequencing, within teaching units, will generally proceed from the societal situation, concern, or debate to a consideration of concepts and information needed for the unit (a breaking-down approach, starting with that which is familiar or topical), rather than attempting a systematic build up of background in a 'science facts first, applications second' approach (an approach going from the unfamiliar and trying to reach the familiar—often unsuccessful and students become bored!!).

d) Student participation approaches will be the main thrust of the teaching method and the intended time distribution will take note of the need for all objectives of the course to be achieved. (Basing time distribution on syllabus content rather than the course objectives has tended to promote a teacher centred approach).

e) Allowance will be made in the teaching time distribution for economic, ethical, social and political considerations within science topics. (Curricula developed, based on content, too easily become overloaded when time allowance is not included for contextual aspects and relating the place of science in the overall education arena).

f) More attention will be given to communication skills such as discussing, debating and role playing, rather than relying on pencil and paper skills, i.e. reports, plotting graphs, manipulating numerical or tabular data. It will be seen as important that communication skills relevant to society are developed through all subject areas.

g) More emphasis will be placed on problem-solving and planning skills. Transference of skills to unknown situations and the development of a scientific approach will be seen as far more important than acquiring isolated concepts, memorizing facts or even carrying out a number of set experimental procedures, based on 'textbook' instructions.

h) Although science and technology are experimental, this will not mean teaching theory first and undertake some recipe experiments or procedures afterwards. The scientific method will call for student participation in all processes of investigation, from identifying the problem and planning the investigation, to acquisition of the necessary knowledge, to analyzing the outcomes and their implications. Curricula will allow teaching time for students to acquire such skills.

i) Science and technology will be promoted with a positive rather than a negative image (syllabus headings such as pollution will need to be avoided) and will promote gender equity. Scientific and technological literacy will be appreciated as important for women and girls as it is for men and boys.

j) A greater link will be established between school science and technology programmes and agencies outside the school (museums, industry) which utilize or promote science and technology. For example, greater recognition will be given and better utilization made of the more exciting manner in which science and technology museums/centres are able to portray information and applications than is ever possible in the classroom situation.

The Potential of Science Teacher Associations to meet Teacher Needs

1. Arguably, the biggest obstacle to future progress is persuading teachers to accept and implement the changes being proposed by Project 2000+. Peer group interaction is seen as vital if teachers are to be persuaded that there is a need to modify their teaching strategies.

The role of science teacher associations is seen as crucial in this respect and this article is an attempt to persuade STAs that this needs to be a major consideration for the rationale of a STA within a country. It is no longer sufficient to help teachers with their day-to-day teaching in 1996;
STAs also need to help teachers prepare for teaching beyond the year 2000. This means a change of philosophy for teachers from that currently in place. STAs need to be at the forefront of such a challenge.

2. Primary school teachers, in so many countries around the world, need help. Often in-service teacher education seems unable to compensate for the lack of school-acquired interest and many teachers develop an inherent fear of teaching science, scared of making a mistake. Attempting a change of attitude and instilling more appropriate approaches to the teaching of science and technology represent huge and long-term undertakings.

STAs in some countries are recognizing the importance of primary science and are trying to help teachers at this level. This article tries to persuade all STAs of the importance of teaching substantial and exciting science at the primary school level. Gone are the days when secondary school teaching can ignore previous teaching and assume that students have no previous science knowledge. This article also tries to persuade STAs of the important role they can play in helping primary school teachers implement meaningful, relevant and exciting science and technology.

3. Many science specialist teachers need to change their outlook, philosophy and practice if scientific and technological literacy is to be more than a stated goal by curriculum developers. Specialist teachers in the science sub-divisions must be persuaded that they should not set themselves up as role models. There is always the danger that such specialization encourages science and technology to appeal only to few students at the expense of popularization of science and technology for the many. It is of crucial importance that teachers are guided to look carefully at the education they are providing for all students and ensure that their teaching strategies promote relevant science.

Science teacher associations can do much in this aspect.

4. Where teachers are not involved in the development of the teaching process and do not understand its goals, they are poorly prepared to implement any change. Furthermore they are usually poorly motivated to read any documentation about trends in science education, or the intentions of the change. In general, teachers rarely, if ever, read science education journals (Holbrook, 1992). They continue as before unless there are strong incentives for putting effort into change. Such incentives could be:
   a) change of the external examination (the usual stimulus for change)
   b) financial incentives for teachers (e.g., promotion, higher salary)
   c) teachers feeling ‘ownership’ and that their ideas and opinions are important and carefully considered
   d) strong and relevant (as perceived by teachers) inservice education presented to teachers as if teachers are part of a team and have expertise.

Whilst STAs, as professional bodies, are not involved in the welfare of teacher, e.g., salaries, there is much that STAs can do to involve teachers in putting forward ideas on increasing the validity of examinations, publicizing teacher ideas and opinions and in taking the lead in meeting teacher needs through peer group in-service provision.

5. An important approach in persuading teachers to try out new ideas is through the development of teaching materials that are attractive, easy to use and highly motivational for students. These materials can be directly related to the syllabus, e.g., reorientation of the approach to teaching, which has as goals
   (i) greater relevance to everyday life
   (ii) greater educational value in meeting skills
   (iii) greater student involvement
   (iv) more logical and interesting, looked at from the students point of view

   Or a number of alternative materials can be made available for teachers from which the teachers select whatever they consider appropriate. Choice increases the professionalism of teachers as teachers are called upon to make their own decisions and are thus required to think about their teaching strategies. Besides the above goals, these materials have the advantage that they could also
   (v) carry new scientific information
   (vi) be a source of information for teachers from which they then develop their own materials

Of interest here is the growing quantity of written ‘enrichment’ material being developed by non-Governmental groups e.g. (on the international scene) ICSU CTS and ICASE, (and nationally) science teacher associations, which endeavor to provide the teacher with add-on or possible replacement material for their teaching. Examples, internationally and regionally, are the materials on Global Change and Science in Space, Science across Europe, Science across Asia/Pacific, whilst
nationally SATIS (Science and Technology in Society) is a well known development by the
Association for Science Education in the UK. Science teacher associations are well placed to
publicize exemplar materials, to train teachers in the development of local materials and to initiate
and coordinate the widespread local production of such materials.

6. Once the classroom door is closed, lessons proceeds based on the skill of the teacher. The
teacher thus needs to be a professional and attempts to undermine this, are likely to lead to ineffective
teaching. There appears to be no such thing as teacher proof lesson packages that can be taught
irrespective of the traits of the teacher. Where the teachers is poorly equipped to deal with social
issues that demand a scientific input, or their science is inadequate to handle technological
issues, (as they only know the ‘scientists science’), more attention is needed to support and guide
teachers.

Science teacher associations are uniquely placed to recognize the needs of teachers and make
available updating provision that is appropriate.

7. Scientific and technological literacy is not a ‘have or have not’ situation. It is built up during the
process of schooling and guided and emphasized by concerns and needs of society. This does not
mean to say that every teaching topic should be provincial, because science is worldwide, the world
is a global village and concerns such as global warming, the ozone layer, deforestation,
environmental issues, health, energy resources and industrial pollution are universal. It does not even
mean that there is one global solution. Decisions needed in one community will reflect the priorities
of that community and these can differ from the priorities of another community, or even the same
community related to another time period. Science education is seen as having an important role in
guiding students in this realization and a model of science education solely promoting science ideas
that have a unique solution is no longer applicable.

Science teacher associations are able to play a major role in helping teachers relate their science
teaching to the decisions being made within society and hence enabling students to realize the societal
importance of developing scientific and technological literacy.

8. A bottom up approach to a recognition of the needs of teachers relies on peer group support playing a
major role. Teacher groups can play a major role in meeting actual, rather than perceived, needs.
Teacher groups are extremely active where developmental projects are widespread and it
should come as no surprise that teacher groups—science teacher associations—are instrumental in
the development of many of these—SATIS (UK), STAV Physics Series (Australia). An important
trend in the promoting of Project 2000+ ideas is the involvement of teachers, through teacher
groups such as science teacher associations. Such groups can play an invaluable role in raising
morale, in making available teaching resources, in provide support for the teacher, in stimulating
new directions and above all in the dissemination and monitoring of change. Project 2000+
advocates teacher groups by the creation of National Task Forces (UNESCO, 1993) in which
all groups interested in the development of education are represented and have a voice.

9. Teacher rely heavily on the use of textbooks. Research has shown that the more insecure the
teacher, the more the textbook dictates the direction and pace of the lesson. Promoting scientific and
technological literacy is a problem if textbooks concentrate on factual knowledge and conceptual
understanding and pay little more than lip service to the wider goals of science and technology
education. Unfortunately most textbooks, and even student workbooks, are weak in meeting objectives
such as developing problem solving, decision making and communication skills. Textbooks are
often geared to the assessment emphases of examinations and based on an examination syllabus, where scientific fundamentals are
highlighted. This promotes conceptual goals but makes textbooks poor in guiding attitudinal gains.

Science teacher associations are able to help teachers reflect on the choice of textbook, its
advantages and disadvantages. Also science teacher associations are able to help teacher
question the role of the textbook in their teaching so that the teacher is implementing the goals
intended, rather than those perceived as appropriate from slavishly following a textbook.

10. Training teachers with specialisms in interdisciplinary areas, such as sustainable
development, global change, assessment of risk, energy, etc. is rare and it is much more likely that
teachers have received their science education, both at undergraduate and, if applicable,
post-graduate levels, confined to rigid man-made divisions of biology, chemistry and/or physics.
Undergraduate programmes reflecting the interdisciplinary of science and drawing on a less
specialized school education are needed, especially in the preparation of future teachers.

Science teacher associations can play an important role in persuading tertiary institutes of
the need to provide a more balanced education at the undergraduate level.

11. Teacher background is also partly responsible for teacher intransigence to curriculum change. Science educators in institutes of higher education have a responsibility to reflect on the type and breadth of education that is needed at primary and secondary level, both for those undertaking science/technology and non-science/technology courses and to guide teachers accordingly through pre-service and in-service courses. This is especially true in developing countries where securing places at the tertiary level is highly competitive and examinations, governing selection, have traditionally emphasized factual knowledge and pencil and paper question-handling techniques, rather than scientific and technological literacy.

Science teacher associations, have an important role to play in increasing the validity of selection procedures and in breaking the cycle of inappropriate primary and secondary science education leading to teachers having backgrounds that make them poorly equipped to cope with change.

Partly the intransigence is guided by the poor professionalism of teachers, where the teaching emphasis, especially of specialist science teachers, is all too often guided by the demands of tertiary education, rather than by the needs of the student.

Science teacher associations provide a valuable channel for peer group support in recognizing how the curriculum should be interpreted and how the needs of all students can best be met.

The Role of Professional Teacher Associations

Related to the comments already made, major ways in which teacher, and more explicitly groups of teachers, i.e., science teacher associations, can be involved in promoting Project 2000+, and hence scientific and technological literacy, are suggested below. These have been grouped into those considered possible by any STA and those more likely only where the STA has sufficient resources, or additional support.

Level 1—Simplest level for STAs—should be possible for all STAs

a) By means of seminars, workshops on exemplary teaching and publications, such as a newsletter, persuade teachers to support the new direction and guide them to realize its educational potential.

b) Providing in-service support for teachers through seminars and workshops to introduce, plan trials and evaluate strategies and materials related to the new direction.

c) Developing support materials and other resources to help teachers prepare for a new direction and encouraging teachers to trial them in their classrooms.

d) Providing seminars, resources, etc., which teachers may find useful for updating their background knowledge in societal related (technological) science.

e) Producing a regular bulletin/journal on teaching ideas and developments in science education.

Level 2—Intermediate level where STAs are strong enough to be involved in curriculum development, guiding examination papers, policy making and textbook/workbook design

f) Encouraging teachers to activate ideas, monitor progress and allay concerns of teachers through coordinating action research geared to the teaching approach and the curriculum.

g) Commenting and forwarding submissions on the current curriculum and the examination system and putting forward ideas for greater curriculum and examinations validity in terms of the goals of science education. Involvement as an official representative on curriculum development and examinations committees.

h) Review textbooks with special reference to their validity in helping students attain Project 2000+ goals; publish such reviews in the bulletin/journal; run exemplary seminars by teachers that are geared to how to use textbooks and workbooks in science teaching.

i) In countries following the UNESCO suggested pattern and creating a National Task Force, playing a leading role as a member of a national task force in initiating and implementing projects.

Level 3—Higher level for well established STAs improving education by accreditation schemes, awards for excellence and taking measures to promote exposure to developments internationally

j) Development and running of improvement courses for teachers with certification and/or the accreditation of courses run by others.
k) Creation of groups to put forward policy guidelines, e.g., development of appropriate criteria for the implementation of awards for good teaching; making such awards.

l) Running symposia with regional and international links, encouraging members to attend meetings overseas and the organisation of educational tours.

The involvement of teachers within a country in science education development is growing through engaging science teacher associations in areas such as developing the intended curriculum, the needed resources materials, the in-service support for teachers, the evaluation of the curriculum, dissemination and implementation, and modifications to the course in the light of developments (see for example articles in the Science Education International, the ICASE quarterly journal). Furthermore with the growth and involvement of teachers through science teacher associations, there has been a growing tendency to encourage classroom research where the teacher is recognized as a researcher. Data from actual classroom practices should prove invaluable in promoting scientific and technological literacy.

ICASE has been instrumental in helping the formation of professional teacher groups (often called a science teacher association although the actual name and orientation is in line with current curriculum practices and governmental—non-governmental alliances within a country). These groups, involving teachers, almost invariably involve teacher educators, Ministry of Education inspectors, curriculum developers and often person from industry. ICASE is delighted to help any group to form a professional association interested in furthering education in an area of science and technology at the primary and secondary level, irrespective of location, language or financial status. For more information contact the Executive Secretary.

ASTRONOMY ACTIVITY AND RESOURCE NOTEBOOK PUBLISHED

The Universe at Your Fingertips, an 813-page astronomy activity and resource notebook for teachers in grades 3-12 (and astronomers who work with them), has just been published by the Astronomical Society of the Pacific. The loose-leaf collection includes 90 hands-on activities, dozens of annotated resource listings, featuring reading material by topic for students and teachers, and audio visual aids, computer software, and organizations that assist teachers, as well as a catalog of national astronomy education projects. In addition, the notebook contains articles on student learning, astronomy basics, and fitting astronomy into the science curriculum at various levels.

The Universe at Your Fingertips is $24.95 plus $6.00 for shipping and handling to U.S. addresses. California residents please add sales tax. Send orders to Astronomical Society of the Pacific, Notebook Order Dept., 390 Ashton Avenue, San Francisco, CA 94112; phone 800-335-2624.
RECRUITMENT OF SCIENCE TEACHERS—THE GATEKEEPING
FUNCTION OF INITIAL TEACHER EDUCATION
By John Oversby
The University of Reading
Bulmershe Court, Earley, Reading, UK

Introduction
In many countries, teachers in publicly funded schools have to hold a recognised qualification to teach. Recruitment to the courses which provide this qualification is, therefore, an important gateway through which potential teachers must pass and, therefore, provide an essential gatekeeping role. This article describes the practice, and the theory behind this secondary science teacher education course at The University of Reading in England.

This new postgraduate course was established in 1993. School teachers and university tutors formed a partnership to design course content and methodology. Recruiting suitable candidates for a course in which students spend two-thirds of the 36-week programme in schools became a significant issue. The course was to identify desired student teacher qualities and value decision making by teachers and tutors equally. The reflective practitioner model of student teacher learning was adopted by the Reading Schools Partnership while respecting the influence of other educational theories and recognizing local context in which teaching takes place before decisions concerning planning, teaching methods, or lesson evaluation. In no way is the model simply an acceptance of theories or of traditional school views. Student teachers are expected to critically examine research and practice aimed at producing personal theories about education. The resulting understanding will underpin everyday practice of their teaching for years to come.

The following criteria formed the characteristics necessary for candidate acceptance:
• open to new ideas in a critical framework;
• willing to learn about science and about science education;
• committed to secondary science teaching (11-18 years old); and
• thoughtful about science education and its purpose.

The process of recruitment also created the need to assess these characteristics.

Application and Selection
Application forms are received from the Graduate Teacher Training Registry throughout the year. Applicants’ forms are sent to one Higher Education Institution at a time for consideration. An offer from that institution and acceptance by that candidate completes the process.

Applicants are required to have a degree in science or a science-related subject (e.g., engineering). In addition applicants must have mathematics and English grades of a “C” or equivalent. Students are placed in schools where they are expected to teach all sciences to 11- to 14-year-olds, two science to 14- to 16-year-olds, and one science to 16- to 18-year-olds. Originally, only these students who had studied all three sciences up to 16-year-olds and two from 16 to 18 were invited for an interview. This proved too restrictive for physicists and so they were required only to have studied two sciences to 16-year-olds and one from 16 to 18. Perhaps this is a case of market forces in action. We also were aware that some groups are under-represented in our course and it was decided to relax requirements for females in physical sciences, ethnic minorities, and for some students who had taken an unusual route to gaining a degree, such as studying part time. Such applicants were invited for interview even if they had studied only one science.

Applicants are required to provide a reference. The reference comments are extremely variable and many are simply judgment statements with little evidence to support their evaluations. These are ignored. Negative references indicating characteristics such as lack of commitment or unreliability are rare but usually lead to rejection.

Most applicants give positive reasons for wishing to teach, such as enthusiasm for the subject or wishing...
to give something back to the community. Many had some involvement with teaching in some form or another; for example, teaching their own children or working on summer camps. Males are more likely to have little or no experience.

Applicants are instructed to visit at least one science lesson being taught to 11- to 14-year-old pupils in a nonselective publicly-funded school prior to the interview. Assistance with this arrangement is given if needed.

The Interview

It is usual to invite six to eight candidates at one time. Interviews are conducted by a tutor and a teacher. The interview begins with introductions and a description of the course, emphasising its professional nature and the seriousness of the commitment they are being asked to make. Opportunities for asking questions are provided frequently throughout the half-day process.

A group interview of about 20 minutes provides an opportunity to listen to the applicants’ ideas and see how they work in a group. The group is given a task which to consider themselves as science teachers in a school making suggestions for improving science teaching. Cards with various suggestions, such as setting classes by ability, or by gender, improving staff understanding of research in education and using more computers, are provided and the group has to come to a conclusion about the relative importance of these suggestions. A checklist is used by the teacher and tutor observers. Individual comments are frequently taken up in individual interviews later. In general, contributions during this session are often very good but candidates who dominate unduly, those who make little contribution, and those who find difficulty in expressing their ideas give cause for concern.

Individual Interviews

During the individual interviews which follow, applicants are required to write about their visit to a school. The purpose of this activity is to check their writing ability. The writing also serves as additional evidence regarding their beliefs concerning teaching.

Each applicant is interviewed separately by a teacher and a tutor. These 15-minute sessions focus on different aspects of the applicant. The teacher questions views about the classroom and the tutor gathers insights concerning educational theories and principles.

The teacher’s questions cover the following areas: learning based on the school visit level of interest in teaching all sciences; interest in teaching pupils of all abilities; and interest in being a form tutor with pastoral responsibility.

The tutor’s questions cover the following areas: the applicant’s view of science as a subject; the relationship between teaching and learning; commitment to the intellectual challenge in learning about education; and the applicant’s expectations of the course. It is inevitable, in such a short interview, that some areas will not be covered, and this is acceptable.

The Final Judgment

It is assumed that the applicant already has the requisite subject knowledge. Given the fundamental characteristics required for acceptance mentioned above, the tutor and teacher attempt to reach an independent decision on the acceptability of each candidate. Agreement to accept or reject leads to an easy decision. However, a disagreement between the two judges leads to a rejection since the applicant needs to satisfy both partners, school and university. Excellence in each characteristic is not required for acceptance, simply an indication of a minimum standard. Applicants have generally expressed satisfaction with the procedure with only one complaint from more than 100 interviewed.

Applications from biology graduates have been good, leading to a high proportion of acceptances. Applications from chemistry and physics graduates are declining both in number and quality, particularly from males.

Summary

Teachers and tutors have agreed that personal characteristics are an important part of the selection procedure and should be the main focus of interviews. At each stage, minimum criteria are established and applicants failing to reach this minimum are rejected. At the final stage, those with acceptable characteristics are offered a place in the course. Experience with the 1995 entry process found that some candidates who accept the offer of a place to search for alternatives and subsequently withdraw. This is more frequently the case for men (six withdrawals) than for women (two withdrawals) and more so for physics (seven withdrawals from 14 acceptances). Biology only hand 1 withdrawal from 20 acceptances.

Editor Comment

With limited resources and the need to maximize our efforts toward only those who truly qualify, we must continue to explore early identification strategies. Please share your own experiences and strategies by submitting brief project descriptions and results to SEI.
DOES A MULTICULTURAL TREATMENT OF SCIENCE GUIDE OR DISGUISE SCIENCE CLASSROOM DILEMMAS?
Dr. Randy Yerrick, East Carolina University
Mr. Jeff Nugent, East Carolina University

Author’s Comment
As you read this article please contemplate comparisons that might exist in your own country or classroom context. Many times new insights can be gained by reflecting upon these differences and similarities around the world. The issue of multicultural science education has at times been quite heated in the United States. The solution has not yet been found for such a complex problem. Our perspective is meant to stimulate and perhaps complicate ongoing conversations between those who research and those who teach. We welcome responses, comments, and reactions to our perspectives and hope it serves ICASE mission to examine ways of promoting scientific literacy for all students around the world.

Introduction
Few would argue that American education is often shaped and determined by its response to trends, issues and movements within social and cultural contexts. Indeed it is difficult to see how it could be otherwise. The development of the American curriculum has in many ways been a struggle of representation with deep political investments. Questions like, "Whose voice should be valued?" and others surrounding the development of multicultural influences on education are a testimony to this fact. But it is important to remember that current science education reform (AAAS, 1989; CA Framework, 1992; MI Framework, 1991; National Science Education Standards, 1995) promote a notion of scientific literacy. For first time in science education history, has been targeted as not for one specific audience but for all citizens. Can an emerging multicultural perspective help to achieve the calls for national and international reform? How does such a perspective help to identify or detract from important issues of study and attention overlooked in the past?

Multiculturalism: A Movement Informed By Many
The lack of consensus regarding what constitutes multicultural curriculum or pedagogies lead one to suspect that it has yet to develop the support to mature into a movement. But some argue that the concern for and mobilization of multicultural education as a movement began during the era of the Civil Rights Movement in the 1960’s. It was during this time that America as a nation was involved in social upheaval primarily concerning the unequal treatment of African-Americans, women and other marginalized groups. The 60’s were a time of tremendous social change, where those with power and authority came under increased scrutiny and pressures to change. Schools were not immune to these demands. In some ways the development of multicultural education can be identified as a response to the demands for social equality brought on by the Civil Rights Movement.

Historically speaking, the promoting of the term literacy as an educational standard also exemplifies social injustice. Scholars such as Apple, (1990) Michaels and O’Connor, (1990), Anyon (1981), and Oakes (1985) have well reminded us of the role of schools and the unjust effects schools’ embracing of constructs like “literacies.” Schools themselves have taken on (or been forced to adopt) the role of privileging certain achievements and attributes (Willis, 1977; Anyon, 1981; Apple, 1990) for preparation of citizens for the appropriate role in the workforce or society. In the process of privileging certain “literacy” many researchers have reminded us that one discourse cannot be held up in high regard for attainment without another being considered less important (Au, 1980; Heath, 1986; Warren and Rosebury, 1991; Michaels and O’Connor, 1990; Anyon, 1981; Delpit, 1988). Schools themselves have played the role of privileging certain discourse often to the demise or counter production to the achievement of students. Only when the students life outside the school was investigated did researchers begin to understand how school discourse ran counter to what students had come to know, value, and make sense in their school experience.

The Role of Science in Asymmetry
Past science reform efforts and their subsequent implementation into school science courses have played large roles in historically stratifying students. Curricula, implementation, and pedagogues of choice have been matched by decreases of minorities in science classrooms, especially college preparatory and advanced placement courses, and have exacerbated existing differences among students. Lemke has argued that one mechanism for this stratification is through the treatment of scientific knowledge in such abstract and rhetorical ways that it has restricted membership and achievement within the ranks of school (1990). Many scientists argue
that maintaining a rigid sense of important concepts and ways of producing knowledge is important for retaining the integrity of the discipline without recognizing such effects on outsiders. While it may be important for science classes to reflect the discipline, few have discussed how restrictive membership actually promotes high prestige and subsequent elitism.

Science is a complex discipline to make accessible to all students. As an example, to become a physicist Traweek (1988) documented that students become familiar with the heroes and success stories of past achievers. Her textbook analysis revealed that most depictions were of serious, rational, anglo males scientists. This was the standard that physics graduate students were to aspire. In light of science education reform efforts, exclusive membership is not a desirable component of the scientific discipline in schools and to reflect this is contrary to the charge of “science for all.”

The United States is an always has been tremendously diverse; socially, culturally, ethnically, racially and sexually. Many believe that institutions and people who have traditionally been and remain in positions of power—predominantly rich, white, anglo-saxon males—have maintained their power by marginalizing minority populations and treating them unequally. To recognize the role of school science as restricting its membership in any way is to suggest nothing less than social reproduction, which in many ways has precipitated devastating effects on minority children and females (Bourdieu, 1977; Bowles and Gintis, 1976; McCarthy & Crichlow, 1994; Apple, 1990; Kozol, 1992). How to correct those past educational wrongs is an ongoing debate. The call for multiculturalism in schools represents an attempt to bring about equitable changes in American education.

**Multi-faceted Response**

In the attempt to correct educational misrepresentation and injustices some multiculturalists are concerned with promoting what can be called cultural awareness. This involves advocating cultural diversity and recognizing it as central to American culture. This group of multiculturalists is most interested in promoting inclusive language in textbooks, having images and pictures in textbooks depict the range of culturally diverse people in America. There is also an emphasis from this perspective to include and make known the contributions of traditionally marginalized groups (African-Americans, Asian-Americans, Latinos, Native-Americans, and Women) to the various fields of knowledge. That is, they view multiculturalism as developing curriculum and lesson plans that create an awareness of the diversity of American culture.

Some of these efforts are informed by research on learning style research of varied cultures (Atwater, 1994). There are additional efforts originating from this camp to develop bilingual programs for non-native speakers as a means of preserving their own rich cultural heritage. Such positions are coming under increasing scrutiny for not expounding upon the context in which studies are conducted. It has been argued that such a treatment of minority concerns could be responsible for promoting categorical claims, delineation of learning, and the elimination of any cultural gray areas of the social context (communities and classrooms). There exists the danger of naive or uninformed readers taking such recommendations as laundry lists, exhaustive by nature and collections of quick prescriptions for complex problems.

Another facet of multiculturalism maintains that diversity is not just to be tolerated through awareness, but must be recognized as an essential and necessary component of a democratic nation. It is from this assertion that resistance to multicultural curriculum development seems to have taken a dramatic turn. The curriculum itself becomes a site of struggle for representation and the outcomes and demands placed on education are transformed into debates and struggles for representation. Take for example the heated controversy which ensued in New York state over the Rainbow Curriculum, which in addition to a focus on African and Native-Americans had included materials which discussed homosexual lifestyles. The Rainbow Curriculum was initially adopted for use in NY but after severe protests the entire curriculum was replaced by a more traditional curriculum. Clearly there are deep investments in maintaining what can be considered multicultural. The American curriculum is itself a site of struggle about representation and identity, and there are very powerful interests that influence its content, shape and development.

Another facet of multicultural education wages its battles outside school contexts. There is an ongoing intellectual struggle over the very meaning of multiculturalism that is concerned with interrogating the social institutions themselves and determining the ways in which they contribute to the reproduction of social inequality and oppression. There is a concern for understanding not only the representation of minority and marginalized groups, but also a concern for critiquing the ways dominant culture is represented and reproduced. Those involved in this aspect of multiculturalism are committed to theorizing about the relationships between identity and representation, as well as understanding the very real connections between knowledge and power.
Yet Multicultural Attempts Fall Short

One dilemma of adopting any single perspective of multicultural science to view diverse classroom is that a single criteria cannot be applied to both science and school contexts. (People use totally different lenses to compare the two different communities and cultures.) The scientific community has for centuries been judged by a self promoted and skewed perspective on the values, process, and products of its community. It is by these highly refined sets of concepts at the end of a long and arduous venture that populations of students despite their background, have been measured. “Did students understand and correctly apply the concept of photosynthesis to this problem,” is the question that is often asked, failing to recognize that the scientific community themselves took hundreds of years to develop such a view of the world.

Currently, researchers are beginning to question the long held claims of virtues of objectivity, rationality, and even factuality (Traweek, 1988; Mayr, 1982; Fleck, 1979; and Latour and Woolgar; 1975). Closer examinations of real laboratory life has revealed other aspects of the scientific community before denied and kept beneath the surface. As Latour and Wolgar (1975) have argued there is a growing public,

“dissatisfaction with outside observers’ reliance on scientists’ own statements about the nature of their work... procedures and achievements central to scientists’ work become largely immune from sociological explanation. Approaches which implicitly adopt this standpoint have been roundly criticized on several grounds... Many of these analyses exemplify sociologists separation of the “social” from the “technical.” Much criticism concerns the lack of empirical basis for the ethos of modern science which these analyses outline. More recently, it has been pointed out that the existence of norms and counter norms in science derives from the insufficiently critical appraisal by sociologists of scientists statements to outsiders about their work... . Even if the norms he specified were found to be correct, the sociologist might just as well be describing a community of expert fishermen, for all he tells us about the nature or substance of their activity.” (pp. 22-24)

In other words, it seems impossible to investigate any questions about the compatibility of two vastly different communities unless there exists a consistent framework to apply to both. For example, it doesn’t make much sense how comparisons can be made about how rural blacks learn science that keeps them out of science as a discipline without also considering how scientists learn within their culture. From a pedagogical perspective one can make claims about school science being discriminatory, but this doesn’t mean that science as a discipline is discriminatory for the same reasons. In order to understand these issues better, there is a need to develop another handle in which to grip these issues with. Gee’s construct of discourse (1987) is one such handle. By discourse, Gee refers to a

“socially accepted association among ways of using language, of thinking, and of acting that can be used to identify oneself as a member of a socially meaningful group.” (1987, p.3)

There are ways in which science and local discourse communities need to operate differently and, hence, have developed distinctly different ways of attending to the “work” of the community. Gee argues that other ways of viewing science will perhaps reveal ways in which aspects of diverse communities can be valued as well. Conversely, attempts to discuss the pedagogical approaches which appeal to women and minorities and science comes dangerously close to isolating school science from all the other factors influencing student achievement or to treating school science as real science. School science and real science are not the same and pedagogical issues relate only to school science. One must apply a different lens to understand why science is exclusive to minorities.

Falling short of such a broad acceptance and definition for a cultural discourse, diverse communities are portrayed in curriculum efforts and other science reform initiatives, only certain selected pieces are selected to examine and portray the culture as it “really” is. Rarely do we talk for example about valuing or privileging most or all of the controversial components like rap music and the like as acceptable in science classrooms (Lemke, 1994). Multicultural educational conversations have often referred to a sort of “museum display type multiculturalism” This will not suffice. We as public educators need to speak of multicultural education as something other than some sort of museum piece, cleaned-up to represent a view that is washed by an Anglo perspective of political correctness.

Conclusion

We have been seduced by science reform rhetoric that represents science as promoting truly multicultural opportunity and democracy while suppressing the fact that it has never been either. Yet, reforms state that scientific thinking can promote such ideals. If this is

ever to be accomplished, science educators need to adopt a different lens through which to view problems of teaching and learning science. Discussing science more as a discourse among members of a community as opposed to a list of concepts to be learned is but one example of such a shift. Science education as a discipline needs to develop new ways of talking about science learning, teaching, and scientific literacy if we are to better understand science classroom and ultimately influence the ways science is taught to "all."

We as a science education community are far from creating concrete methods of implementing reform visions that actually value all forms of discourse including science for all. The United States is in its own quandary about its melting pot image having not even addressed at this point urban vs. rural discourse perspectives of a science. Not to mention the conspicuous silence of literature regarding levels of education like lower track classrooms and different treatments of science at many levels. Past solutions to this problem have fallen short. Future solutions may also fail unless studies explicate the ways in which accepted classroom organization and treatment of knowledge runs counter not only to science as a discourse, but also how schools privilege certain cultural discourses above others. In addition, an understanding of how science is treated as a "second weeding" of those students who don't belong is essential.

Given the fact that multicultural education is a site of political struggle and is concerned with questions of identity, representation, knowledge and power, it is of little surprise that those who feel most threatened by change have mobilized forces to maintain their privileged positions. Hirsch (1987) and Bloom (1987) have argued that multicultural education is a threat to the cultural traditions in America, and that its further advancement stands to destroy the important notions of what "we" have come to see as valuable and important in western civilization. Their objections stand as a testimony to the strong investment some have made in marginalizing and oppressing minority populations. The fact is America has always been a diverse nation, yet the few in power have been successful at maintain the myth of a singular national identity by promoting and supporting a canonical school curriculum. It is the author’s opinion that resistance to such movements ought to be used as indicators of need and serve to focus attention. From the students who chose not to engage in new pedagogical, epistemological, and ontological treatments of science to the political activists seeking to confound the vision of science for “all Americans,” resistance is an indication of conflict between parties maintaining different but closely held values.

It is clear that part of the debate over the American curriculum is about identity, representation, knowledge and power, and as such it will remain an intensely political battle for some time to come. In many ways schools remain firmly entrenched in the middle of this battle. At the very least schools need to be committed to the fact that diversity is an essential and necessary component of democracy. Furthermore, schools should be places where students can engage in multiple dialogues with diverse viewpoints to discuss the notions of identity, representation, knowledge and power. Perhaps in doing so they themselves can begin the challenging task of developing and defining an education that is truly multicultural.

JOURNAL OF RESEARCH IN SCIENCE TEACHING

Theme Issue: “Science Education in Developing Countries”

Deadline: July 1, 1996

Manuscripts are being sought which describe factors that influence science education in developing countries or detail emerging priorities for science education in the 21st century. Manuscripts ought to be theoretically and contextually grounded. For example, authors may wish to describe science education praxis grounded in Paulo Freire’s project of critical consciousness and liberation; or authors may describe ways in which the goals of science education are being constructed to advance a broader discourse oriented toward cultural struggle and possibility.

Inquiries and submissions indicating the Science Education in Developing Countries Theme Issue should be addressed to:

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

The Nepal Association of School Science Teachers was formed at a meeting held at Sanothimi on Friday Asadh, 2052 (30th June 1995). Present at the meeting were a group of interested science teachers from Kathmandu, Bhaktapur and Lalitpur districts and invited advisers from SEP, SEDP and CERID. It was stated that school science teachers have needed such an association for the past few years. It was unanimously agreed that an association should be established. The purpose of this association is to enable science teachers to meet and share their experiences, organise workshops and conduct seminars, exhibitions and other activities. These will be designed to motivate students and teachers, to improve the quality of science teaching and learning and to promote the public understanding of science and its applications in daily life.

Now in its third year of publication, THE INFORMAL SCIENCE REVIEW has established itself as an essential resource for all interested in the business of informal science education. The ISR reviews and analyzes current trends, opportunities and events in informal science, with an emphasis on how science is made available to the broad public. Its expanding readership includes staff of science centers and natural history museums, zoos, aquariums, botanical gardens, nature centers, broadcast media, university educators, exhibit designers, museum and zoo consultants. The ISR brings together, in one place, information and commentary useful to this diffuse group of institutions and professionals.

THE INFORMAL SCIENCE REVIEW is edited and published by:

Contrary to popular belief Rwanda appears, on the surface at least, to be working effectively. Electricity and water are available in Kigali, the capital and in most of the surrounding countryside except in the remote areas. Power cuts area fact of life but most big businesses are buildings have stand-by generators. The main roads are tarmac, although currently without street lights or traffic lights. The side roads are passable with care; it helps to have a four wheel drive but those leading to villages are used regularly by public transport (the ubiquitous 12+ seater minibus). Mines appear to have been cleared from the public thoroughfares.

There are road-checks, more frequent close to the borders with Burundi, Uganda and Zaire but these do not seem unduly aggressive so long as papers are in order.

My impression of the country, which is about the size of Wales, is of green, intensively cultivated terraced hillsides with deep valley bottoms, opening out to bush pasture to the north. There are several spectacular lakes and after the rains, waterfalls. Bananas, sorghum and beans appear to be the main crops, with tea and coffee plantations beginning to be worked once more. I saw several quite large markets with a good variety of vegetables and other goods for sale. Towards the north of the country herds of long horned local cattle are common, together with sheep and goats.

Evidence of the most recent war (1990-1994) is there when you look closely at the buildings, many of which show signs of damage or of recent repairs. Young soldiers with guns are stationed at major cross-roads in the city and at towns in the countryside; and both in the city and in the countryside the vehicles of the support agencies; WHO, UN, UNICEF, UNAMIR etc. are easily recognised. It is an indication of the relative peace of the country however that two large UN guns, complete in their wraps, could be left unguarded by the roadside awaiting collection.

There are two distinct groups of returned refugees to Rwanda; the first are those from the most recent war who are being settled, after a time in transit camps, in under-populated areas or communes. The national park, Akaghe, has become a focus for those with cattle. The other large group consists of those who have lived much longer in neighbouring anglophone countries; mainly Uganda and Tanzania. This latter group contains those who have been educated through the medium of English and includes professionals, many of whom have property and business interests in the capital. These Rwandans want anglophone education for their children.

In response to this demand, anglophone community schools have been set up. These are not government funded and are entirely self-supporting, charging fees and relying on grant-aid from overseas. Most of them have taken over existing government schools left empty by the war. These appear to have been systematically looted and vandalised so that although the basic structure may be sound there remains much to do in the way of repairing, re-roofing, making secure and re-connecting water and electricity.

All this has to be done by the school; pupils, parents and teachers working together. The head teachers of these schools have in the main been trained in Uganda and they are managing to attract back to Rwanda ever-increasing numbers of Rwandan anglophone teachers also trained mainly in Uganda with a minority trained in Tanzania, Kenya and Britain.

My task, funded by ODA through the Crown Agents, was to visit these recently established anglophone secondary schools together with several government schools with anglophone streams, to assess the feasibility of providing basic science equipment and textbooks in English to help with the teaching of science to overseas ‘O’ level equivalent.

Rwanda was formerly officially francophone with designated government schools containing anglophone streams. This, apparently, was never entirely satisfactory since textbooks and teachers could not be relied upon and the curriculum was not open to accreditation or validation through the mainstream francophone assessment procedure.

The country is now, officially, bilingual anglophone/francophone with Kinyarwanda as the common language of spoken communication. Many government ministers have come to appreciate that English is essential for access to aid and other economic support from countries such as the USA, Japan and China, as well as most of Europe.

There is, inevitably, still a tension between those who wish to retain their historic cultural ties with Belgium and France and those aggressively promoting anglophone educational practices. My impression is that this will continue until a common curriculum has been established, capable of being taught and examined in either language. To this end the Minister of Education
has set up a curriculum seminar to which key francophone and anglophone teachers, government ministers and other officials have been invited as a first step towards establishing such a common curriculum.

The university is also currently receiving supporting from the USA and Canada with the specific intention of establishing anglophone classes on a par with francophone. The long-term objective is to produce students bilingual in English/French, able to access classes in either language.

In working towards this objective teachers of English as a foreign language are clearly key people, together with those able to teach the school curriculum in English. The head teachers of the anglophone community schools have joined together to form the Rwandan English Medium Educational Service (REMES) in which all heads of anglophone schools as well as those of government schools with strong anglophone streams are invited to join together to promote anglophone education. This group has powerful friends in government and I was told that the ambassador-designate to the U.K. is being briefed by the REMES committee. It was this committee, through the offices of the then Chargé d’Affaires for the U.K., Lilian Wong, who contacted the ODA and obtained the promise of funding to support science teaching which the Crown Agents are now in the process of procuring.

The long term goals of REMES include the establishment of an anglophone teacher training college as well as polytechnic to provide much added technical competence. In the medium term they wish to set up a teachers’ centre to support the exchange of information teaching methods, equipment and materials as well as to provide a focus for the upgrading of untrained teachers and other in-service education. To this end they are seeking the support of overseas agencies to make limited in depth contributions to summer schools as well as more long-term commitment to projects such as teacher education.

Why the focus on science? The main clue seems to lie in the difference in teaching methods between anglophone (especially commonwealth) and francophone traditions. Science in anglophone countries includes biology, chemistry and physics, taught practically, (that is experimentally) with students using investigative methods. Francophone science emphasises physics with mathematics, with chemistry a poor second and biology linked with geography. The traditional method of teaching is through teacher demonstrations. Those teachers and parents returning from long-term residence in anglophone countries want to perpetuate the empirical, “hands on” methods by which they were educated, believing these to be more effective to student learning in science which they see as a key factor in the re-establishment of a united Rwanda.

🚀 Note to Member Organizations

Please ask your members to submit material to Science Education International. We are looking for:
• Teaching activities and lessons, especially for elementary
• Action research articles which talk to the practicing teacher
• Research articles which focus on practice, not research strategies
• Informal and nonformal articles which address “Things to do” in these settings

PLEASE INCLUDE PICTURES AND OTHER DRAWINGS OR GRAPHS.
Manuscripts may be sent to:

Introduction

Understanding earth systems is required for developing practical solutions for environmental and natural resources problems on local, national and international scales. Improving peoples' understanding of earth systems and, more importantly, general scientific literacy at all levels, requires strong communication between professional earth scientists, science educators, and parents. The Nebraska Earth Science Education Network (NESEN) was developed to provide a mechanism for enhancing linkages between K-12 earth science teachers and the resources and professional expertise at the University of Nebraska-Lincoln (UNL). The Conservation and Survey Division (CSD) of the Institute of Agriculture and Natural Resources at UNL is the lead organization. CSD is a multidisciplinary research, public service, and data-collection organization including the state geological, water, and soil surveys, as well as a center for remote sensing and geographic information systems. State geological surveys, such as CSD, can be particularly effective in enhancing these linkages because of their local expertise, their access to data and publications, and their ability to relate to general audiences. Commonly, surveys also have access and linkages to broader university expertise.

The needs and concerns of Nebraska teachers (Gosselin et al., 1995) are similar to those addressed at numerous education-related meetings (for example, Mayer and Armstrong, 1990; American Geological Institute, 1991; Geary and Zen, 1993; Metzger, 1993). However, implementing solutions vary from state to state, region to region, and on an international scale, country to country, depending on educational policies, geographic and population variability (for example, rural versus urban), monetary and human resources, and available equipment and materials. NESEN employs multiple strategies to enhance and expand earth science education in Nebraska by working directly with teachers because they are the most effective means of reaching students. These strategies include: 1) participating in pre-service, in-service and other professional-development activities with particular emphasis on the annual state science teachers' meeting (this type of in-service training and support for teachers is essential since many do not have formal training or education in earth science); 2) providing an annual summer workshop series, as well as developing new workshops, on earth science topics as a basis for lesson-plan development (that is, combining the information and expertise available at CSD and UNL with the pedagogical knowledge of teachers into lesson plans and activities that are classroom ready—most of which are available on the NESEN homepage; and 3) enhancing statewide communication using electronic media. It is one of NESEN's goals to electronically transfer across the network Nebraska-relevant earth science educational materials. Although Nebraska-relevant material is the primary objective, the connection to the Internet also provides teachers with access to earth science and other information on a national and international level.

NESEN also recognizes that many of its members, especially those in less populated, more rural Nebraska, do not yet have the electronic infrastructure to connect to the Internet. Therefore, NESEN takes appropriate steps to work with these teachers. Some of these steps include: a quarterly newsletter and our annual NESEN Resources Guide and Directory (currently in its third edition). The Guide includes most of the relevant material that is on the NESEN homepage and, as mentioned earlier, extensive participation in the annual Conference.

NESEN currently has nearly 300 members. Of these 300, approximately 230 are K-12 Nebraska earth science teachers and 70 are post-secondary earth science educators from UNL and other post-secondary
institutions within Nebraska. In addition, there are several teachers and post-secondary educators who are members from outside Nebraska.

The purpose of this paper is to: 1) relate our experiences and progress on an electronic-communication pilot project funded by the U.S. National Aeronautics and Space Administration (NASA); and 2) describe a related project, Students and Teachers Exchanging Data, Information, and Ideas (STEDI), that has evolved as part of the grant.

**NASA-Funded Electronic Communication Project**

Through this project and a variety of other initiatives, including state legislative action, access to electronic connectivity will soon be available to all Nebraska teachers. Although the infrastructure will soon be available, there are numerous problems with implementing an electronic communication network among teachers, which in turn minimizes the effectiveness of this media. These problems include access to electronic media, software availability, and compatibility, relevance and usability of materials, limitations on the time teachers have to learn the system, and the participants’ apprehensiveness of computers and other electronic media.

The specific objectives of our electronic-communication project are to connect geographically distant classrooms to the Internet and distribute materials and information over the network. Pilot sites were selected to provide: 1) a broad geographic distribution; 2) a range in computer knowledge from novice to a moderate level of expertise; and 3) a range of grade levels from middle school to high school. It was also considered useful if the selected teachers had previous interaction with CSD and/or NESEN staff.

Complete electronic connectivity and/or computer hardware, as well as software support, has been provided to eight pilot schools across Nebraska. In order to help these teachers learn about the electronic network, a workshop was given by CSD and UNL Information Services in March 1995. Although the network focuses on teacher support, we recognize that their students are often more computer-literate and have more time to become familiar with the technology than their teachers. To take advantage of this situation, students also participated in this workshop with the intent of instituting “reverse mentoring”. In this program, student participation will reduce the time the teacher needs to learn the system and reduce the hesitancy of teachers to use electronic media. Although this reverse-mentoring process was instigated, its successful implementation was minimized because of varying school policies regarding Internet access by students and the fact that students availability changed from one semester to the next. In addition to the workshops, NESEN staff have spent variable amounts of time with the participating teachers helping them with computer configurations and hardware installations and addressing teachers’ questions about software and network access. We found that providing a computer and access to the electronic super highway was only the beginning of getting teachers on the “Net.” The teachers and their schools also needed local in-house technical support that many of them did not have.

To distribute information and materials over the network, we initially established an electronic bulletin board. With the development of the World Wide Web (WWW) and web browsers, we established a homepage (http://nesen.unl.edu/nesen.html) that contains detailed information about NESEN. Some of this information includes, but is not limited to: “Ask-a-NESEN-Scientist”; hundreds of earth science activities/lesson plans designed by NESEN teachers and pre-service teachers; lists of earth science materials that can be borrowed by NESEN members; newsletters; earth science announcements; activities, background and benefits of NESEN; information about the Students and Teachers Exchanging Data, Information, and Ideas (STEDI) project and access to STEDI’s data entry/retrieval system; an earth science feature of the month; information about the secondary science education program at UNL’s Teachers College; and many links to other earth science workstations. New information is being added to the homepage daily. For NESEN teachers who desire an email account, one can be provided to them through NESEN resources.

Interaction via email is common between NESEN members. Approximately 40 percent of NESEN K-12 members and 50 percent of NESEN post-secondary members reported having email addresses. NESEN has created several alias email lists for easy communication with most, or selected parts, of the membership.

The K-12 members with email access were surveyed regarding their interaction with the NESEN homepage and activity with the WWW. Seventy-five percent of the respondents said they knew NESEN had a homepage and approximately 50 percent had visited the site at least once. Inability to connect to the WWW was the primary reason for not visiting the homepage. A few responded that they visit the site at least once a week. Of the schools that can access the WWW 30 percent have teacher-only permission for access and 60 percent have student-supervision access. The remaining 10 percent allow the students to have unsupervised access (usually after some sort of agreement is made between the student and the school about appropriate access on the WWW.) Teachers were also asked if they found material on the WWW usable for their classes. Fifty percent said they found an
adequate amount of information. The remaining 50 percent said that most of the information they found was not suitable for various reasons (for example, too much preparation time required, supplies or equipment not available, supplies or equipment too costly, etc.).

STEDII Project

The STEDII project evolved out of the electronic-communication project as a way to focus the acquisition of educational resources from the Internet and the sharing of these materials with the other pilot sites. The current topic, weather, is ideal because students experience it every day and it is generally quite variable across Nebraska.

Along with the eight pilot schools, six other schools, which are independently electronically-connected, are involved in the project. As part of this project, students learn how to use weather instruments and proper procedures for collecting data. Where needed, NESEN supplied the schools with maximum/minimum thermometers, sling psychrometers (relative humidity instruments), barometers, anemometers (wind-speed instruments), and rain gauges. These instruments allow the students to collect the following data: maximum and minimum temperature, relative humidity, wind-speed and direction, cloud cover, barometric pressure and precipitation. Frequently, data is gathered in small groups in which the students learn teamwork and cooperative learning skills. Having every student in a group taking measurements has the added benefit of reducing the chance of significant error. Students eventually became adept enough at their data-collection activities to recognize “good data” from “bad data,” that is, the beginnings of quality control.

Additionally, some of the STEDII teachers use the weather data to teach other skills such as mathematics and statistics (means, modes, and medians), graphing, mapping and simple weather forecasting. Some schools have established weather clubs that continue data collection beyond the weather unit. In fact, several of the local newspapers ran stories about the school’s weather-collection activity and reported those data in their respective town newspaper. Students and/or teachers have also explored the possibility of finding partner sites in other parts of the state, country and world with which they could exchange data.

Originally, the data was exchanged between participating schools and the project managers at UNL via email. This added the advantage of students gaining experience and knowledge of email and the Internet. However, this method become mundane and offered little in terms of data use. Later, a homepage was created for STEDII (http://nesen.unl.edu/stedii/mmsearch/stediihp.html—or access may be made directly from the NESEN homepage) whereby data was entered and retrieved via an on-line form. The students enjoy entering the data via the WWW, which has encouraged them to further explore the resources that the WWW offers.

STEDII has had the bonus of developing a strong relationship with the secondary-science education program at UNL’s Teachers College and with its director, Dr. Ron Bonnstetter. As far as we know, this three-way linkage between the resources of a state geological survey, pre-service science teachers and in-service teachers is unique in the United States.

During 1995-96, four pre-service science educators, as part of the requirements of their science methods coursework, participated in STEDII. Each pre-service teacher was assigned two or three participating in-service teachers. The pre-service teachers provided some technical assistance to the teachers and offered ideas for activities using the Internet. In turn, the pre-service teachers were given opportunities and experience in working with practicing earth science teachers and use of the Internet in classroom situations.

The STEDII project has similar components and structure to another school/research interaction group on the Internet, the GLOBE (Global Learning and Observations to Benefit the Environment) project (http://globe.fsl.noaa.gov/). GLOBE has many more schools collecting data, but fewer types of weather measurements are taken. With numerous locations collecting data, not every school needs to collect data to provide an adequate spatial and temporal coverage to produce useful activities that allow comparisons between schools.

Program Benefits and Summary

K-12 students are the primary beneficiaries from NESEN activities, either directly through participation in STEDII or through other teacher-enhancement activities through which their teachers become more knowledgeable, the students will be better informed and more capable of addressing future environmental and natural-resources issues. The NESEN initiatives will provide teachers, many of whom do not have formal training in the earth sciences, the opportunity to get current technical information on Nebraska’s natural-resources issues.

Through our projects we have observed that technology can play an important role in improving K-12 education. Electronic technology provides teachers with a mechanism for expanding this knowledge and increasing their students’ access to new experiences. However, technology is only a tool and only part of the solution to our educational problems. Many fundamental changes are required within the educational system before these technological tools can be used effectively. Specifically, proper local technical
support must be available to ensure that frustration with the technology does not minimize its classroom implementation. Technical support should apply to both hardware and software. Time must be made available for teachers to not only learn the technology, but to learn what are the best pedagogical approaches for using this technology in the classroom. Addressing these issues is especially important in rural areas where local support may not be readily available. In concert with addressing local support issues, educational materials on the “Net” need to be created that are more user-friendly and focused on specific topics which support current curriculum guidelines, such as the National Science Standards in the United States. Proper development will allow Internet materials to be more efficiently implemented in the classroom. Finally, local cooperative partnerships and communication systems, such as those used by NESEN, are required to improve the quality and effectiveness of science education.

A REPORT ON INTERNATIONAL LINKS IN 1995 AND THE ANNUAL MEETING OF THE ESTONIAN CHEMISTRY TEACHERS

Miia Rannikmae, Secretary EACT

The annual winter meeting of the Estonian Chemistry Teachers has, by now, become a tradition. This year is the 26th time for chemistry teachers to come together and the second under the umbrella of the Estonian Chemistry Teachers Association.

But this year marks a significant change. Since joining ICASE in 1995, EACT has started to think more about the international network at the ordinary teachers level. The major efforts in recent years in the political arena in Estonia have been focused mainly on the economical problems faced by all and the need to rethink the education system. As a consequence the school curriculum is currently undergoing a change and science curricula for 1997 will have new subject content. And the planned course at the grade 7 level introduces new science teaching ideas unfamiliar to teachers. To put this into practice will involve the teacher adopting unfamiliar approaches, a step never needed in the prior—Soviet times, when teachers only needed to rely on their own experiences. This means teachers now need to be aware of what is going on in other countries and of the major priorities and directions in the field of science education. Only then are teachers able to play a useful role and influence the direction of curricula change. With this in mind EACT joined ICASE in 1995 and became involved in the international scene.

THE EACT’s International Links in 1995

In January 1995, the ICASE Executive Secretary, Jack Holbrook, accepted our invitation to talk to our association and by giving seminars in different places of Estonia, introduced teachers to the philosophy of Project 2000+ and the goal of science for all. An early EACT decision was to follow these ideas and think more about how to promote scientific and technological literacy among students. It was recognised that this would prove to be a time-consuming process as not all the implications of Project 2000+ are acceptable in the first instance, because of pressures from and familiarity with the old-system.

In May 1995, EACT together with IOSTE (International Organisation for Science and Technology Education), ran the first Central and East European Symposium on Contemporary Trends in Science and Technology Education. In this symposium, the President of EACT, Aarne Toldsepp, presented results from an international study on pre-conceptions in science and technology of 6th grade students, undertaken with the help of members of EACT and science educators in other countries.

This symposium recognised the need for the existence of ICASE as an umbrella organisation linking science and technology professional associations. All the Baltic countries—Estonia, Latvia and Lithuania have similar historical and cultural characteristics. During the symposium, the differences in the level of science and technology education development work was noted in the different countries. For faster development, it was agreed that greater coordination and cooperation was needed.

At the end of the 1995, representatives from EACT, together with the ICASE Executive Secretary, visited the Chemistry Teachers Associations in Latvia and Lithuania. The purpose of the visits was to hold initial discussions on possibilities for future cooperation and to fix when this could occur. Both associations subsequently joined ICASE. In addition, during a visit to Saint Petersburg, a Russian Chemistry Teachers organisation and a Russian Association of Chemical Pedagogical Education were established and agreed to support and promote Project 2000+ ideas and become ICASE members.

In teacher seminars given during the visits, exemplars that help to promote scientific and technological literacy were introduced by the ICASE Executive Secretary and the Estonian experience on how to use them in teaching was shared. The officials of the teacher associations were introduced to the idea of running writing workshops to help teachers appreciate the new direction and gain useful teaching materials. The proposed ICASE writing workshop for Eastern
European countries was explained. All organisations saw the urgent need for that and promised to start planning their participation.

**Annual Meeting of Chemistry Teachers, 26-27th January 1996**

The annual meeting, held in Secondary School number 14, Tartu, attracted about 100 participants. Five invited guests were present—the President of the Latvian Chemistry Teachers Association (Asis Buiva); the Vice President of the Lithuanian Chemistry Teachers Association (Salvinija Sleziene), the Secretary of the Russian Association of Chemical Pedagogical Education (Andei Zhegin), Attila Villanyi from the Executive Committee of the Hungarian Chemistry Teachers Section of the Hungarian Chemical Society and Onno de Jong from the University of Utrecht, the Netherlands.

This meeting concentrated on providing teacher help in two areas of the curriculum by means of an in-service course and in discussing the following:

- an overview of the present situation and perspectives of the work of different teachers associations,
- to identify ways for international cooperation between teacher associations
- to determine the role of the teachers associations in in-service provision and in curriculum development
- to determine ways to help teachers obtain useful teaching materials

Dr Onno de Jong ran the in-service courses on:
- “Teaching and Learning Chemical Calculations, Difficulties and Remedies”
- “Teaching and Learning Electrochemical Cells: Problems and Solutions”

Both topics are difficult for students and there is a urgent need to improve the teaching approaches in these areas. It was suggested that a more student-centred approach, taking into account the students individual development and abilities, was needed. Also needed was for teachers to change their teaching style from the direct transmission of knowledge to a style of facilitating a process of knowledge development. This needs to offer students the opportunity to work together in small groups, to develop their own problem solving methods, to stimulate students to analyse problems and to plan solutions extensively. Dr. Onno de Jong suggested the teachers themselves should develop the materials.

All participants received certificates to indicate they had passed the in-service course and became qualified to supervise others in dealing with questions on this part of the curricula.

**Need to Provide Non-Governmental In-service Training**

Of special interest were the discussions held on the role of non-governmental in-service training. As governmental in-service provisions offered mainly subject orientated courses, the teachers personal teaching skills, knowledge and information on what is happening in the rest of the world were neglected. To guide the EACT in meeting teacher needs in the future, a questionnaire was given to the participants. The findings will be taken into account in planning future courses. Teachers indicated they needed help in both subject updating and developing their teaching skills and hence suggested in-service training should be balanced and cover both areas.

Teachers indicated they were interested in getting more information about the different educational systems in the world, about topics in science that were very topical at this time and in how to promote scientific and technological literacy (STL). As there is lack of teaching materials, the teachers should be able to create it themselves. For that the special in-service courses are needed.

Discussion followed on a writing workshop planned by ICASE, in conjunction with EACT, for Eastern European Countries in May 1996. The workshop is intended to guide participants in writing supplementary teaching materials for use by teachers in teaching science subjects.

After the workshop the participants should take the responsibility to share their experiences within the associations and encourage others to be interested in follow up activities at a national level. It was suggested that the teacher associations should play a major role in ensuring this follow up and the production and distribution of the developed teaching materials.

The meeting welcome the writing workshop idea.

**Contract Between the Baltic Countries**

Cooperation in many fields of Education had been an old tradition between Latvia, Lithuania and Estonia during Soviet times. At that time the teachers ran yearly summer courses in the different countries.

At this meeting contact was re-established as signified by the presence of the Presidents of EACT and the Latvian CTA and the Vice-president of the Lithuanian CTA. During the meeting an Agreement was signed to re-establish cooperation between the Baltic Countries. To continue this cooperation an agreement was specified as follows:
1. To carry out joint Projects supporting Project 2000+ ideas.
2. To exchange, on a regular basis, curriculum materials, textbooks and all types of teaching materials.
3. To invite, every year, two to three representatives from the other associations to participate in annual meetings.
4. To run yearly in-service courses in different countries each summer, lasting for four to five days. The number of participants from each country is agreed to be 15. The host country is to be responsible for the accommodation and the planning of the programme, which should include activities for the participants. The participants are to receive certificates.
5. The final details of contract and research projects are to be fixed in May 1996.

The first summer seminar will be held in Vilnius in the summer of 1996. Representatives from the other teachers associations will be welcome. The working languages will be English and Russian.

(Left to right) A. Arne Töoldsepp, Estonian Association chairman; Salvinija Sleziene, Lithuanian Association vice president; Ansis Buiva, Estonian president; (standing) Miaa Rannikmäe, secretary EACT; Andrei Zhegin, Latvian Association president
THE PUPIL RESEARCHER INITIATIVE
BRINGING CUTTING EDGE SCIENCE TO THE CLASSROOM

Marianne Cutler, Regional Coordinator for PRI
Dept. of Biological Sciences, Keele University, Staffs ST5 5BG
Telephone and fax: 01785 813460
email: bic02@cc.keele.ac.uk

The Pupil Researcher Initiative (PRI) is an exciting and innovative science curriculum development project in the U.K. funded by two of the major government Research Councils: the Engineering and Physical Sciences Research Council and the Particle Physics and Astronomy Research Council, for an initial period of three years until September 1997. The Initiative is coordinated by Sheffield Hallam University.

The main aims of the Initiative are to provide resources, activities, strategies and support within curriculum time for science teachers and their pupils, so that the pupils, specifically aged 14 to 16 years will experience the excitement and relevance of science and engineering research, and so develop a lasting interest and enthusiasm.

To achieve these aims, the Initiative has developed several components, some of which are outlined below.

Thirty Pupil Research Briefs (PRBs) have been written by an experienced team of teacher writers, working in collaboration with researchers from a wide range of research establishments, including universities, research councils and industry, so that wherever possible, they reflect frontier developments in science and engineering. By setting a variety of realistic contexts, each PRB reflects the development stages of a real research project, so that pupils may be motivated by the experience of working in the way that real scientists and engineers carry out their research work. PRBs are particularly useful within the experimental and investigative areas of the science curriculum and they frequently provide ideas for various applications of IT, including monitoring, designing and using spreadsheets and databases, word processing and desktop publishing.

Figure 1 shows the general model for the PRBs using the Catalysis PRB as an example.

A selection of PRBs with a number of interactive databases, designed by science and engineering researchers on the Internet, will allow schools to pool their results electronically.

Pupils may also communicate their results by submitting an article to the PRI Journal, PRISM based on PRB work or indeed on any other interesting aspect of science that they wish. PRISM is circulated to every secondary school in the U.K., to contributory schools outside of the U.K., as well as to many research establishments. Contributions to the December issue are requested by the end of October.

Students studying for their doctorate in the sciences or engineering have also been involved, in the Researcher in Residence component of the Initiative. During a short placement in a school, the students act as positive role models offering advice on scientific concepts and processes which is particularly useful to pupils in developing their investigative and communication skills. The teachers gain from the support from qualified scientists in the classroom and from the opportunity to discuss further links with the research establishment. The students, themselves also gain from the insight into current education practices and from the chance to develop their own communication skills with a non-specialised group. They have often extended their liaison with the school to support extracurricular activities such as helping to run a Science Club or a Science Fair, organising residential field work and visits to the research department. During the first year, evaluation from more than 500 student and school participants in this part of the Initiative has been especially positive, and we hope to place an equal number of students in schools in this final year.

Schools are also encouraged to communicate their results from work based on PRBs, with Researchers in Residence, or indeed any other stimulating aspect of scientific work by running their own Science Fairs, for which they receive support from PRI. The number of Science Fairs is continuously growing, and we are very encouraged by the enthusiasm of the participating pupils and the quality of the work. We are hoping that more
schools will also wish to communicate their scientific achievements to a wider audience, in this way.

PRI has produced a comprehensive resource booklet for schools on Science Fairs in conjunction with the British Association for the Advancement of Science, and we would be most interested to exchange ideas on Science Fairs in general with the readership of Science Education International.

On a larger scale, PRI has recently run a series of regional Conferences, across the U.K., giving pupils the opportunity to present their own science and engineering research to real scientists, during informal discussion settings. The Conferences are run on the same lines as a proper scientific conference but with the pupils taking the leading role and presenting their research work as visual, interactive workshops to audiences of professional scientists, the media and other pupils. Pupils are most enthusiastic to take on the role of researchers and have presented work on a huge variety of topics including meteor activity, concrete and the chemical industry, coral reef bleaching, the appliance of science in the design of lifts, the ripening and picking times of cider apples for a commercial producer. Evaluation on the Conferences has been extremely encouraging from all participants including teachers, pupils, scientists, science advisers and professional representatives, so we are planning to run a national event in March 1997 as part of National Science Week (SET '97), when pupil delegates from outside of the U.K. will be invited to attend.

From the above components plus others, PRI is confident in achieving its original aims: above all, the success of this project will be judged by the pupils’ enthusiasm for science and the quality of their learning.

Further information on any aspect of PRI may also be obtained from:

email: N.A.Fuller@SHU.ac.uk

Figure 1. Outline of Catalytic Traps PRB

Context setting: Research Council Press release calling for research project proposals in Catalysis.

Background knowledge: Pupils, as researchers, work through two short papers produced by a research group meeting.

Paper 1 describes the background science to Catalysis, continuous flow fermenters, and possible future projects.

Paper 2 provides a description of the continuous flow fermenters using immobilised enzymes and Alginate beads.

Investigation: Pupils use their knowledge gained from Papers 1 and 2 to begin to plan and carry out an investigation into the feasibility of developing a continuous flow reactor which uses immobilised inorganic catalysts.

Communication: Pupils produce a feasibility report which will inform the decision of the research group when they develop research proposal to the Research Council.
AN EXPERIMENT WITH SOAPY WATER

Challenge:
What Happens When You “Pop” a Soap Film.

You Need:
— A piece of flexible wire about 40cm long. Any available piece will do, but wire of 0.6 to 1mm diameter will work best.
— A piece of string, and a piece of cottedng thread.

Instructions:
1. Bend the wire and make a frame as shown in the sketch.
2. Next, take some cottedng thread and make a loop. The loop should be small enough to fit in the frame.
3. Tie a piece of string at two opposite points on the loop; attach each loose end onto the wire frame. Make sure the string is not tight but loose.
4. Prepare some soapy water. You need enough to immerse the wire frame into. Immerse the frame in the soapy water and then gently lift out. A thin film of soapy water will form inside the frame.
5. Take a pencil and pop the part of the frame that has formed inside the loop of cottedng thread.
6. The part of the film which has popped will form a nice circle. Even if the attached strings are shaken the loop will always return to the shape of a circle when released.

Notes to the Teacher
The purpose of the experiment is to observe what shape the loop will take at this stage. It illustrates how a film of soap is pulling from all sides shaping the loop into a circle. This is an example of surface tension and the pupils will see practical proof of the fact that among all possible shapes that can be formed out of a given circumference, the circle will take the greatest surface area.

A NEW INTEGRATED INSERVICE COURSE
FOR SCIENCE TEACHERS:
BACKGROUNDs AND EXPERIENCES

Onno de Jong
Utrecht University
CSME, Department of Chemical Education
Princetonplein 5, 3584 CC Utrecht, The Netherlands

The Need for a Professional Development of Science Teachers

In many European countries during the last decade, science teacher education has changed rapidly. Although developments differ from country to country, some are shared. One of the most interesting common trends concerns a growing interest in inservice courses for science teachers. This trend is triggered by a number of diverging factors. The main factors can be summarized as follows.

Firstly, the implementation of new science curriculum topics or even a whole new curriculum for science (e.g. in the UK). These changes require the 'updating' of teachers' knowledge and skills, especially in the case of the introduction of new educational technologies, e.g. computer assisted instruction.

Secondly, the rise of new ideas about teaching and learning science, such as the constructivist points of view regarding knowledge acquisition. According to this perspective (see e.g. Driver, 1989; Osborne and Wittrock, 1983), learning is a dynamic and social process in which learners actively construct meaning from their actual experiences in connection with their prior understandings and the social setting. A major implication for teaching is the idea that science teachers should have insight into students' (pre)conceptions of science topics and should facilitate learning by creating conditions enabling conceptual change.

Finally, dissatisfaction with existing ways of science teacher training. For example, many inservice courses primarily consist of a direct transfer of knowledge and skills. However, this 'top-down' approach excludes an active participation of teachers and, moreover, many courses do not link up well with (practical) needs of teachers. Therefore, effects of this type of teacher training are often felt to be rather disappointing (OECD, 1981).

In sum, in line with the trend of paying attention to the professional development of science teachers, a need to improve the quality of inservice courses is necessary.

New Aims of Science Teacher Training

In this article, an improved science teacher inservice training program is reported. This training was developed as part of a Dutch research and development project, initiated by the Chemical Education Department of the Centre of Science and Mathematics Education at Utrecht University. The newly designed inservice training can be characterized as a practice-oriented course on a constructivist foundation. The basic aims are:

a) To help teachers to connect (classroom) practice with (course) theory. This aim implies that training activities will not only be carried out during meetings of participating teachers, but also during and after lessons at school.

b) To stimulate teachers to become (more) aware of their own teaching beliefs and classroom practices. This aim implies that a lot of attention will be given to reflection on own conceptions and actions.

c) To encourage teachers to change their conceptions of science teaching and to reconstruct their teaching activities. This aim implies that learning conditions will be created which give teachers the opportunity
to participate in an active way and to explore new teaching ideas and actions.

During the last few years, our Chemical Education Department has worked with several groups of chemistry teachers in the context of teacher training. In all cases, a training programme was developed which integrates elements of classroom practice, course theory, teacher reflection and conceptual change. The key features of the design of such an integrated training programme are described in the next section.

Design of the Integrated Inservice Course

The first part of the course consisted of two or three meetings of the participants. During the first session, the teachers exchanged ideas and experiences regarding (difficulties concerning) their current teaching practice. During the next session(s), they discussed a new course in a particular chemistry topic. The course materials were based on a constructivist point of view and consisted of a self-instruction package for students and an accompanying teacher guide. The teachers had to carry out the main students’ tasks which were described in the student package.

The second part of the training programme was mainly carried out at school. All teachers gave their students a copy of the packages and told them to work in small independent groups, mostly pairs. Each group was supposed to produce its own written answers. All the tasks (experiments, questions and so on) required the students of the same group to go on discussing until consensus was reached. At the end of each lesson, the teacher received a copy of the written answers of the groups. Only those answers were accepted which had been developed without any help of the teacher or premature comparison with final booklet answers. Each teacher analysed the answers and used the results to reflect on old and new teaching strategies.

During the lessons period some additional meetings were organized. During these meetings the teachers presented the results of their analyses. Together, by means of subsequent discussions, they reflected on their teaching beliefs and practices.

The final part of the course consisted of two or three meetings involving an evaluation of personal learning processes as well as a course evaluation. The last mentioned activity was focused on the in-service course itself as well as on the students’ course, especially on the materials used.

Investigations

It is not only important to develop new teacher training, but also to investigate the course impact on teachers. During the last few years, our research has focused on several new courses for chemistry teachers.

The courses under consideration were:

1. A course in teaching methods for solving proportion problems within a science context, e.g. problems involving the concept of concentration (De Jong, 1995). Nine experienced teachers were involved in this course.
2. A course in teaching the concept of mole and stoichiometry (De Jong, 1990). In this course, 12 experienced teachers participated.
3. A course in teaching the topic of electrochemistry (Acomo and De Jong, 1994). A new group of nine experienced teachers were involved.

The research focused on teachers’ learning processes in changing teaching conceptions and in reconstructing teaching activities. The main research data were obtained from classroom observations and audiotaped discussions in training meetings. In addition, written students’ answers concerning classroom tasks were collected and analysed.

Main Teachers’ Learning Outcomes

When the three courses mentioned before are considered together, the main teachers’ learning outcomes can be summarized as follows.

a) Better knowledge of students’ (pre)conceptions and methods of problem solving. For example, the teachers appeared to have learned a lot about ‘alternative’ conceptions of students. They became more conscious that their knowledge of these conceptions was inadequate. Frequently they had been astonished when faced with results after analyzing students’ written answers and discovering the great variety of methods used by the students. In addition, they became aware that sometimes there is a discrepancy between their prescribed methods and effective methods of students.

b) More competence in talking less and listening more carefully to students. For example, the teachers appeared to be more perceptive of students’ oral and written statements. The teachers reported to introduce new chemistry concepts more carefully and to be more considerate of students’ methods of problem solving. They acknowledged that this approach implies an important change of their usual teaching strategy.

c) Growing awareness of their own conceptions of teaching and learning science. For example, on the one hand, the teachers were inclined to think that efficient learning is
realised when teachers try to transmit knowledge in a direct way. On the other hand, the teachers also believed that it was important for students to learn in an active way by observing and interpreting natural phenomena by themselves.

Final Comments
There is an increasing interest in teacher training founded on a constructivist perspective (Clark, 1986). The interest in stimulating teachers to reflect on their own classroom practices is also growing (see e.g. Baird et al., 1991). However, little is known about inservice courses which integrate elements of classroom practice, course theory, teacher reflection and conceptual change. In my opinion, because of the importance of the integrated teacher training, it is necessary to develop and investigate such courses more extensively. The results will contribute to improve science classroom practice as well as science teacher education.

IMPLEMENTING A SCIENCE EDUCATION FIELD EXPERIENCE

Don Nelson and Michael Jacobson
Western Illinois University
49A Horribin Hall
Macomb, IL 61455
(309) 298-1411

This article describes our initial efforts to incorporate a science field experience for our upper division elementary education majors (fourth through sixth grades) into the teacher preparation program. For many readers, supervising students’ field experience may be rather routine. It was not for us. This narrative relates what we did, what worked, and what didn’t.

For many years, the science educators in our department have complained about the lack of science field experiences for our upper elementary students. While the students’ program included an extensive pre-student teaching field experience, this practicum centered on language arts and reading. Any science, social studies or mathematics lessons that the students may have prepared and taught were entirely incidental. We argued with our reading and languages arts colleagues about the value of a field experience that did not reflect the breadth of the elementary school curriculum. This past semester, however, we learned anew the relevance of the old adage, “Be careful for what you wish for, it may come true.”

It was decided that one third of the students’ time in the schools, two hours a day for four weeks, would be devoted to science and social studies instruction. From the very beginning, implementing this practicum for 20 students was akin to sailing a ship while it was still under construction.

The first task was to find area elementary teachers who would take our students from 9:00 to 11:00 a.m. during the month of September. This proved to be more difficult than we had anticipated. Our university is located in a rural region with a low population density. We were competing for teachers with the student teaching program and the language arts and reading practicum. Additionally, few self-contained classroom teachers taught science and social studies during the morning (that time period was reserved for the “really important stuff,” reading and language arts). To find enough teachers, it was necessary to place some of our students 30 miles from campus and to double-up several students with one teacher. After some scrambling, we were able to find classrooms for all of the students. However, that was not the end to our problems.

From some students we heard, “How can I get out of one class at 8:50, drive 45 minutes and be at school ready to teach at 9:00?” and there were the concerns of the corresponding group, “How can I leave school at 11:00, drive 45 minutes and make my 11:00 class?” There were anxious commuters who didn’t want to drive to campus and then turn around and drive out to the schools. There were also nervous student-parents who needed to get their children to or from day care. It became apparent that organizing a canoe trip up the Amazon during the rainy season would be easier than coordinating the students’ schedules! Eventually, however, the major transportation problems were resolved. We were ready to move on to the next crisis.

With only one month to work, we wanted the students to be as prepared as possible for their first week in the schools. A letter was sent to the participating teachers asking what science and social studies topics they would be covering. This seemed like a logical thing to do, but was not particularly helpful. The teachers’ responses ranged from wide open (“Whatever”), to vague (“Something about space”) and, finally, to the noncommittal (“I won’t know until I get there”). Having the students personally call on the teachers was somewhat more useful, but several of the teachers complained that being contacted by the students was a bother. In the end, our efforts at advanced preparation were negligible and most of our students began their experience in the schools without a clear sense of their teachers’ expectations.

Once in the classrooms, the students quickly learned that the scope and quality of their field experience would be determined, not by their college instructors, but by their supervising teachers. Most of the students were welcomed by their teachers and soon felt like members of the school community. Unfortunately, other students sat in the back of their teacher’s classroom, seemingly unnoticed. Students who worked with a single teacher, in a self-contained classroom, fared better than those in departmentalized situations. The departmental programs’ rigid schedules and constant class changes made it difficult for our students to get to know and interact with either the teachers or the students. Several departmental teachers’ perceived need to “keep all their classes together” placed additional pressure on our students to mimic the teachers’ managerial and instructional practices.

Our field experience, like most, was intended to provide our students with a “real world” context in
which to apply what they had learned in their college classrooms. Not surprisingly, much of what our students saw in their classrooms was at odds with what they had learned in their methods courses. While we stress active hands-on learning in science and social studies, most of what the students saw was traditional text-driven instruction. Their journals reflected their observations and their frustrations.

I have observed that both teachers to very much by the book. The lessons are designed mainly by what the book says. I feel it is important to do different activities instead of reading the book, doing the questions, filling out a worksheet, and taking a test. Science has so many activities and experiments that help the student become excited about learning—instead it’s the same thing day after day.

The students also observed teacher behaviors that did not fit their preconceptions of how teachers should interact with their students.

I’m disappointed in what I am seeing. She is supposed to be our role model and she is displaying teaching methods which we have been warned not to practice. It’s going to be hard to motivate children who are scared and not even respected by their teacher.

As one student wrote, reflecting back on his experience, “I can’t say that observing my teachers was all that valuable. Overall I learned a lot about what I will not do.”

Once the students were in the classrooms, our job was to help them prepare their lessons and to evaluate their instruction. We quickly learned how challenging these tasks were to be. Finding time when both we and the students were free to meet was the first major obstacle. During the mornings, we were on the road observing students and they were in the classrooms being observed. During the rest of the day, both the students and ourselves had other courses to tackle. Office hours became an abstract concept, as were literally “on call” whenever and wherever students might find us. In addition, we faced the same transportation issues as our students. We often spent more time in the car than we did in the schools. Despite our efforts to coordinate our visits with their teaching, we now and then missed connections. It was not unusual to arrive at school only to find out that a test, school pictures, or an assembly had been scheduled. Our students experienced similar frustrations when we occasionally failed to make it to their classroom. As one student lamented, “Where were you yesterday? My lesson was awesome and you missed it!”

While we had expected our efforts would be invested in observing and helping the students with their lessons, we did not anticipate the time we put into counseling. After being in the profession for 25 years, we tend to forget how significant these early teaching experiences are to students as they confront both their hopes and their fears. Not surprisingly, many students had bad days. In those cases, we were there to help them put these experiences in the proper perspective and to move on. Several students expressed serious doubts about whether teaching was right for them. Perhaps it’s not, but it was crucial that we be there to assist them in making realistic appraisals of their performances in the classroom.

At the end of the four weeks, we met individually with each student for an exit interview. We reviewed their required paperwork, their teacher’s comments, and our observations and evaluations. The students’ journals proved to be one of the most important evaluation tools. Their own thoughts provided important insight into the value of the field experience. After the ups and downs of our experience, it was gratifying to read such comments as, “I loved going into the schools and working with my teacher. The kids were wonderful. This course was very valuable to me.” The students’ journals and our final interview proved to be much more meaningful, to the students and to us, than the “Satisfactory” or “Unsatisfactory” they would receive on their grade report.

As a result of our experience, and that of the colleagues who followed us, we have taken steps to refine the field experience. Some of these changes include:

- Moving the field experience to the end of the semester to allow students more time to meet with their supervising teachers and to coordinate and prepare their lessons;
- Arrange the course times so that students can meet with their supervising teachers either before or after school;
- Provide supervising teachers with more specific information as to our expectations for them and for our students;
- Screen potential supervising teachers so as to provide positive rather than negative models for our students; and
- Coordinate the supervisors’ transportation schedules to maximize observation time.

In retrospect, the most important lesson we learned was that flexibility must be demonstrated by supervising teachers, students, and, of course, the university instructors if a field experience is to be successful. While advanced planning may be crucial, it is only as useful as reality allows it to be.
SCIENCE CENTRES AND WORLD WIDE WEB: THE INTERACTIVE
CHALLENGE
Reprinted from the
3rd INTERNATIONAL INTERACTIVE MULTIMEDIA SYMPOSIUM
Proceedings

Brenton Honeyman
Manager, Education & School Programs
The National Science and Technology Centre
Canberra, Australia

Abstract
Questacon—The National Science and Technology Centre is one of several interactive science centres around the world using World Wide Web as a strategy to provide virtual tours of their exhibitions and information about their programs. Some centres, including Questacon, are developing web sites with a difference—after all, they are centres which encourage hands-on approaches and as much interaction as possible. This paper will explore ways in which centres like Questacon are developing interactive approaches on the web.

A question of interactivity
More and more science centres around the world are issuing an invitation for people of all ages to enter the fascinating world of science and technology through their computer. Science centres are discovering that the Internet—in particular, World Wide Web—provides a rapidly escalating opportunity to reach a wider audience, thereby promoting a greater public understanding and appreciation of science and technology and their impact on our everyday lives.

The capacity of web browsing software to integrate text, images and sounds has attracted many science centres to the idea of establishing a presence on the Internet. However, those science centres which emphasise hands-on, interactive experiences, are looking forward to developments in web browsing software which will achieve far greater ‘interactivity’ in contrast to the more passive, page-turning experiences that today’s web users are familiar with. Such developments may then provide an experience which is genuinely interactive, where users encounter science phenomena in engaging ways, manipulating devices and data to test and develop their understanding.

The interactive approach
During the 1980s, interactive approaches to learning began to attract more widespread attention among education researchers and teachers. An interactive approach to learning science, according to one group of science education researchers (Biddulph et al., 1986), has an emphasis on ‘identifying learners’ present ideas and interacting with them to help them to modify or extend their ideas . . . nudging their thinking as far as possible to enable them to make better sense of their world.

At the same time, the rapid growth of science centres produced an additional community of science communicators and educators developing exhibition and program experiences also defined as ‘interactive’. When visitors interact with hands-on exhibits and activities in science centres, they are able to test their understanding of ideas as they interact with phenomena and with each other.

When the physicist Frank Oppenheimer founded the Exploratorium in San Francisco, he felt concerned that people were becoming information rich and experience poor. He wrote (Oppenheimer, 1968): ‘On the whole, people have very little opportunity to have any direct experience with the separate elements of nature or technology. They watch ocean waves, but have never been shown how to observe the way waves
pass through each other, bend around corners or bounce off cliffs. In a science museum, one can provide these direct experiences with the behaviour of light, sound and motion. One can set up these experiences in such a way that they not only generate, but partially satisfy curiosity. Science is not just a process of discovering and recording natural phenomena; it is a process which develops our ways of thinking about nature and which enables us to find the connections that simplify and at times enrich our comprehension and awareness of nature.*

Designing for diversity

Visitors to science centres bring with them great diversity in terms of their previous knowledge and experience, their assumptions and their expectations, as well as their ways of thinking and learning. Science centres expect this diversity and design their exhibits and programs accordingly—as open-ended opportunities which provide flexibility in the manner and level of investigations individuals and groups may wish to undertake. Some visitors will want to explore a phenomena in depth—and may find out things which were never intended by the designer! Others will spend only a few seconds with an activity before proceeding to another—rushing to experience as many activities as possible (albeit superficially) in the time they have.

Feher (1990), in an article about the role of interactive science museums in studying how people learn, refers to an excerpt from a Grade 4 textbook which states 'Light is energy that you can see. Light travels through space in the form of waves.' She goes on to relate how statements like this are abstract and uninteresting because ‘...there is nothing you can do with it. There’s nothing to go home and try out. There’s no experience of nature. The problem is endemic in our schools: teachers teach abstractions, definitions and explanations of phenomena that, for the most part, students have never explored, or, worse still, that students may not even know actually occur. If schools so often put the cart (explanations) before the horse (first-hand experience of natural phenomena), modern science museums reverse the process. Science centres ‘...present natural phenomena in the form of exhibits that are interactive and manipulable, exhibits whose express purpose is to enable visitors to explore and experiment’.

Visitors to science centres have an opportunity to test their understanding as they interact with science phenomena through exhibits and activities—the more compelling the experiences, the more likely learners will develop their understanding of the phenomena.

A recent article in American Scientist describes how many science centres are now delivering hands-on experiences direct to the school or home via the Web. ‘Although some of the science centre Web sites lack any useful information beyond museum hours, location and so on, many of them offer enriching experiences, almost like making a real, rather than a virtual, visit.’ (May, 1995)

Questacon’s Web site

Questacon—The National Science and Technology Centre was established in Canberra, Australia in 1988 to promote understanding and appreciation of science and technology. Through its interactive exhibitions and an array of public and school programs, the Centre has become one of the major science centres in the world. Each year, over 350 thousand people visit the Centre in Canberra, and more than a million people are reached through Questacon outreach programs. Questacon is active in touring exhibitions and conducting programs beyond Australia, particularly in the Asia-Pacific region.

In May 1995, Questacon launched its World Wide Web site. Here you can take a virtual tour of Questacon’s six galleries to see some of our hands-on exhibits, find out how to organise a group visit and obtain information about the Centre’s programs for schools and the general public across Australia. Many web sites provide information like this, but Questacon has been developing a site with a difference—after all, Questacon is a centre which encourages hands-on approaches and as much interaction as possible! Hence, you will find much more than information on the Questacon Web site. On a rainy Saturday afternoon at home, or to liven up the school classroom, have some fun and learn at the same time by trying some of the hands-on activities on Questacon’s web site. The activities use readily available materials and provide plenty of fascination for all ages. Practice your problem solving skills in Puzzleguest. Try an intriguing experiment, and explain how it works. Questacon’s Web site can be located at http://sunsite.anu.edu.au/Questacon.

Hands-on science centres worldwide

A useful place to begin your search for science centres and the various programs they are establishing on the Web is a directory of hands-on science centres worldwide, located at http://www.cs.cmu.edu/~mwm/sci.html

The future

With the arrival of Java, a new programming language developed by Sun Microsystems, and similar software development initiatives, the web will feature considerably increased levels of interactivity. Java, for instance, is designed to interact with the user, providing not only the text, images and sound that current users
are familiar with, but also software ‘exhibits’ or ‘lab benches’ on which experiments can be set up and simulated, regardless of the user’s computer operating system. With Java’s multi-threading feature, we can look forward to better interactive responsiveness and real-time behaviour—at least to the level that the underlying computer operating system will permit.

Questacon is currently developing some trial activities utilising features of the new version of Netscape 2.0 incorporating Java. These activities provide a much higher level of interactivity—users can manipulate objects in order to experience and explore scientific phenomena.

Editors Comment

Technologies such as World Wide Web offer many educational opportunities. Please let us know how these tools are being developed in your country.

About the author

After 20 years as a science educator and administrator in schools, Brenton Honeyman joined Questacon—The National Science and Technology Centre in Canberra, Australia, as Manager of Education & School Programs. Brenton and his team coordinate a wide range of public and school programs across Australia, focusing on interactive approaches to learning and experiencing science and technology as they relate to our everyday lives.

Brenton’s career as a science educator includes a diverse range of positions and appointments, including President of the Australian Science Teachers Association; Convenor of the World Conference on Science Education and the Quality of Life; and Editor of Science Education International. He is currently the President of the International Council of Associations for Science Education (ICASE) and is working with UNESCO and other international organisations on worldwide projects to enhance scientific and technological literacy for all.

His current interests include broadening teaching learning repertoires so as to increase student engagement in learning, science communication, international science education, and educational uses of electronic and information technologies.

Book Reviews

TOWARDS MORE EFFECTIVE SCIENCE TEACHER DEVELOPMENT IN SOUTHERN AFRICA

Leo de Feiter, Hans Vonk, Jan van den Akker, Vrije Universiteit
Amsterdam, The Netherlands

Published by VU University Press, De Boelelaan 1105, 1081 HV Amsterdam (1995)

ISBN number 90-5383-438-9

From the outset it needs to be pointed out that this is more than a book describing science education in Southern Africa. As the authors point out in the introduction, it is the result of a literature review and presents an exploration of the current state of affairs regarding science education (certainly in the three Southern Africa countries of Botswana, Lesotho and Swaziland) and of literature relevant to in-service teacher education activities.

The book is the product of cooperation and discussions between specialists in the field of in-service education through links between the universities of Southern Africa and the Vrije Universiteit Amsterdam. A major problem experienced in the early 1990s with regard to in-service science teacher education projects was how to design interventions for optimal effect and how to establish their effectiveness. This book explores efforts made in this regard and their links with the research findings put forward in the literature.

This is a very readable book that gives a very clear insight to the educational system in Botswana, Lesotho and Swaziland and the in-service professional development programmes for science teaching. Chapter 2 looks at some of the major factors characterizing science education in secondary schools in the three countries and based on this, leads to implications for science teacher development. In so doing international developments are considered and the trends in curriculum development towards science for all and more societal interaction are included.

From an ICASE point of view it is disappointing that scientific and technological literacy is not mentioned as an important goal for science education. The review of the literature did not extend to the ICASE, nor the UNESCO, publications which are rich in this area. This raises the dilemma for ICASE—should it put more efforts in putting forward articles in research journals, or is it more appropriate to emphasize the message to teachers. It would seem, judging by this book, that ICASE is not achieving either of these goals at present.

Chapters 3 and 4 of this book are excellent reading for all science educators. Chapter 3 expands on effective science teaching and covers constructivism, the notion of 'less is more' and in a simple and easily read manner, what research says about effective science teaching. Chapter 4 considers effective science teacher development. It points out that governments have begun to regard teachers as key persons in the process of educational change. This is at the very heart of STA development and the rationale for the existence of ICASE. It is not surprising, therefore, that the book elaborates on the concept of teacher professional development and areas such as individual development, school-based teacher development and teacher development activities at the national level. The book concludes with a reform strategy based on an adaptation of the Vespero’s stage model illustrating the types of intervention possible depending, among other things, on the teacher background, professionalism and reaction to innovation. Missing is the role of the science teacher association. With much attention placed on the professionalism of teachers, this is really surprising. It perhaps illustrates the difficulty in developing a self based development strategy when teacher motivation and confidence are low and where efforts to organize help groups are thwarted by obstacles. Nevertheless teacher associations do exist in each of these countries and they are sufficiently active to have a place in the teacher development equation.

In conclusion this is a book to be recommended to all science educators and especially to all teachers in Botswana, Lesotho and Swaziland. The illustration of the approaches to science teaching and science teacher development should be of great interest. Although ICASE’s promotion of scientific and technological literacy as the main rationale for the teaching of science is missing, many attributes that lead to this are clearly described. If science teaching and teacher preparation could develop along the lines advocated in this book, many of the ICASE goals would be fulfilled.
SCIENCE/TECHNOLOGY/SOCIETY AS REFORM IN SCIENCE
EDUCATION

Editor Robert E Yager, Science Education Center, University of Iowa, Iowa City 52242 USA

State University of New York Press, State University Plaza, Albany, New York
12246-0001, paperbound US$19.95 plus US$ 3 for shipping and handling

ISBN 0-7914-2770-6

Here is a compilation of articles on the STS (science—technology—society) movement presented in five parts—STS as a Reform Movement in Science Education; What an STS Approach can Accomplish; What the STS Approach Demands; STS Initiatives Outside the United States; Supporting the STS Reform. The book is 337 pages long with 29 chapters. The first two parts represent Yager's thinking and much of the early chapters are either written by him or his former students. These chapters compile much of Yager's writings in the literature on the STS movement.

Without doubt this is an important publication covering the rationale, the research base, as well as the teaching strategies that are related to STS as a reform movement. The evidence for this approach, as expounded in Chapter 2 is overwhelming whether it is mastery of basic concepts, process skills enhancement, promoting the affective domain, creativity or application of learning. By the substitution of STS with STL (scientific and technological literacy), the book reinforces the philosophy of Project 2000+, as initiated by UNESCO and ICASE.

The book reminds us that STS is an American initiative and that there have been many attempts to initiate STS programs into secondary schools. However it points out the term STS was coined by John Ziman in his book Teaching and Learning about Science and Society (1981), published in Britain. Section 4 illustrates STS initiatives outside the United States. STS is seen as a response to many of the perceived problems of traditional science teaching—students cannot use the science they learn; most students not to attain functional scientific literacy; lack of interest in science and the diminution of creativity skills even though these are central to basic science. Above all STS, is seen as a means to attain the educational goals often overlooked in traditional teaching, because the content becomes the sole focus of teaching.

This book suggests that the more able students will receive a more challenging, all round education if exposed to the STS ideas, surely a factor of great importance for science education. But if cognitive gains are not measurably greater through STS teaching, certainly higher achievement is illustrated for creativity, problem solving and self motivation. STS also enhances the opportunities for low ability students. In fact a whole chapter is devoted to exploring the value of STS for less successful students in giving them the confidence to play a more active role through working at their own pace. Teachers must surely welcome this. With education for all and the need for all students to study science education comes the need to provide an appropriate and motivational education for the average and less able student, as well as the much smaller in number, more able students.

The book is excellent. The message is clear. The text is very readable and easy to follow. Many examples are given and surely every teacher can find something that is useful and can guide them along the STS approach. Science needs to be taught in an approach put forward in this book. What is the problem?

The first problem is that most teachers will not read this book. For many US$20 is too high a price to pay and anyhow where does the foreign exchange come from? Making it available in science education libraries is important but how do teachers gain access to these? It is clear that science teacher associations need to do more to bring the message of the book to science teachers. ICASE is undertaking the first stage by making STAs aware of its existence through this review. ICASE continues to promote Project 2000+ and the need to take steps at the national level for scientific and technological literacy.

The second and more serious problem is that even if teachers know that the STS (STL) approach is important, still they fail to change their practice, often citing 'must finish the syllabus', 'don't have resource materials', 'it is not as given in the textbook', 'must teach for the examination', etc. What this shows is that teachers do not really understand the STS or the STL movement. They fail to grasp that at the heart of the problem is the teacher, the teacher background and the manner in which the teacher views education. Even though the evidence in the book is overwhelming, teachers continue to believe they must be the centre of classroom action and the fountain of knowledge for
students. Even though teachers will agree with the message in the book that students do the learning (not teachers), they still say the teacher must finish the syllabus, rather than the teacher must help the students to learn through interacting with the syllabus. The book cannot help to put the ideas into practice - here is the importance of the science teacher association. Thus the importance of the book is indicated by the value placed on the ideas contained by the science teacher association. If the association endorses the research findings and the practices being expounded, and is willing to promote them to teachers, then the book may stand a chance of succeeding in its mission to promote a megatrend in science teacher education. Without that and it fails.

The endword in the book indicates that not only is there an increased need to understand large national issues, there is also an increasing need to understand the way science and technology affect us as individuals. It asks 'Can we shift our goals, programs and practices from the current overwhelming emphasis on academic preparation for science careers for a few students to an emphasis on preparing all students to grapple successfully with science and technology in their own, everyday lives, as well as to participate knowledgeably in the important science-related decisions countries will have to make in the future? This is certainly the challenge and this book does much to bring this challenge to our attention.

Science/Technology/Society as reform in science education is important. Its goals is scientific and technological literacy at an operational, structural and multifaceted level. This coincides with the goals of Project 2000+. The book provides an extremely useful guideline to the direction science teaching should take and the philosophy and research findings behind this. These aspects are clearly set out in very readable chapters. Thus the book is nothing less than crucial reading for all in science education reform. Reforming science education, ICASE hopes, applies to all science teacher associations.

TARGETING STUDENTS’ SCIENCE MISCONCEPTIONS

by

Joseph Stepans, Ph.D.

The Conceptual Change Model enables teachers to uncover students' naive beliefs in science, confront their beliefs through activities, and develop more scientific concepts. Each unit includes common misconceptions about the topic, teacher background, reference list, and a series of hands-on activities.

15 Physical Science Units Include:

- Matter
- Liquids
- Electricity
- Light & Color
- Heat
- Force, Work, and Simple Machines
- Motion
- Density
- Magnetism
- Levers
- Waves
- Models
- Pendulums
- Sound
- Air Pressure

Laura Martin, Arizona Science Center

Focus
This special issue will discuss perspectives on informal learning and present research findings documenting the role that experiences play in promoting people's science interest, knowledge, and supporting and reinforcing the science learning that occurs in schools.

Targeted Topics
1. Relationships between learning and the physical and social environments of many informal settings.
2. Applying theoretical learning strategies, such as constructivist learning theories and concept formation to informal settings, or developing theories specific to informal theories.
3. Defining and measuring informal learning, e.g. family learning in museums or the home.
4. Dynamics between informal and formal learning settings.
5. Play and curiosity as components of learning.
6. How the characteristics of informal settings influence behavior and learning.

Timeline
Manuscripts Due: November 1, 1996
Reviews Returned: February 1, 1997
Revisions Due: May 1, 1997

Manuscripts should run between 5 and 20 double-spaced, typed pages. Other information for contributors can be found on the last pages of Science Education. Diskette submissions are encouraged. Manuscripts must be submitted in quadruplicate (one original and three copies) to Kirsten Ellenbogen, Vanderbilt University, Peabody College, Box 506, Nashville, Tennessee 37203.

This will be a competitive, peer-reviewed process. Please contact the editors if you are interested in reviewing submissions for this special issue.

Inquiries concerning this special issue should be directed to: Lynn D. Dierking at (410) 268-5149 or by email to sli@internetmci.com or Laura Martin at (602) 257-1450 or by email to lmartin@pc2.pc.maricopa.edu.
2-5 July, 1996
World Congress on Engineering Educators and Industry Leaders, UNESCO, Paris

This congress is jointly organised by UNESCO, the United Nations Industrial Development Organisation (UNIDO), the International Union of Technical Associations and Organisation (UATI) and the World Federation of Engineering Organisations (WFEO)

All correspondence and inquiries concerning the Congress should be addressed to:
Secretariat of the Congress
UATI
Maison de l’UNESCO
1 rue Miollis
75732 Paris, France
Fax 3301043062927
email unispar@unesco.org

Inquiries regarding the conference should be directed to:
Gemma Friedlieb
Faculty of Education
University of Canberra

Cartoons as a Stimulus to Learning in Science

Our research involves exploring the use of cartoons as a means of teaching and learning science. The cartoons are based on alternative viewpoints about everyday situations. They have been used successfully with primary and secondary pupils, undergraduate and postgraduate students, primary and secondary teachers, parents and members of the public.

We can be contacted at the following address:
Brenda Keogh and Stuart Naylor
30 Mill Hill Lane
Sandbach, Cheshire,
England CW11 4PN

ICPE Conference in Bangkok, Thailand
16-20 December 1996

Modern Science and Technology in School Physics Curricula for the 21st Century

Sub-theme for concurrent sessions:
—New Approaches in Physics Teaching
—Information Technology in Physics Education
—Computer and Multimedia in Physics
—New Technology and Equipment in Experiments
—Environmental Physics

OBJECTIVES:
The conference provides an opportunity for science educators, teachers from schools and universities, scientists to meet together in order to:

- share ideas and experiences in physics teaching
- interact with educators from different fields of interest in physics community
- provide awareness of environmental problems and issues through physics teaching

ORGANIZER:
The Institute for the Promotion of Teaching Science and Technology (IPST)

Supported by:
—Ministry of Education of Thailand
—ICPE at IUPAP
—UNESCO (Principal Regional Office for Asia and the Pacific)

CALL FOR PAPERS:
Contributed papers highlighting news and recent development in the areas covered by the conference are invited.

The closing date for receipts of titles and abstract (not exceeding one A4-page) is August 31, 1996. The abstracts should be camera-ready on A4-size (297mm x 210mm) the text must be type within the frame of 220mm x 150mm. The name of the author is to be underlined. Instructions for typing camera-ready manuscripts may be request from the secretary of the organizing committee. Abstracts and full paper text can also be in the form of 3.5" or 5.25" diskette (for IBM-PC) or email. Full paper must be submitted by October 15, 1996.

On request, the secretariat of the conference will send a personal invitation for participation in the conference. It should be understood that such an invitation is only meant to help participants raise travel funds or obtain visas, and is not a commitment on part of organizer to provide any financial support.

PROGRAMMES:
There will be keynote, plenary lectures, paper presentations, workshops, poster displays and exhibits. Details of the conference will be available in the second announcement.

VENUE:
The conference will take place at The Institute for the Promotion of Teaching Science and Technology (IPST), center of Bangkok

LANGUAGE:
The conference will be conducted in English. The national language is Thai. English is widely spoken in tourist centers and hotels.

VISA:
Those visitors who require a visa to enter Thailand should consult the Royal Thai Embassy or Consular Office for Visa information.

ACCOMMODATION:
Accommodation will be reserved upon request. Special room rates will be arranged at the venue of the conference and in nearby hotels, details of which are available from the secretariat.

REGISTRATION FEES:
Active Participants—U.S. $100
Accompanying person—U.S. $80

ALL PAYMENTS MUST BE IN BANKER’S ORDER OR BANK DRAFT

CONTACT:

THE CEFIC SCIENCE EDUCATION AWARD

The European Chemical Industry believes that its future prosperity rests on the quality of the science education of Europe’s people. A thorough understanding of the fundamental principles of science and an appreciation of the impact of technology on our lives, and on the nature of the society in which we live, is already essential for survival in the modern world. European society cannot “opt out” but must equip itself to survive and prosper.

It is in this spirit that CEFIC has created its annual award for “Excellence in Science Education.” This award helps to:

- promote excellence in the teaching of science
- recognise the importance of teachers as major opinion-formers and show our desire for partnership with them
- build on the natural curiosity of young people about science
- show the industry’s willingness to be involved as a player equal to others in the community
- demonstrate our support for science and scientists.

The award

The award recognises excellence in science education, achieved by a teacher and a group of students. It is made on the basis of a project dossier created by the teacher and the pupils, which demonstrates both effectiveness in teaching and effective learning by the students.

Ann Burke from the winning school (Ireland) receiving the award from the president of CEFIC (Amsterdam 14 June 1996)

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

ICASE GENERAL ASSEMBLY
Prepared by Jack Holbrook, ICASE Secretariat

According to the ICASE constitution, a General Assembly is held every four years. The last was held in Paris in 1993. It is very important for ICASE that member associations are strongly represented at the General Assembly as they are the Governing Body. Furthermore, the election of new officials is only possible if the General Assembly is constitutionally convened.

ICASE is making plans to hold the next General Assembly at the end of December 1997 in the UK (immediately prior to the ASE annual meeting). Earlier plans to hold the General Assembly in South Africa in July 1997 have collapsed. I will be able to give further details later in the year. I welcome queries and comments from any member organisation concerning the General Assembly, the manner in which new officials are nominated by member organisations and the procedure by which they are elected.

ICASE Homepage
ICASE now has a worldwide web site on the internet. The address is: http://sunsite.anu.edu.au/icase.

ICASE encourages all its member organisations to find ways to connect to the “web” and to establish email facilities. Email is easing worldwide communication and the “web” is certainly facilitating the dissemination of information. If you can be contacted by email, please tell me. My email address is: icase@zenon.logos.cy.net.

In the future, I would like to communicate by this means.

UNESCO Links
The ICASE worldwide web homepage is linked to the UNESCO homepage via information on Project 2000+ (the joint mobilizing project of ICASE and UNESCO). This link will be extended as ICASE and UNESCO work together to develop STL (scientific and technological literacy) teaching materials and other ideas useful to teachers.

Every member organisation should be receiving UNESCO’s INISTE/Project 2000+ bulletin. This is a biannual production, written for UNESCO by ICASE. (If you are not receiving a copy please contact me, or even better write to UNESCO directly: Chief STE, UNESCO, 7 place de Fontenoy, 75352 Paris, France. In your letter mention you are an ICASE member organisation.) I would welcome information about your activities to include in the bulletin. Please send also any feedback you may like to provide on the usefulness of the bulletin.

STL Teaching Materials
ICASE is encouraging the production and collection of teaching materials (individual lessons, courses, etc.) that are related to STL. To this end writing workshops have been held in Vanuatu (1995) and Estonia (1996) and further workshops are planned for 1997. ICASE will be publishing these STL teaching materials on the ICASE web site.

1999—The Year of International Links in Science Education

The ASE (UK) and ICASE are currently developing plans for schools to link across countries on a common project and for the outcomes to be available in 1999. ICASE hopes that its member organisations will be interested in promoting this scheme and help ICASE draw up a register of interested schools. A brochure will be made available shortly to explain the scheme in more detail, but the link is designed for students at any age level, studying any topic with the project proceeding for any length of time. The link may be between two schools in two different countries or could involve many schools in a multitude of countries working on the same project. ICASE would welcome expressions of interest in these ideas.

Membership Grows
Your organisation may be interested to know that the ICASE family continues to grow and currently there are 132 member organisations. This is double the 65 members in 1986.
SCIENCE TEACHER DEVELOPMENT IN DEVELOPING COUNTRIES

Ed van den Berg
Science and Mathematics Education Institute
University of San Carlos
Talamban Campus
Cebu City, Philippines
e-mail: edberg@durian.usc.edu.ph

Let me take you across the globe to a tropical island to a school in a small town on the other side of the mountains. One of my former students is teaching there. School facilities are reasonable, among the best of the island but all is relative. Only about 7 out of 45 students have a textbook, a rather common problem in many countries. When I attended one of the lessons my former student spent half the lesson dictating. We had trained her to use more creative methods, but what could she have done without books and with lots of exam pressure?

We board a flight to another country, where science is often taught by teachers trained in other subjects. Less than 10% of the teachers currently teaching physics are certified and in Chemistry only 20% are certified. At one in-service center I met about 60 teachers who now have their normal teaching load compressed into 4 days and spend every Friday and Saturday in certification courses. These teachers face classrooms with 50-70 students and most have extensive family duties as well (90% are women).

In yet another country, national plans require student laboratory equipment for several thousand schools. The investment will be 20-40 million dollars. But many teachers have had no pre-service teacher education and just a little in-service. In many countries expensive equipment projects have only had very limited results: science teachers long for equipment but do not use it due to a variety of factors including lack of familiarity, lack of teacher time (side jobs), lack of curriculum time and perceived irrelevance of lab activities for national or district examinations. Indeed, for teaching content, student laboratory may not be any better than demonstrations which require less equipment (Bates, 1978; Hofstein & Lunetta, 1982; Garrett & Roberts, 1982; Hodson, 1993).

Many developing countries are understandably in a great hurry to catch up and leaptfrog into the industrial era. Science education receives a high priority as science and technology are considered keys to industrial development. Many countries have carried out or are in the process of executing large, expensive, nation-wide teacher education projects in science. This paper will present some conclusions and suggestions with regard to teacher development based on common sense, research, and experience. The suggestions are presented as general, but may need some reinterpretation in each country and context.

Ausubel (1968) said: Determine where the student is (conceptually) and teach him/her accordingly. When thinking about teacher professional development, one should also ask the question: where are the teachers? And, where are their principals, where are their schools and educational systems in terms of management, facilities, vision, and resources?

Where Are Teachers, Principals, and Schools?

Teacher and school conditions can be categorized according to table 1. The table is a modified version of the one which originated in Beeby (1966), and was developed further by Verspoor (in Farrell & Heynemann, 1989, p. 54) and again by Feiter et al. (1994). In the table teachers are spread across a continuum which ranges from poorly trained teachers who do not sufficiently master the subject matter in the school curriculum, to professional teachers with good mastery of subject matter as well mastery of pedagogy and methods of teaching and learning science. Beeby (1966) conceptualized educational development as a four-stage growth process, moving from unskilled, to mechanical, routine, and professional phases. Unskilled teachers are those who do not sufficiently master the school subject matter they teach. They may be teachers from other subjects who are forced to teach science or they may be people who entered the system at times of great shortages of science teachers. Mechanical teachers
may master the school subject matter, but may use just
one dominant teaching method which is used
mechanically. The routine teacher does have proper
subject matter mastery, also beyond the school
curriculum, and mastery of a repertoire of teaching
methods. However, the routine teacher is not yet or not
anymore involved in professional development in which
teachers continuously develop their repertoire of
teaching methods, examples, and background
knowledge, or has regressed to use only a narrow band
of teaching methods.

In many (but not all) low-income or developing
countries unskilled teachers are still quite common.
However, also in high income countries one finds many
teachers who are not certified (and perhaps not able) to
teach subjects like physics. Also in high income
countries most teachers are functioning at the
mechanical or routine levels rather than the professional
level. The main difference between low income and
high income countries may be in the proportion of
teachers at the unskilled and mechanical levels (higher
in low income countries) and the routine (higher in high
income countries) level.

School conditions can be similarly categorized
(Berg et al. 1995), but do not necessarily exactly parallel
the teacher column. In most countries a thin upper layer
of top schools is well organized and disciplined with a
professional teachers corps. Below that there is a broad
layer of “average” schools which experience the typical
problems of developing countries: low budgets,
teaching staffs with limited motivation and outside jobs
to supplement their low incomes, and management of
varying quality. Below the middle layer of “average”
schools is another big layer of poor quality schools with
high percentages of deprived students. These schools
are inadequately financed with under-qualified staff,
poor management, and poor discipline (frequent absence
of teachers, poor grading practices, etc.). On average
poorly managed schools have more unskilled teachers
than well managed schools. However, a well trained
teacher may be stuck in a poorly managed school and the
other way around, especially in countries where
teachers are hired and placed by Departments of
Education rather than by schools.

Beeby’s model can be linked conveniently with
implementation of new curricula and teaching methods
in which there might be a progression from non-use (of
new methods/materials), mechanical use, and routine
use to refinement and integration of new instructional
materials (for example: a new curriculum) and teaching
methods (Joyce & Showers, 1988). Both the
characteristics of the teachers and the characteristics
of the schools put serious limits on what is possible
in educational improvement or reform. Frequently
the different categories of schools and teachers are not
recognized and countries design uniform programs for
all schools and all teachers.

Table 1: Classification of teacher and school
conditions (modified from Feiter et al., 1995)
(see page 8)

Teaching Methods

Many countries and “expert” consultants like to
promote the most “modern” teaching methods in their
projects such as constructivist teaching, inquiry, pupil-
centered, etc. The problem is that most methods under
these broad and fashionable categories require high
sophistication from the teacher and rather favorable
boundary conditions in the school. Furthermore, the
superiority of such methods for many educational goals
(especially those tested by the traditional exams of many
countries) has not been proven on national scales,
although success may have been demonstrated in special
settings (Walberg, 1991). Sophisticated methods can
only realistically be promoted for teachers and schools
from the “professional categories” and even then the
methods will have to be adapted to use with large classes
(40 students per class or more in most developing
countries).

To determine what can be done in the lower
category schools with lower category teachers we might
want to look at the literature about effective teaching.
Joyce and Showers (1988, p. 55) state that the more
effective teachers:
• teach the classroom as a whole;
• present information or skills clearly and
   animatedly;
• keep the teaching sessions task-oriented;
• are non-evaluative and keep instruction relaxed;
• have high expectations for achievement (give more
   homework, pace lessons faster, create alertness);
• relate comfortably to the students, with the
   consequence that they have fewer behavior
   problems.

Based on a review of many studies, including
studies in developing countries, Walberg (1991, p. 44)
comes to a very similar list. Successful teachers practice
the following steps:
• daily review, homework check, and, if necessary,
  reteaching;
• rapid presentation of new content and skills in
  small steps;
• guided student practice with close teacher
  monitoring;
• corrective feedback and instructional
  reinforcement;
• independent practice in seatwork and homework;
• weekly and monthly review.
Fuller and Clarke (1994) in their synthesis of studies from developing countries found support for some of these practices as well. For example, frequency of homework was a significant factor in 80% of the studies which included homework as a factor.

What Can be Done at the Different Levels of Table 1?

Unskilled teacher, poor school: To turn an unskilled teacher into a skilled one who masters the subject and its pedagogy takes years (the years of pre-service!) and there is no guarantee that the unskilled teacher can succeed. Changing school management from poor to good may require replacement of principals, vice-principals and even school boards (private schools), which is difficult in any culture. Making sure that kids and teachers are in their classrooms when they have to be, would already be an improvement in many cases. What could be done is to provide textbooks and teach teachers how to use them (without special training, many teachers continue to dictate). If more funding is available, one could think of certification courses for unskilled teachers who have sufficient potential. Such courses should apply a well defined minimum level for graduation (e.g. mastery of school science at the level of final exams for secondary schools in that country). Furthermore, one could promote those effective teaching practices which do not require much skill such as giving and monitoring homework (random but regular checks to limit teacher work), use of tests which are relatively easy to mark taking into account the subject matter mastery and time of the teacher. In-service could focus on simple homework assignments and how to monitor and correct them and the same for tests. However, one should be aware that poor school conditions might interfere with any in-service efforts.

Routine or mechanical teacher, average developing country school conditions: Here one could try to improve conventional teaching by adding variation, and improving mastery of school science (McDermott, 1990). By necessity one would have to concentrate on changes which require little teacher preparation time and are correlated with performance on the typical exams of the country concerned. One should concentrate more on fine tuning and extending (Joyce & Showers, 1980) existing teacher repertoire than adding completely new methods which require in-class coaching. Table 2 summarizes suggestions. A beautiful resource for demonstrations with simple equipment and spectacular results is the book Invitations to Science Inquiry by Liem (1987). The book is popular in the USA as well as developing countries. We used it very much in pre-service as well as in-service activities in Indonesia and the Philippines. Secondary school students respond very positively to variation, demonstrations, and whole class discussion. The demonstrations require good classroom control, but disorder is less of a problem in most developing countries compared to industrial countries.

Obviously one should try to get the mechanical teacher to cross over to the professional category by trying to involve them in school-based development and in professional organizations.

Table 2: Improving Conventional Teaching

- Mastery of school science with emphasis on conceptual aspects and examples and applications in the student's environment;
- Increasing classroom interaction through questioning;
- Training in interactive demonstrations with universally available equipment;
- Training in the use of Predict-Observe-Explain demonstrations;
- Making concepts more "visible" through use of common objects as teaching aids;
- Linking science with the local environment and technology;
- Teaching systematically through use of objectives and a logical sequence;
- Frequent home work and monitoring of student work and achievement;
- Attention for individual students;
- Attention for student conceptions;
- Attention and regular feedback for student assignments;

Professional teachers and schools: One could promote sophisticated teaching methods here as teachers have the ability and are willing to spend the time to implement them. However, teacher educators should focus on teaching methods which are realistic in large classes as even top schools enroll over 40 students per class and sometimes over 60. Furthermore, one would have to keep in mind the nature of the matriculation and university entrance exams students are preparing for. The teaching cannot be too individualized. Predict-Observe-Explain demonstrations (White & Gunstone, 1992), concept maps, use of analogies, (open-ended) problem solving and other "minds-on" teaching methods could be promoted. Use of the laboratory is possible and recommendable if one is mindful of the many pitfalls of laboratory teaching (Hodson, 1993). It should be realized that sophisticated teaching methods need labor intensive and expensive in class coaching for teachers to overcome the typical implementation dip (Joyce & Showers, 1980, 1988). Such expert coaching.
is often difficult to provide in both developing and industrial countries. On the other hand, many professional schools in developing countries have great opportunities with eager and smart students and dedicated teachers. In such cases one should set ambitious targets for educational development.

Laboratory Equipment
Considering the many studies raising question marks regarding the use of the laboratory (Hofstein & Lunetta, 1982; Garrett & Roberts, 1982; Hodson, 1993) one should be very cautious in recommending large scale equipment projects, especially as many such projects in developing countries have failed and equipment remains under used. Student laboratories may only be meaningful for teachers and schools who/which are at the mechanical or professional level. Other schools and teachers should at least have simple demonstration equipment. When selecting equipment, one might want to go for demonstration only if the purpose of the experiment is mainly to illustrate concepts and theory and reserve the multiple set-ups for experiment where the focus is either on exercising manipulative and measurement skills or on training investigation (inquiry) skills.

Conclusions
Teacher development projects in developing (and industrial!!) countries should not provide universal recipes for all schools and all teachers, but should choose different approaches depending on teacher and school backgrounds. In certain situations simple actions (homework) can have large effects while expensive actions (provision of laboratory equipment) may or may not have effects. Promoting improvements of conventional teaching (table 2) may have more effect in “average situations” than promoting the “top ten” modern teaching methods from the haute couture of science education.

Notes
With developing or low income countries I mean low and moderate income countries located mainly in Asia, Africa, Latin America, the former Soviet Union, and the Pacific. No narrow and linear conception of “development” is implied.

The author worked in Africa with UNESCO, taught for ten years in a science and mathematics teacher education program in Indonesia, worked for five years in teacher education in the Netherlands, and is currently stationed at the Science and Mathematics Education Institute of the University of San Carlos in the Philippines in an inter-university cooperation project with the Free University of Amsterdam.

British Council International Seminar  
(Number 9679)  

Technology Education in the Core Curriculum  

12-19 March 1997  

London  

Directed by Professor Paul Black and Justin Dillon  

The seminar will explore different rationale for technology education in the school curriculum, and the traditions from which they arise in different countries.

Main themes will include:

• Technology as the appliance of science or as a design
• Preparing a citizen for a technological society
• Basis for a better educated workforce

The programme will be of particular interest to those responsible for curriculum development and teacher training.

Fee: £1,750 (residential)

<tbody>
<tr>
<td><strong>Unskilled</strong></td>
<td>Frequently only one or a few textbooks per class of 40+ students, absence of other instructional materials, or not used.</td>
<td>Emphasis on rote learning. Students copy from blackboard or dictation; no monitoring of individual students.</td>
<td>Continuous financial problems, focus on survival. Poor management, sometimes corruption with money and exams.</td>
</tr>
<tr>
<td><strong>Mechanical</strong></td>
<td>About 20% of the students may have science textbooks. Almost no other instructional materials. Some science equipment available but often not used.</td>
<td>Rote learning, slavish adherence to curriculum, short term activities and objectives, rigid application of one teaching method. Dictation not uncommon.</td>
<td>Management limited to administrative control and compliance (or not) with regulations. Little attention of leadership for what happens behind classroom doors.</td>
</tr>
<tr>
<td><strong>Routine</strong></td>
<td>20-100% of the students may have textbooks. Limited sets of science equipment available but under used. Other support materials (books, etc.) present.</td>
<td>Memorization still, but increasing attempts to introduce &quot;learning by doing&quot;, medium term planning using textbooks and materials in a more goal-oriented way, limited variation, attention for individual students.</td>
<td>School is run in a routine way without a development plan. There is some attention for school development through occasional in-service and some spending on instructional materials.</td>
</tr>
<tr>
<td><strong>Professional</strong></td>
<td>All students have textbooks, alternative textbooks available, well-stocked school library, variety of instructional materials. Complete laboratory.</td>
<td>Self-generated habits of learning; ability to generate new ideas; longer-term instructional planning allows teacher to adapt use of materials and curriculum sequence to student needs; individualized or multi-group instruction.</td>
<td>Competent management and school discipline, there is a school development program with a realistic budget, ample attention to pedagogic support, sometimes support services (media, technical) available.</td>

*Subject matter mastery in this paper means mastery of the science in the school curriculum (not mastery of college level science).
DIFFICULTIES OF SCIENCE INSTRUCTION IN THE KINGDOM OF LESOTHO

Dr. A. H. U. Talukdar
Head of Department
Department of Science Education
National University of Lesotho
PO. Roma 180, Kingdom of Lesotho

A Historical Perspective

During the colonial period, the missionaries controlled the education system in the kingdom of Lesotho and laid down the foundation of modern education. However, they did not integrate the system with the indigenous approach that reflected the local culture and had prevailed in the country for centuries (Moletsane, 1982). Consequently, the lives and aspirations of the local people are poorly represented in the modern system of education in the country.

During the colonial period a strong infrastructure for modern education was built, especially at the secondary level, but science education did not have a significant place in the curriculum. Today this missionary based educational system has little value for a society in need of science and technology training. After independence the government took over control of the education system and emphasized science education for national development. Since then the government has been trying to improve its science education programmes at all levels.

In spite of all efforts, it seems the situation has not been improving much. The nation is yet to meet its manpower requirement in the areas of science and technology. Over the years students' performance in science at various levels have been declining instead of improving (Talukdar, 1989). However, the nation is desperate to improve its education, particularly science education. A land locked country like Lesotho with almost no significant natural resources cannot afford to ignore the role of science and technology in its economy.

Develop its educational programmes. Many donor agencies came forward to help the country. American peace corps, German development workers, and Nigerian volunteers are very active in Lesotho and have been trying to improve science education programmes as quickly as possible. Similarly, the Dutch government, the European community, and the British council have also been contributing generously in many ways.

The department of science education at the National University of Lesotho prepares science teachers for secondary schools in the country. In the department, the Free University of Amsterdam and the European community have been supporting science and mathematics teachers' training programmes through the Centre for Inservice Education of Mathematics and Science Teachers (CIEMST). The centre has been in existence for more than a decade now. During this period it has been very active in supporting the inservice as well as the preservice science and mathematics teachers' training programmes. The centre staff regularly visit schools, liaise with the ministry of education officials and other interested parties with the goal of improving science education. The German development services provide development workers to support many activities of the centre.

The centre is now planning to extend its activities to non-science teachers. To accomplish this the CIEMST is attempting to become an independent entity in the National University of Lesotho within the faculty of education. The proposal is awaiting approval at the time of publication.

Partners in Development

Like many developing countries, after independence the kingdom of Lesotho was faced with economic problems as well as a dirth of expertise to
Science in Education

Primary Level

The duration of primary education in Lesotho is seven years. There is no minimum of maximum age limit specified for entry into the school system. Presently there are more than 1200 primary schools employing about 6000 teachers. About 7/8ths of the nation's student population are at the primary level. A small fraction of primary level students proceed to the secondary schools. It seems primary education is the terminal schooling for most of the people in Lesotho. At the end of this level, pupils write Primary School Leaving Examinations (PSLE), conducted by a local examining body.

Science is a compulsory subject at the primary level and about 15 to 20 percent of the teaching time is given to it. However, there is no separate teacher for teaching science. The primary level teachers studied very little science in their training programme. That knowledge is not adequate for teaching science. Often nontrained teachers are asked to teach the science.

Secondary Level

The secondary education is of five years duration consisting of three years junior secondary and two years senior level. Presently there are about 200 secondary level schools in Lesotho. At the end of the junior level, a junior certificate examination is administered. After two years of senior secondary education, the Cambridge Overseas School Certificate (COSC) examination is taken.

Only about 1/8th of the nation's student population study at the secondary level. A very small portion of those have the opportunity for higher education.

Science is compulsory for all during the first three years of secondary education. At the senior level, science subjects are optional and follow the COSC syllabuses. Combined science is the most popular senior option in Lesotho. Very few schools in the country are in a position to offer separate science subjects because of lack of qualified teachers and facilities.

Tertiary Level

The condition of higher education is also not very encouraging. Less than 1/2 of 1 percent of the entire student population in the country have an opportunity for tertiary education. Among them only 10 percent opt for science or science based disciplines (World Education Report, 1991). The main higher educational institution in the country is the National University of Lesotho. The National Teachers Training College, Lesotho Agricultural college and few other technical schools provide post secondary education but not at the degree levels. The opportunities for tertiary education are very limited.

The National University of Lesotho has well developed faculties for science and agriculture which aim at preparing highly qualified manpower for the nation. The university basically offers four-year programmes leading to first degrees. The diploma programmes are of three-year duration whereas some one year certificate programmes are also available. The honours, masters and Ph.D. degrees are offered in some departments. The statistics for the last 15 years suggests that the university has not been expanding in terms of number of intakes or facilities (Talukdar, 1989). Presently, about 20 percent of 1800 students of the university are in the areas of science.

Problems of Science Education

Lack of Qualified Teachers

Perhaps the teachers' role in classroom instructions is by far the most important component to our national science educational goals. It is the teacher who implements a curriculum or programme of study by teaching courses, organizing teaching learning activities, and using other available resources for instructions. Without the support of an efficient teaching force, no programme of study can be effective. Even a lavish budget is sure to fail to produce a positive result without a strong, professional and dedicated teacher community.

It is not surprising to see that many nonscience teachers teach science in Lesotho school system. The supply of science teachers is far below the demand. The countries 200 secondary and high schools need at least 1000 teachers to teach science adequately. Most of the schools are under staffed in all subjects, especially science. Nongraduate science teachers constitute the main body of science teaching staff.

The only university in the country produces about 20 to 30 science teachers annually. This does not include another 25 agriculture teachers who also teach science, mainly at the junior level, or the National Teachers' Training College who prepare a small number of teachers with science background annually. To add to the problem, a significant proportion of these science teachers find employment across the border, join other sectors of the economy or travel abroad for further studies.

Teachers in Lesotho have been complaining about their low wages compared with their counterparts across the borders. Many good teachers, local or expatriate, are migrating to neighboring countries.
Shortage of Resources

The success of teaching and learning science depends, to a large extent, on the proper use of resources. For science teaching especially the way the curriculum is designed, a laboratory is essential. In Lesotho schools, the laboratory facilities are seriously lacking and some schools teach science without a laboratory. In addition the condition of school laboratories is very poor. Many schools which have laboratories, have no water, no electricity, and no equipment for teaching science. Some of these laboratories are used as normal classrooms or staff rooms (Chisman, 1985). Schools have simply not developed a system of maintaining laboratory facilities at a reasonable level. The funds available for the laboratories are very limited and often insufficient. Even when funds are made available, schools fail to utilize the fund meaningfully and economically. Poor management and lack of adequate funding are two prominent reasons why the schools in Lesotho are short of resources for teaching science effectively.

Nonchalant Attitude of Teachers and Pupils

It is not only the subject knowledge of teachers but also the right type of attitude toward work which is essential for successful teaching. Even when their content knowledge and pedagogical skills are satisfactory, the nonchalant attitude of many teachers toward their work and science contribute to the poor student performance. A significant number of teachers do not show any interest or enthusiasm for their profession. For example, they are late to class, do not mark the continuous assessment properly, lessons are poorly organized, and at the time of examination teachers overload pupils with assignments and other work.

This nonchalant attitude is not a problem of science teachers alone. Other teachers as well as pupils also behave in this manner. Pupils are not serious in their studies and home assignments are not done regularly. Pupils' main purpose of study is to pass the examination, hence they study only on the eve of examinations.

Of course pupils' attitude is greatly influenced by the teachers' attitude. When pupils see that their teacher is not coming to class on time, gradually they also learn to come late. When the pupils notice that the teacher does not mark their assignments on time, they tend not to complete their assignments in time. If a teacher is considered to be the model, definitely the model described above cannot be acceptable for shaping the behaviour of our children. It seems nobody gives any attention to this aspect of teachers' and pupils' behaviours.

The Problem of Books

The lack of locally produced textbooks and other related literatures is a serious problem in the country. Some textbooks for primary and junior secondary levels are locally produced. The textbooks for upper levels are all imported and hence do not reflect the local conditions. Students do not see the reflection of their local environment in these books which reduces their interest in reading them.

The other problem is the high cost of books. The books are too costly compared with the income of many parents. For example, one volume of junior science textbook which is produced locally, costs in the range of R30-R40 in the market. An imported book of that type will cost even more, something around R100. A parent who finds it extremely difficult to pay the school fee of about R200 per year for a child, can definitely not afford to buy a couple of such books. It is not just one book a parent has to buy. This is truly an obstacle against acquiring and using science books. It is vital that something be done about this.

Weakness in English and Mathematics

A strong background in English and mathematics is essential for success in science. In Lesotho the weakness of pupils in English and mathematics is a great obstacle for teaching and learning science (Talukdar, 1995a).

One of the unfortunate things for the children of Lesotho is that they must study at schools in a foreign language and not their mother tongue. Many times children have to give more effort to learning the language than understanding of the subject. In Lesotho, English is the medium of instruction for the primary level. But the English language ability of pupils is extremely poor. The COSC results from 1979 to 1988 show a steady decline of student's English performance (Department of Science Education, 1991). The trend continues today.

There are numerous scientific concepts in English which do not have equivalences in local language. It is difficult for science teachers to teach such concepts. It is also well documented that the properties of concepts must be experienced by the learners before they can grasp their meanings correctly. Many teachers are not even aware of this problem or its solution.

Communication in the class becomes even more difficult when different teachers speak English in different accents. The children find it difficult to switch from one accent to another. Add these problems to the fact that teachers frequently move thus forcing children to adjust to yet another accent or style of language.

A strong background in mathematics is another prerequisite for success in science. In fact, mathematics
is the language of science. Mathematical arguments, logic, and symbolism are used to communicate the ideas in science. In Lesotho, pupils are very poor in mathematics. The results in this subject are so poor that many fail to fulfill the admission requirement for higher education.

Inefficient Management and Administration

The management and administration of educational institutions is another critical factor which affects the performance of pupils in their academic achievements. The ineffective management and poor administration of educational institutions in Lesotho have contributed greatly to the poor standard of education.

Schools, for the most part, fail to monitor the activities of individual teachers, manage laboratory funds, or recognize the special need and status of science instruction. Even if some donation of equipment or materials goes to a school, they are not properly maintained or stored. It is a problem of gross inefficiency. At times, it seems that no one is accountable to anyone for his or her activities. The lack of proper accountability is a serious problem of management and administration.

What Should Be Done?

Many teachers and other interested parties genuinely believe that the issues discussed above should be taken seriously. Just talking, discussing and lamenting will not help. Something concrete has to be done. Otherwise the situation will not improve. At this juncture, the country needs dedicated researchers and sincere workers to address these issues.

Debate and Research

The university and the ministry of education should initiate research and debate in the society aimed at understanding clearly the real problems of science education. Such research and debate could yield reliable information about the status of science education in the country and lead to dependable solutions. The research is costly and time consuming; whereas, the debate is quick, less expensive and does not involve specific technical expertise. The debate has the advantages and disadvantages of taking into consideration the political views of the people.

Nurturing Right Attitudes and Behaviours

Teacher education institutions such as the National University of Lesotho and National Teachers Training College should accommodate the question of teachers' attitude and behaviour in their programmes of teacher training. Workshops, seminars, and debates should be organized regularly on these matters. One cannot change the attitude of people overnight by mere advice. Long term education is needed. Such education will give the teacher an opportunity to analyze the matter and understand the pros and cons of it. The ministry of education should also take definite steps to address the issue. The CIEMST at the National University of Lesotho may be in a better position to launch various short-term programmes about the values and attitudes of teachers. Regular visits to schools by dedicated inspectors and their advice to teachers may also provide positive results.

The possibility of imposing punitive measures such as temporary suspension from work, withholding increment in salary, or transferring a teacher for wrongdoing should be implemented.

Supply of Textbooks

The government should formulate a policy of publishing and supplying educational books at a reasonable price. Many Third World countries are doing so. The government of Lesotho should try to encourage local writers to write books, set up printing and publishing techniques, and develop structures for marketing educational books cheaply, and to sign agreements with foreign publishers to publish books locally. A good network of public and school libraries must be set up and maintained as well by establishing a provision for such expenditures in the yearly national budget of the country.

Supply of Qualified Teachers

Special arrangements or provisions should be made for ensuring the adequate supply of qualified and dedicated science teachers in the school. Careful consideration should be given in recruiting science and mathematics teachers so the poorly qualified cannot enter the system. A poor teacher will produce low achieving graduates who, in turn, affect the national economy as well as the future teaching force. This vicious circle will continue without higher standards being implemented.

The government should devise some mechanism to give additional incentives to science teachers, perhaps by giving them additional allowances or other benefits. Presently, a science graduate can get more salary and benefits in other sectors of the national economy. There is a tendency to move from teaching to nonteaching jobs. An adequate incentive is needed to reverse the movement so that the schools can attract better people into teaching.

Improving English and Mathematics

Urgent attention is to be given to the English language acquisition at all levels of Lesotho education. The teaching of English language must be emphasized
at the primary level where the foundation of language is developed. Without the mastery of language, the study of science will continue to be hampered.

School must have enough English teachers for small group instruction appropriate for learning a foreign language. Moreover teachers should be trained with appropriate methodology suitable for local school situations.

Similarly, the problem of mathematics should be dealt with right from the beginning (i.e., at the primary level). A strong background in mathematics at the primary level must be established.

The CIEMST within its scope could do a lot about these training concerns. It can design a variety of in-service activities with a view to improve the situation. In addition the preservice teacher trainers of English language at NUL and NTTC could advise CIEMST and together draw a joint plan of action. The same applies to the problem of mathematics.

The Question of Research

The government of the kingdom of Lesotho, like many other developing countries, cannot afford to supply sufficient equipment and materials to a ever increasing number of schools and other educational institutions. This is a problem for all Third World countries, and it will remain for many years to come.

For teaching science, especially at the lower levels, many locally available materials must be used. Too many teachers have developed an attitude that fancy and sophisticated equipment and materials are the only resources for teaching science. They hardly see things in their environment which can be used for teaching science almost without any cost. The government should take the initiative to train teachers in using such materials for teaching science. This is the only way to solve the problems of equipment in our school system.

Conclusion

The geographic and the present economic conditions of Lesotho require that human resources be developed to the fullest. They have to be educated in science and technology to be competitive in the job market. The country must expand its industrial base for creating jobs and goods which require the application of science and technology. Only then can Lesotho move toward it's full potential.

NATIONAL SCIENCE EDUCATION STANDARDS: GUIDELINES, NOT CURRICULUM

Gerry M. Madrazo & Gretchen Van Vliet

The United States National Research Council released the National Science Education Standards in December after a year-long process of public review and comment. The goal the NRC hopes to achieve is to give all students regardless of gender, race, motivation, or physical or learning disabilities the “opportunity to attain a higher level of scientific literacy than they do currently.”

With funding from the Department of Education, the National Science Foundation, NASA, and the National Institutes of Health, the NRC sought input from educators, school administrators, school board members, parents, business leaders, curriculum developers, publishers, scientists and engineers, and public officials. The result is a 262-page document that offers standards for science content; science teaching; professional development for teachers; assessment of teachers, students and programs; science education programs; and entire school education systems.

While the Standards are voluntary, the NRC emphasizes that the Standards do not suggest a science curriculum; rather, they offer guidelines and tactics for analyzing our progress toward a higher national standard of science education. The NRC recognizes that implementation of the Standards will be “costly, time-consuming and require major changes in much of the country’s science education.”

The underlying principles of the Standards are outlined as: 1) science is for all students; 2) school science reflects the intellectual and cultural traditions of contemporary science; 3) learning science is an active process; and 4) improving science is part of systemic education reform.

The largest section of the Standards document focuses on science content standards. These outline what students should know, understand, and be able to do at various grade levels. The eight categories identified are: unifying concepts and processes; science as inquiry; physical science; life science; earth and space science; science and technology; science in personal and social perspectives; and history and nature of science.

The content standards break down into what students should learn in grades K-4, 5-8, and 9-12. For example, in life science, the standards specify that students K-4 should know the characteristics of organisms; life cycles of organisms; and organisms and their environments. In grades 5-8, students are expected to learn the structure and function in living systems; reproduction and heredity; regulation and behavior; populations and ecosystems; and diversity and adaptation of organisms. For life science, students in grades 9-12 need to be taught about the cell; the molecular basis of heredity; biological evolution; the interdependence of organisms; matter, energy, and organization in living systems; and behavior of organisms.

The other standards outlined in the NRC document offer direction at all levels of the educational system. Science teaching standards include direction for planning a science program; guiding and facilitating learning; assessing learning and teaching; designing and managing the physical environment; building learning communities; and school planning. The standards for professional development identify it as a continuous, life-long process; is applicable to the teacher’s daily work; requires learning science content through inquiry; provides professional intellectual growth; and is not skill-based technical training.

The assessment standards focus on assessment with clearly-defined purposes; measuring student achievement and opportunity to learn; matching technical quality of data with consequences; avoiding bias; and making sound inferences. The program standards look at school and district opportunities for students to learn and teachers to teach. These consist of consistency within and across all grades K-12; effective curriculum; science coordinated with mathematics; quality resources including teachers, time and materials; equity and excellence; and schools as communities of learners.

Finally, the Standards document looks at system standards that provide criteria for judging the components of the science education system. These standards include a common vision and coordination across the system; continuity over time; a program supported with resources; equity; unanticipated effects; and individual responsibility.

To order a copy of the National Science Education Standards for $19.95 contact the national Academy Press at (202) 334-3313 or (800) 624-6242. An overview of the Standards is available on World Wide Web at http://www.nas.edu.

A COMPARISON OF PRINCIPLES OF TECHNOLOGY AND TRADITIONAL PHYSICS

Steve Wignall

This article will take the Principles of Technology (PT) curriculum offered through the Center for Occupational Research and Development (CORD) and compare it with traditional physics classes offered in high schools across the United States. As a classroom teacher, my reasons for researching this topic are to discover the similarities that I believe exist between these two curriculums, and also to find some of the issues that have caused concerns in both programs. This will be accomplished by discussing the Principles of Technology in four parts. The first part will cover the reason for the conception of the course, the second part will discuss its development, third will be a discussion of advocates of PT, and fourth a Physics perspective of the course related to subject matter previously discussed on PT in the research.

Conception of Principles of Technology (PT)

The creation of PT began back in 1983 when the State Directors of Vocational Education began worrying about students, in their states, math and science abilities (Agency of Instructional Television (AIT), 1983). They were concerned that students did not possess the tools from the way the high school programs were being taught to enter into the work force at an acceptable level. Because of this they asked the Center of Occupational Research and Development (CORD), with the assistance of the Agency of Instructional Television, if they could recast the typical Physics class and make it more applicable for a vocational student going into the ever more technical work place of today. A statement by one of the developers, Leno Pedrotti (Barinaga, 1990), sums up the intent of the Principles of Technology project. He stated: “Our target was to bring more kids into physics, but not into the higher track. It’s physics for technology and technicians. We use the laws of physics to show how everyday industrial devices work.” With these goals in mind the project was then developed.

Development

When the development of PT is discussed the only way to look at this is from two viewpoints. The first is the historical perspective, and the second is the changes in the traditional school curriculums that had to occur for it to be implemented.

In order for the development of the PT curriculum to begin CORD and AIT had to first collect funding from Consortium schools in the amount of approximately two and a half million dollars to start the project (AIT, 1983). A consortium of thirty four state and Canadian provincial agencies bought into the original project. In the United States the monies that the states devoted to this project were through money that each had received through the Carl Perkins Vocational Educations Act. The Perkins money is still a big part of this program today. Examples of this include: funding and stipends for those training to teach PT, purchasing some of the equipment used in PT, and paying for substitutes and travel allowance to let teachers visit PT schools to expose them to this concept of instruction.

Instructional Design

The instructional design of this program was the hardest thing for the developers to attain. The original time line for this project called for implementation by September of 1986. This did not prove to be the case. Due to arguments in the Consortium meetings about Technology and Science, math skills, and having the equipment to do PT “In House,” the curriculum went through another revision from 1989 -1992 before it reached the final version used today. The developers listened to the states, schools, teachers, and students to get the best feedback from all.

The areas covered in the original project were separated into two years. Year 1 covered Modules 1-6 and Year 2 Modules 7 - 13. The modules would cover approximately 4 weeks of instruction each. The modules for year 1 were:
After field testing the original curriculum in 60 high schools around the country (Pedrotti, 1996) the only content changes made to the two year program, involved adding one more module and revising the order of units taught (Center for Occupational Research and Development [CORD, 1992]). The final units and their order are as follows:

1. Force 8. Momentum
2. Work 9. Waves and Vibrations
3. Rate 10. Energy Converters
4. Resistance 11. Transducers
5. Energy 12. Radiation
7. Force Transformers 14. Time Constraints

The first year of instruction is units 1-7, and year two is units 8-14.

Advocates of PT

To show the support that the Principles of Technology program is receiving throughout the country, I will review how the PT curriculum is viewed by businesses, and schools.

Businesses—Many, if not all, companies in the United States and the world are seeing the survival of their business resting in the hands of technology. If employees are not trained in the use, and understanding of these technologies then their work place must provide this education. This need has gotten many companies actively involved in the implementation of programs such as PT into schools. An example of this is The Boeing Company which met with Washington state education leaders to determine what help they might provide to ensure that schools were putting out more qualified graduates into the future work-force. The Washington state educators and The Boeing Company agreed that the company could assist in the following manner no matter what program graduates might eventually be employed in (Wang and Owens, 1995):

1. Using its influence as the state's major employer to convince education policy-makers at local levels of the benefits of applied academics courses.
2. Validating that new kinds of basic skills are needed in the workplace.
3. Providing seed money to local schools with applied academics programs to purchase equipment and materials and to reimburse expenses for teacher release time.
4. Providing opportunities for applied academics teachers to see their subject areas being used in state-of-the-art work settings.
5. Providing incentives and resources to encourage high school and community college faculty to link
their programs and to encourage community college faculty to change selected curricula to applied approaches.

Though not mentioned above, the programs that The Boeing Company primarily supported were PT and Applied Math (AM) as recipients of their help as shown in “The Boeing Company Applied Academics Project Evaluation: Year Four” (Wang and Owens, 1995).

Many schools in Washington state have eagerly accepted the PT programs and other applied classes into their curriculums, but what about other schools not as fortunate to receive help from outside to the extent of these schools, do they also accept PT as a course they are excited to receive?

**Schools**—Richard L. Goodworth a superintendent at Bonneville High School in Idaho gave this analogy of PT (Selland, 1986):

“We found it to be a highly academic, yet motivating, vocational course which can and does provide much needed skill training for students electing to participate. We are very pleased with the opportunity of working . . . in this most creative course.”

John Roper, a principal at North Shore Regional Vocational High School in Beverly, Massachusetts agrees that PT is an excellent vocational class, but goes one step further in his expectations of this course. He states (Roper, 1989):

“If we change the way physics is taught, we can communicate with those who learn in different styles. We should not drop the courses that are successful for some. Rather, we should add courses that might be successful for others. One such course is the *Principles of Technology* physics program.”

Before getting into the benefits seen by teachers who instruct PT, one question should first be raised. That question is “Who should teach *Principles of Technology*?” The original answer to this question was the vocational teacher at the school. But, according to CORD (1992) in the field testing, several types of teachers successfully taught PT:

1. Vocational electronics or electromechanics teachers (some drafting teachers with one or more courses in college physics).
2. Industrial arts teachers with one to three courses in college physics.
3. Physics teachers with some industrial or applications background and interest in *Principles of Technology* course format.
4. Teams of teachers with a physics teacher doing the classroom (frontal) teaching and math labs, and a vocational teacher doing the hands-on-labs. The team teaching approach has been found to be particularly successful where the two teachers sit in on each other’s class.

From the list above, it becomes apparent that in order for this curriculum to be successful the instructor needs to have at least some knowledge in physics, math, and some vocational experience (Moreira, 1994). As stated by an Introductory Information paper put out by CORD (1992),

“Teachers with more extensive physics background tended to be more successful in implementing *Principles of Technology*. Although most students demonstrated a learning gain, those students whose teachers had a more extensive physics background tended to have more pronounced learning gains.”

The information above gives a background of the type of teachers that tend to have favorable experiences with PT. This does not mean that teachers without some science background, or vocational experience cannot also be successful in this program. Through proper training in workshops offered for assistance in teaching PT, these teachers can also develop programs that are very beneficial, and satisfying.

The advantages of PT instruction in the material reviewed from a teacher’s standpoint really can best be categorized from the results gathered in a survey on “Schools Opinions on PT” by G. Gloeckner in 1990. In this survey Gloeckner reveals that:

- 71 percent of the students earned an “A” or “B” in their first semester PT class.
- 47 percent of the students who responded stated that they planned to enroll in a science course next year; 34 percent indicated that taking PT made them want to enroll in future science classes.
- 80 percent of the students who responded agreed that PT classroom demonstrations clarified mathematics and physics concepts for them.
- 67 percent of the students felt that PT instruction, as compared to other traditional science courses, better prepared them for a technical career.

The data collected in the survey not only looks favorable from the standpoint of the teacher, but more important, the students who are taking the PT class.

**Physics Perspective**

Traditional physics is definitely broader in its teaching than the PT curriculum. While PT emphasizes mechanical, fluidal, electrical, and thermal (CORD, 1992), traditional physics classes also teach these topics, but on a more advanced level (Serway and Faughn,
PT provides a base level of the technical aspects of physics with less theory, and more "working knowledge." If a student is looking for a physics class that is advanced math applicable, less hands on and more abstract, then the traditional physics class will best suit their needs. This statement leads us to the question: "Who is PT targeting, and are these individuals receiving a physics education that will help them reach their goals?"

Principles of Technology was originally developed for the middle 50% of the students attending high school. It is a course that uses applied concepts of physics and is not historical or theoretical to the extent of a traditional physics class. The reasoning behind this was that if you make a class more basic and hands-on you will touch more of the students who typically do not take Physics. The average student is more likely to succeed in this type of instruction because the material being covered seems more real life to them. What about the top 20% who normally take traditional physics classes? Do these students get the benefits they need to go on to college?

This question can best be answered through information from four different research papers on this topic. The first paper written by Baker, Wilmoth, and Lewis (1991) provided this conclusion:

Based on the data analysis, given a set of malleable student and teacher variables, it was concluded that Principles of Technology is a sound academic course, equivalent to physics, in terms of student performance on a test of physics (mechanics, heat, and electricity) items. Under that conclusion education counselors should not hesitate to encourage both college bound students (both 2 and 4 year) and students who will upon high school graduation immediately enter the engineering related technology/mechanical work force to enroll in Principles of Technology courses.

The data analyzed in this research were based upon testing of 226 students in PT and 306 students enrolled in a traditional physics course. The students all were separated into four quartile groups according to scores on the math section of the SAT. The 30 questions for the test were selectively chosen from the areas of mechanics, heat, and electricity from the NSTA/AAPT High School Physics Exam. Teachers were also a variable in this research and it was speculated in this paper that students in the lower quartile of math would have greater success with the teachers of more experience and physics background.

The second paper written by John Dugger an associate professor of industrial education and technology at Iowa State and David Johnson (1992), presented the results of a two year study comparing student performances in traditional physics classes with those taking the Principles of Technology modules 1-6 (first year). The study involved 675 high schools students in 15 Iowa school districts taking a pre-test and post-test composed of a 120 questions. These questions were developed around topics recognizable to both groups. The tests were submitted to a group of five secondary physics teachers and a community college physics teacher to review and ensure that the topics and terminology were presented in a typical high school physics class. In a summary of the results of the research Dugger stated:

All students took a pre-test to determine their physics knowledge before starting the Physics and PT courses. As expected, the physics students outscored the industrial education students by an average of five points. The test was re-administered after one year of Physics and PT instruction. PT students not only made up the initial five-point differential, but they outscored the physics students by an average of 11 points, a total swing of 17 points. The physics students gained 12 points while the PT students gained 29 points.

Dugger continued this research (Dugger and Meier, 1994) but this time tested students who had completed year 1 of PT and were currently enrolled in year 2 (modules 7-14) to compared with the physics students. This time the 120 test questions were derived from year 2 objectives in PT. Only 160 students and 3 sites were accountable for the data collected. Again the research saw the same results with PT and physics students making gains from pre-test to post-test, but the scores of the PT students were the highest in both percentage and improvement.

The last summary of research (Wang and Owens, 1995) constitutes the findings of a four year study, from 1990-1994, on applied academics. This study was conducted through Northwest Regional Educational Laboratory by contract from The Boeing Company. The purpose of the study was to see if the help the company was providing was having meaningful results at the schools in Washington state that were provided with assistance. The research of interest in this evaluation were the PT results and the student survey. The findings as summarized in the conclusion were:

Although PT comparison students appeared to score significantly higher at first glance, PT students were actually doing equally well and sometimes better when certain variables were kept constant, such as overall GPA and grades in
mathematics and science. Since more “low achievers” were enrolled in the PT classes than the traditional physics classes, test scores tended to skew in favor of PT comparison students when academic backgrounds were not controlled in analysis. The results of student surveys show that AM and PT students who were at the lower end of academic achievement tended to gain greatest in applied academics courses. They were also found to be more confident about their ability to learn mathematics and science.

Discussion

These papers are not suggesting that PT replace “all” traditional high school Physics classes. These traditional Physics classes are still very much needed for the upper 20% of students who have the ability to learn in these more historical and theoretical settings. What they are saying is that for the average student, PT seems to get the student to learn physics and also to take a course that might normally scare them away. In addition the traditional Physics student in a PT course learns enough of the core curriculum of physics to succeed in physics courses that relate to technology at the collegiate level. It is important for students to view PT as an alternate path, not an easy path to learn physics.

In closing I would like to present a personal perspective of Principles of Technology and my hopes of where it will lead the physics program in our High School. With the current positive perception of PT, by most, I can not help but be excited about this class. I feel this curriculum will finally help me teach those students who have been struggling to succeed in the previous physics class, and I also think that this course will offer the material needed by the advance student to hold their attention and prosper as well.

About the Author

Steve Wignall is a high school physics teacher in Seward, Nebraska, USA.

TURNING AN EVERYDAY EXPERIENCE INTO ONE OF LEARNING
SCIENCE—VISITS TO MUSEUMS AND ZOOS OF PRIMARY CHILDREN
AND FAMILIES

Sue Dale Tunnicliffe
Homerton College Cambridge England

A museum visit becomes a salient memory for life
but is more meaningful in terms of remembered content
if the exhibits are already familiar in some way to the
visitors (Falk and Dierking 1996), a crucial fact to be
borne in mind by educators, be they from the schools
of the pupils, or the educators of the wider audience of
the totality of the museum visitors—the designers,
museum educators and interpreters.

One of the main missions of zoos and to a lesser
extent museums is to inform and heighten the awareness
of the public about the conservations of endangered
species, however, families and primary school groups
are not interested if interest is measured by comments
about the topic (Tunnicliffe 1994). One of the main
missions of the school groups during field trips to zoos
and natural history museums should be to help their
pupils learn science, including conservation biology.

A field trip to a zoo or museum should provide
primary aged children with opportunities to use the
knowledge about animals that they have acquired in their
school science, indeed, when visits link with curriculum
topics already covered the pupil’s remember more
effectively (Wolins et al. 1992). Moreover, this
emphasis on particular content would be expected to
be heard in the conversations of these groups. A family
or other leisure type of visit also provides a similar
opportunity within which social dynamics are the
predominant feature (e.g. Rosenfeld 1980). The
accompanying adults, teachers and parents, can
reinforce existing and assist new learning for the children
or they may reinforce the everyday or basic
understanding of animals that they, and the children,
already possess.

Museum research has shown that visitors talk about
the exhibit when in front of it (McManus 1987;
Tunnicliffe 1996) and they talk about what they
observe—that which interests them. Falk and Dierking
(1992: 100) summarize this link of interest with
previous knowledge.

“Museum visitors must somehow perceive
information before they can store it in memory.
Under normal conditions, people pay attention to
things that interest them. Their interests are
determined by experiences, knowledge, and
feelings. This is a classic feedback loop: People
learn best those things that they already know about
and interest them, and people are interested in those
things they learn best.”

But in what topics are visitors interested when they
look at animals as exhibits? Can institutions use the
information to render exhibits more ‘accessible’ for their
visitors in terms of what is observed and commented
upon.

If Falk and Dierking are correct in their statement,
the content of the conversations of groups of visitors
should provide information about what is of interest to
the individuals at the exhibits. Such topics may not
necessarily be those about which the institution, the
producers, thought visitors, the consumer, would
comment and about which the message of inherent
within the exhibit is concerned. Moreover, that which
interests the visitors and attracts their attention is likely
to be that which visitors expect to see, those features
and attributes that are possessed by their model of an
animal. Thus we have the producers’ ideas and model
about which visitors attend but which may be at odds
with the actuality of what this large segment of visitors,
primary schools and families, do attend, if this is gauged
by the content of the conversations. Knowing the
content of the conversations is the starting point for the
producer in understanding the visitor’s interest and hence in designing effective exhibits, if that is defined by one whose message the visitors receive, translate and discuss.

Analysis of content of conversations at museum and zoo animals has shown that the content so similar, irrespective of the type and species of the animals, alive or preserved, and that there is surprisingly little difference between the content of that of primary school parties and family groups (Tunnicliffe 1995b) but that a museum is the site of preference to help children observe and develop ideas about animals (Tunnicliffe 1996).

This suggests that either families are very well prepared for their visit in terms of knowledge and understanding which they use to interpret the animals they see or that the primary schools are not making maximum educational use of the visits in terms of the children discussing the content of zoology or the science process.

Visitors hold a mental model of animals before they visit and which serves as the basis for their interpretation of the animal exhibits. What is their mental model of the animals?

**Figure 1**
The mental model of an animal held by school and family visitors

They have expectations that they see animals and that they will be able to provide a category or name for the animal and that they will be able to interpret the animal, name any parts of the body or behavior that catches their attention. They have an expectation that they will be able to both recognize the animals in broad terms and fit them into their existing sets of familiar animals. Data from a study of the content of conversations of primary groups and families at a animal specimens in different locations (Tunnicliffe 1995b) show that there is a model of animals held by the visitors and it is the salient features and behaviors that feature in the model and these are the topics about which the visitors comment. These groups of visitor do not focus on the criterial attributes used by zoologists (Tunnicliffe 1995a).

Comments about salient features and expected aspects of animals is not science, it is everyday commentary. Science is about making accurate observations and about raising hypotheses, constructing investigations that can test the hypothesis, observing, recording evaluating and communicating the findings (Lemke 1990) in other words, ‘talking science.’ I did not hear the type of conversation that would indicate these processes in action.

The results of the analysis of the content of conversations suggest that neither teachers and pupils from schools were particularly ‘talking science’ when undertaking these outings during school time, nor, not unsurprisingly, were families visiting for leisure reasons not educational ones, were heard to do so. It is not unreasonable to expect children to ‘talk science’ when visiting zoos and museums rather than ‘talking everyday’ in a pattern similar to that shown by families on a leisure outing.

Reading the transcripts showed that these groups were not talking science but they were making everyday observational commentaries. Typical comments were as follows, child: ‘Oh look, it’s a zebra,’ to which the adults might reply, ‘Yes, so it is,’ or say nothing. In a ‘talking science’ situation the adults would take this opportunity to ask the child why s/he thought the animal to be a zebra, what criterial attributes the specimens possessed that ‘made it a lion’ the children could have consolidated and extended their experiences and knowledge of grouping animals. However, such opportunities were never grasped by teachers any more than by parents, with school groups or families.

It is most frequently the children who start of the dialogue, as in the above comments where they made a statement or in a question, typically, ‘What is it?’ Such a reversal of the traditional teacher initiated dialogue is referred to as INVERSE TRIADIC DIALOGUE
(Tunnicliffe 1995b:387). Instead of giving the everyday name of the animal as happened in the transcripts I collected, the adults could ask the children what they thought it might be and encourage and help them to work out the features possessed by the animal and which matched those of other animals familiar to them. They could also work out which features were shared by a wide range of animals, such as hair or dry scales, and which were more specific to a few types. Children could use keys to allocate specimens to major groups. Such categorization requires careful observations.

Pupils in school are expected to hypothesise and then plan a course of action, collect results and evaluate their findings, teachers could encourage pupils to follow this same science process within the zoo or museum. If a child focused on the long legs of a bird, an ostrich for example, a ‘talking science’ question could be to ask whether all birds had long legs and the children could design and carry out their own investigation within the zoo or museum to find the answer. Alternately the children could investigate through first hand observations whether all long legged birds have large white plumes (feathers) and small wings not used in flying.

Museums on the one hand, their exhibit designers and educators, and the people, teachers and parents, who bring children to museums and zoos on the other, can both work towards turning a visit to the animal exhibits from that of an everyday commentary and observation experience to one of science learning.

It takes very little to invite visitors to look more closely and with interpretation beyond that of a glance and identification in everyday terms of a specimen. Provide almost instant labels about new aspects of the animals (McIntosh 1993). Create more permanent labels that are large labels and written with an invitational question—‘Can you see the very long tongue of the giraffe?’ for example or explain what the visitors is likely to think. For instance visitors often mistakenly refer to the Oryx as a ‘goat’ so at this type of animal tell the visitors that although it may look rather like a goat it is not, explain why and tell the conservation story in a few words. The visitors, the consumers, can focus the attention of their groups on the animals and on the invitational interpretation but they can also challenge the identification remarks made by children or instead of providing an identity for the animal to the children for an unknown animal, encourage the child to work out what the animal can be, not perhaps at the species level but at the family or order level.

A visit to the museums or zoo is a partnership event. The producer, the museum or zoo, works in partnership with the visitors, their consumers. The onus is on each party to participate in a partnership of observation and comment. The one to provide information in a way that is meaningful to the visitors, who in their turn need to actively work with their observations and the information they both bring with them and acquire to turn the visit form a series of everyday observations to those of science in which the science process is used.

Abstract

Constructivist philosophies of teaching, currently in vogue in classrooms today, are the catalysts for designing curriculum with hands-on/minds-on discovery science. Many curriculum designers subscribe to the belief that any teacher can effectively teach this high activity curriculum. An oversight in this philosophy is the critical role of teachers’ attitudes in the classroom. This paper documents the process of the pilot project of the WETLANDS, an interdisciplinary environmental science curriculum that incorporates the discovery approach to learning. The vignettes included in this article illustrate the powerful influence of the teacher in the classroom.

Teachers in USA schools today work with culturally, ethnically, and racially diverse students. Teachers’ attitudes about students and student learning abilities affect their effectiveness in the classroom. “Decisions teachers make in response to their views of students and student abilities greatly influence the overall impact of their instruction” (Armstrong & Savage, 1994, p. 57). Usually, effective teachers believe in themselves, in what they teach, and that they can make a difference. Turner (1991) asserts that to be effective, teachers must create a place of belonging and have a clearly defined program for the students.

An oversight in curriculum development and the push toward national standards is not acknowledging the role of the teacher in the effectiveness of any curriculum. Yager (1991) reports that scientific educational research has focused more on students than on teachers. The teacher’s attitude is crucial to his or her effectiveness in the classroom and to the successful implementation of curriculum. What follows are pivotal glimpses into two science classrooms that emphasize the teacher’s role in the success of designing and delivering a new generation of curriculum.

The WETLANDS Pilot Project

Teachers, in collaboration with the Department of Education and under a 1993 grant from the Environmental Protection Agency, developed five environmental science distance learning units. These units focused on environmental education processes that enhanced students’ skills of critical thinking, problem solving, and decision making and encouraged students to become responsible and concerned citizens who are active in environmental issues in this nation. The units adopted a constructivist philosophy and included student initiation of ideas, students testing their own ideas, use of cooperative learning strategies, and collection of real evidence. Learning was to be an active process; “knowledge is not acquired passively” (Yager, 1991, p. 55).
In the broadest sense, the purposes of the units were to:

- model exemplary teaching methods using interdisciplinary strategies.
- highlight environmental projects being conducted across the nation.
- use current environmental issues and problems to motivate students to acquire scientific knowledge and investigation techniques.
- mobilize young people to work with others in their extended communities for purposes of monitoring their environments and taking actions to protect the local and global environment.
- use distance learning and telecomputing technologies to broaden the impact of environmental education.

The units reflect student-centered curriculum as opposed to teacher-centered curriculum. The focus shifted from teaching information to emphasizing learning processes. Significant improvements in the environmental science curriculum include the interdisciplinary nature of the units, the discovery approach to learning, and the networking of students across the nation (Collins & Pawloski, 1995).

The constructivist view demands a shift of patterns traditionally associated with teacher and student roles (Condon, Clyde, Kyle, & Hovda, 1993). Constructivist teaching is a complex process focused on active learning. WETLANDS pilot teachers could not stay in the classroom and lecture, but were required to set up cooperative learning situations, allow students to design their own research projects, take students on field trips, and quite frankly, be in charge of an active classroom full of 9th grade students. Pilot teachers had to “buy into” not only the design of the curriculum, but also the underlying philosophy.

During the pilot process, the WETLANDS project coordinators kept reflective journals, observed classroom and field settings, and held personal conversations and interviews with participants. (Complete results of the pilot project are reported in Collins & Romjue, 1995.) What became apparent during the pilot was that each coordinator saw a distinctly different educational setting. These classroom settings are written as closely as possible to the reality of each situation. The information in these vignettes illustrates the influence of teacher attitude upon of teacher effectiveness.

Vignette #1

The 9th grade Biology Honors class at Everly High School is one of the pilot schools for the Environmental Science Distance Learning Project. Ms. Sally Carlson, a graduate of the state university, taught the class and has been at this school for over 20 years. The classroom was empty except for the usual trappings of a Biology class. In about 5 minutes the bell would ring and hot, sweaty kids would come into the room to take seats at flat black tables. Bolted to the floor and facing the front of the room, the tables were in four rows, two students seated at each table.

The students came into the room talking with each other, laughing and chatting about the important events of their day. It was midmorning and some of them had been together 2 or 3 hours; there was a lot to say. Students took their seats without much persuasion.

Sally Carlson was a veteran teacher. Her dark hair was curly and beginning to show some gray. She was tall for a woman, almost 5'11” and medium build. Her complexion was somewhat ruddy and tanned from spending many hours outdoors, possibly at field trips to the nearby wildlife refuge. She enjoyed these field trips very much and “moon lighted” during the summer as a guide for groups interested in seeing the refuge. She had many tales to tell about close encounters with one form of wildlife or another. These topics kept reoccurring in the conversation as she spoke to her students.

The class is a mixture of both male and female students, predominately white with three African American and one Hispanic student. For the most part they are quiet, but do not seem particularly interested in what they are doing. According to the unit design, today’s assignment was to learn about topographic maps, each group is supposed to have its own set of maps and follow prescribed activities. They were to work in cooperative learning groups, each student with a particular role.

Sally begins the class by talking about the week’s schedule and what they can and cannot bring on the bus on Friday for the field trip. She tells them a little about the wildlife refuge where they will be going. There is some discussion about the poisonous snakes they might see and the possibility of seeing a wild fox. After Sally talks for about 25 minutes, she instructs the first of the four rows to go to the back of the room where she has set up one set of the topographic maps. The maps cover the same area as the refuge that they will visit on the field trip. The students are to locate 8 specific things on each half of the map and then to figure out what the symbols mean. Each of the groups takes a turn going to the back of the room while the others talk quietly at their seats during the activity. They finish early, so Sally talks to them some more about some of the work she’s done at the site and some of the people with whom she has worked. She points out that while others have gone on to become well known in
field biology, she has remained at school to teach them. She is definitely very knowledgeable about the flora and fauna that they are going to be seeing and talks about what is common and not common for the area.

Apparently some of the students are not interested any longer and they put their heads down on the tables, waiting for the bell so that they can rush out the door to their next class. When Sally stops talking, some of the students even get up from their chairs and go back by the door, waiting for the bell to ring. The bell rings and the class is quickly emptied.

Before I leave, we talk about the next day that is to be the first live broadcast. The teachers are to interact with the television teachers to get the “kinks” out of the telecommunication. Sally announced to me that Mr. Hooper would do the television “thing” and she was going to spend another day with the students on the topographic maps. She told me earlier in the month that she had never touched a computer and never would and that the technology was up to Mr. Hooper. The students were to do one other map assignment, but it appears as though they will skip it. I extend my thanks to Sally for allowing me to visit the class that day and arrange to meet them at 7:30 a.m. on Friday for the field trip.

I visited the class as they viewed one of the tapes from the video cast. Students were sitting around tables and watching a couple of TV screens. Many had their heads down on the tables and were silently watching the program. Sally talked during the program and told the class that the TV teachers were obviously not professionals, and that she could do just as well. After the program was over, they returned to their classroom. There was no attempt to process any of the activities that were shown on the broadcast. I found out later that the class only viewed about three or four of the total eight broadcasts and that they had only done a small portion of the activities. Sally lectured during the rest of the time and the students were to take notes. She was going to quiz them over those notes, so they needed to be good.

The Field Trip . . .

Mr. Hooper had arranged to have two older students go out with the group on the field trip to do photography and videotaping. I walked out to the bus area with the fellow who was to do the videotaping. He appeared to only know that he was to get them in action and a few other shots such as the sign at the entrance.

Sally got the students on the bus and began to take attendance. She joked with several of the students. While taking roll, one student did not answer when Sally called his name. Sally said that they couldn’t be lucky enough that he wasn’t going, and then the student said, “I’m here!” Sarcastically, Sally said that she hoped that the student would behave on the trip. She told the students to take notes about everything she said and other things they would see.

On the drive to the refuge, Sally pointed out flora and fauna along the way to me and would occasionally say something to the students. When we arrived, we went into a visitor center to watch a film. Sally talked throughout the film explaining specific points. The students were attentive and tried to take notes in the dark room.

When we left the visitor center, Sally told them again that whenever she spoke they were to take notes. She started talking as we drove down some of the paths and kept on talking until we came to a stop. One student asked her how they were going to see these birds if they had to write everything down, and she told him she had some good pictures back at the school where they could see the details. One African American girl asked Sally at least four times to show them where a turtle bit her. When we finally arrived at the site, she had the bus stop and started telling the details of the event. She hadn’t talked very long when the same girl blurted out, “Hey Ms. Carlson, what’s that bird over there?” Sally shortened her story, sat down beside me, and said, “She’s through listening to the story.”

When we got out of the bus the second time, Sally instructed the students where and how to put out the diatom collectors. One girl in shorts was bitten many times by mosquitoes and had large welts on her legs; from that point she and couple of others were uninterested in the trip. After a short hike to view a specific area, the group headed back to the bus. The students were beyond listening anymore because Sally told them they would eat and then go home right away. They hurried back to the bus and started to eat their lunch. When we got on board she talked to the black girl and asked her, “What do you have for lunch? Chittlins and neckbones?” She asked her this more than once. The girl didn’t respond. I’m not sure what triggered the next question to the other black girl behind her, but Sally said to her, “I see you got a seat by yourself and we white folks had to bunch up,” again no response. We arrived at the school in time for students to get to their regular buses and head for home.

One day I returned to visit class and found students looking at the diatom slides that had been broken and carefully put in place on the microscopes. Students had apparently not used the microscopes before and Sally told them not to move the slides. They were to draw what they saw and to go back to their desks after they sketched their slide. Students were then to try to identify their drawings from some books that Sally had provided. I later found out Sally had gone out to retrieve the diatom collectors but most of them were missing. The purpose
of the activity was to let students search the slides and make comparisons to discover what diversity might be at each of the sites. Like the earlier activity, students were more passive than active in the process.

Vignette #2

Tim Hoffman’s class is at the far end of the old part of the high school building. Holcomb High was built in the late 1960’s but has one wing that is relatively new; the elementary classes are located in that wing. Once inside the science classroom, I could see three students working, one washing test tubes—a girl about 15 years old with short brown hair and brown eyes. She smiled as I entered and went about her work. A boy about 14 years old, with reddish hair and freckles, was moving boxes to the corner of the room. The third youth was busy in the back of the room, but I couldn’t see what he was doing. I could see Tim working with papers at the front of the room. Tim was not a very tall man and was somewhat heavy for his build. He had short sandy blonde hair and always seemed to have a grin on his face. He greeted me when he heard me talk to the kids. I had never been in this room before, but I had known Tim previously and had known some of his students through their work on science fairs. The room was “alive” with animals and plants, equipment, charts and a couple of computers. We had only a few minutes to talk before students started coming into the room.

There seemed to be much excitement. I heard one girl talking to a tall boy about how they were to be the video crew on the field trip and that they needed to take some time today to plan which groups they would follow and who was going to do the talking to explain what was on the video. The tardy bell rang and everyone rushed to their seats. The tables grouped students so that four students could sit together. When I looked around the room, I could see that most of the students were of what appeared to be of northern European decent. There were a couple of kids who had Latino names and probably were from the few Mexican-American families in the area.

When Tim got up, in what would have been the side of the room in most classes, the students stopped their chattering and turned to watch what he was going to do. Apparently the class had spent some time learning how to sample and conduct specific water tests. They also were familiar with the general area of the marsh that they were going to study. Each group had their copies of the topographical map on the wall, with their group names written on the bottom. Remnants of pieces of styrofoam and glass slides to make diatom collectors were still on the lab desk in the back of the room.

Tim started to speak to the entire group now, and students started asking questions. It seems as if he had already divided them into groups, and each of the groups had volunteered to master one phase of the learning activities that were to take place at the marsh. The girl and tall boy and the other two at their table were to take both photographs and videotape of the activities. Another group was responsible for getting the canoe out to a specified site on the marsh to anchor the diatom collectors that everyone in the class had made. Other groups chose to take various chemical tests, soil samples, and complete a variety of other activities at the site. One group was to be in charge of communicating with the other schools on the Internet. Most of the students’ questions dealt with the mechanics of getting the equipment to and from the site, the time allowed for each of the activities, and how they were supposed to report their findings. One table had a computer on it and the students reported that they had made contact with at least four other schools and also with the TV teachers the day before. They seemed to be very proud that they had managed to make the software work in spite of their earlier problems. They had written and sent a description of their school and town to the other schools and were anxiously waiting to hear replies from them to find out about the other pilot schools. The kids were going to be “talking” via the Internet. The students had already participated in the first of the live TV broadcasts and were hoping that the rest of the schools could receive the broadcast during their class time too. In fact, their school had shifted its whole schedule so that they could participate “live” during the broadcasts.

After about 20 minutes, Janet King entered the room and smiled at the students. They all seemed to recognize her and smiled back. Janet was about 5’6” tall and of medium build. She was an attractive lady, probably about 38 years old. She went up to where Tim was standing and said she was sorry for being late. Tim said that was all right because they needed to clear up some of the science details and that had given them time to talk. Janet then turned to the class and asked them what questions they might have concerning the writing activities on the field trip. One student raised his hand and asked if they were to write about their feelings or just what they saw. They discussed it for awhile, and another student asked if they could just put what they were thinking on a cassette tape. Janet evidently knew the students quite well, and said that if that was easier for them, it would be just fine, she would help them put it in a written form when they got back. I think that this student might have had some sort of learning disability and this was his normal method of doing this type of work. It seemed as if we had just started, and the bell rang to change classes. I told Tim that I would see them on Friday for the field trip and hurried back to my car to another appointment.
The Field Trip

By the time we got off of the main road and through the dirt road leading to the water’s edge at the Mitchell Marsh, it was about a 45 minute drive from the school. We had quite a caravan: a bus, two vans (one pulling a canoe), and my car. When we got all of our things together, Tim gave each team leader final instructions and the groups took off in different directions to start their various tasks. One girl had forgotten to bring a jacket, so I went and got her one of my old sweatshirts. It was just chilly enough that you needed something to wear, plus there were more mosquitoes than one would like for a day-long field trip.

I watched four girls take the canoe and put it into the water. After they dawned their life jackets, they gathered up the diatom collectors and started off to place them around pre-selected sites on the marsh. As they left, I heard Tim yell, “Write when you get there,” and I heard them giggle and keep going. The mosquitoes were really thick, so some repellent appeared and seemed to help drive them away. One group of students had already started collecting water samples and had the nitrate water test kit out. Tim went over to them and another group nearby who were obviously starting to test for another chemical. I heard Tim talk with them as they went through the steps of the tests together. Tim bent down on his knees and showed them how to compare the colors on their samples with the indicators and then how to read the results. They had obviously done this in class but must have wanted some reassurance that they were doing it right.

Janet King was with another group. They were observing the shoreline and she was talking to them about how she wanted them to take a few minutes to sit quietly and just listen to the sounds and take in the different sights and smells, and then to start writing. She told one student that she was going to make a sign and rename the marsh “Mosquito Marsh.” They thought it was funny and went about their work. The camera crew moved from area to area taking pictures and video shots of everyone as they went about their work. When we broke for lunch, students were still not finished with their tasks. They asked how much time was left and Tim said that we were going to have to hurry if we were going to make it back in time for volleyball and football practice. We only spent about one more hour at the site before it was time to pack up and go back to school.

Back at school, the students gathered up their things and put them back in the classroom. There was much laughter and some new songs that they had learned during the day. Everyone had a great time. They told Tim, Janet, and me good-bye and off they went.

Discussion

The most critical impression from the classroom vignettes is that, even with the most innovative curriculum and advanced technology, the teacher makes the curriculum and the environment of the classroom “work” for the students. Thoughts that teachers have about the content and the students they are to teach influence the way in which they will teach (Hewson, Kerby, & Cook, 1995). School experience for students is firmly entrenched in interactions with teachers and influenced by teacher attitudes. Even with hands-on, constructivist curriculum, students can still be in the roles of passive learners.

Constructivist teaching is a complex cognitive process focused on active learning. For some teachers, the ability to change instructional methods may be too great of a burden to bear. For teachers who adapt well to new situations, the possibilities may be endless. Adaptive teachers seem to be more effective in successfully promoting educational encounters since teacher responsiveness is positively correlated with teacher behaviors and student outcomes (O’Keefe & Johnston, 1989). As seen in these two vignettes, curriculum relies heavily on teachers’ abilities to adapt and respond to new situations, as well as their attitudes toward the possibilities.

According to Rogers (1969) significant learning depends on attitudes that exist in the relationship between students and facilitators. Important is realness, valuing learners, and a climate of empathic understanding. Another factor is the spirited attitude of the teacher. “One of the most striking characteristics of the excellent teacher is enthusiasm for what he or she is teaching” (Ryan & Cooper, 1992, p. 474). No matter how “teacher-proof” the curriculum may appear, teachers are the key to success. The manner in which they approach teaching and the attitudes they have toward their students will influence whatever curriculum they use.

This section focuses on the interface between non-formal, informal, and more traditional formal science education. Articles expose the world of out-of-school and public science experiences.

SCIENCE CENTRES: BUILDING BRIDGES WITH TEACHERS

Brenton N Honeyman
Manager, Education and School Programs
The National Science and Technology Centre
King Edward Terrace, Canberra, Australia

Abstract
The interactive approach to learning science is as relevant to the classroom as it is to the science centre. We live in a time when we need to forge partnerships between both formal and informal education sectors if we are to meet the challenge of developing scientific and technological literacy for all. As well as being fascinating places for people of all ages to visit, science centres are becoming important places of inspiration and support for teachers in their quest for a curriculum which relates science to daily experience and a learning approach which engages the mind of the student. The National Science and Technology Centre in Australia is helping to enrich school curricula through ‘hands-on, minds-on’ interactive programs. This paper outlines ways in which the Centre is developing curriculum resources for schools and providing professional development and training for teachers. These programs observe certain ‘hands-on minds-on’ principles to enhance the effectiveness of learning in primary and secondary classrooms.

The Interactive Approach
During the 1980s, interactive approaches to learning began to attract more widespread attention among education researchers and teachers. An interactive approach to learning science, according to one group of science education researchers (Biddulph et al., 1986), has an emphasis on “identifying learners’ present ideas and interacting with them to help them to modify or extend their ideas... not... trying to get them to some predetermined knowledge goal, but of nudging their thinking as far as possible to enable them to make better sense of their world”.

At the same time, the rapid growth of science centres has produced an additional community of science communicators and educators developing exhibition and program experiences also defined as ‘interactive’. When visitors interact with hands-on exhibits and activities in science centres, they are able to test their understanding of ideas as they interact with phenomena and with each other.

When the physicist Frank Oppenheimer founded the Exploratorium in San Francisco, he felt concerned that people were becoming information rich and experience poor. He wrote (Oppenheimer, 1968):

On the whole, people have very little opportunity to have any direct experience with the separate elements of nature or technology. They watch ocean waves, but have never been shown how to observe the way waves pass through each other, bend around corners or bounce off cliffs. In a science museum, one can provide these direct experiences with the behaviour of light, sound and motion. One can set up these experiences in such a way that they not only generate, but partially satisfy curiosity. Science is not just a process of discovering and recording natural phenomena; it is a process which develops our ways of thinking about nature and which enables us to find the connections that simplify and at times enrich our comprehension and awareness of nature.

Duensing (1993b) reports that Oppenheimer saw a science centre to be like a forest of natural phenomena, a rich environment where visitors can explore on their own terms, linger where they choose, experiment as they please.

Schools, Science Centres and the Constructivist Approach

The growing amount of research supporting a constructivist model of learning is of interest not only to those involved in formal schooling, but also to informal education institutions such as science centres. Science centres provide exhibit experiences and other programs on the understanding that visitors bring with them great diversity in terms of their previous
knowledge and experience, their assumptions and their expectations, as well as their ways of thinking and learning.

Science centres expect this diversity and design their exhibits and programs accordingly—as open-ended opportunities which provide flexibility in the manner and level of investigations individuals and groups may wish to undertake. Some visitors will want to explore a phenomena in depth—and may find out things which were never intended by the designer! Others will spend only a few seconds with an activity before proceeding to another—rushing to experience as many activities as possible (albeit superficially) in the time they have.

Feher (1990), in an article about the role of interactive science museums in studying how people learn, refers to an excerpt from a Grade 4 textbook which states 'Light is energy that you can see. Light travels through space in the form of waves.' She goes on to relate how statements like this are abstract and uninteresting because '... there is nothing you can do with it. There's nothing to go home and try out. There's no experience of nature. The problem is endemic in our schools: teachers teach abstractions, definitions and explanations of phenomena that, for the most part, students have never explored, or, worse still, that students may not even know actually occur. If schools so often put the cart (explanations) before the horse (first-hand experience of natural phenomena), modern science museums reverse the process'. Science centres '... present natural phenomena in the form of exhibits that are interactive and manipulable, exhibits whose express purpose is to enable visitors to explore and experiment'.

There is a growing body of research into visitor behaviour at science centres. In the light of this research, more and more centres are re-thinking the exhibit experiences they offer in order to broaden their capacity to meet a wider variety of individual and group needs. If science centres are to be a community resource, they need to become places which cater for the sectors of that community—children, teenagers, adults, family groups, school students, people with little background knowledge of science, as well as scientists, science educators and those for whom science is a key part of their work.

In the design of exhibit-based and activity experiences in science centres, the social aspect of visits is an important consideration. School students as well as families often visit science centres with dual agendas—they seek enjoyment from their visit as well as an educational experience. Science centres are becoming more aware of the need to orient programs not just towards the children in such groups, but towards a cross-generational social unit, allowing for social interaction and the communication and experience of ideas at varying levels (McManus, 1993).

Visitors to science centres have an opportunity to test their understanding as they interact with science phenomena through exhibits and activities. From a constructivist point of view, learning involves constructing meanings by forming links between existing knowledge and new situations. As visitors interact with phenomena and with other people, they may encounter information which agrees with their past experience. In this case, the meanings are confirmed and become more strongly held. Alternatively, visitors may encounter information which does not agree with their past experience. They may choose to ignore or otherwise rationalise the new information so that their meanings remain intact, or they may choose to revise their understanding to incorporate the new information (Saunders, 1992). It is this latter outcome that educators, whether teachers in formal schools or staff in science centres, strive to promote. Their goal is to provide experiences for learners to test their understanding. And the more compelling they can make those experiences, the more likely learners will develop their understanding of the phenomena.

**Working With Learning Outcomes and Performance Standards**

With the widespread emergence of curriculum documents focusing on learning outcomes and performance standards, it is understandable that many teachers feel that the most important function of classroom activities is to achieve certain, pre-determined learning outcomes at certain stages of schooling. However, from a constructivist perspective of how students learn, this view is unrealistic. Learning outcome statements can be used to measure student performance but a more exciting option is to use them to measure learning growth. With a constructivist approach, learning outcomes take on a role as 'signposts' to indicate how learning is progressing.

More and more science centres are making use of school curriculum and learning outcome statements in order to develop programs and exhibitions which will better serve classroom teachers and their students. Many centres document how each exhibition and program can be used to support curriculum outcomes (ASTC Newsletter: Sep/Oct 1994).

In 1989 in Australia, the State, Territory and Commonwealth Ministers of Education endorsed a number of common and agreed national goals for schooling in Australia. Since then, statements have been produced for each identified area of learning—science is one area, technology is another—to provide a
framework for curriculum development by education systems and schools (Curriculum Corporation, 1994a). Statements provide an account of the learning area, outline its essential elements and describe a sequence for developing knowledge and skills. In addition, curriculum profiles have been developed for each learning area to assist in the improvement of teaching and learning and to provide a common language for reporting student achievement (Curriculum Corporation, 1994b). Profiles describe the progression of learning typically achieved by students during the compulsory years of schooling (Years 1-10). Profiles and statements are linked—profiles show the typical progression in achieving outcomes, while statements are a framework of what might be taught to achieve these outcomes.

One of the core philosophical positions of the statements and profiles is that effective teaching and learning involves the recognition that students construct their own understanding. This notion, among other aspects of the science statement and science profile, has prompted certain academic and business groups in Australia to challenge the implementation of these documents in most states without addressing the concerns of these groups. It is their view, as represented by Fletcher in an article presenting opposing positions on the statements and profiles (Fletcher & Lowe, 1993), that scientific knowledge is not constructed, but that it is reliable, public, international and free of cultural bias; they express concern that the statement and profile characterise science as 'a way of knowing' and that this implies that there are other 'ways of knowing' that can provide equally reliable understanding. In contrast, Lowe in the same article contends that 'school science has, all too often, given a misleading view of science as eternal truth' and that this approach has 'failed most of our young people by denying them the exciting experience of seeing how the process of scientific inquiry is relevant to their lives' (Fletcher & Lowe, 1993). Despite this debate, education systems throughout Australia are using the statements and profiles as a basis for developing their own systemic curriculum policies and documents.

Science Centres: Contributing to the Process of Reform in School Science

The interactions between science centres and their school communities provide direct and indirect opportunities to effect change in classroom practice. The role of science centres can quite literally be a laboratory or agent for change in school science and technology. Teachers are being stimulated to think beyond the recipe style curricula within their schools to consider the impact of interactive, hands-on experiences in a classroom climate which encourages students to test their ideas and to undertake open-ended exploration.

Various studies report that some teachers view science centres as their 'philosophical home' (ASTC, 1989). In contrast to most schools, science centres are rich in resources and experiences that encourage an approach to science learning that is compatible with a constructivist understanding of how students learn. These teachers, in their contact with science centres, are being challenged to develop new instructional approaches and new ways of relating to their students and to science; their teaching is becoming more hands-on, more student-centred, and more inquiry-oriented.

Learning in a science centre typically starts with exploration rather than explanation. The opposite tends to happen in schools where learning more typically starts with explanation. Duensing (1993b) describes the approach taken by the Exploratorium:

The way in which we develop exhibits is the same process we use to develop the museum's projects and programs. Prototyping is implicit in all of our exhibit and program idea development. If an idea is not intriguing; if it doesn't push us to ask questions or explore in greater depth, we generally reject it. Starting with exploration is a fundamentally different pedagogical perspective than starting with explanation . . . we try to create the shortest distance between the person and the phenomenon, presenting the idea in as rich a form as possible. The richness of the presentation enables physicists as well as young children to be involved . . .

Perhaps it is through a misunderstanding of the pedagogy of science centres, that there has been some concern as to whether such informal places should be taken seriously as a resource in a formal education sense. Tags such as 'fun science' and 'edutainment' are often used when describing science centres. This may seem appropriate in terms of marketing science centre programs to the general public but, when considering visits by school students, such tags prompt the question (usually from a formal education perspective) 'Do students learn anything?' Science centres have responded in various ways. In order to correct any image of 'mindless frivolity', some centres have promoted new 'tags' through the use of slogans such as 'playground for the mind' and 'hands-on minds-on' when describing their exhibition and program experiences.

Since science centre exhibit and activity programs have the capacity to accommodate a variety of visitor start points, experiences and learning outcomes, it is nonsense to try and evaluate the educational effect of an exhibition or program by asking questions such as 'In what year did Robert J. Van de Graaff build his first 'lightning' machine?' This is not an appropriate type of question to be asking in order to find out what learning
is taking place in science centres, and yet, some research efforts have succumbed to this approach.

Although many studies have reported gains in cognitive learning as outcomes of visits to science centres, such gains are not all that should be considered in deciding whether visits are beneficial (Rennie et al., 1993). For example, Price and Hein (1991) define ‘educationally effective programs as those in which products are not emphasised, inquiry is sparked, open-ended questions are generated, and students actively participate and appear involved.’

Science centres are in a particularly unique position to conduct research into how people (adults as well as children) learn as they interact with phenomena through their exhibits and other interactive programs (see for example, Feher, 1990). These research findings can be used not only to develop and refine exhibits and programs in science centres, but also to help teachers develop more effective learning experiences for their students.

Notes
At the International Forum on Scientific and Technological Literacy for All, Paris, 5-10 July 1993, delegates focusing on the non-formal and informal development of scientific and technological literacy identified a number of agencies/activities which utilise non-formal and informal approaches, including: (a) out-of-school activities such as science and technology clubs, camps, fairs, olympiads and competitions; (b) the mass media utilising print, radio and television as a means of communication; (c) informal institutions such as science and technology centres and museums; (d) community-based programs as offered through health centres, technical training centres, etc. For the purposes of this paper, the author uses “informal” to refer to both “non-formal” and “informal” approaches to scientific and technological literacy.

About the Author
After 20 years as a teacher and administrator in the ACT school system, Brenton Honeyman joined Questacon – The National Science and Technology Centre in Canberra, Australia, as Manager of Education & School Programs. Brenton and his team coordinate a wide range of public and school programs across Australia.

Brenton’s career as a science educator includes a diverse range of positions and appointments, including President of the Australian Science Teachers
Association; Convenor of the World Conference on Science Education and the Quality of Life; and Editor of Science Education International. He has been recently elected as the President of ICASE, the International Council of Associations for Science Education, and is working with UNESCO and other international organisations on a worldwide project to enhance scientific and technological literacy for all.

His current interests include: broadening teaching learning repertoires so as to increase student engagement in learning, strategic planning in educational management, industry-education links, science communication, and international science education.

**Surfing for a Good Home Page?**

There are hundreds of websites evolving on the Internet—many of these have great value for teachers and students alike. Here are some you’ll want to access or at least put on your bookmark for future reference.

http://www.nwf.org/kids/
This is the National Wildlife Federations FOR KIDS! section of their home page. It features a cool tour of conservation, riddles, games and more.

http://eelink.vmich.edu/wild/wildhome.html
Welcome to the Project WILD home page! A summary of everything that’s happening nationally with the Project WILD program.

http://www.ngpc.state.ne.us/
This is the Games and Parks home page which features all you ever wanted to know about Game and Parks. If your students use pictures or sounds of selected wildlife species, check out this home page. Plus lots, lot more including Project WILD in Nebraska.

http://www.fws.gov/
The US Fish and Wildlife Service provides a lot of information on species, issues, and programs.

http://www.wri.org/wri/nved
World Resources Institute offers information on global environmental issues, news on major events and trends.

www.discovery.com
The Discovery Channel’s home page for conservation-minded kids.

http://globe.fsl.noaa.gov/
Have classrooms from 20 countries participating in global ecology studies.

www.mbnet.mb.ca/eddy
Eddie the Ecodog rides the Internet teaching kids simple environmental lessons.

http://www.tnc.org
The Nature Conservancy’s page highlighting conservation projects and wildlife studies around the globe.
Book Announcement

Partnerships of Schools and Institutions of Higher Education in Teacher Development

Editors
Ron Hoz, Ben-Gurion University of the Negev, Israel
Moshe Silberstein, Tel-Aviv University, Israel

Editorial Board
Miriam Ben-Peretz, Haifa University, Israel
James Calderhead, University of Bath, U.K.
Naama Sabar Ben-Yehoshua, Tel-Aviv University, Israel
Pinchas Tamir, Hebrew University of Jerusalem, Israel

Ben-Gurion University of the Negev Press announces a new book in teacher development. The book contains three major sections with individual chapters written by a collection of authors.

Introduction—Ron Hoz

Improving Teacher Education through School-University Partnership
⇒ Integrating Knowledge and Beliefs: Promoting the Relevance of Educational Knowledge for Student Teachers—Harm H. Tilløma
⇒ The Professional Craft Knowledge of Teachers: Student Teachers Gaining Access to It—Sally Brown
⇒ Professional Development of Student Teachers during Preservice Training: A Follow-Up Study—Ruth Zuzovsky
⇒ Educating Teachers in Curriculum-Making: The Case of Conceptual Change—Moshe Silberstein
⇒ Who’s Teaching Whom? Learning Opportunities from Student Ethnographies—Stephen M. Ritchie
⇒ Helping Teachers Build Complex Conceptual Frameworks—Susan A. Adler
⇒ The Computer in Teacher Education—A Tool or a Partner?—Michal Ephratt
⇒ Teaching Internships: A Reflective Practice—William Kennedy, Clar Doyle, Andrea Rose & Amjit Singh
⇒ Teachers’ Perceptions of the Interplay between Theory and Practice in a Professional Development Context—Gabriella Minnes-Brandes
⇒ Alternative Certification in Special Education: Efficacy of a Collaborative, Field-Based Teacher Preparation Program—Elana E. Rock & Michael S. Rosenberg

Integrating Theory and Practice in Learning to Teach
⇒ Professionalism in Teaching: How to Save an Endangered Species—Theo Wubbels
⇒ Teacher Education as a Career-Long Process—Ralph Fessler
⇒ School Development through Teacher Development—Howard Bradley
⇒ Teaching Expertise: Theoretical Conceptualizations, Empirical Findings, and some Consequences for Teacher Training—F. E. Weinert & H. Lingelbach
⇒ Teacher Learning over Time: Accommodations, Reconceptualizations and Radical Transformations—Anna O. Soter
⇒ Mentoring in the Full Year Residence Practicum Internship Model—Batyra Bleicher & Ron Hoz
⇒ Unloosening Time for Teachers’ Professional Development—Jill Woodilla, Patt Dodds & Mary Lynn Boscardin

Teachers’ Professionalism and Its Advancement
⇒ Designing Educative Practicum Experiences for Prospective Teachers—Kenneth M. Zeichner
⇒ Professional Development Schools: Linking School Renewal and Teacher Education—Lynne Miller

Association for the Education of Teachers in Science
AETS Monograph

Science Teacher Preparation: An International Perspective

CALL FOR PAPERS

The Association for the Education of Teachers in Science (AETS) is sponsoring a call for papers for a monograph concerning international perspectives on Science Teacher Preparation. Papers relating to policies and perspectives driving elementary and secondary science teacher preparation programs worldwide are encouraged. Papers should highlight the cultural, historical, and theoretical contexts for science teacher preparation, describe research findings, and/or describe specific practices.

Timeline:

December 30, 1996 Paper proposals (maximum 3 pages) due
February 15, 1997 Letters of acceptance sent
July 30, 1997 Manuscripts due
October 15, 1997 Editorial review completed
December 30, 1997 Revisions due
Summer 1998 Expected publication

If you are interested in contributing to this volume, would like information about proposal format, or have further questions, please contact:

**Book Review**

Teaching Ethical Aspects of Science

Edited by
Patrick Fullick and Mary Ratcliffe
for
The Science, Ethics and Education Project
Published by the Bassett Press

This book review has been prepared by Donna Hare, University of Nebraska.

The teaching of ethical aspects of science are being addressed internationally by such efforts as Science, Technology and Society, Issue Science, Scientific Literacy, Science and Technology Education and Future Human Needs, the Harare Generator, Education for Global Change, as well as Project 2000+. At the basis of this issue-oriented trend lie deep concerns in three basic contexts:

- Science—what we can do
- Sociocultural—what we need to do
- Ethical—what we ought to do

The book, Teaching Ethical Aspects of Science, edited by Patrick Fullick and Mary Ratcliffe as part of the Science, Ethics and Education Project and published by The Bassett Press, addresses these concerns in a thorough, logical, practical and versatile manner.

The approach begins with a clear delineation of general purposes and guidelines relevant to content, structure and processes incorporated in a program intended to facilitate the exploration of ethics in scientific endeavor.

The authors propose as a principle of ethical education that, “students have a right to address science-related issues which may affect their future lives,” p. 11, and that as a consequence, teachers have the duty to:

- encourage respect for rational inquiry using logical thinking and a variety of relevant evidence;
- encourage open-mindedness, a willingness to listen to and respect the points of view of others, and to avoid haste in judgment;
- encourage an awareness of similarities and differences in ethical interpretations of science-based issues, and
- avoid indoctrination, p. 11

This clarification of purposes is followed by a very practical, detailed yet concise basic primer introducing the potential user to the field of ethical inquiry and concern: from psychological egoism, to Kant, to Rawls. The next section provides the reader with a pragmatic explanation of, “... how these principles of ethics and ethical analysis can be used to produce effective teaching and learning strategies,” p. 21. The basic learning strategies to be utilized include:

- Consequence mapping;
- Structured decision-making: cost/benefit analysis
- Structured analysis of people’s actions using a “Goals, Rights and Duties” model;
- Focused questions, p. 21

A model for the presentation of this approach is then offered. The proposed model is based upon a series of case studies which constitute the bulk volume of the writing. The authors have included a very “friendly” table (p. 36) which summarizes the case studies offered by title, issue, ethics focus, science focus, learning approaches, and prior knowledge required for students. Some problems arise in the level of difficulty selected by the authors which is evident in the selected case studies. The reading level alone might discourage the classroom practitioner from attempting the incorporation of this approach. But this also points out one of the major strengths of this particular offering. The authors have made an obvious effort to keep the presentation of their proposed approach open-ended, versatile and adaptable. The case studies, which include basic lesson outlines, are offered strictly as models which may be adapted, replicated or replaced to accommodate the individual practitioner’s classroom needs. This publication is contributed not strictly as an overall program of instruction (though it could certainly stand alone as the basis of a focused course of study), but rather as a useful and versatile educational tool which wise practitioners may add to their personal repertoires. Such a presentation elicits a flood of ideas and possibilities for incorporation with highly compatible formats like Multiple Intelligences; Scope, Sequence and Coordination; Action Research; Science,
Sequence and Coordination; Action Research; Science, Technology and Society; Multi-discipline Education; Multi-Culturalism; as well as other more traditional programs of study.

Teaching Ethical Aspects of Science is a well organized thorough, practical, teacher-friendly, and significant offering with great potential for a broad spectrum of science educators. I recommend this innovative tool to my fellow practitioners as an additional element to meaningfully link and extend various approaches they may currently be applying, as well as a catalyst to revitalize and redirect their persistent efforts to provide today’s science students with the vital understandings they will need to carry on the functions of citizenry and to perpetuate a productive, principled, and humane society.

"If you want to truly understand something, try to change it . . . ."

British Council International Seminar
(Number 9679)

Technology education in the core curriculum

12 to 19 March 1997

Directed by Professor Paul Black and Mr Justin Dillon

The seminar will explore different rationale for technology education in the school curriculum, and the traditions from which they arise in different countries.

Main themes will include:

- a comparison of technology curricula in different countries
- the purpose of technology as a school subject, eg technology and environment, technology and society
- classroom implementation and curriculum material

The programme will be of particular interest to those responsible for curriculum development and teacher training.

Fee: £1,750 (residential)

For further information contact: Promotions Manager, International Seminars Department, The British Council, 1 Beaumont Place, Oxford OX1 2PJ.
Telephone: +44(0) 1865 311636. Fax: +44(0) 1865 557368 / 516590. E-mail: international.seminars@britcoun.org

(Programme details are subject to amendment. For a full prospectus please contact Promotions Manager, quoting the seminar number in all correspondence.)
Calendar
1996-1997

20-23 December, 1996
The Second Scientific Conference on The Future of Science and Mathematics Teaching and the Needs of Arab Society
University of Science, Technology and Medicine in Tunisia (Tunis 2)

Conference coordinator:
Mohamad Debs
Arab Development Institute
P.O. Box 14-5300, Beirut, Lebanon

CONASTA 46
Annual Meeting of the Australian Science Teachers Association
June 29-July 4, 1997
University of Melbourne

The Theme
Science Down Under—Extending the Boundaries’ Our aim is to provide science teachers
with up-to-date cutting edge information on the thinking of Australian scientists and near
neighbours. The programme will also highlight practice and theory suitable for all levels of
science education. It is our intention to extend the boundaries of knowledge.

Exhibitions
Throughout CONASTA 46 there will be extensive displays and showcases of science
resources, videos, computer software, laboratory apparatus and curriculum materials.

Excursions
A full range of social and informative excursions are being planned to enhance the program.
A special Sunday welcome function is being organised, along with a Conference Dinner
featuring a mystery tour. A post-conference excursion programme will be available.

Registration
The registration brochure will be available later this year and will be sent to all members of
the Australian Science Teachers’ Association. Initial expressions of interest can be filled in
on the back of this brochure.

Travel
Qantas has been appointed the official airline for the conference and will be offering discounted
conference airfares for conference delegates and accompanying persons. Full details will be
included in the registration brochure.

The hard copy of your abstract should be submitted by November 1, 1996. Further information
will be required by the STAV Secretariat as soon as practical after this date.

Presenters will be notified of their acceptance of Workshops/Seminars and all presenters are
required to register for the Conference.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Educational Research in Chemistry and Physics Education

The 5th international symposium on science education research was organised in the University of Dortmund by Prof Hans-Jurgen Schmidt in May 1996.

This series of symposia has become well known among science educators and researchers, as offering an insight into the relationship between research and teaching. ICASE has been involved with all the symposia having published the proceedings each time for wider dissemination among ICASE members and more widely.

The programme for this symposium included papers from researchers from many countries, within and outside Europe, including two significant papers from Taiwan and one from Mozambique. The proceedings will be available early in 1997 from ICASE; details will appear in this Journal.

This symposium is the last in the series to be held in Dortmund because the initiator and organiser, Hans-Jurgen Schmidt, will be retiring from his post in the University before the next symposium is due in 1998. ICASE has already recognised the contributions that Hans-Jurgen Schmidt has made to international science education by awarding him, in 1995, the ICASE Certificate for Excellence in International Science Education, and would like to pay special tribute to his work in Dortmund for this series of symposia. The next symposium will be held in Utrecht in 1998, and will be organised by Dr. Otto de Jong, a regular participant in the Dortmund symposia. Details of this symposium will be available to all interested researchers and will be announced in the columns of the ICASE Journal in due course.

New Institution Member

Children & Youth Science Centre of China Association for Science & Technology is a non-formal science and technology education institution under the CAST. The objective of the Centre is to promote youth in China understanding of science and technology, and enhance the scientific and technological literacy of the young generation, no matter urban or rural, male or female, through various means of scientific and technological activities.

Children & Youth Science Centre of CAST considers that its objective is similar with the aim of ICASE, “to extend and improve education in science and technology for all children and youth throughout the world,” and is willing to join in the Organization so as to share the information and experiences with other members, and make its contribution to the development of science and technology education world-wide.

ICASE would like to welcome our new member and look forward to their involvement in 2000+ and other ICASE programmes.
CREATING EXEMPLARY TEACHING MATERIALS TO ENHANCE SCIENTIFIC AND TECHNOLOGICAL LITERACY

Jack Holbrook
Executive Secretary, ICASE
and
Miia Rannikmae
University of Tartu, Estonia

Abstract

A workshop was organized to create teaching materials that met stipulated criteria and was used to guide participants to run similar workshops of their own at a national or sub-national level. The reason for promoting such teaching materials was to enhance the teaching of science subjects in the direction promoted by Project 2000— a UNESCO/ICASE initiative to enhance scientific and technological literacy for all. This article sets out to explain the need for scientific and technological literacy, the role of supplementary teaching material specifically created for this purpose and the successes and difficulties in creating STL teaching material in a workshop.

Introduction

Today science and technology invade all our lives. The quality of our life is highly dependent on the technology we use and hence the scientific developments to which they relate. In the future, science and technology can be predicted to invade our lives to an even greater extent, bringing us in contact with more and more scientifically related choices. Not only are we likely to make an increasing number of scientific and technological decisions, but we will need a greater ability to cope with change. This does not simply apply to a few citizens who wish to follow particular careers. It applies to all of us.

It appears that a crucial need for all citizens in the 21st century is the ability to interact with scientific and technological choices and make scientific and technological decisions. If this can be described as a facet of literacy, in the scientific and technological sense, then scientific and technological literacy is a future need for everyone. And what is more, the higher the education level a student receives, the greater the literacy level to be attained. Just as illiteracy in terms of reading and writing leads to social disadvantages, the same can be said, in the future, for illiteracy in terms of science and technology.

If scientific and technological literacy is crucial, as proposed above, what can schools do to promote this? After all schools, by large, are charged with satisfying the educational needs of children who will be the adults of tomorrow. These needs are often expressed as educational goals (see Table 1) and for schools these are usually stipulated by the society and formulated by the Minister of Education. The educational goals signify the curriculum intention and may often be expressed in terms of

a) intellectual development, e.g., ability to think conceptually; develop creative, critical and analytical thinking and the ability to make rational and independent decisions.
b) personal attributes, e.g., promoting of mental and physical health, cultural and recreational interests
c) societal attributes, e.g., identifying and cultivating personal ethical values, a concern for the community, to develop social skills, leadership qualities and a sense of responsibility
d) communication, e.g., to foster an ability to communicate using verbal, written, tabular, symbolic or graphical forms

Table 1. Education Goals: a typical example
(This version was produced by the curriculum development committee in Hong Kong)

1. Help pupils to cultivate their moral and social values, to make critical value judgements and to develop an ability to solve value conflicts;
2. Promote pupils’ mental and physical health and to encourage worthy use of leisure;
3. Nurture pupils’ creativity and to promote their aesthetic development;
4. Help pupils to develop their ability to think logically and independently and to make rational decisions;
5. Help pupils to develop a positive attitude towards life and a sense of responsibility for their roles in the family and the community;
6. Help pupils to develop their ability to communicate effectively in both Chinese and English in relation
to the different roles that each language plays in the Hong Kong community;
7. Provide pupils with a basis of mathematical, scientific, technical and commercial knowledge and skills to prepare them for the fast-changing, highly technological society in which they live and work;
8. Help pupils to develop their potential for further study or work according to their ability and aptitude;
9. Help pupils to acquire an appreciation of the Chinese culture and develop respect for all peoples, their cultures, values and ways of life;
10. Encourage pupils to develop a respect, awareness and concern for the local environment, their society, China and the world; and
11. Help pupils to understand and adapt to the unique situation of Hong Kong—its cultural, social, economic and political characteristics.

I hope you agree that Table 1 represents a good set of aims for education, even though they are presented in a very broad manner and in some places, are specific to Hong Kong. Schools attempt to achieve these educational goals by instruction within school disciplines. Thus science, being on the school timetable in some form, is one subject area through which the educational goals are to be achieved. Science education is thus about achieving educational goals through a context of science. This is put forward as a very important deviation from the traditional goals of science education that are seen as putting forward science education as simply a body of knowledge.

These goals represent the intention. It is the target. Education was never intended as rote memory of isolated facts. But that is how it ends up in many situations. Faced with this, the question is not ‘what are the intentions,’ but rather ‘how do we implement them?’ This is a major problem. Worldwide education have based implementation on 19th century logic and sub-divided teaching into content areas, called subjects. And we are given no guidance as to which educational goals are to be achieved in each subject area. Each subject area, seemingly independently, puts forward its own set of objectives. Until such time as we are ready to influence education en masse, or to operate in a more societal framework, e.g., teaching divisions based on the environment, ethics and social responsibility, etc., let us confine this article to the realm of science education, i.e., the subject called science on the school timetable.

Project 2000+ suggests the one and only goal of science education is to enhance scientific and technological literacy for all (STL) (UNESCO, 1994). This literacy, in line with the earlier educational goals, has intellectual, personal, societal and communication aspects and hence all these aspects need to form part of a science course. Note that content is not mentioned, meaning that content, in itself as something to study in isolated from the educational goals mentioned, is unimportant. It should not be the starting point, nor the prime rationale, for teaching. It is with regard to this lack of importance of any specific, isolated, science content that Project 2000+ begins to introduce the need for a radical rethink of the purpose of science education for the classroom teacher. Science teachers teach students, not science!!

In studying the development of scientific and technological literacy for all, research has shown:

1. The context is more important than the content. It is impossible to cover all science and technology knowledge. Whatever we do we can only cover an extremely small part. All we can do is touch upon the big ‘ideas.’ In doing so, research suggests that the context in which this is done is important. The more the context is ‘real,’ i.e., related to the society, the more motivation enhances achievement.

2. Constructivist approaches are important. We learn by making constructs. These constructs can be reinforced and enlarged or developed by appropriate stimuli. These stimuli can come from self learning, or with the help of others, i.e., teachers. However, it appears that it not possible to give someone ‘the construct.’ For example, we cannot give the full construct that enables us to have a concept of a chair. Only the students can do this. We, as teachers, can only guide. And this has very, very great implications as it means that we need to build on students’ prior constructs. We need to recognize students previous experiences. And then we need to give additional experiences that build and extend on those previously acquired. If we don’t, we could lead to alternative ‘frameworks,’ or misconceptions.

3. Learning is enhanced if the teacher is a facilitator, rather than the centre of wisdom—a giver of knowledge. Students learn when they are involved. Passive listening is at best part of a theoretical approach that allows precious little time for construct formation. And to cap this, it is important to realize that teachers saying ‘I must finish the syllabus’ has little meaning—it is the student that needs to be the centre of attention. What the teacher is or is not able to do, is far from our area of concern. Students need time for constructing information. Some students will need more time than others and all will need less time if previous experiences can be brought to bear.
4. Feedback is crucial. Both the student and the teacher benefit by being aware of the learning taking place and the steps needed to reinforce and enhance this. The greater the feedback by students, the more this can help students to realize their gains and the more the teacher can decide on the next stimuli for learning. Feedback thus enables the educational process to follow a non-linear model, designed to give maximum benefit to all students. Feedback reduces the need for such linear resources as a textbook which has limited educational benefits. But, whatever the approach, resources (appropriate to the educational goals) will be important to enhance the feedback activities.

Based on such findings, it would seem that much science teaching today is inappropriate. It is not designed to promote literacy. It is not designed to help students become responsible and decision making adults of tomorrow. There is a need for change.

One resource which can guide science education towards greater relevancy for the 21st century is the use of STL supplementary teaching materials. These materials are not extensions of the textbook, but are additional resources for the teacher to call upon as required. As such they are optional materials and can be used as and when the teacher feels it appropriate. The materials are based on the belief that, if the materials allow students to engage in activities relevant to STL, they enhance the learning situation and hence guide students to achieve the intended educational goals. So what supplementary materials are needed for STL teaching in the classroom or laboratory?

An important component of any science teaching for a good learning environment is that it needs to be interesting and enjoyable. Interest is governed by two important considerations—relevance and motivation. This also applies to teaching materials. Teaching materials that are relevant and motivational are likely to be found interesting by students.

Thus one challenge we face within Project 2000+ is how to make science education and its teaching materials relevant. Here we consider a change of thinking. We suggest, and this is supported by research, that relevant science education is that which relates to issues or concerns within the society. This could relate to the environment, the home, to do with health, energy needs, population control, industry, communication or to more global concerns geared to global warming. In fact it is no wonder that courses developed around this approach have been labelled STS—science, technology, society. However the philosophy of STS paralleling STL is perhaps better described as [society —> technology —> science] as this approach makes the relevancy overt. It also marks a major differences with science teaching in a science concept/fundamental approach. In a fundamental approach, science is the major starting, or relevant focus and the technological or societal aspects are the add-ons, the applications. At the very heart of Project 2000+ philosophy is that relevancy relates, for students in general, to society, not to science per se. This is a major paradigm shift.

A Project 2000+ approach calls for a resequencing in the teaching of topics in the science and technology curriculum. Research has shown that students construct their own conceptual understanding. This is based on prior learning, often coming from an out-of-school situation. In a Project 2000+ approach, the task is how to introduce scientific ideas which are considered important, and which sometimes may challenge the prior naive ideas held by students. The primary purpose of this is to guide students to solve problems or confront issues within which scientific conceptual ideas can play a role. Note I have not said solve a scientific problem, nor confront a scientific concept. These are but parts of the wider area of relevance embedded in the society. It is thus societal problems and issues that are relevant and science education guides students to utilize scientific understanding in tackling the issue, a factor lacking in conventional teaching approaches.

The philosophy thus proposed is that scientific and technological literacy for all is achieved through approaches in which students participation is pivotal. It is suggested there is a need to develop teaching materials geared to this philosophy. For simplicity, at this stage, it is proposed that the material relate to just one teaching lesson so that it does not confront curriculum issues. Also for simplicity, the materials is proposed as being supplementary, meaning that the teacher has a choice as to whether it is, or is not, used in the teaching situation.

Such teaching materials need, however, to meet certain criteria if they are to be considered STL. As far as we are aware these criteria have not been specifically identified in the literature and with this in mind the following are put forward for discussions and debate (Table 2).

Table 2. Criteria for creating exemplary STL materials

A) education goals are stipulated and form the major focus of the material, i.e. students are participating in the process of educational learning appropriate for the goals of the country and their intellectual development:
B) material is societally related, i.e., students are familiar with the situation and can thus appreciate its relevance;
C) following the material is a learning exercise, i.e., it provides an intellectual challenge and utilizes constructivist principles—moving from the information and understanding already in the possession of students to the new;
D) the activity is student participatory, i.e., the student is involved either individually or in groups for a considerable amount (>60%) of the teaching time;
E) consideration is given to enhancing a wide range of communication skills.

How is the creation of supplementary teaching material achieved? It is suggested that the teacher start from an issue or concern arising in the students societal perspective. This could arise from a student question (often a situation at the primary school level) to a topical concern being expressed in the media (the newspaper, television, radio). Then the skill is to determine an activity (or activities) that could best help students to appreciate the concern or issues in an educational perspective, gain the necessary scientific background and give appropriate feedback to show their grasp of the situation and their command of a communication skill relevant to the teaching situation.

An approach adopted in Eastern Europe was to run a 4 day workshop, and in which introduce the STL philosophy and following the use of exemplars, allow the participants to create teaching materials themselves. The workshop, held in May 1996, was funded by UNESCO (PROCEED—Programmes for Central and Eastern Europe Development, and STE—Science and Technology Education Unit of the Education Sector). The participants for the workshop were invited from 9 different Eastern European countries. As the invitation was sent through NGO channels, it was predictable that the participants were teachers or persons linked with teaching at school. This was the intention as the organizers we interested as to whether ordinary teachers could create STL teaching materials.

Through earlier communication, participants were motivation to collect data related to teaching science in social context (this was to be the base for the teaching material created during the workshop). The first day of the workshop was taken up with introducing the STL philosophy and allowing discussion on its implication for teaching. (The discussion was also intended to help participants appreciate how much they accepted the STL philosophy proposed earlier.) The second day was taken up with an extensive look at exemplars of STL teaching materials, whilst the rest of the time was used for creating their own teaching materials in groups and in presenting this to others.

The workshop had three main goals:

1. To discuss the meaning of STL and how teachers can implement this in practical and interesting ways.
2. Develop STL teaching materials and enhance the participant's ability to follow up this workshop with further similar workshops in their own countries using the national language.
3. To find out how the participant's way of understanding STL changed during the workshop and which were the most difficult problems in writing STL materials.

During the workshop it soon became very clear that teachers did not understand the notion of relating their teaching to the social context and the following aspects were noted:

1. In spite of instructions to collect industrial or commercial data, most participants had only fragments of information on possible utilization of science in everyday life.
2. In getting familiar with the new philosophy, the participants felt uncertain about developing an idea so as to produce STL material.
3. Participants needed to get feedback from the resource persons to confirm acceptance of their chosen problem before they would proceed.
4. The most popular area of problem investigation was related to environmental issues—this being one social context with which participants could easily identify.
5. The participants found it difficult to give attractive titles to their scripts.
6. The titles were kept rather more descriptive than highlighting a problem or issue.

To illustrate the types of changes that were suggested by the resource persons, Table 3 illustrates the titles of the first version of the scripts created by the participants and also the modified title as a result of further development. Beside developing an interesting title, it was very important to introduce the teaching idea in a social context for the learner. Here the participants had many problems. The influence of their current teaching was so powerful that the starting point in virtually all cases was the science.

Usually in their initial version, the participants tried to find wide social applications for common science issues. For example, the sculpture script began with a
consideration of corrosion and this was illustrated by beautiful sculptures in St. Petersburg. Destruction of the sculpture really is a social problem in St. Petersburg, but the introduction did not put it that way.

In due course the various scenarios took the format 'from society to science.' The new starting point for the sculpture script became dealing with the problem that sculptures have changed their bronze colour and were pitted with holes.

The need for student participation was well described in most scripts as participants seems to understand the need for this much better. And it was possible to find a wide range of students involvement ideas. The participants in fact attempted to use role-playing, problem solving strategies and brainstorming sessions in their scripts as well as experimental situations which seemed to indicate they had understood the need for developing communication skills among the students. It would appear that participants, at least in the workshop environment, appreciated the importance of active learning (the participants had themselves been put in a participatory comments and acceptance. To arrive at the final version for trials, the scripts in fact needed to be modify twice. The workshop confirmed the need for similar ones to be initiated by participants in their own countries. By being involved in the developing process, the participants could understand the philosophy behind Project 2000+ and the need for follow up being the only way to introduce a wider number of teachers to the new teaching methodology. The difficulties that arose during the workshop indicated the following weak points in the teaching process in Eastern Europe:

1. Setting up educational goals in such a way that the motivation comes from the society.
2. Overlooking the students activities and involvement for the lesson. The more conceptual objectives the teacher can cover in the lesson, the more perfect the lesson.
3. Setting out the teaching strategy in such a manner that all the objectives could be achieved.

One possible way to improve teaching as described above is to run writing workshops which help teachers

Table 3. The initial and developed titles for the STL scripts

| 1. Dynamics of population development | An investigation of the best conditions for butterfly capture |
| 2. Phosphorus circle in nature | Discovering old settlement sites |
| 3. Corrosion of sculptures | Problems of sculptures in cities |
| 4. Role of Wood Today and in the Future | Wood—a potential fuel for tomorrow |
| 5. Combustion products of different fuels and their influence on environment | Is emulsion suitable as an alternative fuel? |
| 6. How do you heat your home? | (to be decided) |
| 7. Radon in our houses | Radon in our homes—is risk acceptable? |
| 8. Investigation of Harku lake | The problem of Harku lake—can we solve it? |
| 9. How to avoid bicycle accidents | No change |

learning situation by being asked to try out the scripts used as exemplary material on day 2).

To put together the students guide, the teachers guide and let it follow the educational goals was a time consuming process. The first versions of the scripts did not give a full description covering these aspects. Also the participants had difficulties in including socially oriented goals and often these was omitted. These were usually more fully developed or added by the organizers after the workshop.

During the 4 days, 9 scripts were developed. As earlier planned, the criteria put forward during the workshop was used to modify scripts and the modified versions were sent back to the authors to seek their understanding the new philosophy and its need and at the same time enable teachers to leave with STL material. We are charged with satisfying the educational needs of children who will be the adults of tomorrow.

The scripts, developed by representatives from 9 countries, will be translated into the national language and tested by teachers during the current school year. The evaluations will be collected and used by the workshop organizers to improve the tested materials and to add STL assessment strategies.

Science Education Around the World

Member associations and individuals are invited to contribute to this section. Suitable items include brief accounts of specific projects of international significance, science education in a particular country, or international and regional seminars and conferences.

A NEED FOR UNITY IN DIVERSITY, II

B. J. K. Tricker
Hon. Sec.
International Association of Science Clubs
The Firs
Southdown Road
Freshwater Bay, Isle of Wight
P040 9UA, U.K.

Introduction

It may have been evident that ‘A Need for Unity in Diversity, I’ spread into what might be called the ‘Greater Sciences’: Moral; Economic; Domestic; and others, besides having its roots firmly in the Natural Science of Human Biology.

In 1993, a precursor to the S.E.I. article of March 1994 was sent to fifteen of the National Academies of Science preparing for the World’s first Summit of National Academies of Science which was held in New Delhi in that year. In its preparatory stages, lasting some two years, the conference moved from a wide environmental forum to one on population and related issues. ‘Population, the complex Reality’ is the account of the New Delhi lectures.

This article develops points from S.E.I.’s Feature Article of 1994, presents material for direct photocopying for class use, and challenges you to send us notes to further education on population issues.

Graphs and Notes

Figure 1 is presented for direct photocopying for class use.

The latest figure available: that the world population reached 5.7 billion people in May of this year shows that the population explosion continues on its way.

Sir Francis Graham-Smith, editor of ‘Population—the Complex Reality,’ summarises the 400+ pages by calling for zero population growth in the lifetime of today’s young people. This is calling for a horizontal graph line; no upwards slope at all.

Figure 2 is also presented for photocopying for class use. While scientific progress must depend on past discoveries, it also depends on speculation. In this case public opinion and forethought to acknowledge the stupidity of overpopulation is paramount.

Jonathan Porritt has set up a small organization called ‘Passport to the Future’ which encourages groups of young people to make resolutions which they enter in their passports. On the television film ‘Sex, Sin and Survival,’ he says: ‘Best practice in family planning could become commonplace all but overnight, but it is just not happening fast enough. The real blockages can be traced back to the intolerance and complacency of millions and millions of people . . . the short-sighted . . .’

Social Effects of Over-population

The majority of these—the opinions given in our five year forum—should be reviewed in the March 1994 issue of S.E.I. A subject area that does not feature there is the multiple births problem created by recent advances in medical science.

For what might be called ‘the New Delhi Wish’ to come true, on average, each adult may produce but one child—the two child family.
Formulae

Philip Musk, a mathematics research worker at Oxford University, produced the formula below to account for the effect of one exponential on top of another.

\[ y = x^{kt} = (\log x)^{kt} = \log y = (n \log \log x) \]

Plots using this are, appropriately, like graphs of brick walls!

For those who prefer simpler mathematics, try

\[ S = f(P \times L) \]

where \( S \) = environmental stress
\( f = \) 'a function of'
\( P = \) the human population, and
\( L = \) an average standard of living.

- It leaves scope for discussion and diverse interpretations, thus being a starting point for logic radiating out in many directions.
- It may be applied for localities, towns, cities, counties, nations or to the world as a whole.
- Discussion is required in order to choose units so that the physical dimensions are the same on both sides of the equation. \( L \), for example might be G.N.P. or G.D.P., thus bringing money into an environmental equation!

Two formulae of this kind come in Paul Harrison's book, 'The 3rd Revolution'. He quotes Paul Erlich's

**impact** = **population x affluence x technology**.

This, like \( S = f(P \times L) \), stimulates discussion and also needs units.

His own formula is

**environmental impact** = **population x consumption per person x impact per unit of consumption**.

Although quantification is part of the scientific method, over-much of it may defeat the overall aim. In the last resort, as now, common sense is what really matters!

Challenge to You

If you would like to join an educational drive on population education and related issues.

- please send us the ideas you think the most important;
- indicate whether you would be interested in a population forum at the December '97/January '98 General Assembly/ASE meeting in Liverpool, England.

Don't delay. What can be organized in the time depends on early feedback.

References and Addresses

5. Population Concern. 178-202 Great Portland Street, London W1N 5TB.

1. There are now more people alive in the world today than have ever lived in total before. (a) Is this idea new to you? (b) Do you believe it?

2. There are more than 5,000,000,000 people alive today, and the population explosion curve shown on this page shows no sign of levelling off:
   (a) Do you see this as a serious matter?
   (b) Should nature be allowed to take its course, or should measures be taken to help the curve towards a steady level? (Underline the option you support)
   (c) List the main consequences you think go with overcrowding.
   (d) What population control measures do you think are acceptable?
   (e) What population control measures do you think are not acceptable?

3. (a) Do you agree that the greater the number of people, the less the room for wildlife? (b) Does this concern you?

4. (a) Would you like to have children of your own in time? Or (b) how many children do you already have?

5. How many children would you like to have?

6. In view of world overcrowding, how many children do you think you should have?

7. Assuming that it is desirable for all people to have a fair quality of life, and that this does not go with overpollution and exhaustion of resources, what do you consider to be the optimum level for the world's human population?

8. (a) With respect to the possibilities which curve do you think is the most likely to happen? Number......
   (b) Which curve would you prefer to happen? Number......
   (or draw your own versions on the reverse of your answer page, stating which is 8a and which is 8b.)

9. Please state your:
   (a) age
   (b) sex
   (c) locality (town, county or state, country)
   (d) country of birth
Populations sometimes alter sharply as shown above. If the Academies of Science 'New Delhi Wish' is to happen peacefully, worldwide forethought is vital like never before! Fossil fuels will run out in time; environmental damage and destruction will continue; shortages will increase. Your resolutions now will help to make the kind of future you want for yourselves, and for your children in the course of time.

Choices 1-4 below involve catastrophe; No.9 is far too risky; 5-8 possible and reasonable.

I prefer No. .... and suggest these ways of achieving it:

NETWORK FOR SCIENCE TEACHING
IN THE STATE OF RIO DE JANEIRO, BRAZIL

Gloria R. Pessoa Queiroz
Universidade Federal Fluminense/MAST, Rio de Janeiro, Brazil
and
Sandra L. Escovedo Selles
Universidade Federal Fluminense, Rio de Janeiro, Brazil

Introduction

The "Rede Regional Fluminense (RRF)" is a network for Science Teaching based at the Universidade Federal Fluminense (UFF), Niterói, State of Rio de Janeiro and brings together researchers, university lecturers, science teachers and pupils. Its main project is a science teaching center called "Espaço UFF de Ciências" which aim is to promote science and mathematics for schools and general public.

The "Espaço UFF de Ciências" is a sum of several activities which have been developed in the last ten years. The activities started with a project targeted to science teachers in primary schools called "Active Science at Schools." The main feature of the project is the practical aspect of the proposal presented to science teachers. Through the project was possible for teachers and university lectures to discuss about the use of the recent results of research in science education in the classroom. The project adopted an interdisciplinary approach and had made use of experimental activities and created suitable instructional materials to be used by the science teachers.

The work done by the RRF initial group allowed the interaction with some disciplinary groups of the university who were also interested in reflecting upon general problems happening in schools and specific ones concerned to the learning of science and math. The current group in charge of the project is composed of lectures of the Department of Biology, Physics, Chemistry, Mathematics, Earth Sciences, Psychology and the School of Education who intend to develop a methodological proposal for active learning in science. Alternative conceptions as a research approach have been mostly used by the RRF group who recognizes the importance of the pupil's background knowledge to learn new concepts. Conceptual change, as well as interdisciplinary approach for science teaching is an area of interest of our group.

The increase of the number of members in the group and changes in the kind of support offered to science teachers have lead to an expansion of the physical space and a diversity in the activities. Also, an increase in requests from many teachers, schools and even from the Educational Authority of the State of Rio de Janeiro, allowed the existence of many projects. These activities are, for example: video exhibitions, workshops, regional meetings for science teachers, courses in History of Science and Technology, exhibitions in national meetings, etc.

Therefore, the RRF main goal is to carry out these activities aiming to promote science in the State of Rio de Janeiro in such a way that it may contribute to improve the quality of science teaching at schools. Thus, the network goals include:

- divulgence of the results of research about how pupils learn and other related themes linked to science education;
- promotion of group discussion about themes such as: pupil as the one responsible for his/her own knowledge; the role of school and the contribution of science and math teaching towards the formation of the citizenship; transference of the research results into classroom contexts; etc.
- production and divulgence of technical and scientific materials;
- creation of new Science Centers or Science Clubs at the University and at schools;
- improvement of cultural, technical and scientific knowledge of pupils, teachers and general public.

Theoretical Background

As mentioned earlier, the group's research background is related to pupil's intuitive or alternative
conceptions. Children, pupils and adults build up patterns and explanation about the world that surrounding them, since they were born. However, in many cases, their conclusions do not get close to those presented by science.

Researches have shown that the way of approaching scientific knowledge is basically the same for children and scientists. However, "science of children" is quite different from "science of scientists" (Driver, Guesne & Tiberghien, 1985). These differences are due to many factors such as:

- children's self-centered view of the world
- children's curiosity leading to particular explanations related to isolated events without making generalization;
- a scientist's hypothetical reasoning which children do not have;
- distinct languages: words being used with different meanings by scientists and nonscientists;
- some of scientists' conceptions for which there is no example based on direct observation.

Children's explanation make sense for them. Not rarely, they even make more sense than those given by science and presented by teachers ('science of teachers'). In spite of that, it was through abstract thoughts, generalization, decentralized view, appropriate speech and abstract patterns that science developed the power to know and to explain nature in the way we have in our days.

Pupils build up a logical system associated to a group of patterns which allow them to interpret the world. They do that during the period they attend school and even before that, in spite of the influence of school and the influence of the teaching system as a whole. This situation creates a great persistence of what is called 'science of children' which, in many cases, can be found both in primary teachers and graduate students (Viennot, 1979).

These patterns mentioned above have been interpreted, several times, as "pupil's mistakes." However, researches have demonstrated the existence of regularity in these 'mistakes' as well as many analogy with patterns of ancient times of history of science (Villani, Pacca, & Hossoume, 1985).

Also, researchers in physics teaching, followed by researchers of other professional and cultural fields, have studied pupils' alternative or spontaneous system. This not only expanded this area of studies but also directed it to investigation concerning to mental models and its importance in science teaching (Gilbert, 1993).

General Methodology

Basically, the RRF network works through activities which include: research; teaching; scientific events with articulated actions to allow the interchange of knowledge among participants; production of school materials to be tested inside classroom.

All these activities are present at the projects developed as part of the work of the network, which will be described in the following section.

The Network Projects

The network develops several projects, many of them partially supported by the Educational Authority of the State of Rio de Janeiro. In many cities of the state, there are actions which receive some kind of support from the local authorities which, basically, consists of enabling teachers to attend meetings, workshops or in-service training.

Among the projects developed by RRF, the following ones are outlined:

- **Active Science at Schools** (developed with primary science teachers and student-teachers of the School of Education);

- **Physics Teaching Programme** (developed at High Schools and Physics Laboratories at University);

- **Historic-cognitive Analysis and Science Teaching Group**;

- **Science Classroom Project** (study of topics in Biology and production of school materials to be tested in classrooms);

- **Geometry Experimental Laboratory** (application of a specific methodology to geometry basic subjects);

- **Science and Leisure Programme** (interdisciplinary events for general public);
• ‘Science at Square’ (events and classroom activities promoting science to school and general public);

• Science Teaching at Junior High School: Chemistry and Physics topics1 (a project which the research group includes science teachers as well as university researchers);

• “One swallow does not make a summer” (a project that goes to schools and involves science teaching at age 6 up to 14 in three regions of the state of the Rio de Janeiro);

• Science Teaching and Racial Issues.

Some exhibitions have been held at the Annual Meeting of the Brazilian Society for the Advance of Science (SBPC) in places outside Rio de Janeiro: Galileu Galilei (held at Recife State of Pernambuco, 1993); Science and Colours (held at Vitoria, State of Espírito Santo, 1994); Science and Art: Colour, Light and Movement (held at São Luís, State of Maranhão, 1995). An exhibition named Chaos and Fractals was held at the Espaço UFF de Ciências, Niterói in 1994.

The RRF is also linked to the Red de Popularizacion y Divulgacion de la Ciencia (RED POP), a network for science teaching in Latin countries. Every two years a meeting is held in order to establish interactions among the members. The RRF has just started an interaction with Colombia, mainly with the work developed by Julian Betancourt (for a better description of the work, see Betancourt & Cordoba, 1986).

Conclusion

As said previously, the network activities promote a significant interaction among teachers, pupils and researchers who work with science teaching all over the State of Rio de Janeiro. In order to achieve this aim, the network has established a number of interchanges with other universities, research groups, science centers (like the Science Teaching Center of the State of Rio de Janeiro, CECIERJ), science museums (like the Museum of Astronomy and Related Sciences, MAST and the Living Science Museum, “Ciência Viva,” both in Rio de Janeiro city) and others.

By participating at RED POP it is possible to pursue an expansion of the network even to an international extent. It is important to stress that by doing so, the network goes as far as other countries of Latin America which share common needs and common goals that are familiar to us. That is the time to establish cultural relationship with other countries, mainly with those which are respected for their experience both in science teaching and museology.

We hope that other interchanges that may exist in the future represent an effort to promote science for the improvement of the quality of science teaching and the society, as a result.

1 The school year in which pupils are introduced to these subjects.
CONASTA 46
Annual Meeting of the Australian Science Teachers Association
June 29-July 4, 1997
University of Melbourne

The Theme
Science Down Under—Extending the Boundaries’ Our aim is to provide science teachers with up-to-date cutting edge information on the thinking of Australian scientists and near neighbours. The programme will also highlight practice and theory suitable for all levels of science education. It is our intention to extend the boundaries of knowledge.

Exhibitions
Throughout CONASTA 46 there will be extensive displays and showcases of science resources, videos, computer software, laboratory apparatus and curriculum materials.

Excursions
A full range of social and informative excursions are being planned to enhance the program. A special Sunday welcome function is being organised, along with a Conference Dinner featuring a mystery tour. A post-conference excursion programme will be available.

Registration
The registration brochure will be available later this year and will be sent to all members of the Australian Science Teachers’ Association. Initial expressions of interest can be filled in on the back of this brochure.

Travel
Qantas has been appointed the official airline for the conference and will be offering discounted conference airfares for conference delegates and accompanying persons. Full details will be included in the registration brochure.

The hard copy of your abstract should be submitted by November 1, 1996. Further information will be required by the STAV Secretariat as soon as practical after this date.

Presenters will be notified of their acceptance of Workshops/Seminars and all presenters are required to register for the Conference.

Introduction

Studies assessing students’ images of scientists (Krause 1977; Chambers 1983; Schibeci & Sorenson 1983; Fort & Varney 1989; Huber & Burton 1995; Finson, Beaver, & Cramond, 1995) have shown that students possess interesting stereotypic images of scientists. For example, students generally perceive scientists as being white males who work alone in a laboratory. Chambers (1983) and Schibeci and Sorenson (1983) found that as young children progress through successively higher grade levels, their images of scientists become more and more stereotypic until they reach fifth grade. At this time, their stereotypic image of a scientist appears to be fully developed.

The most common technique used to assess students’ images of scientists has been the Draw-A-Scientist Test (DAST) developed by Chambers (1983). In using DAST, investigators ask students to reveal their image of a scientist through a drawing. To provide a reliable and efficient format for analyzing students’ drawings, Finson, Beaver, and Cramond (1995) developed the Draw-A-Scientist Checklist (DAST-C). Each item on the DAST-C represents a stereotypic characteristic derived from reviews of literature relating to students’ images of scientists. During the analysis of a student’s drawing, the more items “checked” on the DAST-C, the more stereotypes appear on the student’s drawing. Although the DAST and the DAST-C are useful tools in gaining insight into students’ concepts of scientists, Finson, Beaver, and Cramond (1995) identify two cautions in the use of these instruments:

“Maoldomhnaigh and Hunt (1989) reported that students may possess more than one definition of the word scientist, and this may result in students drawing different images at different times without having their perceptions changed by a particular treatment. Additionally, Maoldomhnaigh and Mhaolain (1990) found that changing the wording in directions given to students can alter the types of drawings produced. Such results underscore the importance of having a standardized procedure, including standardized instructions, to follow when administering the DAST. In addition, although the DAST-C appears to yield results similar to those obtained through structured interviews (indicating it accurately assesses students perceptions of scientists), it may fail to elicit all the richness of data possible through interviews (p. 204).”

The Portrayal of Scientists in the K-12 Curricula

Since the early 1970’s, concerted efforts have taken place to present inclusive images of scientists and to show how they engage in the scientific enterprise. For example, in K-12 science programs, women and ethnic minority groups are depicted as having active roles in science. In features like “Ask a Scientist” in Addison-Wesley Science, scientists are portrayed as “regular people” who dress in everyday clothes and are able to communicate about their scientific activities to children (Barman et al., 1992). Science related careers are highlighted in Destinations in Science (Brummett et al., 1995), Discover the Wonder (Heil et al., 1993), and MacMillan/McGraw-Hill Science (Atwater et al., 1993)
to show students that “doing science” occurs in a variety of occupations. In addition, some science programs have incorporated features that show students how science occurs in their everyday lives. For example, the “Back Home” feature in Destinations in Science (Brummett, et al., 1995) invites students to use their home or neighborhood to study science and the “Technology and Society” feature in Macmillan/ McGraw-Hill Science (Atwater et al., 1993) shows students how science knowledge and the application of science relate to the everyday life of themselves and their family members.

The way students studied science has also been an area of concern for science educators and curriculum developers. The main issue has been to find ways for students to be “doing” science rather than just reading about it (Kahle, 1992). Therefore, most recent K-12 science materials have included a variety of activities that encouraged students to engage in the same processes that scientists use. In these activities, students describe objects and events, ask questions, construct explanations of natural phenomena, test those explanations, and communicate their ideas to others.

**Procedures**

Because of the concerted efforts since the 1970’s to provide students with a realistic image of scientists and how they go about “doing science,” we are interested in addressing three specific questions related to the way students view science. Specifically, we will focus on the following questions: (1) What are the current images that students have of scientists? (2) How do students perceive they study science in school? and (3) Do students perceive they are using science outside of school? To address these questions, we devised a protocol that incorporated the current methods of DAST, some techniques to take into account the cautions suggested by Finson, Beaver, and Cramond (1995) which relate to using a standardized procedure and structured interview questions, and procedures that we felt would further enhance our ability to understand the students’ perceptions of scientists and science.

An initial concern that we had about DAST was related to asking students to make a “forced choice.” If you ask students to draw a scientist, does this force them to make a choice between a male or a female? Or, if you ask students to draw two scientists, would this provide them with the freedom to depict both sexes? To answer this question, we randomly selected two groups of ten fifth grade students. Each group had an equal number of boys and girls. Group A was asked to draw two scientists doing science while group B was asked to draw one scientist doing science. In group A, 7 students drew two male scientists, 2 students drew a male and a female scientist, and 1 student drew 2 female scientists. In group B, 7 students drew a male scientist and 3 students drew a female scientist. Because the drawing of two scientists took each student twice as long to complete as the drawing of one scientist and because there appeared to be no major differences in the results of groups A and B, we decided to develop our protocol with students drawing only one scientist.

We also wanted to provide students with an opportunity to draw scientists from different racial backgrounds. Therefore, we provided each student with a set of colored pencils or crayons before they were asked to draw a scientist.

Each student was given the following directions and asked questions individually. Even though each student was asked a set of standard questions, each interview session was informal enough to allow the investigator to gain additional information about the students’ drawings and to clarify any of their responses. The responses were audio-taped and later transcribed for further analysis. The set of directions and questions used in each interview session are:

- Will you please draw a picture of a scientist doing science? When you are finished, will you please explain your drawing?

- On another piece of paper, will you please draw a picture of yourself doing science in school? When you are finished, will you please explain your drawing?

- Can you think of some ways you use what you learn in science outside of school?

**Sample**

One hundred and seventeen fifth grade students (57 males and 60 females) from the midwestern and southwestern parts of the United States were chosen for this study. Eighty seven of these students came from one private school and two public schools in a large midwestern city. The remaining 30 students came from a private school in a large southwestern city. The students enrolled in the private school in the midwest were primarily from middle to upper income families while the students from the private school in the southwest were mostly from middle income families. The two public schools from the midwest contained students primarily from low to middle income families. In terms of ethnic background, 73 students were
Caucasian, 40 students were Afro-American, and 4 students were of Asian descent.

Analysis Procedures

The student's drawings of scientists were analyzed using the DAST-C. Each drawing was rated for specific stereotypic images and additional information obtained from the student interviews was compiled and reviewed (Table 1).

The drawings of students doing science were grouped into two main categories: (1) those who pictured themselves as passive learners such as reading about science or taking notes at a desk and (2) those who saw themselves as active learners (Table 2). Additional information obtained from interviews was also compiled and analyzed.

Data related to students' perceptions about using science outside of school were gathered from the interview transcripts. These data were categorized into four main groups: (1) students who think they can use science but are unsure how, (2) students who only see themselves using science by repeating activities from school, (3) students who could generalize the use of science knowledge and processes to everyday situations, and (4) students who did not see any use of science outside of school (Table 3).

Results

Perceptions of Scientists

As shown in Table 1, the students in this study had similar images of scientists to those revealed in previous studies (Chambers 1983; Fort & Varney 1989; Finson, Beaver, & Crammond 1995; Huber & Burton 1995). Generally, the students perceived scientists as being white males who do their work in some type of laboratory.

A few other items worth noting about the students' drawings of scientists are related to the scientists' clothing and their facial expressions. Scientists wearing regular clothing such as bluejeans and t-shirts are depicted by 20% of the students while 26% pictured the scientist in a lab coat. In regard to showing any facial expressions on the scientists, most of the students depicted scientists with no expression. However, 23% of the students did draw scientists with smiles on their faces. When asked to explain this aspect of the drawing, the students generally indicated that the scientists enjoyed their work.

Perceptions of School Science

When the students were asked to draw a picture of themselves doing science in school, 56% drew themselves at desks either reading a science book or taking notes. When asked about their drawings, several of the students said that they usually sit at a desk and read their science book. However, these students also indicated that they would prefer to do some type of activity during science. Doing some type of science activity was depicted by 27% of the students while 17% drew themselves outdoors looking for insects, leaves, rocks, or plants.

Perceptions About Using Science Outside of School

The majority of the students (60%) viewed the use of science outside of school as an extension of their school experiences. Students cited specific school activities that they did at home such as mixing vinegar with baking soda. Several students stated that they were able to help one of their younger siblings with their science homework because they had been given similar assignments. It was felt by 26% of the students that they never use science outside of school and 5% thought they probably use their science knowledge and skills outside of school, but they were unsure as to how they use the knowledge or skills.
A total of 9% of the students were able to connect the skills and knowledge they gained from science to everyday activities. For example, these students cited how they use problem solving, making observations and inferences, identifying small animals and plants, predicting weather, and caring for plants and pets in their everyday lives.

**Typical Student Drawing of How Science is Studied in School**

![Image of a student drawing]

**Discussion**

Although steps have been taken by curriculum developers and science educators in the last few decades to highlight women and minorities in science, most of the students in our sample perceive scientists as white males who practice science in some type of laboratory. This points to a continued need to search for ways to show K-12 students that scientists are represented by both genders and are from a variety of ethnic backgrounds. In addition, scientists should be portrayed as everyday people. Therefore, teachers need to be encouraged to use the special features in science textbooks that highlight science careers, depict scientists as everyday people who are capable of sharing their work with non-scientists. Resources, like *Dragonfly* (Project Dragonfly 1996), could also help teachers present students with an inclusive image of science and scientists. *Dragonfly* is a publication in which students interview scientists and publish the procedures and results of studies they have conducted. In addition, this magazine highlights the work and daily lives of scientists.

The most recent K-12 science curriculum programs include activities to engage students in "doing science." However, a large number of students in our sample perceive their school science experience as either a reading exercise or a time to listen to someone lecture about science. The National Science Education Standards (National Research Council 1996) has explicit recommendations about teaching science as a process of inquiry. Teachers need professional development which provides dialogue and concrete examples designed to help them put these recommendations into classroom practice.

Videotapes featuring scientific expeditions and investigations would present scientists in a dynamic mode. Inviting women and minorities to talk with the class about how they learn about and use science would offer opportunities for students to broaden their ideas about scientists on a more personal level. Building on these experiences, pointing out the scientific contributions by females and minorities would continue to broaden student perspectives. The historical sequence in the development of our understandings about the way things work would help students gain an appreciation for the personalities of scientists as "real people."

Our findings in this study indicate that most students do not see a connection between what they learn in science and how it can be applied to their everyday lives. Students need to be presented with concrete examples that demonstrate the connection between school science and what they do outside of school. For example, teachers could engage students in activities that show them how specific skills like observing, measuring, and classifying are used in everyday activities (Mercier & Ostålund, 1996). Students could be encouraged to make collections of things such as rocks, leaves, insects, etc. in order to discover patterns and to develop classification skills.

Engaging students in product testing is an effective strategy for learning how to use the skills of science. As students conduct a "fair test" for various products they will learn how to control variables in an investigation. This may help make science more relevant for students. Additionally, involving teams of students in long term investigations will help them get a feel for the work that scientists do. These projects simulate what scientists do, e.g., working together to formulate a question, making observations, gathering data, drawing conclusions, sharing and challenging conclusions drawn from data, and finally trying to reach
consensus. Additionally, making connections with math and communications creates a realistic view of doing science.

Science classes could also incorporate live communication with scientists. For example, Internet connections can involve classes around the world in conducting research and sharing data on phenomena such as the pH of rain. The Jason Project is another way students can engage in doing science with active scientists.

Final Note

The next step is to plan and implement a pilot program using some of the ideas presented above. Since assessment often drives the curriculum, if students’ ideas about scientists and how they use science everyday is evaluated, teachers will be more likely to employ strategies to increase realistic perceptions. The information that we obtained in this study has been limited to a few schools in the midwest and southwest. We encourage others to use the protocol discussed in this paper to gain insights about how students in different parts of the United States perceive science and its relevancy to them. We also believe that the protocol discussed in this paper should be used on a continual basis by teachers to collect information about how their students’ views about science change over time. These data would provide valuable feedback to teachers regarding whether their students are developing a realistic perception about science and its usefulness to them. This information could serve as an evaluation tool for teachers to assess the effectiveness of their science instruction.

Introduction

The Harare Generator was a meeting of African educators at which participants first exchanged ideas on innovative approaches in science education, generated resources, tried them out in schools and then discussed how they might be refined. The results included draft written guide materials, videos and slides, relevant to their own work all in 2 weeks. These were subsequently edited in Africa by a small group of African educators drawn from the Generator.

The aims of the Harare Generator included the following:

- encouragement in the use and adaptation of the product.

It was seen that the product of the Harare Generator could be the means by which some new ideas and directions might be injected into the teaching and learning of science in Africa, particularly through teacher education programmes.

The Generator philosophy

A generator is an energy conversion device which requires some significant input in order to be of any use. The underlying philosophy of the Harare Generator was a hands-on approach. Many science educators feel that effective science learning typically involves some problem-solving activity. If this problem relates to some major area of human need it may also be linked to applications of technology in such fields as agriculture, environment, health or industry. In this way, science may become more relevant and meaningful to the learner, and applicable to the society in which he or she lives. The Harare Generator attempted to improve the efficiency of the teaching and learning of science in African schools by means of a shift towards a more problem-centred approach. This was done by focusing

* Present address: Secondary Education Project, Box 2201, Kathmandu, Nepal
** Formerly, Chairman, Committee on Teaching of Science, International Council of Scientific Unions (ICSU)
‡ Curriculum and Teaching Studies
on (i) information transfer, (ii) visual media, (iii) creativity development, (iv) low cost teaching resources, (v) science, technology and social issues.

The Generator

The participants were drawn from a wide spectrum, by a system of recommendations nominating those who were actively engaged in science education in Africa, and who would have the opportunity to continue to use, adapt and generate ideas after the event. These were mostly lecturers, teachers, curriculum developers and education officers, drawn from fifteen African countries which responded to the invitation, with a few others from outside Africa. Further, primary and secondary teachers from Harare and nearby participated and also helped participants to try out their ideas in their schools.

The organising committee was drawn from the Faculties of Education and Science at the University of Zimbabwe, the Zimbabwe Ministries of Education and the local science teachers’ association with the guiding hand of Mike Robson, of the University who was also on the Committee on Teaching of Science of the International Council of Scientific Unions (ICSU CTS) the lead international agency for the meeting. The organising committee was responsible for inviting the resource persons and participants, soliciting ideas for the programme and making all the necessary local arrangements.

The actual meeting developed in four stages: inputs, generation, performance and product. It began with inputs which included presentations illustrating new ideas in audio-visual techniques, design and technology in schools, developments in primary science, generating useful materials, popular science publishing, preparing project proposals, production of low-cost science equipment, science education and future human needs, science education beyond the classroom, and science, technology and society.

The second phase of the Generator involved the generation of ideas, plans and practical programmes based on the earlier inputs. Participants chose two (out of 18) areas of focus to develop ideas and materials for trialling. During the second week these ideas were then tried out in schools and evaluated and redrafted with teacher guide notes in the third phase. The materials developed were collected together in a package from which a report and proposals for future activities were produced by each of the working groups, the first part of phase 4. On the final morning of the conference, each working group made a poster and verbal presentation describing the work they had done.

Each phase of the Generator was recorded by photo and video and the ‘rough’ versions were ready early enough to show to the participants on the last day.

The last part of phase 4 was entrusted to four participants, led by Patrick Whittle, who edited the resources which have been published by ICSU CTS (1).

The Generator products

(i) Intangible outcomes

Individual participants had the opportunity to listen to the accounts of innovations in their own and in other countries and to participate in the brainstorming, planning, adapting, modifying and testing of new ideas under the pressure of tight deadlines and limited resources. While they are all frequently called upon to do these things at home, and are used to severe constraints of time and finance, few of us are able to enjoy the opportunity of collaborating with so many other like-minded specialists with such a varied and wealth of experience. We have several examples already how contracts, established across international borders during the Generator, have prospered.

(ii) Project proposals

After reflecting on their endeavours, each group made lists of suggested projects related to their area of study, which might be attempted in their own countries, with detailed plans and costing, and several have already been submitted to funding agencies and are now being implemented. It is hoped that the Generator itself will be replicated in other countries.

(iii) Written materials

Each of the eighteen working groups of the Generator kept a detailed written record of their initial discussions, their plans and how they were developed. They also described field trials with children in the schools, reported the evaluation of those trials and suggested various follow-up project proposals. These written resources formed the basis of a book which has been substantially edited to give coherence (1).

The eighteen products of the working groups have been clustered into five chapters on related areas concerned with (i) pupils’ activities, (ii) pupils’ thinking, (iii) school science facilities, (iv) environmental resources, and (v) more sophisticated teaching/learning aids. The reports, written with teacher educators in mind, have been presented in a form which can readily
be used by science educators in Africa, and in other developing and developed areas.

(iv) Slides and videotapes

Two sets of sixty slides each are available. Set A illustrates the nature of the Harare Generator concept, process and product. Set B shows the five clusters of activities carried out by the working groups, with the major focus on the trials of these activities with children in local Zimbabwean schools. These two sets can thus be used to examine the Generator concept, or to explore the innovations in science education themselves.

There is also a three-hour VHS/PAL videotape containing: (i) a preview of the Harare Generator and its 18 group activities; (ii) Unit 1, the games group’s preparation, trial and evaluation in some detail and (iii) extracts of the main activities of the remaining Units 2 to 18. These can be obtained at the same time as the book (1).

Using the Materials

(i) Generating generators

The Harare Generator report and the accompanying resource materials can be used in many ways. One suggestion is to use the Generator as a model from which to replicate the event for groups of teachers and science educators at a local, national or regional level. The actual purpose may be different but the same approach can be adapted. The manual gives suggestions about the way to set about it. The starting point would be the book, together with Slide Set A, or Section A of the videotape. Ideally one of the original organisers or participants would provide some first-hand advice, but this is not essential, provided a core of science educators exists to form a planning committee, under the aegis of an association, institution or ministry, in that country.

(ii) Pre-service science education

Each of the eighteen projects carried out at the Harare Generator is a worthwhile topic for study by student science teachers. These projects can be replicated within a teacher training college or university education department, as some already have. The relevant chapter of the book provides the necessary background information, together with a list of references. References to further reading are also provided.

Suggested approaches for individual units for teacher education are included at the end of each chapter in the book. The essential element is to expose the student teachers themselves to an activity which will provide some personal experience of the particular “innovation” being considered. This may involve discussion or analysis of some visual material, a simulation or role-play activity, or a mini-project. Some possible objectives for these teacher education activities have been included in the teacher education notes.

(iii) In-service education

Practising science teachers bring their own experiences and felt needs to an in-service programme. Again, suggested approaches are made for the format of meetings using resources from the Generator. The check-list adopted by the INSTANT in-service project in Namibia has much to commend it, advocating a teacher-centred, teacher-driven approach with a strong classroom focus. One suggestion is to show the preview videotape of the Generator, or the set of slides of the conference, and then ask participants which of these methods they have tried. Some members could then describe their own experiences as an introduction to a particular unit.

(iv) Non-formal science education

The Harare Generator slides and videotapes are a useful resource for audiences who are not necessarily specialists or students of science education. They may be used at seminars, conventions, conferences, or open-days, when educationists, students, parents or the general public are being informed about current trends in science teaching.

(v) Cross-curricular activities

Many of the community and real-life centred approaches which were advocated by the Generator impinge upon other science-related subjects such as agriculture, environmental studies, geography, health education, home economics, mathematics or technical studies. Consequently these activities provide a good opportunity for cross-curricular work by a team of different subject specialists. Science education does not have a monopoly of all the best ideas and methods. Some of these ‘new’ science teaching techniques have been used for many years by teachers of the humanities, so it may be profitable to engage in activities with them particularly when social or ethical issues are being discussed.

Since the Harare Generator resource materials include many examples of general educational principles, in an African context, lecturers in educational...
foundation areas may also find them of use. English language education specialists will also find they can make use of them. They may also be used in a general teaching methods course, where the slides and/or videotape will provide non-science specialists with sufficient background information to be able to discuss the technique.

While these suggestions are intended to aid design of appropriate learning experiences for teachers based on the units, experienced teachers could also use the Harare Generator examples as a springboard for developing other innovative techniques or experiments in their science teaching. Cross-curricular work where different specialist teachers combine efforts to plan some learning experiences for their pupils which cut across the normal strands of school subjects is worthwhile because it is closer to real life than the normal subject lesson. Integrated projects or studies are valuable because they involve the problems and pleasures of daily living. Several of the innovations described lend themselves to such cross-curricular activities both between pure and applied science subjects (2) or between sciences and more sociological school subjects.

Postscript

But, let us finish with the words from a recent review. "The book is a gold-mine of ideas which have direct classroom application; they will be especially useful as stimulus material in pre- and in-service education" (3). It is hoped that the resources can be distributed widely and for in-service programmes to be presented using them. If so, the organisers of the Harare will feel that their work is not in vain and the generous assistance from the International Council of Scientific Unions, the Rockefeller Foundation, the British Council, the Commonwealth Foundation and Unesco will be repaid.

Acknowledgements

Besides the funding agencies whose generosity has been acknowledged above we thank Mike Robson of the University of Zimbabwe whose original idea it was to mount the Generator, who directed it and without whose zeal and faith, it would not have occurred.

Note to Member Organizations

Please ask your members to submit material to Science Education International. We are looking for:

- Teaching activities and lessons, especially for elementary
- Action research articles which talk to the practicing teacher
- Research articles which focus on practice, not research strategies
- Informal and nonformal articles which address "Things to do" in these settings

PLEASE INCLUDE PICTURES AND OTHER DRAWINGS OR GRAPHS.

SATIS 8-14—AN STS RESOURCE FOR YOUNGER PUPILS

John Stringer
Project Director, SATIS 8-14

How well does science in society (STS) material travel? The answer would seem to be ‘very well’—certainly judging by the success of the SATIS (Science and Technology in Society) projects of the United Kingdom’s Association for Science Education. SATIS materials for older students—14-16 year olds and 16-19 year-olds—have been widely translated and used in countries across the world. Building on that success, the Association first published a SATIS Atlas, and then wholly new projects for secondary school students—Science across Europe, Science with Technology and Science across the World. More recently, SATIS materials have addressed the younger age ranges—first children from 8-14, now 6-8, and soon, 3-6 years old.

SATIS materials place science and technology in context—sometimes a United Kingdom context, but more often one that any pupil might identify with. They are written by teachers for teachers; and their accuracy is authenticated by experts in the field—professional scientists, technologists, doctors, engineers, agriculturists. The materials are designed to enhance the prescribed curriculum, and, as a science programme might, SATIS presents an exciting and eclectic range of topics—see later for examples—that offer opportunities for teaching science concepts and practising science skills. All the units have curriculum connections—taking an unusual, sometimes unique, slant to familiar subject areas.

SATIS materials can be photocopied—but more often than not they are used to inspire and inform teachers; and to interest and engage pupils of all ages. Additionally, SATIS materials are industry sponsored, and so they are sold without profit.

The SATIS Atlas is a book of outline maps, easily copied or made into slides or overhead projection sheets. Every map is concerned with science and technology. While some of the maps are—understandably—about the United Kingdom, others tackle whole world issues, including energy and environmental questions. Overlaying one map on another is enlightening: putting the map that shows the parts of the world where clean water is limited on top of the map that records average life expectancy for each area produces a close and disturbing correlation.

Additionally, the Science across Europe initiative of the Association, in collaboration with British Petroleum, has produced seven units of work so far in ten European languages—English, French, Danish, German, Spanish, Catalanian, Italian, Dutch, Portuguese and Swedish. Each book contains maps, data, and teachers’ notes, together with copyright waived pages. Titles to date include ‘Using energy at home,’ ‘Domestic waste’ and ‘Global warming.’ More units are in development, together with fresh initiatives in other parts of the globe.

Science with Technology presents 18 photocopiable books covering the areas of Sense and Control, Anthropometrics, Food and Textile Technology and Green Issues, as well as appropriate Core Skills for the 14-19 age range.

Details of both these resources are available from

The Association for Science Education
College Lane
Hatfield
Herts
AL10 9AA
United Kingdom

SATIS 8-14

The material for 8-14 year-olds has potential for wider use. SATIS 8-14 has over 150 units of pupil material; like all the other SATIS projects, it is teacher-written, expert-endorsed, and low cost. Its range is exciting and stimulating; and while some of the topics are specific to Britain, others reflect the general interests of young people in any country—and the common view of the primary school curriculum.

SATIS 8-14 has Health Education units, for example, on subjects like:

Are you average?—what does it mean to be of average size?
Left or right-handed?—why are around ten per cent of us left-handed?
Standing on two feet—how do we keep our balance?
Cholera—a matter of life and death—the connection between cholera and clean water.
Brace up! — the western enthusiasm for bracing children's teeth.
Fit for something — the definition of fitness, and attacks stereotypes.
Going for a swim — the precautions we take when using a swimming pool.
No smoking, please — tackles this problem in a way that doesn't preach or criticise.
Zoo on you — the real truths about parasites and infestation.
Using energy in the home — an audit of fuel use.
Renewable energy.

In addition, there are units for older pupils on

HIV — misconceptions about AIDS.
Making the water flow — the work of WaterAid with African villages.
Free soap — the causes of a fictitious pollution problem in Zimbabwe.

How well does material like this travel? It can't be denied that some of SATIS 8-14 is specific to the United Kingdom in its context — not every country will be interested in traffic cones or electricity pylons, for example — but for children between the ages of 8 and 14, much of the SATIS material is intended for teacher support — for stimulus, inspiration, and good ideas. This makes SATIS 8-14 a valuable resource for any teacher of science, extending and refreshing their personal knowledge and understanding. It's other great strength is in its range of teaching strategies — which would make it a valuable resource for teacher-trainers, too. There are over fifty different teaching approaches in each box — ranging from true/false quizzes to carefully-structured role-play. SATIS 8-14 units have translated into Polish, Slovak and Japanese; they are currently being translated into Swedish, and adapted for use in Australia.

SATIS 8-14 is also available from the Association for Science Education at the address given above. It can be bought in North America from NSTA at 1840 Wilson Blvd, Arlington, VA 22201-3000, USA. There are three boxes — all low-cost, each with over fifty units of material and additional resources. Box 1 — the Green Box — is for pupils from age 7 upwards to around 10; Box 2 — the Yellow box — is for pupils from 9 to about 12; and Box 3 — the Blue Box — is for 11-14 year-olds and higher.

The Yellow box can also be bought as five theme books — Health, Environment, Technology, Materials and Transport.

New materials this year will resource teachers of the younger age ranges 3-6, and 6-8.

A recent review described SATIS 8-14 as 'inspirational' and 'motivating.' It concluded of SATIS 8-14 'Buy it — the price is right — and share it around for excellent value.' Why not look for yourself?

THE STARTER EXPERIMENT APPROACH (SEA) TO TEACHING CHEMISTRY AND PHYSICS IN THE PHILIPPINES AND INDONESIA AND THE REST OF THE WORLD

Jürgen Schönhere (creator)
Karlstrasse 22
D-64665 Alsbach, Germany

Ed van den Berg (scribe)
USC
Talamban Campus
Cebu City, Philippines

Preface (Ed van den Berg)

What do you do in a country where experiments are rarely used in Physics and Chemistry and where science is taught mainly verbally and frequently without textbooks but with an overcrowded curriculum, to classes of 45-65 students, where equipment is lacking, where students have never experienced the thrill of investigation and discovery and where many or even most teachers were trained in a discipline other than the one they are assigned to teach? How can you then involve teachers and students in experiments and how can you train the teachers? This time we present the answers of Dr. Jürgen Schönhere, a German consultant who spent more than a decade in in-service training in S. E. Asia. He asked me to draft an article based on a video tape of the method and his writings, and then saw the final draft, reacted, and approved.

The description provided below is particularly apt for the schools in South East Asia. However, both old and recent research data (Tamir & Lunetta, 1981; Germann et al., 1996) suggest that students are rarely made to go through the phase of conceptualization and design of experiments. Most experimentation is limited to measuring and some standard analysis following recipes. Here is a method which emphasizes design in a very systematic and manageable (for the teacher) and open (for the student) way.

The experiments are surprisingly simple and yet provide many opportunities for generating hypotheses which can be tested experimentally with very simple equipment (thus can be done in SE Asian classrooms). An example experiment is reported below.

Starter Experiments

In most countries overcrowded syllabi dictate what teachers do in the classroom. There is little or no room for experiments and what is taught and tested is mainly ‘content’ and little or nothing about the methods of inquiry. As we cannot easily change curricula, let’s do something which can be done within any curriculum. The basic idea is to start a new topic or chapter with a set of experiments, and perhaps not more than 3-6 times a year, but do it well. The other lessons on the chapter can just be taught whichever way the teacher is used to. A bird’s-eye view of the method is as follows:

Step 1: Students observe a demonstration experiment (here called starter experiment) and write observations individually.

Step 2: Observations are collected by the teacher and clarified by the students.

Step 3: The experiment is repeated to make observations more complete and to verify them.

Step 4: Students write ‘attempted explanations’ individually.
Step 5: Groups of students design verification/falsification experiments.
Step 6: Groups of students execute the experiments.
Step 7: Groups of students demonstrate their experiments to each other and report results.
Step 8: Students try to write conclusions with regard to the relationships between concepts involved.
Step 9: Students document the lesson in their notebooks and teachers make sure this is done properly.

The first lesson on a new topic starts with a demonstration experiment where all students observe. The reader may wish to read the description of the starter experiment which accompanies this paper.

Step 1: Observation. Each lesson following the Starter Experiment Approach (SEA) has to 'start' from looking at nature. The teacher must bring a bit of nature in to the classroom. This bit of nature is an experiment, easiest conducted by the teacher as a demonstration experiment. Sometimes it can be done as a student experiment, but that will require more preparation time of the teacher.

The materials used for the Starter Experiment should be taken—if possible—from the environment of the students. Special science equipment will be used later in the course of the lesson when students conduct their verification/falsification experiments. The experimental set-up should be simple and clear. The teacher must see to it that each student can make detailed observations, big classes will be grouped by the teacher and the groups will take turns for observation.

I want to discourage the very common, but useless naming of parts of the experiment (common in Asia). Instead students will learn to describe things they have not seen before in their own words. The name of the part will be given later by a student or the teacher when it has already been described by the student. This way we help students to improve their communication skills.

Students individually write all kinds of observations. Of course some of the observations are false and some are poorly worded. The teacher does not speak during this phase. When he or she feels that the students are missing out on something important, the teacher can demonstratively go near the experiment and do this observation. Students will quickly learn to understand our body language.

Since observations are the basis of all learning, the teacher must take utmost care that all students take part in this activity. There are a number of useful methods to achieve this:

1. The Starter Experiment should not contain unnecessary items.
2. The experimental set-up should be simple and preferably composed of materials and items taken from the students’ environment.
3. Students must have close access to the experiment for using as many senses for their observation as possible. The teacher must warn the students in cases where tasting, smelling, or touching is dangerous!
4. If the class is too big to allow all students close observation (classes in the Philippines can be 60 students or more) the teacher should group the class and let them take turns for observing the experiment (or use more than one set-up).
5. If necessary, the teacher must repeat the experiment to allow all students to observe properly.
6. Students should be advised to write all their observations down, preferably each observation on a separate piece of scratch paper. It is a good idea to let the students number their observations.
7. Students must not talk during the observation phase nor copy each others observations (somehow this is more easy to control in Asia’s big classes than in European small classes).

After all students have finished writing down their observations, the teacher starts to collect them. Again all students can take part in this activity if the teacher observes the following procedure:

1. One student is asked to read the first observation from her/his scratch paper.
2. The teacher takes this observation and asks who has noted the same thing, even using another formulation and collects them without reading them again.
3. One representative of the first observation is displayed on the board, either by writing it, or—to save time—by sticking students’ scratch papers on the board.
4. In the same manner, all the other observations are collected and for each new observation, one representative is displayed on the board, organized under each other in one column.
5. The teacher must watch out not to accept attempted explanations as observations. During the first few times the SEA is used, students usually have difficulties to understand the difference between an observation and an explanation.
Steps 2 and 3: After some discussion of the observations, the demonstration experiment is repeated to verify selected observations. Improvements of formulations should be made here if necessary, wrong observations are taken out or replaced by correct ones, missing observations are added. Students should now be given some time to sketch the experiment and note the observations into their notebooks. In the meantime the teacher selects those observations which are related to the concept and marks them by giving them big numbers. (In order not to discourage the students, the teacher must stress that observations not being selected are not bad or rejected, but that not all observations can be taken up at the same time and that some observations need not be explained since they are evident or trivial.)

Step 4: In this phase of the lesson again the students are working individually. For each of the selected observations they try to explain why these phenomena happen or can be observed. The students are asked to use separate pieces of paper for each attempted explanation. The teacher should stress at this point that it is not important that the attempted explanation of a student is ‘correct,’ but that it is important that each student must try to explain the phenomena with her/his own words and by her/his own ideas. Again the teacher must discourage the students to discuss their ideas or copy from each other.

Thus, the teacher has the opportunity to get to know students’ pre-concepts (a rare opportunity in lessons following traditional methods). This knowledge is important to actually confront the pre-concepts of the students with the more scientifically acceptable concepts at later stages of the lesson. Piaget nicely explained that the learner must feel a need to give up the pre-concept in order to replace it by a better one (restructuring).

Step 5: Verification/falsification. Students are grouped and each group is given one observation with the corresponding attempted explanations. Their job is to find out experimentally which of the hypotheses (attempted explanations) is correct, which one is wrong. As long as students are not familiar with SEA, the teacher is in high demand, helping students first of all understand the task, meaning analyzing the hypothesis and determining the parameter to be controlled (changed) and the other parameters to be kept constant (not changed). Inputs regarding equipment and procedure are also much needed in the beginning.

If possible the groups should not exceed five students, groups of three members are optimal. In case there are not enough observations, the attempted explanation for one or more observations can be split and given to two groups for verification/falsification. It is also possible to have two groups working parallel on one and the same set of attempted explanations.

I often observe that teachers have prepared verification/falsification experiments in advance, even sheets with the cookbook style procedure for the experiments were given to the groups. Though it is strongly suggested that teachers should try to anticipate the lesson they are planning, I would like to discourage the habit of ‘thinking for the students.’ Giving the students a ready made verification experiment plus the ‘User’s Manual’ is depriving them of a very important step of the SEA, the design of a veri/falsi experiment on the analysis of the attempted explanations. This very task is boosting students’ creativity, it cannot be skipped!

Step 6: Experiments are carried out. After the design and procedure for the ‘veri/falsi’ experiment have been approved by the teacher, the students collect the necessary equipment and start setting up the experiment. If sensitive equipment is involved, the teacher should require students to have their set-up inspected before starting the experiment. The teacher should always mention necessary precaution measures and give hints on how to conduct the experiment and how best to collect the data.

After conducting the experiment, the students have to write a summary on a big sheet of paper to prepare for the report to the class about their experiment and findings. The experimental set-ups will only be dismantled after the groups have given their reports.

Step 7: When all groups have finished their work, the teacher will ask all students to gather around the table of the first group. The group members will explain what they have done, starting with the original observation and ending with the findings of their veri/falsi experiment. The class then will have to interpret the results and decide whether the attempted explanations are correct or false.

The activity will be repeated until all groups have reported and all hypotheses have been assessed.

Step 8: Formulation of the concept. The teacher will ask the students to try writing draft formulations and conclusions for the concept(s) individually. For students still unfamiliar with the SEA it is helpful to collect some key-words first, noting them on the board. The students should be allowed to use their mother tongue if they have difficulties to translate their ideas into the official medium of instruction. The translation
can be done later and will serve the students as an additional language training!

For the final formulation of the concept, students and teacher will work together. It will be written in a prominent way on the board. Concept mapping might be appropriate at this stage.

**Step 9:** Fixing the lesson in students’ notebooks. At an earlier stage, the students have already sketched the Starter Experiment and noted the observations. Now they will add the attempted explanations and the veri/ falsi experiments by copying them from the report sheets of the groups being displayed in the classroom and the final formulation of the concept.

The teacher should make the students understand that this work of documenting the proceedings of the lesson is important, because it constitutes a reference for them for the future. Students who do a good job at keeping good lesson records should be singled out for praise. Please note that this is even extra important in classes where many students do not have textbooks.

Postscript (Ed van den Berg)

In the hands of good teachers, the SEA works very well in the classroom, even in the large classes in the Philippines and Indonesia. However, it does require sufficient time for training and it does require a certain minimal level of subject matter mastery. Without that teachers do not feel confident to use it. In a future article we hope to report more on teacher training methods. Schönherr has developed a certain training strategy he calls the “Model-Transfer-Strategy” which was developed over the years and has turned out to be effective in developing countries.

**Endnotes**

1. The Starter Experiment Approach and the accompanying teacher training strategy were developed while the first author worked at the National Science Teaching Instrumentation Center (NSTIC), Suldon, Lahug, Cebu City, Philippines. NSTIC is a joint effort of the Philippine and German governments.

**References**

**Figure 1**

**Beaker A:** Water with ice cube  
**Beaker B:** Oil with ice cube
Lesson 1: The Starter Experiment

The teacher simultaneously places an ice cube of similar size into each of the 2 beakers, one containing water and the other containing an equal volume of cooking oil (Figure 1). Please do not explain the set-up like “This is a beaker, it is filled with water, that is an ice cube.” All these are part of your students’ observations!

A list of possible observations could be as follows:

<table>
<thead>
<tr>
<th>Beaker A</th>
<th>Beaker B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Liquid is colorless, odorless and tasteless.</td>
<td>1. Liquid is greasy, yellowish and smells fragrant.</td>
</tr>
<tr>
<td>2. The level of the liquid rises when ice is placed in it.</td>
<td>2. Same observation as in beaker A.</td>
</tr>
<tr>
<td>3. Ice floats in the liquid.</td>
<td>3. Ice sinks in the liquid.</td>
</tr>
<tr>
<td>4. Bubbles generate from ice and while increasing in size move rapidly upward to the surface.</td>
<td>4. Tiny bubbles from somewhere near the surface fall very slowly towards the ice.</td>
</tr>
<tr>
<td>5. The container feels cold.</td>
<td>5. Fine white particles accumulate or hold on to the exposed surface areas of the ice, forming a cotton like appearance.</td>
</tr>
<tr>
<td>6. Moisture appears on the outside surface of the container.</td>
<td>6. The outside surface of the container remains dry.</td>
</tr>
<tr>
<td>7. Ice completely melts within 3 minutes.</td>
<td>7. The bottom of the container feels colder than its upper portion.</td>
</tr>
<tr>
<td>8. A single-phased liquid is observed.</td>
<td>8. Bubbles generate from ice, one at a time and move towards the surface.</td>
</tr>
<tr>
<td></td>
<td>9. Ice gradually melts while solid particles of oil disperse and melt into the liquid.</td>
</tr>
<tr>
<td></td>
<td>10. Ice completely melts within 3 hours.</td>
</tr>
<tr>
<td></td>
<td>11. Two layers of liquid are formed, oil on top of water.</td>
</tr>
</tbody>
</table>

These are the essential observations. Students may observe other phenomena like reflections or movement of the liquid. That is fine and they should be encouraged to observe whatever there is to observe.

Actually, after the repetition of the experiment and the observations, students could sketch and describe the experiment in their notebooks and copy the observations. Then the formulation of attempted explanations could be done as home work.

Lesson 2

Discuss first the different explanations the students come up with from their homework. Group the student explanations with the observations they are trying to explain. Do not comment on the correctness of the explanation.

There will be possible explanations with regard to the following questions:

a) Why do the levels of the liquids in both beakers rise when ice is placed?
b) Why does ice float in liquid A and sink in liquid B?
c) What causes the formation of bubbles when ice is placed in liquid A?
d) Why do bubbles rise faster in liquid A than in liquid B?
e) Why is the outside surface of beaker A colder than the outside surface of beaker B?
f) Why does ice melt faster in liquid A than in liquid B?
g) Why does moisture appear on the outside surface of beaker A but not on beaker B?
h) Why does a white cotton-like substance form around the ice in beaker B?

For example, question e) might be related to g) and could be explained by:

e1: In beaker A ice readily absorbs heat from the liquid and its container whereas in beaker B absorption of heat is obstructed by the presence of the cotton like substance around the ice; and/or
e2: The liquid in beaker B may be a poor conductor of heat;
g1: Water vapor in the air condenses rapidly on the outside surface of beaker A forming moisture because of the very low temperature of the container.
Student explanations are grouped according to similarities. Groups of students are assigned to design verification experiments for the different explanations. This could be continued as homework.

Lesson 3

Groups present the designs for the verification experiment. Then equipment is distributed. Students then carry out their experiments. To investigate explanations e1, e2, and g1 students could:

1. Take the initial temperatures of water and of oil.
2. Repeat the starter experiment.
3. Take 10 temperature readings in both containers at intervals of 10 seconds.
4. Compare the temperature readings near the ice and near the glass in both containers.

Similarly students would have alternative explanations for the other questions (a-h listed above) and procedures could be designed for verification/falsification experiments. For example, question h) might elicit an explanation involving the freezing of oil around the ice. One could investigate this further by dipping a test tube with oil in an ice bath and observing whether a similar cotton like substance forms. Then students could prepare for reporting their results in a presentation to the class.

Lesson 4

Different groups report to the class and then time is spent on concept formulation (for example, formulating propositions which involve the basic concepts). Finally in the lesson or in homework students write an individual summary of the steps carried out during the last four sessions.

British Council International Seminar
( Number 9679)
Technology education in the core curriculum
12 to 19 March 1997
London
Directed by Professor Paul Black and Mr Justin Dillon
The seminar will explore different rationale for technology education in the school curriculum, and the traditions from which they arise in different countries.
Main themes will include :
• a comparison of technology curricula in different countries
• the purpose of technology as a school subject, eg technology and environment, technology and society
• classroom implementation and curriculum material
The programme will be of particular interest to those responsible for curriculum development and teacher training.
Fee: £1,750 (residential)
For further information contact: Promotions Manager,
International Seminars Department, The British Council,
1 Beaumont Place, Oxford OX1 2PJ.
Telephone: +44(0) 1865 311636. Fax: +44(0) 1865 557368/516590.
E-mail: international.seminars@britcoun.org
(Programe details are subject to amendment. For a full prospectus please contact Promotions Manager, quoting the seminar number in all correspondence.)

The British Council
The British Council, registered in England as a charity no. 209131, is Britain's international network for education, culture and technology
Physics Infomall is an impressive library for physics education on a CD-ROM. The “library” originated from a project to assist the many unqualified physics teachers (over 30%) in American high schools. Many of these teachers are working as the sole physics teacher in their rural schools, there are no qualified colleagues who can assist or answer questions or supply ideas. So the idea was to prepare a large library of ideas for them culled from books and journals in physics education. The National Science Foundation funded the idea. A team under the guidance of Bob Fuller of the University of Nebraska and Dean Zollman of Kansas State University went to work and so Physics Infomall was born.

As most of the references are taken from journal articles which have been written for an audience of qualified/trained physics teachers (BS level and beyond), Infomall has much more information to offer to the qualified physics teacher than to the unqualified one. The latter will often run into texts which are just beyond his/her level. Infomall is certainly not a solution for the many unqualified and underqualified physics teachers in S.E. Asia who will need a lot of physics training to be able to benefit from Infomall, let alone in those countries where English is not used much. A listing of which information sources in Infomall to use and which ones to avoid might solve the problem for the mildly underqualified physics teachers (e.g., avoid the American Journal of Physics references if you do not have the equivalent of a BS Physics).

System requirements

Physics Infomall is available for both DOS-Windows and Macintosh. The minimum system requirements are: any IBM-PC compatible computer which has at least 2MB of RAM, Windows 3.1 or higher, 2MB of free space on the hard drive, and a CD-ROM drive. Recommended is an 80386 or higher with a minimum of 4 MB of RAM and a hard drive with at least 4 MB of free disk space. We ourselves tried out the Windows version on a 100 MHZ Pentium with Windows 95, an 850 MB hard disk, 16 MB of system memory.

The Contents of the CD-ROM

The CD-ROM was very easy to install (the trial version had been more difficult) under Windows 95. When entering the program one arrives in shopping mall where one can choose to enter stores like:

b. The Book Basement with 11 books such as the well known How Things Work by Richard Crane who regularly writes articles explaining the physics of every day apparatus such as the fluorescent lamp or the photocopier, Teaching Physics: A Guide for the Non-Specialist by Osborne and Freeman, a very useful book written particularly for non specialist physics teachers in UK, Biography of Physics by well known joker and Nobel price winner George Gamov, and the thoughtful Guide to Introductory Physics Teaching by Arons.

c. A Calendar Cart of events in physics history, nice to edit yourself and print a monthly calendar for display in the classroom.

d. A Catalog Collection with catalogs of three major equipment suppliers.

e. A Utility Closet with various useful things such as a list of constant, the periodic table and various other materials.

f. Demo & Lab shops with several well known laboratory books such as the Demonstration Handbook for Physics by Freier & Anderson and The Castle Project for teaching about electric circuits of Steinberg et al.
g. *Pamphlet Parlor* with various small booklets such as products of the AAPT Physics and Technology Modules (The Bicycle, The Camera), the AAPT Guidelines for Teaching High School Physics, etc.

h. *Problems Space* with various sources for problems.

i. *Study Guide Store* with study and teacher’s guides.

j. *Teachers Treasures* with contributions from various teachers including demonstrations, activities, and quizzes.

k. *Textbook Trove* with nineteen textbooks including *Physics for the Inquiring Mind* a classic innovation of the 1960s by Eric Rogers, one of the men behind the big curriculum projects of the 1960s.

l. A list of physics specialists and teachers who are willing to answer questions from Infomall users. This feature was typically incorporated considering the American target audience of under-qualified, lone physics teachers in rural high schools.

m. There are tables of contents of some popular textbooks which are in print and popular (e.g., Hewitt’s Conceptual Physics) for which no permission could be secured for inclusion on the CD-ROM.

The Search Engine

The search system is easy to use. Specify one of the sub-categories (a-m above). Type key words like *refraction or super-conduction, or computer assisted instruction* and the computer tells you how many references it found. One can then specify additional keywords to narrow down the search, or one can start browsing. Obviously not every word works, there is a list of keywords for the search system. We tried to look for references on safety and electrical installation and did not find any. It turned out that the AAPT2 data base (see below) did not give any references either. So good chance the AAPT journals which constitute an important resource for the CD-ROM never contained an article about the subject. However, most other words we tried generated lots of “hits” and interesting readings.

Price and ordering

The price is US$ 295—and having it delivered Federal Express cost us another US$51—but did save us all the trouble of import and import tax, etc. In many countries having the CD mailed as a book in an envelope would be cheap and also save customs trouble. The price is high, but the price of all the articles and books contained on the CD is obviously a multiple of this amount and, actually, quite a few books are not easy to get or perhaps not in print anymore. A first inquiry about a special price for Asia did not produce a sensible answer. However, when we contacted the supplier again recently, he seemed to be willing to offer a special price if there would be a market. A collective order might bring the price down quite a bit. Infomall is now marketed and sold by:

*The Learning Team, 84 Business Park Drive, Armonk, NY 10504*  
Fax: 914-273-2227 Telephone: 914-273-2226

A CD-ROM in the age of Internet?

One might wonder what to do with a CD-ROM. Much information is available from Internet nowadays, are not CD ROMS like this already outdated? Well, we are not so sure what is available on the Internet as we have only a 64 kB link from our university while our modem is only 14.4 kB. We are far from the superhighway and small access roads are choked. Many other physics lecturers are farther yet from Internet than ourselves. Another argument is that the team producing the CD ROM has made a useful selection while at the Internet one would have to do a lot of looking around.

Another alternative for searching for information on physics education is the data base for the *American Journal of Physics* and *The Physics Teacher*. The data base is available from the American Association of Physics Teachers (AAPT) for US$32. But this data base will only provide references to articles and not the articles themselves. This data base is useful if one has the two journals in the library, but not if one only has recent issues or no subscriptions to the two journals at all. The AAPT data base requires about 12 MB of hard disk space and comes in three diskettes.

Development and production

The developers had a tremendous job contacting all the individual authors of the thousands of articles on the disk. I myself received a special form for a one page article my wife and I published years ago. One can imagine the problems in getting all these forms back and in negotiating permission from authors and publishers for reproduction of complete books. Then there was the job of getting the texts on disk. Scanning turned out to be too unreliable. So typists in the Dominican Republic and in the Philippines typed in all the text. Each article was typed twice (different typists...
and different countries) and then a computer program checked the discrepancies and that way typing errors were discovered and corrected easily. The obvious assumption was that two typists are not likely to make the same error. Presumably spelling checkers were used as well.

**Original books and journals and the CD-ROM version**

This production process with all the re-typing means that the book and journal pages on the screen do not look like the ones in the originals. The screen contains the same text, but not in the same pleasant layout as in the book. Furthermore, figures are separated from the text although easily available with a click of the mouse. Figures are also at a much lower resolution than in the original articles, otherwise they would not fit on such a comprehensive CD-ROM. All of us would probably prefer to read from the original book or journal rather than from a computer monitor. However, if one does not have the original books and journals, or cannot get out-of-print classics contained on the disk, the CD ROM is a nice and cheap alternative. And, of course, the primary reason for publishing on CD-ROM rather than on paper is not as an alternative for reading books and journal articles, but for making searches possible and finding answers very quickly.

**Other possibilities and comments**

One can also copy and paste. For example, when one is making a problem worksheet, one can look for problems and copy and paste them into the worksheet. Or when writing laboratory instructions, one can copy and paste from the laboratory and demonstration manuals. When writing a hand-out about solar radiation recently, we copied a description of the electro-magnetic spectrum from one of the textbooks contained in the "textbook trove." Unfortunately superscripts and subscripts get copied as regular text, so one does have to screen copied text carefully to restore special symbols. We also tried to copy figures, but still had some trouble. Figures can be rotated over various angles, they can be enlarged or reduced to different sizes, but we had some trouble copying them and did not succeed in printing. That problem is probably our own problem rather than Infomall’s. We will just have to try again and learn more about processing of graphic information.

All the books listed in the appendix can be accessed and basic program operations seem to work properly. However, there are some special features which do not yet function but there is a proper message so one does not get stuck.

There are also graphics where one gets a message that the graphics have not been included, either because it would take too many bytes of storage, or because no permission was granted to include the graphics. The pictures from the book Crystals and Crystal Growing did not come to the screen for that reason. Quite understandable, beautiful photographs of grown crystals would take too much storage. Disappointing of course.

**The User’s Guide**

There is not much we can tell you about the user’s guide as the CD-ROM is friendly enough, so one does not really need the User’s Guide. We only used the installation instructions and for the rest just ran the program from the screen. Only now when writing this paper we started looking in the User’s Guide.

**Summary**

**Advantages:**
- A large and useful library is now available on a small disk for a reasonable price.
- The search system can find answers to questions in seconds and link many references.
- The disk is portable and can be brought anywhere on travel for workshops etc.—a pleasant alternative to bringing a suitcase with books.
- Parts of texts can be easily worked into one’s own laboratory worksheets or other lesson materials (of course mentioning the original source and giving credit to original authors).

**Disadvantages:**
- The price . . . expensive for Asia, but a discount can be negotiated when people order collectively.
- Reading from paper is more pleasant than reading a computer screen.
- The resolution of figures and photographs is poor.
- In copied text super- and subscripts show as normal text and need to be restored manually.
- Basic features work well, a few special features do not function yet but there is a proper warning.
- The collection of test questions is too limited.
- There are a few little errors, but not disturbing.

On balance, Physics Infomall constitutes a beautiful and useful resource for every University Physics Department and Library and for high school
teachers with a good physics background. We are happy with our purchase of Physics Infomall.

Endnotes

1. Ed van den Berg and Nelson Rosaroso are connected with the Science Teacher Education Project Southern Philippines (STEPS), which is a joint effort of the Vrije Universiteit in Amsterdam (Netherlands) and the University of San Carlos (Philippines) and the Netherlands government.

June 21-24, 1997
International History, Philosophy and Science Teaching Group
North and South America Regional Conference
Calgary, Canada

A regional conference of the International History, Philosophy and Science Teaching Group will be held in June 21-24, 1997 at the University of Calgary, Calgary, Canada. The Dean of the Faculty of Education, Professor Ian Winchester, will be the conference chair. Although a regional conference, all members of the International Group, and others, are welcome to attend. Calgary is situated at the foot of the Canadian Rockies, near to the mountain resort of Banff. The conference programme will include an optional visit to the Rockies.

International and national groups that have interests in the role of HPS in science, mathematics and history teaching are encouraged to use the conference as an occasion to present their work and to consolidate networks.

Proposals for contributed papers, workshops, discussion groups, and exhibits of curricular and instructional materials related to the purposes of the conference are now being accepted. Four copies of the proposal or paper should be sent to Ms. Linda Lenz at the address below. The proposals should include:

1. A cover page with paper title, authors name(s), institutional affiliation, address, telephone numbers, FAX number, and e-mail address.
2. A 100-150 word abstract of each proposed paper or session.
3. Three self-addressed envelopes.

Due date for receipt of papers and other proposals is February 15, 1997.

Format:
Papers should follow the format, style and referencing conventions used in the group's journal Science & Education. Please pay particular attention to form of title, authors name and address, an Abstract of 100-150 words, referencing conventions. Disc submission is necessary. WordPerfect or Microsoft Word for PC or Mac platforms is preferred, but ASCII is acceptable.

Final papers should not exceed 5,000 words. They must be submitted by February 15, 1997. Early submission of proposals and final papers is encouraged in order to facilitate programming and production of Conference Proceedings.

Journal Participation:
It is anticipated that some scholarly journals Interchange and/or Science & Education will publish special issues related to the conference. To be considered for these issues, papers need to be forwarded by October 31, 1996.

Proposals and papers should be sent to, and registration information can be obtained from:

January 23-26, 1997
Fifth Annual Meeting of the Southern African Association For Research In Mathematics and Science Education
University of the Witwatersrand, Johannesburg, South Africa

The Local Organizing Committee, on behalf of the Southern African Association for Research in Mathematics and Science Education, cordially invites all science and mathematics educators interested in research in these fields to join us at the FIFTH ANNUAL MEETING of SAARMSE.

The meeting will be held on the West Campus of the University of the Witwatersrand, Johannesburg. Accommodation will be provided in Barnato Hall, the new university residences which is just a short walk from the conference venue, the New Commerce Building.

Aims of the Conference:
1. To foster a sense of community cooperation amongst researchers involved in mathematics and science education in Southern Africa.
2. To provide a forum for debate and discussion on research methods and research findings.
3. To assist in the development of research skills of new researchers entering this field of research, and to develop further expertise in those already involved, by means of capacity-building workshops, discussion and debate.
4. To make research available and accessible to researchers, educators, curriculum designers, and policy-makers.
5. To provide an opportunity for liaison between stakeholders interested in science and mathematics education.

Capacity-Building Strategies
We are making a special effort this year to help inexperienced researchers to develop their research and presentation skills.

Science Globalizes: Search for Global Goals of Science Education
International Conference on Science Education,
Seoul, Korea,

The conference, organised by KEDI (Korean Educational Development Institute) and co-sponsored by ICASE and UNESCO, has as its theme 'Common Problems/Questions in Science Education Around the
World: Moving Toward Worldwide Science Education Standards.’

The conference will focus on discussion and debate concerning the following six themes using current research and common practices.

1. Defining appropriate science for all: What is meant by appropriate science for all?
2. Learning: how do humans learn science?
3. Teaching strategies: What form of teaching is required for science?
4. Assessing learning: How can we determine that learning has actually occurred?
5. Needed resources: What materials will promote systemic reform?
6. Building partnerships: Who are the needed allies in solving the problems?

The Symposium will be held in Lublin, a town situated about 170 kilometers south-east of Warsaw. It is easily reached by train or bus (travel time: 2 and half hours). Lublin is considered one of the oldest settlement sites in Poland. It is a large industrial and commercial centre, as well as scholarly, cultural and a tourist one.

The Symposium language is English, however, the organizers will provide some help (interpretation into Polish and Russian) for the participants from the East European countries.

Registration fee: 30 USD (IOSTE members 20 USD)
The organizers will do their best to make the participation costs (accommodation and meals) of the Symposium as small as possible.

June 21-24, 1997
International History, Philosophy and Science Teaching Group
North and South America Regional Conference
Calgary, Canada

June 2-5, 1997
Second IOSTE Symposium for Central and East European Countries Science and Technology Education For Social And Economic Development
Lublin, Poland

The problems discussed during the Symposium will include:

• Development of knowledge in science and technology indispensable at the turn of the millenia.
• Changes taking place in a way of thinking of dents being affected by science and technology education.
• Prospects and citations of integration in science and technology education. Studies in development of cognitive abilities in science and technology education.
• Common research problems in physics, chemistry and biology education.
• Regional cooperation in the field of science and technology education.

A regional conference of the International History, Philosophy and Science Teaching Group will be held in June 21-24, 1997 at the University of Calgary, Calgary, Canada. The Dean of the Faculty of Education, Professor Ian Winchester, will be the conference chair. Although a regional conference, all members of the International Group, and others, are welcome to attend.

Calgary is situated at the foot of the Canadian Rockies, near to the mountain resort of Banff. The conference programme will include an optional visit to the Rockies.

International and national groups that have interests in the role of HPS in science, mathematics and history teaching are encouraged to use the conference as an occasion to present their work and to consolidate networks.

Proposals for contributed papers, workshops, discussion groups, and exhibits of curricular and instructional materials related to the purposes of the conference are now being accepted. Four copies of the

Science Down Under--Extending the Boundaries. Our aim is to provide science teachers with up-to-date cutting edge information on the thinking of Australian scientists and near neighbours. The programme will also highlight practice and theory suitable for all levels of science education. It is our intention to extend the boundaries of knowledge.

October 1-5, 1997
8th International Conference of ISATT (the International Study Association on Teacher Thinking)
Kiel, Germany

The Conference theme is “Teachers’ Work and Professional Development.” The work of teachers is changing due to systemwide policies, global economic and technical trends, equity issues and changes in the nature of school subjects. These trends place teachers in new roles. How do teachers respond? In times of change it is important to consider the implications for the individual, social and cultural development of the teaching profession. What now constitutes, “professional” development? What is the impact of research and curriculum development?

Registration fee will be 400 DM for nonmembers and 350 DM for ISATT members or students.

Information about the forthcoming conference are provided on the Internet:
http://www.ipn.uni-kiel.de/isatt

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides means for associations, institutions, centres, foundations, companies and individuals concerned with science education to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Educational Research in Chemistry and Physics Education

The 5th international symposium on science education research was organized in the University of Dortmund by Prof. Hans-Jurgen Schmidt in May 1996.

This series of symposia has become well known among science educators and researchers, as offering an insight into the relationship between research and teaching. ICASE has been involved with all the symposia having published the proceedings each time for wider dissemination among ICASE members and more widely.

The programme for this symposium included papers from researchers from many countries, within and outside Europe, including two significant papers from Taiwan and one from Mozambique. The proceedings will be available early in 1997 from ICASE; details will appear in this Journal.

This symposium is the last in the series to be held in Dortmund because the initiator and organiser, Hans-Jurgen Schmidt, will be retiring from his post in the University before the next symposium is due in 1998. ICASE has already recognised the contributions that Hans-Jurgen Schmidt has made to international science education by awarding him, in 1995, the ICASE Certificate for Excellence in International Science Education, and would like to pay special tribute to his work in Dortmund for this series of symposia. The next symposium will be held in Utrecht in 1998, and will be organized by Dr. Otto de Jong, a regular participant in the Dortmund symposia. Details of this next symposium will be available to all interested researchers and will be announced in the columns of the ICASE Journal in due course.

1999 Science Links Year

ICASE, in conjunction with the ASE in Britain, is planning a major scheme for linking schools throughout the world in the year 1999. The idea is that groups of science students from different cultures can work together on selected projects—sharing ideas and learning about each other as well as their science. Many schools already have links with schools in other countries. This scheme for 1999 is designed to build on this experience and to encourage other schools to establish links to develop science-related projects. There will be an opportunity for the best projects to be displayed at a special meeting in 1999, probably in London.

Details about the scheme, which will be coordinated by national science teachers' associations, may be obtained from the President-elect of ICASE or the ICASE Treasurer (see inside front cover for addresses), from the ASE in Britain (ASE, College Lane, Hatfield, AL10 9AA, UK) or from the appropriate national science teachers' association. More information will be published in the ICASE Journal later in the year.
The Need

The students for the new millennium must be an active problem solvers, prepared to function in a highly technological and computerized world. They will need to develop the skills and the literacy to make effective use of computers and electronic information network to learn about new scientific discoveries, and to problem solve around emerging concerns. It has become increasingly important that the students recognize and appreciate the interaction of science and technology and their cumulative effects on society, and to recognize and appreciate the importance of sustainable development. Students need to realize that technology and scientific research present problems and that we have the capacity to determine solutions.

Traditional methods of teaching science curriculum do not adequately prepare our students for the 21st century. Teaching science curriculum needs to be more than the presentation of laws, theories, science concepts and facts. A measure of a student’s success should not be based on more than her/his ability to regurgitate these facts. Students must become active rather than passive participants in their own education. They must be prepared to discuss issues that will affect their lives and to arrive at possible solutions to these issues. They must be willing to look at alternative solutions to issues and to decide which alternatives will be acceptable.

There are many STS, SD, and STL issues of concern in today’s society. Threats to our environment, our atmosphere, and our energy supply, are but a few areas of concern about which our students should be thinking. How to deal with the explosion of technological devices and processes is a challenge to all. Society is demanding that the scientists of the future have both ethics and a conscience. To develop this, our students should be encouraged to look carefully at this important interdependence of science-technology-society and to become both scientifically and technologically literate. This can be accomplished by having the students research issue topics, share their information and arrive at possible answers to these issues.

For students to become effective problem solvers, teachers need to provide them with a structure or framework that they can follow. This became evident during year 1 of the project. Although the topic was introduced and students were given ideas as to how the topic might be approached, they were not given a framework for independent problem solving to guide them. Their research was sound but the essays were mainly descriptions of the issues, with few answers being presented. I realized that to help students come to higher levels of analysis and synthesis some direction on how to develop acceptable alternatives and answers to the issues was needed. There are a few students in each group who do not require a framework. These creative individuals develop there own framework.

The Program

Issues and Answers: A Problem Solving Approach

To respond to this need, a team of teachers have been developing and evolving an ethical research program for senior high students at Miles Macdonell Collegiate in Winnipeg, Manitoba. The program is the result of coordinated efforts over the past six years between a science teacher, a teacher-librarian, and a computer technician. The chemistry teacher was responsible for discussing STS and the generation of topics for research and evaluation. The teacher-librarian instructed the students on research techniques, referencing, copyright, and writing strategies. The computer technician exposed the students to the different software programs that were available to them in the resource computer system and helped the students with files and their final publication. All three members were involved in developing a knowledge base of student files to be stored in the computer system.

We wanted a program that would provide a framework for student work and would enable the students to make choices and have options. With this...
kind of program flexibility, the student could choose to apply part of the program or opt for the total package. Several models for research and writing programs were critically analyzed. Amongst the most informative was the curriculum for study of bioethical issues by Iozzi (1982). This program developed in 1982 established the framework for our program. In 1992, we incorporated the work of Toews and McCrath (1990) and put the Issues and Answers program into a computer format. In one year, we went from pen and paper projects to a computer-based program. The result of our work was a program in the computer which students could work through individually to assist them with research, analysis, synthesis and solution formation. Students then went on to use technology as a tool for their final work and presentation.

Issues and Answers: A Problem Solving Approach

The following is a brief description of the major headings of the Issues and Answers program. Each topic is quite comprehensive with specific directions and questions to help the students with their research, analysis, synthesis and presentation.

Understanding the Issue. This introductory section is designed to help the student focus on the task at hand. Students fill in a questionnaire identifying the major "players" or stakeholders, the scope of the issue and possible alternative solutions to the issue. Throughout the gathering of information and the synthesis stages, the student refer back to this section and make any necessary adjustments. This provides a focus or the direction to the project.

Researching the Issue. There are many sources from which students can gather information, CD's, books, magazines, Day Media Files, Internet, videos, audio tapes, personal interviews. The objective is to find appropriate materials and to keep a record of the important facts for future use in presenting arguments and possible answers or solutions.

Creating files. One way to keep these records is to produce personal files of information. It is important that each text file be in the student's own words. These statements can then be used directly by the student in analysis, synthesis and final presentation of the project, with little or no change in text. Students are encouraged to keep an accurate account of where they obtained the information. This is needed for end notes, footnotes, and bibliography.

Analysis and synthesis of file information. A student creates an analysis sheet which contains the main headings from the research. Using the "copy" and "paste" functions on the computer, information is transferred from files to the analysis and synthesis sheets.

Determining important values. The analysis sheets may contain values or ethical categories which contain both positive and negative arguments. Students are encouraged not to state their own opinions but to gather the opposing opinions from their research. The students do not need answers for each of the categories listed in this section. They only use those sections which apply directly to their project.

Alternative actions. Students should look for alternative actions to their issues, rather than concentrating on one action. These actions might be some which are already in practice or they could be actions that the experts proposes for the future. Students may make choices as to which alternatives are realistic and possible to implement.

Presentation of Results

There are various ways that the student can present the project:

- a written essay
- essay format with pictures
- multimedia software such as Director, PowerPoint, HyperCard, HTML

The presentation method chosen will be determined by the categories and materials to be presented. For example, if the student has several pictures and the text is straightforward, use a simple processor presentation with text wrap function. If the topics are related and are best presented as separate topics, the student may choose to create a multi-media, interactive presentation.

The Project

Early in the semester, students are exposed to the Issues and Answers program and are given a list of possible research topics. Working in pairs, each group of students will select one issue for research. Students do have the option of proposing their own issue. Prior to starting their research, the students undergo a two period training session to prepare them to deal with information obtained by audio, visual, and electronic means. We have found that students are adequately trained to handle hardcopy but they are not as competent when the information comes from videos, television, audio tapes, CD's or Internet.
Files are an integral part of the project and a certain percentage of the final grade comes from the quality of the student's files. The files are retained in our own information base, InfoBase, in a central computer. These files are invaluable in assisting the next generation of students with their projects. The files provide the students with a base from which to start their research.

Students are requested to have approximately ten pages of single spaced text for their final presentation. This text can then be altered and placed into different software programs. At this time, the computer teacher may spend many hours after school, and even on weekends working with the students. The project is completely paperless.

Results

For the past six years I have been collecting and saving student project work to use as a baseline for evaluation, and as models for student use. Over the this period of time, there has been a steady improvement in the quality of research and presentation. We attribute this improvement to the incorporation of the problem solving framework and the integration of technology. Student projects have far exceeded our most ambitious expectations. The quality of work has been steadily improving with each new group of students. Each new class is presenting a more sophisticated project than their predecessors. Many of our graduates have returned to the school with positive comments about the project. They are neither frightened nor intimidated by projects assigned to them at universities or colleges. One student in particular was reluctant to participate in the project while at our school, and contemplated transferring to another chemistry class. He wrote the team a letter from his university thanking us for teaching him how to research and write papers. This English Second Language (ESL) student obtained a mark in his first university essay that was in the top 10% of the class.

Information Base (InfoBase)

An information base is created by using student files. A file may be an abstract, graph, chart, scanned picture, a computer generated picture, or digitized audio or video materials. Every file generated by the student is not automatically entered into the base. The file must have sufficient information and be constructed in an acceptable manner. Instructions are given as to the different methods of producing acceptable files. Each file must be run through the system spell checker to eliminate spelling errors.

The Miles Macdonell InfoBase contains over 2000 files covering over 60 topics in chemistry and biology. We also retain complete student projects in the InfoBase. This provides new students with examples that they can look at and follow. The project becomes less intimidating when they see what fellow students have accomplished.

At present, the base contains approximately 100 final presentations. Many of the presentations are multimedia, developed by using both IBM and Macintosh software packages. Students are asked for their permission to allow their work to remain in the InfoBase. They are informed that their projects cannot be distributed without their consent.

Project '97: Sustainable Development

The Issues and Answers program will provide the research and problem solving framework for a joint, three-school project on sustainable development. Students from Miles Macdonell Collegiate will become involved in sustainable development research with students from two rural schools, Steinbach Regional Secondary School and Neepawa Collegiate. A pilot project involving Miles Macdonell and Steinbach will occur during the 1997 spring semester. Students from Neepawa Collegiate will enter into the program in the 1997 fall semester.

The pilot project is both interdisciplinary and student interactive. This interdisciplinary project will involve students from Technical Writing 40S and Chemistry 40S classes. Students will be presented with nine sustainable development issues. Working in pairs, they will choose one topic for research. Students working on the same projects from three different classrooms will communicate using Internet, E-mail and conference calls. They will have access to the project teachers from both schools. Completed projects will be added to the InfoBase: Exemplary projects will also be added to the student work section of our School Home Page on Science.

The pilot project was launched with a sustainable development forum held at Miles Macdonell Collegiate, February 1997. During the morning session, students heard presentations from a panel which included a provincial cabinet minister, an environmentalist and a member of the business and industry community. Students had opportunities to pose questions to the panel. During the afternoon, the students interacted in a round table simulation on environmental issues. Students assumed roles of stake holders in the issue and were able to observe first hand the process of trying to
reach a consensus on a controversial issue. In addition, students from the two schools had an opportunity to meet informally with co-researchers. A meeting is planned for May, 1997 at Steinbach where the students will present their topics and have closure to the project.

The project is expected to expand to include 40S geography class form Neepawa, in the 1997 fall semester. The students at Neepawa are taught by ICASE Past-President, Robert (Bob) Lepischak. Students from three distinct regions on Manitoba will be linked by technology, and will share research experiences as they attempt to solve issues which may help ensure a sustainable world for tomorrow. The global village is fast becoming a reality.

Neither Issues and Answers: A Problem Solving Approach, nor Project '97 would be a reality without the collaborative effort of many people. The following educators have been involved or are presently involved in these endeavours:

Ernest Kuch  
Program developer, Project team leader at Miles Macdonell, Chemistry/Biology teacher, Winnipeg

Heather Panaschuk  
Program developer, Library Consultant, River East School Division, Winnipeg

Don Ewonchuk  
Program developer, computer technician, Miles Macdonell Collegiate

Bill Morrison  
Project Teacher, English Technical Writing, Miles Macdonell Collegiate

Brian Straub  
Project Teacher, Computer/Science teacher, Miles Macdonell Collegiate

Sid Greenstone  
Project Leader, Steinbach Regional Secondary School, Chemistry/Biology Teacher, Steinbach Mb.

Bob Lepischak  
Project Leader, Neepawa Collegiate, Neepawa, Mb. Geography/Science Teacher, Past President ICASE

PRIMARY SCIENCE IN FINLAND

Dr. Tuula Asunta
University of Jyväskylä
Jyväskylä, Finland

Introduction

At the moment there are going educational changes occurring at the moment in every level of the Finnish school system especially in the area of Science. These changes are concentrating on rearranging the curricula of the schools as well as changing the methodology of teaching, making Science courses more laboratory and field oriented, producing appropriate books and other teaching materials as well as in teacher training. After the Leikola committee in 1989 which stated several points including that our teaching and learning should be oriented to raise the level of our students internationally, Universities and schools started little by little to change their curricula.

This year our National Board of Education has started a program to improve the quality of mathematics and science teachers of different schools and school levels. The Board of Education has been chosen 25 communes to be so called PILOT-communes in this improving project and at the moment the inservice training of teachers includes 118 schools covering different types of schools (see diagram, Fig. 1) and at all school levels starting from nursery school. All schools in Finland are public (supported by state). Mathematics and Science teachers have also their own organizations or associations which are for teachers from primary schools up to University teachers. These associations that take care of the inservice training of their members by arranging meetings two three times per year and inservice training courses throughout the year all around Finland.

Schools and School Science

Nowadays most children in Finland have an opportunity to attend day nursery school nowadays. There is very little, if any, science instruction in the nursery schools. Many of these nursery schools arrange however so called pre-school for 6 year old children. Usually this type of pre-school lasts for 5 hours per day and includes learning different things—also some science activities in many pre-schools.
The formal primary school covers children from the age of 7 to 12. Science is taught in separated subjects, mainly until now as biology and geography with very little chemistry and physics.

From the ages of 12-15, children attend secondary school (compulsory education) and science is taught in separated subjects such as biology, chemistry, physics, etc. by science teachers, who have had University training for subject teachers and have usually specialized for two or three subjects as for example mathematics and physics, computer science and physics, chemistry and physics, etc. From the age of 15 to 18 years, children attend to high school and science is taught in separated subjects in an advanced level.

Each year children have to reach a certain level in their learning. That level is assessed by using either national tests or more usually the tests made by the teachers, who also decide for the next step. It is very seldom at the primary level that children is not moved up to the next class. The teacher must discuss with the parents if he/she thinks that some child is not capable enough to reach the requirements needed during next class. At secondary level and at high school there are some students every year who are not moved to the next level.

**Primary School**

In a primary school class, the average number of pupils is around 20 to 25. There are two types of primary schools:

1. Primary schools of four grades in two classrooms, where two first grades are in one classroom and grades three and four are in another classroom and fifth and sixth grades in separate classrooms.

2. Primary schools with all six grades in separate classrooms.

There are also some primary schools that only have four grades. Those are called “village schools” and they are usually quite small having from two to four pupils at different grades.

The assessment for primary school pupils is different in different schools:

1. Many schools use only an oral test in first five class and in sixth class a written grade mark from written exams in each of the subjects taught during the school year.

2. Some schools use a written grade in each class.

There are two main terms in a year. Pupils are tested in different ways during school terms. They must have certain ability of basic skills, such as reading, writing and calculating. If a teacher thinks that a pupil is not capable enough to be moved on to the next class in the spring she/he has to discuss with the parents before doing any decision. At the end of the terms parents will receive the record of achievement—either oral or written.

After 6 years schooling children will attend lower secondary school for three years and then they need to choose if they want to go to upper secondary school (called high school) or stay one more year (10th class) at the secondary school or go to vocational and after that attend vocational universities or polytechnic-schools. Vocational university and polytechnic schools are very new in Finland. This level was started three years ago so it is still “looking for its place.”

**The 1994 National Curriculum and Primary Science**

The National Board of Education publishes a guide book to the curriculum for schools. This guide includes the most essential contents of subjects that every school should teach (POPS, 1994). The guide was produced because all schools should teach approximately same basic knowledge to all pupils.

Until 1960 children had more science content in their primary curriculum, but after that for 20 years they had only biology and geography contents with minor exceptions which depended on the interests of the teachers. Now we have finally put science back to the primary curriculum but it will take many years until we get all the teachers trained to teach science contents including chemistry and physics. This belief is based on the fact that science we have not had these subjects included in our teachers training program, most of our primary teachers are not confident to teach other science content but biology and geography. However many primary schools have now integrated science four to six hours per week and they have reserved one hour for chemistry and physics.

We have several new textbooks in primary science that teachers can use, but all of them are still more or less biology oriented. That is why teachers who want to teach more science content, must make their own materials and worksheets mainly relying on the
secondary level textbooks or the material produced by different teachers organizations. The department of Teacher Education have this year included more science training in the program than there was a year before and the amount will be growing every year. Elementary student teachers have now first time in over ten years an opportunity to specialize in chemistry and physics, and no doubt some of them will use this opportunity. One teacher usually acquires expertise in one or two subjects.

For the first time for a long time student teachers will now study a subject called "science and community," that includes integrated chemistry, physics, biology, geography and mathematics.

Environmental education has an important part of students training program. It includes for example the following studies: Introduction to environmental education, Introduction to water pollution, Environmental education in school, Environmental education in practical teaching work, Environmental philosophy and ethics, Finland's water systems, Introduction to water pollution and so on. There are also several integrated courses as for example: Environmental studies and natural history and various integrated themes in primary and early education that students can take if they are interested. Specialization studies in environmental education include the following studies: Theory and methods of environmental education, Environmental philosophy and ethics (seminar), Foundations of environmental protection, Introduction to ecology, Environment and natural history, The constructed environment, Introduction to environmental protection technology, Legislation and administration of environmental protection and General seminars reviewing and synthesizing course contents.

Results on the New National Curriculum and Textbooks

As it seems to be in most countries also our primary teacher is responsible for many different subjects. Because science is now included in the curriculum it has caused some stress for a number of primary teachers. They must include some science in their teaching and that means they have to train themselves. New textbooks include programmed material for learning and teaching methods (student activities, learning targets, didactic actions, evaluation, etc.) although there is still lack of problem solving oriented books. Anyway it will take some while before all schools will have suitable equipment and laboratories for teaching science properly. Those teachers who feel themselves inadequately prepared to teach scientific contents will especially suffer.

Fortunately there are a great many primary teachers who have been teaching some scientific contents all the time and also many teachers who are very enthusiastic to learn and teach science. Our teachers have shown that as long as the teacher has creative imagination and wondering mind he/she will find the way to teach science without any specific equipment or room provision. At the primary level the most important thing is that the teacher allows pupils to wonder at different phenomena and let them think why certain events occur. The good teacher can say to pupils: "I do not know but we will find out."

THE "SUCCESS WITH SCIENCE" INSET PROJECT FOR
PRIMARY TEACHERS IN JAMAICA: A DISTANCE LEARNING
INITIATIVE TO PROMOTE SCIENTIFIC AND TECHNOLOGICAL LITERACY

Eric Parkinson
Canterbury Christ Church College, UK

and

Lena Swire-Walton, College of Agriculture
Science and Education, Jamaica

Much current institutionalised learning takes place in a closed and prescribed format and this occurs in classrooms through face-to-face delivery of courses. Typically classes are held on a regular basis at an agreed location. The pace of teaching and learning is largely defined by the progression of content within the course itself. The learners have to "keep up" with the sessions or risk falling behind and possibly, losing a place within a course.

This pattern however is changing.

Teaching and learning styles are evolving so that they place greater emphasis on accommodating the learning situation of the student. Some of these styles are referred to as "open" and "distance learning" (ODL), and they have certain similarities. They are all essentially quite similar in that some aspect of engagement within these learning patterns may not be conducted in a traditional face-to-face delivery mode, in a formal centre and within "normal" educational working hours.

The term "open learning" (Briggs et al., 1987) has been used to refer to a process which makes;

... learning openly available to learners no matter who they or where or when they wish to study ... while much open learning has used distance-teaching techniques it does not necessarily do so. Open learning can mean, for example, that a college stays open for longer hours, and makes learning materials available to students as well as providing classes and lectures (p. 9).

Distance education (Briggs et al., 1987) is defined as an educational process in which a "... significant proportion of the teaching is conducted by someone removed in space and/or time from the learner" (p. 9).

Within this paper, distance learning is interpreted as a learner-centred perspective within a distance education framework.

A benefit of the adoption of ODL measures for course delivery may be that long and sometimes difficult journeys to a learning centre become unnecessary. Open and distance learning can be supported and delivered by all manner of written materials, videos and support kits. More lately, a whole battery of information technology has started to make giant strides in opening up entitlement to education via ODL.

A few of the differences between ODL and "traditional" teaching and learning modes can be summarised thus:

**Face-to-face learning**

- Is delivered in a centre.
- Students travel to the place of learning.
- Students learn together at the same time.
- Students gain benefit from direct interaction with tutor.
- Course content may be written as course is delivered.

**ODL**

- Can delivered in a centre or off-site.
- Learning is brought to the students.
- Students may learn independently at times of their choice.
- Interaction with tutor may be limited and may be delayed (postal/e-mail).
- May need less direct tutor support but must work in a flexible mode.
- Course content prescribed by learning materials and requires much initial preparation.
- Learners may feel isolated.

Clearly, ODL and traditional face-to-face modes of course delivery do not have all the answers to the
problems of teaching and learning. Each has advantages and disadvantages—and these will be perceived differently as much by students with a range of needs in different learning environments as by course providers with a careful eye to resources and budget controls.

**ODL can be an effective way of delivering in-service education and training (INSET) for serving teachers INSET for primary teachers perhaps has special significance in the fields of science and technology. There is a need to update teacher knowledge of scientific content and teaching methodology can be seen as part of the continuum of entitlement to scientific and technological literacy embodied in Project 2000+ (1993).**

De Jong (1996) describes three fundamental areas which concern the professional development of teachers of science. These areas address the implementation of new curriculum topics or even new curricula, dissatisfaction with existing ways of science teacher training, and the impact of new ideas about teaching and learning science. This last area of concern is the so-called constructivist dimension in which learners actively construct meaning from actual experiences, often from the ashes of challenged past beliefs which are referred to as “misconceptions.”

There has been an explosion of comment and research endeavor in primary science education over recent years. Such activity has explored children’s alternative belief patterns that are seen to be at odds with widely accepted scientific “truths” (Driver et al., 1985; Ollieranhaw & Ritchie, 1993; SPACE, 1990-1992). This has led to new approaches to the science curriculum and the development of innovative teaching strategies and materials (Nuffield-Chelsea Curriculum Trust, 1996). No doubt such changes could be said to have placed new demands on teachers.

Perhaps a response to perceived economic factors, curriculum development in many countries now often embraces design and technology. This too places fresh demands on teachers serving the primary sector.

It is no surprise therefore that in a developing country such as Jamaica, delivery of INSET can pose problems for students and tutors. Teachers in rural areas may be disadvantaged in their quest for continuing professional development by poor communications and difficulty in finding or providing funding for such activity. Many teachers are unable to afford their own transport. Transport by taxi and minibus can be unpredictable. Difficulties in transport, and the need to give careful consideration to the costs of INSET are particularly important in the mountainous north east of Jamaica. Teachers in small rural schools face especial difficulties of isolation.

The parish of Portland is situated in the northeast of the island and it is served by the picturesque regional centre of Port Antonio. On the first day of 1996, just three miles outside Port Antonio a new institution in Jamaica was born. Situated just off the coastal highway in a richly forested setting, two colleges were merged to become the College of Agriculture, Science and Education, or CASE. Through the merger, this institution now has considerable academic capacity. It has degree-awarding powers and is able to combine the fields of agriculture, science and teacher education through college-based teaching programmes and the imaginative development of research and outreach applications.

One area of development which draws upon the full strength of the College is a research and outreach venture to assist primary school teachers in their delivery of the scientific area of the curriculum. INSET through distance learning was clearly seen as a possible strategy to overcome some of the problems of delivering INSET to far-flung rural schools.

Through the office of the Minister for Education, Youth and Culture (MoEYC), a request was made to the Commonwealth of Learning (COL) in order to obtain samples of distance learning materials. These were seen as offering innovative ways of delivering science INSET to teachers of children in the primary years of schooling. COL is a Commonwealth-supported organisation. Briggs et al. (1987) state that the long term aim of COL is directed so that “any learner, anywhere in the Commonwealth shall be able to study any distance-teaching programme available from any bona fide college or university in the Commonwealth” (p. 60).

It was decided that for the purpose of the Jamaican pilot a small number of local schools would be asked to volunteer staff to take part in a trial of the INSET course using just a part of the distance learning materials received from COL. It seemed advisable to start the trial in a small way so that tutors and teachers were not over-burdened with novel experiences. The local trial would involve an introductory day or “welcome workshop” in which participants would have a chance to familiarise themselves both with the content of the learning materials and ways in which distance learning can be carried out.
A strength of the ODL materials from C4 has always been that they have provided a platform of ideas for classroom teaching and at the same time promoted learning by the teacher. Activities from classroom application can be used as a basis for reflection and analysis so that the teacher can probe his or her understanding both of science and of professional issues. Following the welcome workshop it is planned that teachers in the pilot project are to pursue the trial INSET course largely in their own schools, with tutorial advice supplied by visiting staff from CASE.

The trial INSET course will end with a final day-school in which participants will display work undertaken during the course and provide verbal feedback to colleagues. Experience in the UK of this sort of final course experience has suggested that teachers value the professional exchange that can occur when looking at work achieved by children as well as ideas they as teachers may have used as vehicles to motivate their classes.

Of course, as in all applications of distance learning, student isolation can be a major problem. The initial and terminal workshops are thus offered as a way of strengthening relationships both within the pilot course membership and with CASE staff.

However, besides management, there is the question of the content of the materials themselves.

The core of scientific content has not needed to be changed significantly. It is a feature of accepted scientific ideas that their meanings are widely shared; the science is relatively stable. The contexts in which scientific ideas can be presented however, can vary considerably.

It was decided during the second consultancy visit, that editors' workshops would be held so that CASE staff, local teachers, local education officers and representatives from the Ministry of Education Youth and Culture could participate in the process of changing the ODL learning materials to meet the specific needs of teachers in Portland.

It was decided that it was better to invest in quality rather than quantity with the limited time available. Therefore only a few of the original distance learning materials from The Commonwealth of Learning were edited. However, as a result, a sense of "ownership" has grown up with the edited units.

The changes to the original ODL units have been considerable. Essentially "Euro-centric" text has been given a thorough editing to reflect the local environment. For example in the text on "Using the Environment" local place names and features have been used wherever possible. Reference to fruits and wild creatures now reflects the indigenous flora and fauna of the Caribbean.

Some of the activities in the distance learning units were completely out of place in a Jamaican context. At an editing workshop undertaken during a humid 33 degree afternoon at the start of the rainy season, an activity on "keeping warm" was seen as outrageously funny and given savage treatment with the editors red pen!

A further strand which influenced the re-writing of the materials was the Jamaican Curriculum itself. At the primary level this is contained in six grade-related books which specify content and progression Foundations of self-reliance: A curriculum guide for the Primary Stage of education, Grade 1/2/3 (1980a) and Foundations of self-development: A curriculum guide for the primary stage of education, Grade 4/5/6 (1980b) have formed the basis for the curriculum for a considerable number of years. This is soon to change.

The Curriculum Development Unit in Kingston, a division within the MoEYC, is currently undertaking a review of curriculum content. Within this review, there are exciting possibilities for the exchange of information between CASE and MoEYC so that an innovative distance learning INSET scheme and a new curriculum can inform each other.

There is more to the INSET initiative at CASE than just the introduction of distance learning materials for science. Besides materials from COL, CASE has copies of new materials to support teaching and learning in design and technology. These were written by Parkinson and Plimmer (1996) with the support of British Nuclear fuels. These too may play a part in the dialogue between CASE and MoEYC. Design and Technology still has to find a formal place in the Jamaican curriculum.

Further development on the design and technology front towards increasing scientific and technological literacy may come from innovation in the early years of education. Many developed countries have a strong tradition in the use of construction kits to extend manipulative skills and support the interaction of hand and eye to produce something "useful." At a fundamental level this type of activity can be justified on one facet alone—it allows children to develop their imagination, which many would say is at the root of the education process itself.
Imported goods are expensive in Jamaica. Precision made plastic construction kits are beyond the finances of the vast majority of Jamaican schools. Yet within the scope of the INSET project in Jamaica there is a classic opportunity to develop something for the home market which can use local resources and employ local people.

CASE is poised to take up this challenge. The excellent cross-section of skills represented in an institution which has expertise in agriculture—including some mechanical engineering, science and teacher education provides a unique platform for original thinking and development of Caribbean ODL materials.

THE TOOLS OF A GOOD TEACHER

Michael Laing
Department of Chemistry
University Natal, Durban

To be a good teacher you must:

1. Be a master of the subject.
2. Have a desire to teach and impart this knowledge to others.
3. Know the methods of teaching, and have the technical ability to do the task.

First and foremost is Knowledge. You have to work hard to become a master of the subject. It is done by reading; reading everything possible, not solely the syllabus outline. Nowadays there is much talk of Process. All Process and no Knowledge is a thought crime.

If you have become a "teacher" because of job security or some other reason other than a Desire to teach, then you will never succeed. You MUST love teaching to be successful.

As for Technique, this is a learnable collection of tricks. Effort can always produce competency; genius is born in the person.

But we are all teaching some aspect of Science—we are all Scientists. It is therefore worthwhile to ask: what are the Attributes of a Scientist?

A scientist must:

1. Be interested in everything.
2. Have a wide vision, be open-minded, able to evaluate radical suggestions objectively and not be blinkered; and be ready to consider unusual options.
3. Have imagination, and see in something what others cannot.
4. Think laterally, and not keep plodding in the same old rut.
5. Be skeptical, and not a blind follower of accepted dogma.
6. Be a collector of data and a classifier of facts; always on the lookout for the unusual.
7. Be a creator, tester and destroyer of theories.

So a teacher of any branch of science must always: be interested in learning more and more; and be able to use this new information to progress. A good teacher always has a built-in junk filter. All the policies and structures in the world are valueless if the teachers are ignorant—if they know no facts. And only they can learn the facts; they must do it for themselves. To master Content, one must use the Process of reading. Everything that we need has been written down—20, 30, 40, 50 years ago. But it takes effort and imagination. Use jokes, anecdotes, Calvin and Hobbes cartoons, songs—everything to show that learning is an enjoyable activity.

It is interesting to compare the attributes of those famous teachers of 50 years ago against our requirements for success as a scientist and teacher (see Five Famous Teachers, 1994).

It takes effort to be a good teacher, to be a master of the subject, to do it right. True teachers and scientists get excited when they make an unexpected discovery or a breakthrough. J.L.B. Smith described the feeling as being "struck by a heavy blow, a white-hot blast, feeling shaky and queer all over; my body tingled." This is the same as the blast of lightening when you fall in love!

George Patton's comment was "God, how I love it!" That is how a teacher of science must feel as he walks into his laboratory—"How I love the smell of chemistry in the morning, I smells of fun" and if it is not fun, quit: get out as fast as possible and find a job elsewhere.

Oh: the "Tools?" Any teacher can figure that out.

Brain: to hold the knowledge
Eyes: to read everything
Ears: to listen for new ideas
Mouth: to discuss with others and tell your pupils
Hands: to write articles, as well as on the chalk board
Feet: to carry you to the library to gain more knowledge

**SCIENCE & SOCIETY: TECHNOLOGICAL TURN**

*International Conference on STS, Japan*

*March 1998*

Topics include the following:

- Network Assessment of Science
- Transnationalization of Corporate Science
- Science and Technology in Asia
- MIT and Innovation Policy
- Cultural Studies
- Gender
- Social Epistemology of Science
- Implication of STS on Science Education
- Human Resource

- Knowledge Production Mode 2
- Technology and Media
- Japanese Studies on STS
- Post-Colonial Studies
- Expertisation and Public Awareness
- Medicine
- Religion and Science
- Science Education Policy
- International Relation in the Post-Nuclear Age

Invited speakers include the following:

- Michel Callon
- Deepak Kumar
- Brian Martin
- Rustum Roy
- Peter Weingart
- Sheila Jasanoff
- Morris Low
- Arie Rip
- Song Sang-Youg
- Robert Yager

Comparing Misconceptions in Physics Between Chinese and American Students

Roy D. Unruh
Physics Department, University of Northern Iowa

Lixia Li, XiuLan Meng, ShuMin Zhang
Physics Department, Hebei Teachers College, Shijiazhuang, PRC

Introduction

In physics education, for some time science educators have realized that meaningful learning in physics involves the mastery of concepts rather than facts and problem solving using equations (Lightman & Sadler, 1993; McDermott, 1984, 1990, 1993). It is becoming increasingly apparent that success in manipulating equations is not necessarily a reliable measure of conceptual understanding of physics. The most significant indicator of students’ understanding is the grasp of basic concepts.

The focus of this study is to investigate to what degree high school students of the People’s Republic of China and students in the United States differ in their understanding of basic concepts of physics measured by the incidence of certain misconceptions they have after instruction. Specifically, 12th grade student’s misconceptions associated with electric circuits were tested by administering simple circuit problems developed by the Physics Education Group, University of Washington, Seattle, Washington (McDermott & Shaffer, 1992).

Population of the Study

The population in this study consisted of physics students in the United States and the People’s Republic of China. Because of the association of the investigators with specific districts of the two countries, students were selected from Shijiazhuang City, Hebei Providence, People’s Republic of China and from the state of Iowa, United States. Chinese students in grade 11 and American students in grade 12 were selected because electricity was taught during these grade levels.

In China, there are different levels of secondary schools. Key high schools have been developed for the main purpose of preparing students to go to college. A second group, high schools of good reputation, also prepares students for college even though they have not been appointed as key high schools. The third group, ordinary high schools, also prepares students for college, although a minority of their students pass the college entrance examination. The fourth type is the vocational secondary school (from grade 10 to grade 12), whose main purpose is the direct training of the work force. Its curriculum is more flexible, and usually physics is not taught in this type of high school.

At the end of the 9th grade, all of the students are selected into different types of senior high schools based on their scores on entrance examinations administered by the Province Education Commission. Since these students are selected into these school based on their ability and since the motivation of entering college is different in the schools, one often finds dramatic differences in student achievement.

In Shijiazhuang, a provincial city with a population of three million people, there are 48 high schools, of which three are high schools with good reputation, 234 are ordinary high schools and three are vocational high schools. Five schools were chosen among three types of high schools: one key high school, one high school with a good reputation and three ordinary high schools. They were chosen because of the author’s accessibility to them. The sampling of American students involved three high schools in northeast Iowa. There were 238 Chinese eleventh-grade student and 140 twelfth-grade American students that participated in this study.
Procedures

The assessment of students' understanding of electric circuits was conducted by administering simple circuit problems developed by the Physics Education Group, University of Washington. The tests were administered approximately one month after students had completed their study of electricity. The test sheet was translated into Chinese and sent to one of the authors, Miss Xioulan Meng, a faculty member of the Physics Department, Hebei Teachers College, who then contacted secondary school physics teachers and administered the test. Students were asked to compare brightness of light bulbs and give reasons for their answers or show how they arrived at their conclusions. No extra instruction was given to the students such as the ways of using or not using equations to solve these problems. Twenty minutes was allowed for the students to take the test. Students' answer sheets were returned to the University of Northern Iowa, where all answers from American and Chinese students were evaluated.

The data are displayed on the bar graph for each of the levels of Chinese schools; the high schools (Key) the high schools of good reputation (GR) and the ordinary high schools (Ord) for the performance of the student on each of the problems. Also shown on the bar graph is the total score for all Chinese students and United States students in the study.

Table 1

<table>
<thead>
<tr>
<th>Electric Circuit Problems</th>
<th>Chinese and American Students</th>
</tr>
</thead>
</table>

As can be seen in Table 1, the Chinese students, in general, scored higher than the American population on the electric circuit problem one. Fifty-three percent of the 12th grade Chinese students from all five schools answered the first circuit problem correctly. There is considerable variation in scores between the various high schools in this Province of China.

Only 13 percent of the American 12th graders answered the first circuit problem correctly. The most common error by the American students (23 percent of all students) was to say that bulb B was brighter than bulb C. These students showed confusion related to the properties of both current and voltage. Some students said that the voltage is greatest when entering B, not distinguishing between potential and potential difference. The other difficulty was in believing that current and electrons get 'used up' as they travel through resistors.

Another 18 percent of the American students indicated that bulb A would be brighter than bulb D and E. Students believed that if there was only one bulb in the circuit, then that one bulb would receive all the power. They argued that if there were two bulbs in the circuit, such as D and E, then the power would be split between the two bulbs. They fail to demonstrate a basic understanding of the general model for properties of series and parallel branches in a circuit.

Sixteen percent of the American students thought that bulb A and bulb B would have the same brightness. It appeared to them that if there was no resistance between the battery and the first bulb in the circuit, then the bulbs would have the same brightness. American students do not have a good understanding of what factors in the circuit are responsible for determining the brightness of the light bulbs.

For the Chinese students the most common incorrect answer given was D = E > A > B = C. Chinese students used formulas very well in making calculations, but there were times when they did not discern correctly what they had calculated. They said that the power through E was greater than the power through A because they took the current through E to be twice the current through A.

Science Education International, Vol. 8, No. 1 March 1997 17
The Chinese students showed their reasoning through derivations using equations. They started their calculations with the equation \( P = IV \). They used symbols throughout their calculations and never selected numerical values for any of the elements in the circuit.

**Electric Current Problem 2**

In the second problem, shown in Figure 2, students were asked to compare the brightness of bulbs A, B, C, and D with a similar format as in problem one and explain their reasoning. Whether or not students consider the internal resistance of the battery, the brightness of the bulbs would be given as \( A = D > B = C \).

**Figure 2**

Eighty-seven percent of the Chinese students answered this problem correctly. In contrast only 24 percent of American students answered this question correctly.

Forty-five percent of the American students said that \( A > B = C \). Students reasoned that most of the current was “used up” in getting through the first bulb and that very little was left for the fourth bulb, D. Some of the students also used the concept of voltage erroneously, feeling that there is less voltage as the electrons pass through the circuit or that D is toward the negative end of the voltage.

A smaller number of students (7 percent of both American and Chinese) concluded that the voltage was the same across A, B, C, and D. They predicted all four bulbs to have the same brightness. They failed to recognize the effect that resistances in parallel have to the total resistance of the parallel arrangement of bulbs. They also failed to recognize that the current in B and C is half the current in either A or D and its effect on the brightness of the bulbs.

In general, Chinese students did very well on this problem. Some students did not reach the right answer only because of calculating error.

**Electric Circuit Problem 3**

In the third electric circuit problem shown in Figure 3, students were again asked to convey their understanding regarding the circuit by comparing the brightness of the five light bulbs. The most direct comparison can be made by comparing the current through each of the bulbs which yields the comparison that \( E > A = B > C = D \).

**Figure 3**

This problem proved much more difficult for both the Chinese and American students. For the Chinese students, 57 percent answered correctly while only 3 percent of the American students answered correctly. On this problem the kinds of errors made by both the Americans and Chinese were quite similar. The most common incorrect response for Americans (25 percent) and Chinese (18 percent) said \( A = B = E > D = C \). They assumed that the potential difference would be the same across A, B and E and that the voltage across C and D would be half the voltage across E. Some argued that the current through A, B and E would be the same and arrived at the same conclusion. Another 21 percent of the American students and 7 percent of the Chinese students answered \( A = B > E > C = D \). The reasoned that the resistance of A and B was less than the resistance of C, D and E and that the resistance of E was less than the resistance of C and D. They also concluded that the smaller the resistance, the greater the power.

The number of Chinese students answering all three problems correctly varied considerably among the different types of schools in which they were enrolled. Ninety-five percent of the students from the key high school and the high school with good reputation used equations to solve the problem.

**Discussion**

Physics enjoys a much higher level of importance in the Chinese curriculum. Physics is given a central
position in the curriculum ranked lower only than Chinese, mathematics, and English. All students take physics each year starting in the eighth grade and continuing through grade twelve. The Chinese school year is 42 six-day weeks or 252 days. Physics is taught to eighth and ninth grade students approximately 100 periods per year and to tenth through twelfth grade students approximately 140 periods per week for a total of 620 periods of physics. The American student may take a ninth grade physical science course which will be at least one-half physics. With 180 days in the American school year, this translates into 90 periods. Those that take high school physics will add another 180 periods for a total of 270 periods of physics instruction. This exposure is only for the 25 percent of American students taking high school physics. So, clearly, the Chinese students have had a much longer exposure to physics. Usually, Chinese students will have had 35 periods of electricity when they finished high school, whereas American students may have only 15 periods.

In order to attend college, Chinese students must pass the National College Entrance Examinations. Only approximately 15 percent of the students from high school go on to attend college. Also, only about half of the population of eighteen-year-olds are in high school. Society places a high value on students that graduate from college and are rewarded with better job security, higher social status and better benefits. Since physics has the reputation of being difficult, and is a mandatory course for the College Entrance Examination, students spend considerable time studying physics.

There are many variables in making comparisons in outcomes between different cultures. Therefore, it is difficult to import certain practices in hopes of assisting achievement in another setting. In physics education we should, however, be open to observing and analyzing practices by educators in other parts of the world to gain insights into how students think and learning their society. It does appear that when a society identifies a concept or practice as having high value and a commensurate time is spent on attaining excellence in that area that quality results do occur.

Note to Member Organizations

Please ask your members to submit material to Science Education International. We are looking for:
• Teaching activities and lessons, especially for elementary
• Action research articles which talk to the practicing teacher
• Research articles which focus on practice, not research strategies
• Informal and nonformal articles which address “Things to do” in these settings

PLEASE INCLUDE PICTURES AND OTHER DRAWINGS OR GRAPHS.

Manuscripts may be sent to:

THE STEPPING INTO SCIENCE PROJECT

Dr. Sue Dale Tunnicliffe
ICASE Primary Projects Officer

This project began in 1988 as an initiative to encourage primary teachers and their children in engaging in 'hands-on' science activities as well as sharing and emphasising the importance of primary science work throughout the science education world. The project highlights opportunities for science with primary children and the importance of early involvement with scientific process and phenomena and is aimed at primary aged school children, in pre school and then the first six years of formal schooling or to whatever age primary (elementary) education is deemed to finish and is open to any group or individual. It is run under the auspices of ICASE, the International Council of Associations for Science Education, who are represented in each country by the National Science Teachers Association. There are associate members too who may be firms or institutions.

The project is targeted at primary schools and involves pupils doing a number of science activities which involve the science process as well as learning new knowledge. After being involved in at least six projects the pupil may be awarded a certificate and be said to have taken a 'Step into Science.' The science task are not prescribed because each country has its own curriculum and ways of presenting science. The Stepping into Science Newsletter, STEPS, sent to all member of ICASE and available to individuals on subscription, carries a number of activities from around the world which can be used and provide an additional international dimension. The activities may be freely copied for use with pupils. A collection of 50 activities is available in the ICASE Primary Science Book which can be purchased through the ASE, College Lane, Hatfield, Herts, AL10 9AA, UK for £12.

Teachers are encouraged to work with their Science Teachers Association to choose relevant and appropriate activities for their pupils.

The STEPS are: YELLOW—pre-school; GREEN—age 6 - Grade 1; BLUE—age 7 - Grade 2; RED—age 8 - Grade 3; ORANGE—age 9 - Grade 4; GRAY—age 10 - Grade 5; PURPLE—aged 11 - Grade 6.

The Step into Science is taken through being involved and not through getting an experiments 'right.' Some schools and out of school groups run a Stepping into Science Club for interested children whilst other teachers make the scheme part of their school science work but award the certificates to encourage their pupils and to introduce an international awareness into their work.

CERTIFICATES

The certificate printed below can be reproduced locally for awarding to children. They may be used as a white certificate with the colour of the step taken written in or a star or other mark made showing the colour of the Step taken. Alternatively they may be printed/photocopied on the appropriate coloured card or paper. Each child can be given one certificate on completing the first step and additional steps can be shown by adding a collared star or other mark to the certificate. One certificate for a child can be obtained from Dr. S. D. Tunnicliffe, Homerton College, Cambridge, CB2 2PH, England or 18 Octavia, Bracknall RG12 7YZ, England.

LOCAL AWARD CEREMONIES

We encourage local Science Education Societies to have a stock of the certificates and distribute them locally and arranging local award ceremonies to highlight pupil’s achievements in science. Local press releases can be written and the Primary project co-ordinator notified so that the children’s success can be featured in the ICASE newsletter.

COST-EFFECTIVE CHEMISTRY: IDEAS FOR HANDS-ON ACTIVITIES

Peter Towse
University of Leeds
Leeds, United Kingdom

Introduction

A two-weeks International Low-cost Instrumentation Conference was held at the University of Wisconsin’s Institute of Chemical Education, Madison, July 15-26. Funded by the National Science Foundation (NSF), it attracted almost 30 participants from the United States and from Egypt, Germany, India, South Africa, Thailand and the United Kingdom.

The goal of the conference, spelled out in the NSF proposal, were:

1. to bring together an international group of scientists, educators, and students who had developed materials to introduce hands-on chemistry at minimal cost and to the broadest range of students,

2. to construct and test the materials with a variety of individuals (including students),

3. to write up these materials for publication and world-wide dissemination to enable teachers, no matter how low their budgets, to introduce or continue hands-on science activities.

Specifically, participants were asked to bring to the conference examples they had developed of:

1. low-cost instrumentation (USD50 or less),
2. low-cost apparatus (USD30 or less),
3. microscale chemistry and low-cost reagents,
4. chemical and biochemical sensors,
5. low-cost microprocessor-based data loggers and instrument controllers (USD200 or less),
6. low-cost computer interfaces (USD15 or less),
7. low-cost desk top publishing.

The case for hands-on experience

Science is a way of discovering our world using empirical, repeatable data to establish theories. As a process, therefore, science is a verb. As data and theories accumulate, and as scientists generate new hypotheses, the body of knowledge tends to be viewed as the whole of science. To many, science has become a noun. The verb science has regularly been attacked by economists as an unnecessary expensive, dispensable part of basic science education. Science educators generally take exception to the claim that science can be effectively taught by treating it only as a noun and not a verb.

In most countries, science education is seen as a necessary support for technological and economic stability and growth. Those involved in scientific and technological discoveries must not only 'know about science,' they must be able to 'do science.' Learning the facts of science may be properly accomplished through textbook instruction. However, attitudes and science process skills cannot be adequately addressed other than in a laboratory setting. Such issues are important to industry, both for the recruitment of young people to science-based careers and the development of the national economy.

International perspectives of hands-on science

A recent World Bank sector review on education (1995) recommends the abolition of laboratory work at the primary and lower secondary levels on the grounds of cost. Science educators find this way of thinking quite untenable. Learning about science and how to do science are two equally important but different functions of science education, and both are necessary.

Project 2000+ set specific goals for greater scientific and technological awareness and understanding, including practical experience relevant to the needs of local and national communities. Similarly, the International Council of Scientific Unions (ICSU) is presently supporting global hands-on experiences at the primary level.

Science education in developing countries should attempt to increase not only to the number of scientists and engineers, but also scientific literacy among policy makers and the general public so that science enhances rather than detracts from social and economic well being. Issues which embrace health, nutrition, environment, agriculture, and industry can only be fully understood through a practical approach. When the basic concepts and practical applications of science are presented to the students in the broader context of the
interaction between science, technology and society, they become much more meaningful, especially to females.

**The pivotal role of teachers**

Many science teachers have little laboratory experience, have never participated in research, and perceive science merely as a collection of facts rather than as a process. So, although laboratory instruction is clearly built into the curricula of most countries, the reality is rather different. There are at least four reasons why teachers are reluctant to engage in hands-on activities:

1. They consider them time-consuming and of largely academic interest only. Laboratory work and the associated instrumentation have little perceived application to everyday life.

2. They are familiar only with the macroscopic procedures and expensive apparatus portrayed in older textbooks.

3. They consider inexpensive alternatives demeaning and confirmation of a second class status. They would rather not use such alternatives, and offer as an easy excuse the fact that they are unable to provide 'the proper apparatus.'

4. Teacher performance is often correlated with student examinations, which do not include practical work.

**Cost-effective laboratory practices**

Chemistry teachers in all countries should use cost-effective laboratory equipment for the following reasons.

1. It reduces the expenditure on more costly equipment, yet will produce the same kind of data. This is extremely important in developing countries where the number of secondary science students is expanding dramatically.

2. It is typically constructed from materials familiar to the student, and so the final product is not foreign or intimidating. The students are better able to transfer what they know about familiar products to the function of scientific equipment. This helps to take the mystery out of chemistry.

Since it is made of simple materials which are often not enclosed in a 'black box,' the students and teachers can see how it functions (especially if they make it themselves). This gives the students a deeper understanding of how it extends their senses and allows them to focus on the underlying concepts rather than on the technology. Only when they understand the basic concepts are the students truly empowered.

4. Students may gain a more realistic view of the historical development of instruments, originally made in a simpler, more straightforward way far removed from the elaborative, expensive 'black box' commercial instruments of today.

5. Only students engage in primary research need expensive commercial equipment. For educational purposes it is most important that the equipment produces reliable data. To be cost-effective does not necessarily mean it has to be of poor quality.

Ware (1992) states the need to redefine the laboratory instruction in the secondary schools of developing countries, but emphasises the need to retrain it in some form. If the gap between the developing and developed countries is to be reduced, the need for hands-on activities in developing countries is even more urgent. These countries need to develop the skilled manpower that will make them fully competitive in a global economy without having to rely on expatriate manpower and assistance.

The introduction of cost-effective science equipment in developing countries is not new. The World Bank has sponsored over a hundred projects which supported secondary school science, but more than half of them were unsuccessful (El Hage, Rinaldi, Ware, & Thulstrup, 1992; Musar, 1993; Ware, 1992). for the following reasons:

1. technical unsuitability of the equipment,
2. educational unsuitability of the equipment,
3. faults in the procurement procedures,
4. high cost of the equipment,
5. lack of teacher and technician training,
6. lack of incentives to use the equipment,
7. faults in the distribution,
8. inadequate supply of consumable materials,
9. inadequate maintenance, repair, and replenishment.

Today, quality equipment may be produced and quality experiments performed at affordable prices. Much of the equipment to be described in the conference proceedings, which will be in the form of a 400-page source book of ideas for hands-on activities, offers at least partial solutions to the above.
The equipment was developed and tested by teachers and students in laboratory work typical of high school chemistry classes. The equipment should only be used if it enhances the existing curriculum; it should not be used simply because it is easy to produce.

The components are inexpensive, readily available in most places, and easy and quick to assemble. Therefore the equipment is also easy to understand and maintain with little or no training, yet it produces reliable data for educational purposes.

Equipment developed at this conference

The equipment represents five price levels:

1. **Minimum or no cost.** A very innovative approach for countries or educational systems without extensive financial support for science teachers or science teacher training is represented by the improvised semi-microscale equipment developed in Egypt. Teachers assemble their own portable semi-micro laboratory kit for work on a desk top at school or on a table at home. The kit can be used for a wide variety of activities and encourages modification of standard experiments. It poses no storage or distribution problems and could easily be introduced in many Third World countries as an important first step towards meaningful hands-on experience in wet chemistry.

2. **Little cost.** A low-cost microscale kit developed in South Africa provides a potentially easier starting point for countries or educational systems, for example in Africa, Asia or Latin America, with only modest financial resources.

3. **Inexpensive.** Well-established educational systems, for example in Asia and Eastern Europe, could benefit from adopting the inexpensive equipment and technical literature produced in India.

4. **Intermediate.** Much of the equipment assembled from commercially available and inexpensive items is appropriate for rural and inner city schools in the United States and some countries of Western Europe. Industrially developed countries can provide the technical support for equipment based on computers, lasers, and other sophisticated by inexpensive items.

5. **Low-cost equipment interfaced with computers or calculators.** Initially, equipment interfaced with computers or calculators may seem expensive, but over the total period of its use it becomes cost-effective. Computer-based equipment for the acquisition and processing of data expedites laboratory experiments and allows a more in-depth study of chemical or biochemical phenomena. For example, a simple, inexpensive photometer can be connected to a LIMSport system to acquire and process data at costs significantly lower than with any commercial system. Similarly, pH electrodes, conductivity cells, chemical sensors and other transducers can be connected. Also in this category is the microwave oven which is widely available, safe and comparatively inexpensive. It allows a large variety of experiments to be conducted in simple beakers and flasks in just minutes.

Empowerment of the teacher

The World Bank study of over a hundred projects, referred to above, clearly demonstrated that providing school laboratories and expensive equipment alone was not enough to guarantee success. This was often the case with projects in Africa. Projects had a much greater chance of success when relevant teacher training was included, as was more common in East Asia.

Such observations make pre- and in-service teacher training the focal point for introducing cost-effective hands-on activities. Such training must be continuously supported through short courses, workshops, newsletters, etc. and through the creation of networks of teachers active in the field.

In many countries, the morale and social status of science teachers is low. Teachers are not well paid and are often forced to hold two or more jobs. This does not create the sort of climate conducive to the introduction of new initiatives. Conditions have to be created which will lead to changes in teaching strategies, including more hands-on activities, the local production of teaching equipment, the efficient repair and maintenance of existing equipment.

Similarly, it is important that laboratory skills form an integral part of examinations (Gardner, 1989). The status of hands-on activities among students and parents would be strengthened and this would lead to improved work ethics in the laboratory throughout the year.

The curriculum should give committed teachers the freedom to include hands-on, project-based components. By combining laboratory activities with those in local science-based industry (agricultural production, manufacturing, etc.), new opportunities for doing science are likely to appear.
At both the local and national level, governments should help to strengthen hands-on teaching by supporting the local production of cost-effective equipment, rather than importing equipment. Imported equipment is often much more expensive than locally-produced equivalents. In addition, the opportunities for repair and maintenance, and the availability of spare parts, are likely to be more effective when the equipment is produced near the school.

An added, and in many Third World countries very important, advantage of locally produced, low-cost equipment is that the fear of using (and possible breaking) equipment would be reduced. Reports of science equipment which was never used (and, in some instances, not even unpacked), because the teacher was afraid to do so, would then become a thing of the past.

ICASE, UNESCO 2000+, ASE

REGIONAL GUIDELINES AND PRELIMINARY TIME LINES

Step 1 June–July 1997
Regionalizing or nationalizing project material, for example possible translation, addition of local reply address, etc.

Step 2 August–September 1997
Copying and distributing the adapted brochure to all members of ICASE in the region and as widely as possible to any other interested people, schools, or education offices.

Step 3 September 1997–Early 1998
Encouraging and collecting as many names and addresses as possible of schools wishing to take part in the links scheme. Making a regional list or data base of the schools interested in joining the international science links scheme.

Step 4 Early 1998
Send to all interested parties or schools in your region who request links a Key Information Sheet and reply letter.

Step 5 April–June 1998
The ICASE Regional lists of those wishing to participate need to be centralized, matched and the links made. Executive Secretary, Jack Holbrook has offered to do this amalgamating of the lists and data bases.

Step 6 Any time after the link is made
Schools and links will forge ahead.

Step 7 Towards the end of 1999
Information from linked groups wishing to share their international Links Science/Technology Project would need to be collected, certificates issued, and the possible means of sharing the experiences carried out (for example possible exhibitions, news letters, posters, booklets).
SCIENCE TEACHERS AS CURRICULUM DEVELOPERS
OF SCIENCE AND TECHNOLOGY FOR ALL

Avi Hofstein, Rachel Mamlok, and Miriam Carmeli
Department of Science Teaching
The Weizmann Institute of Science
Rehovot 76100, Israel

Introduction

Development of learning and curricular materials by teachers is recognized nowadays as an important and effective method of professional development of teachers (Ben-Peretz, 1990). There is a growing body of information that shows that the imposition of a curriculum by centralized (external) professional bodies in what is called “top-down” fashion, whereby teachers are expected to execute and realize the developers’ philosophy, ideas and intentions, has proved an ineffective way of introducing educational and curricular innovations into schools (see also Eden, 1979; Subar, Silberstein & Shafiriri, 1982). There is an existing recognition for the need and importance of accompanying the work conducted by professional curriculum centers (i.e., The Israeli Science Teaching Center) with materials development activities conducted by school teachers (Connelly & Ben-Peretz, 1980; Sabar & Shafiriri, 1982). Ben-Peretz (1990) claimed that “teachers may function as creators of their own curricula whether through involvement in the process called “teachers based curriculum development” or as “participants in centralized curriculum efforts.”

Several projects conducted in the past (e.g., Ben-Peretz, 1980; Campbell et al., 1994; Sabar & Shafiriri, 1982) involved groups of teachers in the actual process of curriculum development. In such workshops teams of teachers engaged in curriculum development and operated as writing teams. Sabar and Shafiriri (1982) claimed that “participation of teachers in curriculum development is likely to take the teacher from a conscious phase to one greater autonomy and internalization” (p. 310). It is also suggested that teacher based approaches to curriculum development may yield a vast amount of pedagogical ideas and innovative approaches to the curriculum planned.

Science and Technology for All

In the 80’s and 90’s Science and Technology for All emerged as a slogan that embodied a new challenge for science educators. There is a growing feeling around the world that science should be an integral component of education for everybody in school and not only for those who are going to embark on scientific careers. Science and technology should be part of the education of those who will eventually become “future citizens.”

Project synthesis in the U.S. (Harms & Yager, 1981) considered four goal clusters for learning science:

1. Science for personal need
2. Societal issues
3. Career awareness
4. Academic preparation

In order to attain to these goals, in recent years there is a movement around the world to develop and teach science content in the authentic context of its technological and social milieu. Thus, S.T.S. is an effort to produce an informed citizenry capable of making crucial decisions about current problems and issues and taking personal actions as a result of these decisions. It is fairly clear (Hofstein et al., 1988) that the traditional training of teachers both at the pre-service and in-service stages of their development, rarely touches upon the teaching of an S.T.S. based course. In the IOSTE conference in Kiel (Hofstein et al., 1988) the following problems were identified regarding implementation of S.T.S. programs:
• The interdisciplinary nature of the content and unfamiliarity of the teachers with subject matter in which they were not trained.

• Unfamiliarity of teachers with required teaching strategies.

• Inappropriate training techniques and procedures for pre- and in-service teacher training.

The Workshop

The purpose of the workshop described was to involve teachers in curriculum development as part of their professional development and thus to increase their motivation to teach using learning materials that are interdisciplinary and S.T.S. in nature. Such involvement was also expected to reduce their anxiety to introduce unfamiliar subject matter to their classrooms. The workshop was planned as a part of a large scale project in the northern region of the country. This project aimed at enhancing and improving science and technology teaching and learning. The 22 teachers who volunteered to participate in this three year workshop came from different scientific backgrounds (i.e., chemistry, biology, agriculture, nutrition technology and physics) and expressed their interest in curriculum development. These teachers met once a week for about six hours. This time was recognized as part of their teaching load.

The project has three phases:

1. In 1994-95 teachers were involved in collecting and writing learning materials.

2. In 1995-96 a trial version of each of the modules was piloted in schools. Feedback obtained by teachers and observers was used for improving the material and for preparing the next version of curricular materials.

3. In 1996-97 the project's focus is on training more teachers for implementing the modules in more schools.

The teachers were grouped in five groups, each being involved in the development of one of the following learning modules:

• Radioactivity
• Plastics
• Light and Color
• Chemical and biological extermination
• Food and nutrition

Each group has a pedagogical tutor and a scientific consultant. These modules will eventually be an integral part of a new syllabus designed for what is fondly called "science for all." It is suggested that this curriculum will consist of a collection of interdisciplinary (S.T.S) type modules, and the five modules described above are a sample of it.

During the first phase teachers were involved in:

• development of relevant learning material aimed at tailoring the content for non-science oriented students.

• varying classroom procedures in order to increase the effectiveness of the learning effort and students' motivation (Hofstein & Kempa, 1985).

The following instructional techniques were developed for use in the various modules:

• Students small group (cooperative) investigations
• Simulation game and role playing
• Field trips
• Critical reading of scientific articles in newspapers.
• Small scale students' projects
• Structured work sheets.
• Analogies and models.

During the second phase, the modules were tried out in six classes which were defined as "non science oriented," in the following manner:

1) In the first semester, each teacher taught the module which he helped to develop. In the second semester the same teacher taught one of the other modules, developed by his colleagues in one of the other groups.

2) Each teacher, while teaching the module, was accompanied by a peer teacher from his group. The peer teacher took part in all aspects of teaching: lesson planning, preparation and administration of work sheets, tests and additional learning materials.

3) The pedagogical tutors attended some of the lessons, and helped the teachers and their peers.

We are now in the midst of the third phase, in which the teachers are improving and completing the learning materials while teaching them in their classes, and some of them are guiding other teachers in the region with their first experience teaching these modules. Efforts for expanding the program to more schools are made on two levels:
a) introducing the program to more school principals and trying to convince them to adopt it for the appropriate classes,

b) organizing in-service summer courses for science teachers and offering them on going guidance during the school year.

**Evaluation**

The evaluation of the project addressed two main questions:

- In what ways does teachers’ involvement in curriculum development affect their instruction and their attitudes toward teaching and learning? (i.e., on their ability to teach interdisciplinary units, on their self concept as teachers and their understanding of students’ learning difficulties)

- To what extent are the modules suitable for the target population namely “non science oriented” students? (level of interest, relevance, difficulty, prior knowledge of basic concepts etc.)

In order to answer these questions data were collected from teachers and students using a variety of research instruments such as questionnaires, interviews and observations.

The initial results described here are based on data from teacher questionnaires and interviews. Further analysis of the data collected from both participating teachers and students will be completed in the near future. Based on their experience, all participants felt that teachers involvement in curriculum development is very important. They perceived it to be another method to express and utilize their teaching experience and their profound acquaintance with the class milieu, which most of the subject matter experts, when writing learning materials, don’t have.

Most of the participants mentioned that being part of a group was very meaningful for them. They felt that cooperation with colleagues invokes one’s creativity and helps in varying his/her instructional strategies in the classroom. The fact that every group was interdisciplinary in nature with respect to the teachers academic background, made teachers feel that they had a unique impact on the work done on one hand and they learnt a lot from their peers’ experience in other fields, on the other hand.

Few teachers reported that during their participation in the project they gradually incorporated new teaching strategies into their regular classes. They mentioned independent learning of students, or working on projects (individually or in small groups). Three teachers pointed out the fact that their perception of the teacher’s role in class had changed. As one of them said: “Now I don’t teach anymore, I am a guide. As a teacher you don’t have to know everything, you are not supposed to lecture, but to offer the directions and the tools.”

As mentioned above, each group had a scientific consultant. The level of their involvement varied among the different groups. Some of them were part of the whole process of the module’s writing, while others were consulted at the initial stages of planning and helped in defining the main topics and at a later stage were asked to assess the first written version. Tutors felt that the consultants were always available for them and played a very important role, especially in assuring the scientific integrity of the learning materials.

As mentioned above, during the second year of the project a trial version of the written material was implemented in six classes. Each unit was tried out in at least one class. The teachers of these classes and their peers that accompanied them at least in part of the lessons, were interviewed and asked about this experience. The following were teachers reactions regarding the teaching experience:

- The five units which were developed are different in a few aspects: level of difficulty of the materials, the degree of interdisciplinary and the degree of relevance concerning the students interests.

- Coping with the written materials in class gave the teachers an immediate feedback which was used to make proper changes in the next version. The experience in class also affected immediately the forthcoming lessons. Teachers reported that they often felt a need to simplify the materials that were prepared beforehand or to add some materials concerning basic concepts etc.

- Most of the teachers mentioned that since their background is either biology or chemistry, they usually teach high ability students. In this project they had the chance to work with less able students. They were surprised to find out that most of these students showed interest in the scientific topics and were able to participate in the activities held in class.

- It is worthwhile to mention that with regard to two or three classes some problems were
mentioned by the teachers, namely: low motivation to study and lack of learning habits by part of the students, lack of interest in the subject presented or refusal to prepare homework.

Conclusions

We are entering an era in which teachers who were originally trained to teach a certain subject with its unique structure of discipline will have to break the boundaries and teach also topics from other disciplines. Based on the experience gathered in this study, it is fairly clear that one of the methods to reduce teachers anxiety to teach subject matter in which they were not trained is to involve them in both planning and development of the curriculum material. This is in fact a call to train teacher teams in schools with teachers from various disciplines (chemistry, biology and physics) to teach modules and units that are interdisciplinary in nature. It is anticipated that the syllabus in science and technology for all will be flexible and will provide schools with freedom regarding the content. The process of writing learning materials with teachers is tedious and time consuming. However, although the materials produced, need more work in terms of professional scientific editing there is no doubt that this method should not be overlooked as one of the more meaningful ways of in-service teacher education.

Cybercheck

This is a new journal for senior students and teachers. The emphasis is on science and society and, as such, is complementary to the ICASE/UNESCO initiative Project 2000+, scientific and technological literacy for all.

The journal will be published bi-monthly in printed form, but will be available also on 3.5 inch diskettes and through e-mail. Annual subscription is 50 pounds for the printed version, 60 pounds for electronic version. The first issue of the Journal has 40 pages.

A specimen copy of the new Journal has already been distributed to all members of ICASE.

Individual subscribers to the ICASE Journal may obtain a sample copy by contacting the editorial office at Viale Agugliari 12, 21100 Varese, Italy (Fax: 39 332 236 997; E-mail: 100707.3432@compuserve.com)
CONSTRUCTING PAKISTAN’S SCIENCE TEST ITEM BANK

William J. Boone

and
Alyas Q. Tahir
Institute for the Promotion of
Science Education and Training
Ministry of Education
Islamabad, Pakistan

Presently in Pakistan there is a nationwide effort to reform the teaching of science to students and to alter the training science teachers receive. One aspect of the reform involves considering measurement issues that will allow movement toward the development of a mechanism which will enable the achievement of students to be accurately compared and tracked over time. These issues are of use to all countries that are interested in not only reforming science education, but also monitoring progress of teachers and students. In general, the procedures that have been applied to the Pakistani item bank should be an invaluable tool for other developing countries wishing to create and maintain their own science test item banks.

Rationale for a Multiple-Choice Test Item Bank

There have been limited mechanisms by which the science learning of students throughout Pakistan could be quantified. Typical testing procedures usually consist of classroom teachers presenting students with teacher-constructed tests. Furthermore, the vast majority of exams currently presented to Pakistani students do not require higher-order thinking skills, even though the exams are non-multiple choice. Because of this type of problem with teacher-constructed exams, Pakistan’s interest in the use of multiple-choice test items—calling for a range of thinking skills—is an improvement over the present system used to test students in science. Certainly the weaknesses of multiple-choice tests have been discussed in the literature, however Pakistan cannot presently afford the financial encumbrances necessary to develop and evaluate authentic assessment tasks. Pakistan ultimately may be able to move first toward some authentic assessments that use multiple-choice items and then proceed toward the creation of nationwide open-ended exams. But for the present multiple-choice testing, making use of well-conceived items, is the most time-and cost-effective method to follow.

Initial Development of the Science Test Item Bank

Test items for a variety of science topics were developed through a number of steps. First, items were drafted by a team of science educators within IPSET (Institute for the Promotion of Science Education and Training). Second, items were critiqued by a group of the nation’s master science teachers. Third, comments supplied by master teachers were used to further refine test items. Following this process, groups of students who had studied the revised science curriculum were evaluated with the revised test items. During this trial of the science test items, observers sitting in classrooms took note of comments regarding item wording and format that were posed by students to test proctors. Following this administration of the test items, the student comments were used to improve once again the science test items.

Improving, Evaluating, and Utilizing the Science Test Item Bank

To test methods and procedures which might be extended to Pakistan’s entire science test item bank, a subset of the item bank developed for the new curriculum was evaluated. IPSET specifically requested that all 23 test items for the Grade 6 water chapter be evaluated in terms of suitability for making a fair comparison of student performance in four provinces.
To conduct the trial of the test item bank, the revised water items were administered at one randomly selected school in each of Pakistan's four provinces. This division by province was carried out because a comparison of achievement of students in geographically distant regions within the country is one evaluation that needs to be made in order to assess the effects of the reform effort throughout the country.

Analysis of Students' Responses to Science Test Items

Item Response Theory (IRT) was utilized to begin evaluating the appropriateness of using these particular test items to compare students in the four geographically distant provinces. This specific psychometric technique is useful and helpful for a number of reasons. For instance comparisons of Pakistani students can be made when test takers complete a few common items. For example, students of Province 1 could take items 1 through 12 of the water test, while students of Province 2 could complete items 9 through 20. When students complete some common items, often they can still be accurately compared.

Another advantage of using this evaluation technique is that respondents need not answer every item they are administered; test items can be skipped by individuals and a student's ability level can still be computed. Finally, statistics supplied from this analysis help illuminate items which might cause students to answer in an idiosyncratic manner (e.g., highly able students unexpectedly missing an item). Such items may have been poorly written or they might indicate some changes or necessary clarifications in the student text, workbooks, or teacher's guides. Being able to detect items which may have some structural flaw is especially important, for Pakistan hopes to continue its efforts in developing and improving home grown test items.

Results

One aspect of the data analysis was a comparison of the operation of the test item bank as a function of province. More specifically, an investigation was made of test items whose difficulty and/or difficulty ordering is statistically different from one province to another. Analysis indicated that some items functioned in a different way from province to province, but in general the majority of the items seemed to work well for the students.

Another technique used to evaluate this test item bank, involved an analysis of the preconceptions of those who developed the item bank. If test designers really understand the topic and the students being measured, then an accurate prediction of the relative ordering of items by difficulty should be made rather easily. Furthermore, accurate predictions should be possible as to whether or not particular items might cause unexpected responses on the part of students. For example, should any easy items be unexpectedly missed by well performing students? Should any difficult items be unexpectedly answered correctly by students who did not perform well on the majority of test items? By predicting the difficulty ordering of test items, and hypothesizing which items may cause idiosyncratic responses, the appropriateness of this science test item bank can be evaluated in another manner. In order to evaluate the items in this fashion, those who had been involved in the creation of the test item bank (i.e., the second author and others) provided a predicted difficulty ranking of the 15 items which functioned well in all of the provinces. Of these 15 core items, two items did not match the test developers' predictions. One item was predicted to be relatively difficult by the science test developers, but this item was easy for almost all of the students—regardless of province. One possibility for this discrepancy in predicted and actual difficulty may be that the revised text and hands-on activities pertaining to this topic do a very good job of explaining the concept (water vapor) stressed in this item. Another possibility is that the distractors created by the science test item developers did not function as well as in the other items. One item was predicted to be very difficult by reviewers. This was because the item topic (water pressure) was not discussed in detail with students. Nevertheless, the item was answered in a manner by students that suggested it was neither the most difficult nor the easiest test item. Students were apparently able to reason out the answer. Carrying out this step is important for subsequent revision of science test items and as a way of encouraging test item writers to reflect upon the curriculum.

Conclusion

The goal of constructing a single test item bank for a developing country such as Pakistan is a major achievement. Although the demands placed upon the entire science test item bank will be great, item response theory seems to provide a viable technique of easily developing, refining, and monitoring a science test item banks for countries that wish to move toward expanded assessments.

This discussion has presented a number of steps which have been taken to guide the development of a national science test item bank in Pakistan. By following these analytical steps, the Ministry of
Education has begun to build science assessments so that student achievement can be gauged throughout the country and the success of a new science curriculum evaluated. Certainly a larger number of students within each province needs to be evaluated and steps taken to further consider the science items which are to be used for other topics and grade levels. The results of this study suggest that if student measures for particular provinces are to be calculated, then not all of the science test items will be of use initially. In general, those involved in the development of the science test items seem to be able to predict accurately the relative difficulty of test items. Furthermore, the test items evaluated in this study do not seem to have structural deficiencies which caused idiosyncratic behavior. Thus, the test items which have already been developed for this and other text chapters will probably provide a good initial bank of test items.

June 21-24, 1997

International History, Philosophy and Science Teaching Group
North and South America Regional Conference
Calgary, Canada

A regional conference of the International History, Philosophy and Science Teaching Group will be held in June 21-24, 1997 at the University of Calgary, Calgary, Canada. The Dean of the Faculty of Education, Professor Ian Winchester, will be the conference chair. Although a regional conference, all members of the International Group, and others, are welcome to attend. Calgary is situated at the foot of the Canadian Rockies, near to the mountain resort of Banff. The conference programme will include an optional visit to the Rockies.

International and national groups that have interests in the role of HPS in science, mathematics and history teaching are encouraged to use the conference as an occasion to present their work and to consolidate networks.

Proposals for contributed papers, workshops, discussion groups, and exhibits of curricular and instructional materials related to the purposes of the conference are now being accepted. Four copies of the proposal or paper should be sent to Ms. Linda Lenz at the address below. The proposals should include:

1. A cover page with paper title, authors name(s), institutional affiliation, address, telephone numbers, FAX number, and e-mail address.
2. A 100-150 word abstract of each proposed paper or session.
3. Three self-addressed envelopes.

Due date for receipt of papers and other proposals is February 15, 1997.

Format:
Papers should follow the format, style and referencing conventions used in the groups journal Science & Education. Please pay particular attention to form of title, authors name and address, an Abstract of 100-150 words, referencing conventions. Disc submission is necessary. WordPerfect or Microsoft Word for PC or Mac platforms is preferred, but ASCII is acceptable.

Final papers should not exceed 5,000 words. They must be submitted by February 15, 1997. Early submission of proposals and final papers is encouraged in order to facilitate programming and production of Conference Proceedings.

Journal Participation:
It is anticipated that some scholarly journals Interchange and/or Science & Education will publish special issues related to the conference. To be considered for these issues, papers need to be forwarded by October 31, 1996

Proposals and papers should be sent to, and registration information can be obtained from:
Ms. Linda Lenz, Faculty of Education
University of Calgary
Calgary, Alberta
Canada, T2N 1N4

Abstract

Creating interest is a fundamental goal of elementary science. Teachers share with designers of science museum exhibits a desire to craft environments which promote and sustain interest. In both settings, formal and informal, control over interaction, direct experience, social use of language, links to prior knowledge, degrees of anomaly, and the conception of the self as a learner influence the creation of interest. In the formal setting, there are clearly defined expectations for learning. In the informal one, multiple possibilities are more common. In both, choices made by learners matter and consideration must be given to the child’s search for understanding and meaning. By studying the museum environment, teachers can learn practices that succeed in fostering interest and in tempering the role of the teacher as an authoritative source of knowledge.

Introduction

Interest is curiosity about experience sustained over time. It begins with playfulness, works through puzzlement, and depends upon ample opportunities for exploration. Interest seeks to experience the unexpected, thrives on astonishment, and turns each new insight into several more questions, questions which “tell” of something understood in asking about something still to learn. Interest looks for the novel in the familiar and how to grasp the unfamiliar in terms already understood. Interest—anchored in personal experience—must prevail for truly meaningful learning to occur. Interest is basic to learning science. Interest finds expression in questions and responds to an answer with another question. By examining the work of “interest experts”—the people who design exploratory exhibits for science museums—we shall discover many lessons about creating interest.

Asking good questions and meaningful learning

Museum exhibits pose questions and tell answers simultaneously. What good exhibits demonstrate is that “telling” is an essential characteristic of questions. This phenomenon of raising telling questions accompanies the best interactive, science exhibits. Science is a way of doing as much as a way of knowing. Good exhibit design invites participation—it provides a chance to do something that connects answers to the authority of how the natural world responds to our questions. At exhibits, someone usually assumes the role of “expert” and begins to tell answers. The best exhibits acknowledge this social role and help the person behaving like a teacher to ask good questions.

A simple transformation of “telling” can suggest much about the nature of a good question. That transformation is to think of “telling” as being an essential characteristic of questions. Instead of thinking about “telling answers” in science, try to imagine “telling questions” (Gowin, 1981). Notice the shift in the sense of the meaning of “telling” from something you do (tell the answer) to a properly of the question (it “tells” us something while asking at the same time). There is no recipe for how to ask “telling questions,” but when it happens, you’ll know by the interest such questions provoke and the number of questions which follow. “Telling questions” ignite interest and interest sparks telling questions.

In summary, “telling” and “praising” go hand in hand with belief in the educational efficacy of “right answers,” placing in jeopardy the basic goal of creating interest in science. Yet telling has its place and knowing some answers is absolutely necessary. How, then, are these points and the jeopardy they entail reconciled with creating interest?
In words, this reconciliation is straightforward. In practice, it is extremely elusive. It begins by acknowledging that “meaningful learning” (Novak & Gowin, 1984) is possible only when a connection is made between a good question and its appropriate answer. Meaningful learning shifts the focus from answers to the connecting of questions to answers. Concern for these connections is synonymous with having an interest. And, as previously noted, the experts on creating interest are those who design exploratory exhibits in science museums. In these settings, interest is the arbiter of successful design. Of course, science museums entice visitors with entertainment and recreation. But the exhibit designers care ultimately about using such an atmosphere to create interest (otherwise they would seek employment at amusement parks).

**Design criteria from “interest experts”**

Traditionally, classroom teachers look to informal science environments (zoos and museums, for example) only for advice in planning school visits or for special materials prepared to supplement school curriculum. Often, the informal institution has a value message to share with the public—protection of endangered species, for example—and schools provide one pathway of communication. Although by definition informal environments eschew formal evaluation of learning while the very structure of schools depends upon commitment to formal assessments, the individuals who attend and learn are common to both worlds. Rarely do representatives of formal and informal perspectives deliberately study the nature of learning common to both settings with the goal of enhancing basic student understanding and habits of learning (cf., Ault & Herrick, 1991; Nagel, Ault, & Rice, 1996).

Common to both worlds is a fundamental desire in creating interest in science. The design of informal environments suggests principles for innovating in the classroom (Ault, Cohen, Kesling, & Vanausdall, 1987). Designers struggle to attract interest, appeal to the senses, promote imaginative play, respond to diverse social groupings, engage prior knowledge, and enhance visitor control over interaction with the exhibit.

The phrase which best captures the intent of informal environments is “learning from experience.” In attempting to create interest, museums, zoos, and field stations capitalize on ideal conditions for learning from experience. What learning from experience actually means, however, is not so simple. Immersion in experience does not cause learning. Consider: “Fish are the last to see the water.” Jerome Bruner has referred to this French proverb to introduce the ambitious (and ultimately controversial) social and natural sciences curriculum project of the 1960s, “Man: A Course of Study” (Bruner, 1965; Education Development Center, 1968). As metaphor, the proverb reminds us of the very basic level of naivety risked by a overly zealous commitment to “learning from experience.”

What does the proverb mean? In some sense, fish do have an “understanding” of water—they behave in ways which respond appropriately to the fluid properties of water. We might say they have learned from experience how to swim, right down to placing this understanding in their biological machinery itself.

Clearly, the proverb is a metaphor about people and culture, not a literal claim about fish and water. Bruner’s choice of proverb underscores how little experience may contribute to understanding without deliberate effort to reflect upon the regularities of experience. Informal environments predicate an essential role for experience; formal ones make deliberate reflection the primary concern, using numerous demonstrations, simulations, or prose creations as surrogates for experience.

What have those who craft each environment to learn from each other about the nature of learning? Rarely do representatives of formal and informal perspectives deliberately study the nature of learning common to both settings with the goal of enhancing basic student understanding and habits of learning. They ought to do so. Consideration of the role of experience—and the limitations of experience captured in the French proverb—is a good starting point. How exhibit design creates interest out of experience has important implications for classroom teachers.

Interest, of course, is not the only goal for learning in science. However, in its absence the others count for very little. Thus, teaching to promote interest is a professional skill of critical value. The common interest in interest in both formal and informal environments unites educators. What works to create interest works for children because of their human nature as curious learners. These children are the same learners responding to the same interest provoking features of their environment wherever that environment happens to be.

**Four concepts about ideal learning environments**

In creating interest out of experience, museum exhibit designers craft environments according to a variety of principles implicit to good design in both
formal and informal settings. Throughout the application of such principles, four concepts play key roles: (1) choice, (2) language, (3) disposition, and (4) anomaly. Taken together, these four concepts provide educators with a basis for designing environments that create interest consistent with principles of an exploratory exhibit design.

1. **"Choice" in formal and informal learning.**

   Formal learning is based upon careful evaluation of achievement and performance, as guided by socially agreed upon purposes for schooling. Informal learning is based upon the exercise of free choice by learners for their own, intrinsic purposes, free of assessment and evaluation by others.

   This distinction characterizes two different contexts for learning; not what happens when learning occurs. In either context, teachers or exhibit designers do not cause learning; learners do. Learners choose to pay attention, choose to consider what experience and information might mean, and choose whether to alter behavior or reorganize their thoughts according to new understandings. Teachers and designers have control over conditions influencing learner dispositions to do so and over the quality of the resources available to them for use in learning.

   In short, both contexts may exert influence over "choice." Informal settings maximize the learner's control over choice of experiences and the choice to learn; formal ones attempt to control the choice to learn with incentives while restricting choice over what to learn. The resolution to this tension appears to be in answer to questions such as, "Who is making the choices and on what grounds? What are the consequences of learning according to free choice for the public and the individual? What are the consequences of attempts to control choice without the consent of the learner?" In either case, experience appears equally necessary—but the control over choice influences attention given the experience by the learner. In both environments, understanding the role of choice is paramount.

   In informal settings, learners have control over the choices they make. This kind of control, necessary for creating interest, presents a dilemma for formal settings where "schools" choose what students ought to learn. When the teacher's goal is to create interest, this dilemma diminishes, for the teacher has simply to adopt principles guiding informal learning as the means to achieve a basic goal in formal science teaching. Both environments often emphasize experience equally. Direct experience is not at issue in contrasting formal and informal settings. Choice is.

2. **Expert jargon and natural language.**

   Consider for a moment this quotation from a third grade girl commenting on her saucer left to dry on a windowsill over the weekend: "The water evaporated and left a solid solution." The teacher wrote on the blackboard, "The water evaporated. What had been communicated?

   The message from the teacher was that the answer was partially correct—the student had achieved agreement with one aspect of correct usage of the term "evaporated." The water was gone and evaporation seemed the most likely explanation. However, the lessons the previous week had built upon an operational definition of solution: a transparent liquid consisting of two or more substances. This objective assumed the role of a "canon of jargon," the goal of instruction being to achieve agreement with this canon in terms of speaking science properly. The teacher sought evidence of agreement in the use of language and found this agreement for "evaporation." She used from her adult, authoritative position a subtle form of social disapproval—failing to write the entire utterance on the board—to extinguish the notion of a "solid solution." "Solid solution" was not a legitimate thought.

   As the discussion continued, the class clearly began to disagree on whether the white powder on their saucers contained water. They agreed that it was dry, but some noticed a curved surface within a crystal shape that might be a drop of water trapped in the crystal. Others used the word "cloudy" to describe parts of the white substance in their saucers.

   The lesson objective, however, was to show how the physical process of evaporation (a phase change of water) had isolated the dissolved substance, table salt, preserving all of its original chemical properties. The teacher guided the class to conclude that no water was present in order to prove that a solution, according to the operational definition of transparency and multiple substances, no longer existed. As an authority figure, the teacher awarded status and imposed sanctions in order to bring classroom thinking into conformity with an objective predetermined by the curriculum. The objective became correct use of scientific jargon.

   The child's notion or meaning for "solid solution" was not explored. Was this phrase reasonable? An example of creative thinking? Did it have potential to encourage thoughtful exchange among students? Yes, indeed. However, it was, in a small way, punished. Furthermore, the basis in experience for arguing for and against the presence of water was suppressed. No encouragement (or time) was spent on considering whether something other than evaporation may have
happened to the water. The lesson, in effect, “abused” children’s thinking by denying them the legitimacy of their own language and in so doing hindered their access to direct experience of phenomenon. Needless to say, as the lesson progressed, fewer and fewer children chose to speak. The goal was apparent: play a language game of achieving socially approved usage; do not worry about making sense of your own experience with and interpretations of a natural phenomenon.

This judgement is harsh, for, in fact, this teacher admirably devoted five days of third grade science lessons to experiential, experimental study. And she behaved in the manner advocated by the commercially published teacher’s guide. Still, this case underscores a common problem in formal learning environments. The formal situation fosters anxiety over being “wrong,” both from the view of the teacher and the students. The focus on the operational definition for solution and the push for correct conclusions were necessary from the teacher’s point of view to prove that the children had learned what was correct (and, presumably, important). The children in short time mirrored their teacher’s anxiety over being “correct” as well as her desire to gather evidence that they possessed the correct understanding of solution (as inferred from allowed or proper usage of language).

This anxiety does not allow the choice of being wrong, defined as failure to conform with sanctioned usage of “solution.” Experience of cloudy crystals and curved crystal walls derailed the process of making “proper” inferences about solutions consistent with the criteria of transparency and multiple substances. More importantly, any attention to the notion of “solid solution,” or response to the temptation to digress in considering disparate observations of cloudiness and curved walls confuses the task of formal assessment. Emphasis on language conformity, on the other hand, enormously simplifies the task of formal assessment. As a direct consequence, children are compelled to ignore their own experience when, in their minds, it fails to conform to imposed expectations. Furthermore, if they are socialized to please authority, they begin to pay little attention to experiences not associated with rewards, and hence, abandon their own struggle to find language which can express and order their own experiences of events. It is precisely this problem that informal environments have the potential to solve.

3. **Skills and dispositions.** Training in skills to a high level of performance follows from commitment to the need for public certification of competence, a key function of formal environments. Informal environments, by definition, do not certify levels of competence. Yet the lack of that need does not mean that learners will automatically succeed in free choice, socially complex, experiential settings. Learning in formal settings and randomly learning from often indifferent, chaotic settings (for example, commercials) do nothing to ingrained an image of the self as a learner. Ideal experiential learning teaches about learning itself. Learning from experience depends upon the individual’s conception of “self as a learner” in terms of confidence, habits, and dispositions.

Nothing is more critical to elementary education than enhancing the child’s conception of self as a learner, and creating interest goes hand in hand with this goal. A good learner knows what interests him or her and seeks new interests as well. The formal classroom—in the context of treating interest in science as a primary goal—has the opportunity to model the habits and dispositions needed by successful learners. In fact, the measure of formal education is how well it prepares children to learn from informal settings—to become, in effect, independent, lifelong learners.

Consider just how powerful is the image of the self as a learner. When something new and unexplainable is observed, people may react with “That’s fantastic!” or “What’s wrong with me that I don’t understand?” The event itself causes neither response; it is the interaction of the learner’s sense of self as a learner with the experience.

This sense of self includes awareness of prior knowledge and the disposition to use it. Good design reinforces this disposition. For example, several visitors to a “colored shadows” exhibit remarked that the colored shadows worked “like rainbows.” Nowhere had the designers acknowledged that prior experience with rainbows might influence how visitors interpreted the phenomena of colored shadows, nor had they anticipated the variety of misuses visitors would use to account for the source of colors (yellow “from my shirt,” white “from a light above or one hidden underneath somewhere”). The designers installed a series of modifications intended to improve visitor grasp of the principle of color mixing to form white light. As a result, visitors stayed longer and interacted more. The most important conclusion was that both learning and teaching improved. When, for example, labels were designed with the function of parent reading to a child in mind, they were used more frequently and tended to enhance the success of the parent as a teacher. In addition, the simple graphic of how to make hand shadow puppets, for example, prompted a substantial increase in the time visitors spent at the exhibit (Perry, 1989).
4. **Familiarity and anomaly.** Have you ever noticed a very young child (two years old or so) looking to find the rest of an object pictured on a screen or TV? Do you recall the scene in the South African film “The Gods Must Be Crazy” (Uys, 1984) where the Bushman was astounded that all the people had been made small and placed inside a telescope? What we already know—from experience, especially—determines whether a new phenomenon is assimilated as basically familiar or treated as something incongruous. The role of anomaly appears critical to sustaining interest, and the degree of anomaly is a function of prior knowledge. Striking a balance between the familiar and the incongruous is made more difficult by the issue in the previous section: the image of the self as a learner.

Often we construe “prior knowledge” too narrowly in educational settings. Creating interest from experience reminds us to think more expansively. For example, when children first begin to use a microscope, they have already had many experiences with turning and tuning knobs, directing beams of light, and looking through tubes, glass, and even lenses. In the informal science environment, children experiment with the microscope and learn through trial and error and guided practice. They bring with them their prior knowledge gained by looking through water glasses, kaleidoscopes, windows, and other objects, as they make sense of their experience with the microscope.

**Summary**

In either formal or informal environments, experience appears equally necessary to creating interest—but the issue of control over choices critically distinguishes between the two contexts, exerting enormous influence over how the experience might be interpreted and understood. Promoting interest in the context of experience means working with language in social situations, where exchanges (clarifications and negotiations) of meaning proceed freely. Language needs to be “about something” to have meaning. Sharing meaning through language creates the possibilities of sharing experiences.

Excessive concern for getting “the right answer” can cause the open exchange of personal ideas to shut down. In contrast, exhibit designers often illustrate through the function of their displays how nature works. The patterns and relationships on exhibit serve as to answer questions authoritatively. Good design lessens the intimidation of “right answer science” and encourages expressive communication and offers children choices in their interaction with exhibit materials.

The role of anomaly appears critical to sustaining interest, and the degree of anomaly is a function of prior knowledge. Learning from experience depends upon the individual’s conception of “self as a learner” in terms of confidence, habits, and dispositions. Children need to learn how to perform both social and personal roles in keeping with a conception of a self as a learner. Ideally, experiential learning in the context of interest as a goal will teach about learning itself. And lastly, creating interest from experience means respect for individual thinking as well as inviting unconventional outcomes.

Designing environments for creating interest means planning for ways to prompt good questions, build on prior knowledge, include choices of activities, promote social interaction, while providing a rich context for communication about science phenomenon. These are the elements of good exhibit engineering. They are also the raw material of classroom interactions in an environment that creates and sustains interest.

CONASTA 46
Annual Meeting of the Australian Science Teachers Association
June 29-July 4, 1997
University of Melbourne

The Theme
Science Down Under—Extending the Boundaries’ Our aim is to provide science teachers with up-to-date cutting edge information on the thinking of Australian scientists and near neighbours. The programme will also highlight practice and theory suitable for all levels of science education. It is our intention to extend the boundaries of knowledge.

Exhibitions
Throughout CONASTA 46 there will be extensive displays and showcases of science resources, videos, computer software, laboratory apparatus and curriculum materials.

Excursions
A full range of social and informative excursions are being planned to enhance the program. A special Sunday welcome function is being organised, along with a Conference Dinner featuring a mystery tour. A post-conference excursion programme will be available.

Registration
The registration brochure will be available later this year and will be sent to all members of the Australian Science Teachers’ Association. Initial expressions of interest can be filled in on the back of this brochure.

Travel
Qantas has been appointed the official airline for the conference and will be offering discounted conference airfares for conference delegates and accompanying persons. Full details will be included in the registration brochure.

The hard copy of your abstract should be submitted by November 1, 1996. Further information will be required by the STAV Secretariat as soon as practical after this date.

Presenters will be notified of their acceptance of Workshops/Seminars and all presenters are required to register for the Conference.

For more information contact:

Science Teachers’ Association of Victoria,
PO Box 190, Richmond, 3121
Tel. (03) 9428 2633, Fax. (03) 9428 4876

June 2-5, 1997
Second IOSTE Symposium for Central and East European Countries Science and Technology Education For Social And Economic Development
Lublin, Poland

The problems discussed during the Symposium will include:

• Development of knowledge in science and technology indispensable at the turn of the millenia.
• Changes taking place in a way of thinking of dents being affected by science and technology education.
• Prospects and citations of integration in science and technology education. Studies in development of cognitive abilities in science and technology education.
• Common research problems in physics, chemistry and biology education.
• Regional cooperation in the field of science and technology education.

The Symposium will be held in Lublin, a town situated about 170 kilometers south-east of Warsaw. It is easily reached by train or bus (travel time: 2 and half hours). Lublin is considered one of the oldest settlement sites in Poland. It is a large industrial and commercial centre, as well as scholarly, cultural and a tourist one.

The Symposium language is English, however, the organizers will provide some help (interpretation into Polish and Russian) for the participants from the East European countries.

Registration fee: 30 USD (IOSTE members 20 USD)
The organizers will do their best to make the participation costs (accommodation and meals) of the Symposium as small as possible.

June 21-24, 1997
International History, Philosophy and Science Teaching Group
North and South America Regional Conference
Calgary, Canada

A regional conference of the International History, Philosophy and Science Teaching Group will be held in June 21-24, 1997 at the University of Calgary, Calgary, Canada. The Dean of the Faculty of Education, Professor Ian Winchester, will be the conference chair. Although a regional conference, all members of the International Group, and others, are welcome to attend. Calgary is situated at the foot of the Canadian Rockies, near to the mountain resort of Banff. The conference programme will include an optional visit to the Rockies.

International and national groups that have interests in the role of HPS in science, mathematics and history teaching are encouraged to use the conference as an occasion to present their work and to consolidate networks.

Proposals for contributed papers, workshops, discussion groups, and exhibits of curricular and instructional materials related to the purposes of the conference are now being accepted. Four copies of the proposal or paper should be sent to Ms. Linda Lentz at the address below.

Proposals and papers should be sent to, and registration information can be obtained from:

October 1-5, 1997
8th International Conference of ISATT (the International Study Association on Teacher Thinking)
Kiel, Germany

The Conference theme is “Teachers’ Work and Professional Development.” The work of teachers is changing due to systemwide policies, global economic and technical trends, equity issues and changes in the nature of school subjects. These trends place teachers in new roles. How do teachers respond? In times of change it is important to consider the implications for the individual, social and cultural development of the teaching profession. What now constitutes, “professional” development? What is the impact of research and curriculum development?

Registration fee will be 400 DM for nonmembers and 350 DM for ISATT members or students.

Information about the forthcoming conference are provided on the Internet:
http://www.ipn.uni-kiel.de/isatt

March, 1998
Science & Society: Technological Turn
An International Conference on STS
Japan

Topics to be discussed include the following:

• Network assessment of science
• Transnationalization of Corporate Science
• Technology and Media
• International Relation in the Post-Nuclear Age
• Science and Technology in Asia
• Implication of STS on Science Education, Science Education Policy and Human Resource

Among the invited speakers are: Michel Callon, Sheila Jasanoff, Deepak Kumar, Morris Low, Brian Martin, Aric Rip, Rustum Roy, Song Sang-Youg, Peter Weingart, and Robert Yager.

New ICASE Member

The Southern African Association for Research in Mathematics and Science Education (SAARMSE) has become a member of ICASE. The correspondent is the Secretary/Treasurer, Mr. Philip Dikgomo, SAARMSE Secretariat, c/o Chemistry Department, University of South Africa, PO Box 332, Pretoria, 0001 South Africa. (e-mail address: saarmse@alpha.unisa.ac.za). The chairman of the associations is Dr. Audrey Ogude in the same University.

SAARMSE aims to promote mathematics and science education research regionally, nationally and internationally by means of fostering a sense of community among researchers in mathematics and science education specifically by:

- promoting research to improve and develop mathematics and science education programmes in southern Africa in response to current and future needs;
- organising annual conferences at which the results of research undertaken by members can be presented;
- assisting in the development of research skills of people interested in entering the field and developing further expertise through organising workshops, short courses and exchange visits;
- liaising with similar mathematics and science education organisations;
- making research results available and accessible to practitioners through conferences and publications;
- building an open forum for debate encompassing research paradigms.

Membership of SAARMSE is open to anyone who is currently engaged in research in mathematics and science education in the southern African region or who is interested in such research. There are currently 700 members.

ICASE/ASE International Seminar

An international seminar will be held in the University of Liverpool, England on 6/7 January 1998, just in advance of the Annual Meeting of the ASE in Liverpool from 8 to 11 January 1998. The theme of the seminar will be New Directions for Scientific and Technological Literacy—the Project 2000+ theme. Keynote speakers will include Svein Sjoberg, Vice-Chairman, IOSTE and Brenton Honeyman, President ICASE. There will be opportunities for paper and poster sessions on the conference theme. Expressions of interest should be sent to Dr. Mary Ratcliffe, School of Education, University of Southampton, Southampton, SO17 1BJ, UK (Fax: 44 1703 593556; e-mail: mrl@soton.ac.uk).

ICASE General Assembly

The ICASE General Assembly—the business meeting of ICASE at which new officers are elected—will be held in the University of Liverpool on 6/7 January 1998, during the international seminar being arranged by Dr. Mary Ratcliffe on behalf of the ASE and ICASE. Full details of the General Assembly will be sent to all member associations of ICASE during June/July. All member associations of ICASE are entitled to send a delegate to this meeting.
Feature Article

EDUCATION IN INDONESIAN PRIMARY SCHOOLS

Achmad Hinduan, Eddy Hidayat, Dadi Adi
IKIP Bandung, Indonesia
John Penick
University of Iowa, USA

Indonesia, a land of 17,100 islands and about 900 distinct cultural groups speaking hundreds of different languages and dialects, is one of the world's most diverse nations. With a population of nearly 200 million, this nation has faced many seemingly insurmountable problems in creating and maintaining an educational system suitable for its citizens. Like many former colonies, Indonesia gained independence in 1945 with only a minimal school system for natives. In 1940, for instance, only 1,786 native Indonesians (out of a population of about 60 million) were enrolled in secondary school programs. Since that time, this rapidly growing nation has made tremendous strides in raising the literacy rate of its citizens, building schools, creating books and curriculum, and educating a cadre of teachers. Much of this has been described in a prior article in this journal (Penick & Amien, 1992).

Using a few primary schools as examples, this paper describes the general nature of Indonesian elementary schools (known as primary schools in Indonesia) with a special emphasis on aspects of classroom climate, including the role of the teacher, the curriculum, and available materials. Our goal of these visits was to provide a brief look into the windows of a few classrooms, giving the reader a view of the conditions as they exist in this culture as we have seen and understood it (Altheide & Johnson, 1994).

While examples were drawn from interviews with only four schools and six teachers during visits to their schools, much of what we describe generalizes to all of Indonesia. The reader should keep in mind that most of our observations were conducted in the area around Bandung, a city of 1.7 million in the west Java highlands. One school visited was near Yogyakarta, in Central Java. But, the centralized curriculum in these schools is the same as in all Indonesian schools, the teachers meet the same requirements (but may have more than the required minimal education), and have attended the same inservice meetings mandated by the Ministry of Education and Culture for all teachers.

Although this is a relatively small and incomplete case study, Stake (1994) points out that case studies are legitimately carried out because of the researchers' interest in the particular case. Our interest was in the potential for understanding more about Indonesian primary education by viewing these rather dissimilar schools. Further, we were particularly interested in the schools of the Bandung region since we were working with preservice teachers who would ultimately be teaching in these schools.

Some Historical Notes

Prior to 1989, Indonesian elementary teachers were required to complete a special high school program preparing them to be elementary teachers. At this time, a new decree from the Minister of Education and Culture created a five-semester, post-secondary diploma program for all elementary school teachers (Dechow & Raka, 1996). With this new program, more than 1 million primary teachers required new training to be considered qualified. New teachers are now completing an additional four semesters of coursework plus student teaching while inservice teachers are receiving six semesters of intensive inservice workshops and courses, meeting 12 hours every week. Thus, almost all teachers have received recent preservice or inservice training. When applicable, reference will be made to teachers' experiences with these training programs.

While the mandated curriculum and the training of teachers is designed to be uniform throughout Indonesia, the reality here is no different than in any other country; as some schools have more resources than others, the training of teachers is not completely uniform, and the level of affluence and education of community varies tremendously. And, usually even those schools with the most resources, when compared to schools in more developed nations, are poorly equipped.

The Ministry of Education views universal basic education as up through grade 9, but only 69% of all
students finish grade 6, 58% finish grade 9, and 51% complete grade 12 (Ministry of Education, 1995). Tertiary education now enrolls almost 10% of the population ages 20 to 24 (Hollinger, 1996). Thus, the high school is almost exclusively preparation for university admission.

Primary schools are arranged into groups of about eight, with specific schools in the group taking the lead for different subjects. Thus, each school (and its teachers) acts as a resource for a particular subject. At least once a month the teachers of the eight schools meet to discuss curriculum, problems, and new ideas.

**Village Primary School**

Located in a small village only 10 km north of the center of Bandung, this school has 300 students, 10 teachers, and 2 principals divided into two separate schools, one in the morning and one in the afternoon. Teachers have 2 to 14 years experience and earn about 220,000 Rupiah per month ($93.61) as a base. On top of this they get a small allowance for having a family and for additional education. The principals each earn Rp 432,000 base. While these salaries are well above international poverty guidelines, they are not adequate to live on. The current (February 1997) mandatory minimum wage in Bandung is Rp 156,000 ($66.38) per month. To put this in perspective, the government describes the minimum wage as the “local cost of a daily caloric intake of 3,000 for a single worker” for thirty days per month (Jakarta Post, January 23, 1997, p. 1). So, these teachers’ salaries will buy about 4,230 calories of food per day, just a little more than what provided by a burger, fries, and a soft-drink in a western fast-food restaurant. Even the principals’ salaries only provide this level of support for three people. As a result, almost all teachers have a second (or even third) job to help them subsist at a minimal level.

**The School Building**

We visited in the morning, just after 8 AM. The school, down a narrow foot path less than 200 meters from a major highway, looks old, run down, and four of the six classrooms are around a small, paved courtyard where students are playing and gathering. The noise from the courtyard permeates all the classrooms, making them quite noisy. The children playing in the courtyard were, like all the children we observed in schools, clean, healthy looking, well dressed in their uniforms, and seemingly quite happy with laughter the norm. Never did we witness any signs of aggression or violence.

**Grade 1—Science**

The 21 first grade students (7 girls), like all elementary students in Indonesia, wore the traditional red shorts or skirts with white shirts and red neckties. Like all six classrooms in this school, the first grade room was 7 x 7 meters with large windows on one side and 16 two-student tables, arranged in a 4 by 4 pattern. Two two-foot florescent bulbs provided light. A blackboard in front, a bulletin board by the single door, and the obligatory pictures of Indonesian President Soeharto and Vice-President Sutrisno were the major decorations in the room. A series of teacher-made numeral charts around the room did add some color and interest. The charts showed each number up to 25 with 7 lemons or 23 apples and so on. There were no materials or other books visible in the room but there was a large cabinet in the corner. One electrical outlet was visible by the side bulletin board.

During our visit, students finished a math test and, with little teacher instruction, were working on assignments from their books. Minutes after beginning, few were on task and almost all were talking quietly with each other, looking around, or just sitting. They were very polite, though, and not being behavior problems. The teacher was at her desk in the front of the room, grading the tests students had just completed. There was no sense of discomfort on the part of students or teacher, leading us to believe that this was a normal part of the school routine.

Students were using a 96 page student text, the second of a two part series. The problems seemed typical of elementary texts with a lot of circle the number, writing by tracing dots, addition of single and double digits, and the beginnings of subtraction. Quite a few word problems were evident and the reading level seemed quite high for first grade.

The assignment book, 41 pages long, integrated arithmetic, Bahassa Indonesia (language study), handicrafts, and cursive writing. The level of reading again seemed high and the first 22 pages were word problems, writing assignments, and a little traditional arithmetic. The arithmetic sections included counting, logic, exclusion, word problems, subtraction, and even some geometry of angles. There are a few activities where students cut and fold to create shapes. Students must each buy all of their own textbooks. In a local store the books ranged in price from $1.50 to $4.00 each. With primary age students needing as many as 8 books per grade level, a teacher can barely afford to provide books for her own children, much less provide science materials for her students. The cost of books,
transportation to the more distant secondary schools, and lunch probably help raise the cost and the dropout rate significantly.

After the teacher finished grading the tests, she had students clear their desks and then began talking to them, very, very loudly to compete with noise from the courtyard outside. While this teacher, like all, has attended workshops and courses on student-centered learning, she read questions and the students shouted out the answers. The students, having no materials other than books, easily see the teacher as the center of attention. The same behavior is true in science, where the amount of equipment is only adequate for limited demonstrations. Even for this, little was done as the teacher said she was afraid of breaking the limited science equipment available. Like we have seen in many teacher-centered situations, near the end of class the students all put on their backpacks early, ready to go at a moment’s notice.

The class ended with the students, in unison, very loudly reciting a lengthy prayer. Most students were shouting it out, clearly in the appropriate spirit of the moment. When the time came, the teacher dismissed them by row, according to who was good. As in all classes we observed, behavior problems were rare, even though the students have few materials to engage them.

Grade 2—Science

Taught by the same teacher and in the same room as the first grade class just described, the new class entered, very noisy and happy. As soon as the students dropped off their backpacks, they left to go outside. Almost immediately, six students picked up small brooms and began putting up the chairs and sweeping, somewhat randomly but with obvious intent and practice. The teacher was not overtly organizing it in any way, just standing by her desk. On the bulletin board a listing showed which students were responsible for cleaning each day.

After a 15 minute break for snacks and sweeping, the students returned. These 25 (14 girls) began by reciting a prayer out loud. Again, they were very loud and eager. After the opening prayer, the teacher erased the board, slowly and carefully while the students milled around, some out of their desks. After some rearranging of students so that only two students were at each table, the teacher began asking questions and the students, as before, shouted out answers in unison. The topic was The Use of Money. For materials, the teacher went to her purse and collected some money to use in the presentation. She held up paper bills and would ask students to tell the denomination. As before, students shouted out their answers, eagerly and accurately. Most quickly recognized the color and size of each bill and did not even need to see the numerals.

This teacher, in both classes, spent almost all of her time in front of the room, leaning on a student table slightly to the left of center, near the windows. She had to shout to be heard above the noise from outside, which never ceased. She focused most of her attention on the left side of the room, perhaps because she was on that side of the room or perhaps because the observers were in the right rear corner. Several times during the first 10 minutes groups of students came in noisily, got brooms and then left. Each time, the teacher followed them and patiently closed the door behind them. Following 15 minutes of identifying currency, she assigned students problems from their text. Returning to her desk for more paper work, this continued to the end of class.

Grade 6—Physical Education

The teacher, a young man, teaches physical education half time in both the morning and afternoon schools. This room was even more bare than the first and second grade room. Other than 18 two-student tables in this 7 x 7 meter room, only a teacher’s desk and wobbly student benches were visible. Many of the table tops had serious termite damage which would make it difficult to write on. The backboard, about 1.5 x 3 meters, rested on a makeshift easel. As before, two two-foot florescent bulbs lit the room along with six small windows. One electrical outlet by the door was available. No teacher-hung materials and no equipment were visible. And, since there was no cabinet in the room, there could be no hidden equipment. The room is used for teaching all subjects to the sixth graders.

The 25 students (10 girls) in this morning class were listening to the teacher describe rules of soccer, the size of the field, and so on. The boys occupied all of the center two rows with the girls on the outside two rows of two-student tables. Seven girls were to the teacher’s right and three to his left.

The teacher wrote questions on the board and then students wrote down the answers on their papers. Following this, the teacher would ask the questions and students would shout the answers out. Unlike the grade one and two classes, only about half the students were involved in the shouting; most were passively sitting, especially the girls. The teacher was nearer the boys, talking directly to them, and never looking to the
side with the seven girls. Sometimes the girls had answers but, unlike the boys, they raised their hands and rarely shouted out their answers. And, when they did shout out, they did not do so as loudly as the boys. In thirty minutes of observation, the teacher never looked their way or recognized any of the girls, even when they had their hands raised.

Grade 6 science books presented many student activities using simple equipment such as magnets and electrical components and included a variety of practical applications such as plant propagation. But, none of the materials necessary for any of the activities were visible. The principal said there were some materials but they were locked up and he did not have a key. He was referring to the recently developed science kits that had been distributed to every primary school in the country. These kits contain a very small tuning fork, two 50 ml syringes, a knife switch, two flashlight bulbs (but no batteries), 6 small magnets (including a cover to make a compass), iron filings, a few pieces of wire, a few other items for physics, and a collection of biology charts which stress the labeling of body or plant parts. There are no chemistry activities and none that looked like earth or space science.

The Principals’ Office and the Teacher’s Lounge

At the west end of the school courtyard was the principals’ office, a 2 x 4 meter room containing a well-worn couch, a chair, a file cabinet, and a small desk. The walls were bare except for two large dry mark boards listing all of the staff and their relevant data such as birthday, age, experience, salary, and educational attainment. At the east end of the courtyard, a slightly larger room served as a teacher’s lounge. This room had a collection of textbooks, a class schedule, a room to store some materials, and a shiny new world globe. This was the only piece of non-text teaching material we saw in the school.

The science textbooks had an obvious UK and American influence and most were dated between 1994 and 1996. All contained a number of activities appropriate to the grade level. While some readings and activities were rather abstract, they tended to be quite short. The grade six teacher, a well-groomed and neatly dressed woman with eight years teaching experience and a full four-year university degree, said that she could only teach the theory of the science since she has no materials. The principal looked uncomfortable as she said this. Yet, the books usually call for only simple materials such as paper clips, razor blades, soil, seeds, and the like. Even batteries and bulbs should be not too difficult to obtain in Indonesia. The teacher however, like many others here, explained that it was not her role to buy or even obtain the materials needed to teach properly.

IKIP Primary School

Nunan, a 28 year old male with 7 years experience teaches 5th grade and Mimin, a 28 year old female, also with 7 years teaching experience, teaches 4th grade in what was once a teacher’s college laboratory school. The school now has 520 students and 24 staff members. A few months earlier, these two teachers both attended a two-week national workshop in Jakarta designed to teach them how to use the elementary science kits and how to teach their use to other teachers in their region. The school has been nominated as a science flagship school because these two teachers (plus one other) completed a special course in Jakarta and because the school has resources in science that other schools do not have. They had a wall of science equipment, including glassware, models of human anatomy, and the science kits. These materials are not stored in the classrooms.

Nunan and Mimin described the two-week workshop as beginning with a full day of ceremonies and then a second day of lectures about the procedures of the workshop. Thus, they had only 12 days of actual in-service in the use of the kits. Both Nunan and Mimin felt that they needed more time to really become competent in the use of the kits and in how to teach others to use them.

At the workshop, they were divided into three groups representing Physics, Biology, and Earth/Space science. Each group rotated through the topics, spending about 4 days with each topic area. Physics had the most experiments, biology was more descriptive and vocabulary-intensive. Earth/Space science had few activities and there were no chemistry activities.

Mimin and Nunan said that the workshop taught them how to take students out of the classroom and use the outside world for teaching. For instance, they did some simple ecology by picking up moss-covered rocks and looking for organisms. They also had worksheets to fill out that included questions such as: “What animals and plants can you find?” “Where do they live?” “What do they eat?” and so on. Both teachers felt they learned a great deal in this way. And, they learned how to supplement the curriculum with materials and ideas of their own design.

In physics, they said the workshop focus was more on teaching the teachers the content knowledge while
doing a few simple activities with electricity, magnetism, and sound. Since each participant had a science kit, they did get significant hands-on experience. Biology was more a review of plant and animal anatomy and related vocabulary. Earth/space science activities include mapping and compass use as well as paper airplanes.

While these two teachers said that the workshop did influence their own teaching and that they now do some simple demonstrations in their own classes, they are still quite teacher-centered, even though the intent of the workshops was to move teachers toward an activity-based curriculum. Unfortunately, they said they still do not have enough materials for more than demonstrations. While both teachers indicated that they also learned how to improvise and create equipment, neither indicated that they were doing this in their own teaching.

On the positive side, Nunan said that as a result of the workshop he now teaches more about nutrition, including the importance of fats, proteins, and carbohydrates in nutrition. He has students identify the fats in foods by rubbing them on paper. He felt that the workshop was quite useful for him and he recommends it to others. He has also continued his learning since he team taught (with two other teachers) a similar, six-day workshop to 100 teachers in the Bandung region the month after the workshop he attended. The 100 teachers shared 20 science kits that were borrowed from nearby schools. Nunan felt that teaching about the kits allowed him to become more confident about his knowledge and teaching skills.

Mimin said that she is now more flexible in her teaching and less worried about exactly meeting the national curriculum guidelines. She now understands that she can and must modify the curriculum to best meet the needs of her students. She did say that she feels she needs more workshop time, as 12 days was only enough time to see a few examples and not nearly enough time to really learn to modify existing materials or to develop new curriculum. Neither teacher mentioned anything in the workshop related to how they were expected to teach, even though this is designed as one major focus of the two week experience. As seems to be the case in almost all cultures, it is easier to change the curriculum than to change the role and behavior of the teacher.

Grade 4—Science

After talking with Mimin and Nunan, we went to Mimin’s classroom. Her room is 6.5 x 9 meters with windows along both the long sides. Open louvers are above about half of the windows. One door opens to the hall and another goes to a brick-paved courtyard adjacent to the high school. Six florescent fixtures hold a total of 12 four-foot bulbs. One electrical outlet is in the front, above the raised teacher’s platform that extends across most of the width of the room. Three bare wires protrude from next to the light switches, where another outlet may have been. There once was a sink in the front but all that is left is the tile backsplash and a bent water pipe protruding the wall. The high ceiling has numerous cobwebs hanging down and is quite dirty. It has been many years since the room was painted.

In addition to the teacher’s desk located on an 8-inch high platform in the front, there are some overhead cabinets in the rear and two metal cabinets in front. All the cabinets have graffiti scrawled on them, mostly obscenities in English! Students sit at two-person tables, arranged in five rows of five tables each. Girls are seated with girls with one exception, table 12. Student work is glued (not taped as tape is harder to obtain) to the walls in a number of places. Often, the student papers have been stamped with a rubber stamp that says “Good Student!” (also in English).

Mimin’s class was in the second day of making paper airplanes. The prior day they read in their books, Sains 4-B, about how to make them. The book contains several diagrams about how to fold paper into airplanes. Each student had taken one of these designs (or one of their own) and drawn their own plans for making the airplane. The 41 students (23 female) were organized into groups of three. On the day we observed, a teacher education graduate student was collecting data and had given each student a name tag. All students were well-equipped with paper, rulers, scissors, colored pencils, glue, and even tape. Some had stick-on letters and decals. Their task was to make the paper airplane they had designed the day before. After folding their paper planes, they were going to fly them outside.

The designs the students had drawn may have been copied but they had not been traced. They were generally very neat drawings, with great detail. All of the fold lines were indicated with dotted lines. Following some initial instructions, all students were soon folding their airplanes, following the instructions of their designs. They all were on task and seemed quite intent on their work.

The teacher circulated, speaking softly to one group at a time. She gave little in the way of directions, letting the students work on their own. Initially, there was little
talking, even among students at a single table. Ten minutes into the lesson there was more student talk, but usually lesson-related and confined to a single table. They were still very much on task, though. Several students re-drew their plans, after trying to use them. Students seemed genuinely interested in what they were doing, looking very serious as they worked.

Twenty-five minutes into the lesson, students were still very much on task. By this time, many had made two or even three airplanes, each different. Most students were very thorough, coloring, gluing, and adding aesthetic elements. None indicated any interest in the graduate student who was videotaping with a hand-held camera. And, almost no one paid any attention to an American in the room, even though they are rare in this part of Indonesia.

Next, the teacher, speaking very loudly, gave new directions about the next phase, going outside to try the planes out. Each table straightened up their materials and then sat quietly, waiting. Table by table, beginning with the front, the teacher then dismissed them to go outside. In the courtyard, students assembled in a U shape, with the teacher at the open end and the wind coming into her face, from behind the students.

The first team, from the bottom of the U, took a few steps forward, looking toward the open end of the formation. One at a time, each member of the team threw a plane, groaning and laughing when their planes fell short and shouting and laughing at a good throw. Generally, though, for the first six students, there was little success as they were throwing with the wind. One observer asked the graduate student about which direction airplanes usually take off, into the wind or with it. She quickly took that hint and spoke to the teacher, who turned the whole formation so they would be now throwing into the wind. The next throws were more successful. Then, of course, the wind changed. Resourcefully, the teacher now asked each group to fly their planes in both directions. Unfortunately, she did not ask students to measure the wind direction and correlate it with their flying success. In fact, no measuring of any kind was being done. The essence of the activity was to design, make, and fly the planes. At no time did we note students measuring, analyzing, or considering variables, much less manipulating or controlling them.

When Firman, the smallest boy in the class, came up to throw his plane great laughter erupted and we heard even more when his plane went by far the greatest distance, in both directions. The class also loved it when his first throw hit one of us, Achmad Hinduan, in the head.

After 15 minutes, only 9 students had thrown their planes, with 26 to go. It seemed a bit slow. At this time, eight of the boys were throwing independently, behind the formation of students. Soon, more than half the students were throwing on their own while the teacher continued working with the single team in the middle of the courtyard. Noticing the wayward students, she gently called them back to order and moved quickly through the procedure up to group 10. By this time, the boys were off on their own again. This time, the teacher did not call them back into the group.

Twenty-five minutes after the first throw, all had thrown at least once in the middle of the courtyard. The teacher brought them back into the group formation and called a few students, one at a time, into the center to see how far they could throw. The teacher chalked the point of impact of the airplanes of the first two boys and then, somewhat abruptly, sent the students back into the classroom, table by table just as they came out.

The graduate student gave each table a sheet of construction paper and students began attaching their planes to the paper. Each table would have a display of their work. In twelve minutes, almost all students had finished and were off task, talking loudly, bouncing things off the floor and tables, and creating a lot of noise. Several boys literally began climbing over the tables. During all of this, the teacher watched calmly from the front. Then, after consulting her watch, she began calling out table numbers. Quickly, every student was seated, the tables became quiet, and they began cleaning up. Then, looking only at the front, center tables, she dismissed them. Students left in no particular order, slowly, in no hurry, on their way to a recess. Even five minutes after this dismissal, most were still near the doorway but outside the room. When the teacher asked them to pose for a picture with the visitors, most were right there, waiting for the photo opportunity.

**Urban Primary School**

Located closer to the center of Bandung on a major road leading out of town, this school had 21 staff and almost 500 students. Like the other two schools, this one needed some repair and there was not enough room for the students in class or out. The classrooms, while relatively bare, had some basic equipment, although it did not seem to be used very often.
Grade 5—Science

The lesson was about soil, and began with a whole group discussion about how humans and other organisms need soil, where it comes from, and how it relates to the economy. The children went outside to investigate soil in the schoolyard, with specific directions to compare bricks which had moss growing on them to bricks which did not. The activity was taken from the student text. The teacher, who had attended the Jakarta workshop, had a very friendly and supportive manner, and was very encouraging children and worked hard to maintain their involvement. She seemed not too concerned about noise level and seemed to expect active student involvement. The 46 children in the class (21 girls) were very active, and were keen to answer questions, even calling out at times so that the teacher had to ask them to put up their hands.

Back in the classroom, the teacher split them into 5 groups of 9, and circulated around, encouraging them and clarifying the task each group was assigned. The lesson ended with the teacher taking what she wanted out of their oral reports as she summarized the ways in which rocks are eroded to form soil.

She next assigned homework, in which members from each group were nominated to bring a can with soil collected from near a river, in the garden, in the yard, and from a rice paddy.

The lesson provided for student input and for active investigation but we did not see any real opportunity for the children to discuss their ideas, generate any new directions, or ask any questions about the ideas. The teacher was firmly in control of the flow of concepts, which she did very well. While the learning was "active" in the sense there was student input and hands-on investigation, it was not the constructivist classroom promoted by the Jakarta workshop.

Grade 6—Mathematics

The two classes were somewhat drill-and-practice in nature, although one class in particular seemed very thoughtfully run and the teacher had prepared his own problems on the board as a revision exercise and the students were working through these. Both these classes were much quieter than they had been previously. The two teachers wrote problems on the board and students came up to solve them. Students at their desks copied down the problems and the solutions presented. As each student finished a problem, the teachers would ask questions, raise issues, and correct the work. On several occasions, the teacher asked another student to come to the board to try the problem. As this happened, students at their desks could be seen erasing their notes.

Mountain Primary School

Located north of Yogyakarta, this small school had only 200 students and five teachers. The five classrooms were in a one building which had windows down both sides. An area above the windows was screened and open all the time. Each room was almost identical, with bare walls, old furniture (usually two-student desks with benches), and badly in need of basic repairs to the walls, roof, and grounds. A small dirt playground faced the front of the school building. On the day we visited, we counted only 130 students in all of the classes.

Grade 1—Science

The teacher, a woman with 15 years experience and little inservice training except for a recent workshop on student-centered learning, was working with students on their leaf collections. She said that her recent workshop had led her to try some new things with her students. She chose a leaf collection as a way of getting her students more involved, outside, and avoiding the need for expensive materials. As we watched, her 27 students (12 girls) were in groups of two, sorting their leaves, talking, and tracing around the outsides. Later, they would try to match the leaves to the drawings as a way of testing their skills. Students told us that they had collected the leaves themselves and the teacher had only told them to find 25 different types of leaves.

After 15 minutes, the teacher began talking to the entire class, reminding them of her directions (to draw the leaves, mount the leaves on a piece of colored paper, and how to indicate their names). Then, for 10 minutes, she asked a series of questions, almost all of which could be answered with a simple "yes" or "no." Only in a few instances did a student answer in a full sentence and none volunteered any extra information. Students responded well, however, with many eager hands raised to answer. The class, like all we have seen in Indonesia, were very polite to the teacher and to each other. At the end of the lesson, the teacher told students to put their collections on a table at the back corner of the room. They did so and then she dismissed them to go outside for morning snacks.

The teacher told us that tomorrow, after mounting their leaves, they will hang them on the walls. She will then ask each group to stand by their collection and tell the class about their leaves. She said this is a technique she learned about from another teacher in the workshop.
she attended. When we asked if this activity was in the official course description, she told us that it was not but that the lesson helped students to classify, to observe, and to communicate, all goals of the syllabus. We thought she had a strong rationale for how she was teaching.

**Grade 4—Science**

The teacher, a 27 year old male, does not like to teach science. He says he much prefers social studies, art, and physical education. His science lesson for today was about energy transfer in the environment. The 39 students (19 girls) were sitting at tables for two but working independently. They were drawing pictures to depict energy transfer. Almost all students had basically the same drawing—a sun in one upper corner, a lake, trees, a few scattered plants, and a few animals such as birds, tigers, and even an elephant. Students were drawing arrows connecting the sun with the various plants and animals. When we asked students how the energy got from the sun to the organisms, many could not answer and some replied that it was heat energy. When we went on and asked where the sun got its energy, we were met with blank stares. Two students responded by drawing arrows from the trees to the sun.

While the students drew, the teacher sat at his desk, reading papers from a previous class. At no point did he move among the students to ask questions or even to make himself available. After 15 minutes, he told the students to set their drawings aside. He then proceeded to lecture about energy cycling, the water cycle, trophic levels, and decomposers. Some students took notes but most just listened and watched. The lecture continued for 15 minutes and then told the students to take out their textbooks and begin reading. They read for almost 20 minutes, talking quietly to each other, while the teacher sat at his desk and continued reading the papers he had there. Then, he dismissed the students by table and they left the classroom.

When asked, the teacher said he had attended the inservice for student-centered teaching. He felt that the drawings they were making were student-centered in that they were each making their own drawing. He said that he had to lecture to them because they did not know enough to understand energy flow on their own. Tomorrow, he said, he planned to continue the lesson by teaching about photosynthesis.

**Some Conclusions**

Like most settings, the primary schools and teachers we visited in Indonesia were teaching in a variety of ways. Many were deviating from the syllabus or text but most were still quite teacher-centered. Students were on-task but we saw almost no examples of students making decisions, designing experiments or devices, or evaluating. Almost every lesson could have been easily modified to include these components.

The teachers all seemed well-prepared, professional, and fully in charge of their classrooms. They were not afraid to have us visit and were eager to talk with us. This has not always been the case as we visit classrooms, especially in primary schools. We take this to mean that these teachers were confident, had nothing to hide, and were open to ideas.

Unfortunately, we found all the schools to be ill-equipped, the teachers to be under-educated, and the physical setting of the classrooms to be dark and drab. The intellectual climates varied more but still tended to be closed to new ideas, and no evidence of student experiments were noted. By experiment we mean where the student identifies the problem, designs solutions, undertakes the needed activity, and then evaluates the result. Instead, we saw what is typical in almost every country—the teacher identifies the problem and, at best, the student devises a solution. While this is efficient to covering the content, it does little to teach students how to think critically and presents science as a static and dogmatic field of study.

**Some Thoughts for Future Study of Schools**

This brief look at a few classrooms does not allow for generalization. We need to have many hours of visits to numerous classes in a large variety of schools before we may generalize far. The visits need to become more systematic, including more fully capturing the behavior and role of students and teachers. These brief snapshots are just that, a point in time that may or may not be representative of that teacher, class, or school. We look forward to reading such reports from others and to making such observations ourselves in the future.

Introduction

Toward the end of the Origin of Species, Darwin writes a lyrical description of the interrelationships found in one small region of nature, a river bank. He suggests that his readers contemplate

a tangled bank clothed with many plants of many kinds, with birds singing on the bushes, with various insects flitting about, and with worms crawling through the damp earth, and to reflect that these elaborately constructed forms, so different from each other, and dependent upon each other in so complex a manner . . . (Darwin, 1986, p. 373).

In this passage, Darwin seems to anticipate a holistic approach to scientific investigation, the view that a complete understanding of any phenomenon cannot be achieved solely by studying the parts in isolation from each other. In fact, a definition of ecology, "the scientific study of the interrelationships between living organisms and their environment, including both the physical and biotic factors and emphasizing both interspecific and intraspecific relations" (Walker, 1988) seems to be central to Darwin’s thinking long before the birth of the formal discipline of ecology.

In reflecting on Darwin’s words and the modern description of ecology, another environment comes quickly to mind—the school science laboratory. Of all teaching venues, there is little doubt that the laboratory is among the most complex. Hence, the central thesis of this paper is that the school laboratory is best viewed and studied as a rich environment with its own unique interplay of variables and interrelationships. Viewing the laboratory milieu from an ecological perspective can provide educators with a new understanding of the way in which relevant factors interact to support or block learning and suggest ways to enhance assessment of both students and laboratory activities themselves.

Historical Perspective

The laboratory has been widely-used in science instruction for almost a century and is now considered central to science instruction by many teachers. Weiss (1987), reporting the results of a nation survey of science teachers, found that twenty-one percent of total class time in secondary school science instruction is spent in hands-on or laboratory work. In addition, 80 percent of the teachers surveyed agreed or strongly agreed that laboratory-based science classes are more effective than those featuring lecture alone (Weiss, 1987). Even the new science teaching standards count investigative activity among those skills vital to achieving science literacy (National Research Council, 1994).

This interest in and appreciation for the laboratory in science teaching has spawned a virtual research industry. As Tamir (1994) states, “perhaps no other area in science education has attracted so many research reviews as learning, teaching and assessment in the laboratory” (p. 94). Unfortunately, as Blosser pointed out following her comprehensive review of research and opinion regarding laboratory instruction, “most of the research done on the role of the laboratory finds no statistically significant difference in achievement or attitude or lab skills between students given experiment-based lessons and students given lecture-based lessons” (Blosser, 1988, p. 57). “Despite this long history of investigation, science educators are
unable to provide a large amount of evidence in support of the contention that laboratory work would continue in science classes” (1981, p. 126).

Science education therefore is challenged by the realization that teachers will continue to engage students in laboratory experiences, science educators will persist in recommending the use of such inquiry experiences and researchers will continue to strive to show empirically that laboratory work is defensible. Perhaps we have been engaging in an incorrect perspective with respect to research and practice in the laboratory since most studies have examined single isolated laboratory variables. A more holistic view of this unique environment seems reasonable as the laboratory begins its second century of widespread use.

Holistic Study of the Laboratory

The proposal presented here, that the laboratory is best viewed environmentally, has its roots in several kinds of studies. First, much insight into the complexity of laboratory teaching may be gained by reviewing the inventories, checklists and interaction coding instruments that have been specifically designed for use in investigative settings such as laboratories. These schemes are based on a rich view of the relationship between the pedagogical, curricular and interpersonal domains occurring in the laboratory.

In developing a quantitative interaction coding instrument, Smith (1971) was among the first to examine the laboratory teaching environment holistically. Smith’s work was followed by that of Eggleston, Galton and Jones (1975) who produced the Science Teaching Observation Schedule. Another instrument fashioned specifically to examine interactions in the general science teaching laboratory was Science Laboratory Interaction Categories (SLIC) with one scheme to survey teacher roles (Shymansky, Penick, Kelsey & Foster, 1976) and another to help visualize what students do in the laboratory (Penick, Shymansky, Fikins & Kyle, 1976). Other tools for laboratory interaction analysis include those by Power and Tisher (1976), Guy (1982), Beasley (1983), the Laboratory Observation Schedule of Friedler and Tamir (1984) and Hegarty-Hazel’s (1990) System for Observation of Laboratory Behaviour: Tutors/Students (SOLT/SOLS).

A related approach, the Science Laboratory Environment Inventory (SLEI) was developed by Giddings and Fraser in 1989 as reported in Giddings, Hofstein and Lunetta (1991). SLEI was developed to assess student’s perceptions of the actual and preferred laboratory environments, but nevertheless is a useful source of guidance in the development of a description of the principle laboratory variables.

Qualitative examinations of the laboratory environment provide another valuable source of data. Stake and Easley (1978) were among the science education pioneers viewing science teaching itself qualitatively. Their now-classic case studies offer a number of clues into laboratory teaching. Other useful holistic studies include those by Tobin and Gallagher (1987), DeCarlo and Rubba (1991) and Solomon (1991) all of whom have examined aspects of laboratory culture.

The Laboratory Environment: A Proposed Taxonomy of Principle Variables

The following proposed taxonomy (Table 1) of the principal components of laboratory instruction results from several types of analysis; a thorough review of the qualitative analyses and underlying assumptions found in various quantitative interaction coding plans extensive personal investigation of laboratories (McComas, 1991). The final product was filtered through a wide number of practicing teachers who drew on their vast practical experience in the classroom to check for missing elements and review for comprehensibility.

Interestingly, the two major categories—physical factors and personal factors—are closely related to the biotic and abiotic elements found in lists of variables associated with inspections of environments in nature. In the case of the laboratory, variables categorized as ‘physical,’ are those that would generally exist even in the absence of learners and teachers. Issues such as the amount of time available, the arrangement of the room, the level of openness of the activity, and the relationship of the laboratory lesson to the remainder of the lesson exist even if no one actually does the activity. However, included in this category are some issues that require some student-based reference point such as the difficulty of the activity, safety concerns, and even the amount of time required by different students.

In the second major category of the taxonomy are issues pertaining to the human dimension. Student-related issues include both individual factors such as prior conceptions and experiences, psychomotor skills and psychological aspects such as attitude, motivation, and curiosity. Classroom dynamics (for example, class size and cooperative learning) are also included within the student division of the classification scheme. The nature of the verbal questions asked, goals and expectations held by the instructor, the knowledge base of the teacher, the teacher’s comfort level and the role of the instructor are all included in the list of the factors related to the teacher.
Table 1. A proposed taxonomy of the major physical and personal and psychosocial variables found in the laboratory teaching environment.

1.0 PHYSICAL FACTORS

1.1 Physical Arrangement (and limitations) of the Laboratory
   1.11 Space considerations
   1.12 Furniture and workspaces
   1.13 Ambiance of the room

1.2 Time Issues (Requirements and/or Constraints)
1.3 Laboratory Setting (Where is the laboratory conducted?)

1.4 Equipment
   1.41 Equipment available (to the instructor)
   1.42 Equipment available (to the students)
   1.421 Storage of equipment (Is it visible, accessible and open or closed?)

1.5 Curricular Issues (Linked to a specific activity)
   1.51 Goals of the laboratory (stated or unstated)
   1.52 Choices (problem, procedures, data collection and display modes) to be made by the students (student discretion)
   1.53 The problem to be investigated (teacher or student generated?)
   1.54 Exercise difficulty (clarity of task, number of variables, etc.)
   1.55 Relationship and positioning (timing) of the laboratory to instruction with respect to the lecture, text and the curriculum
   1.56 The level of difficulty of the written laboratory questions
   1.57 Assumptions of the laboratory (language, computation necessity, technical skills, developmental level, etc.)

1.6 Safety Concerns
1.7 Assessment Issues

2.0 PERSONAL FACTORS

2.1 Student-Related Issues
   2.11 Student’s Cognitive Abilities
      2.111 Prior conceptions (knowledge) held (supporting and blocking understanding)
   2.112 Student’s comprehension and reading abilities

   2.113 Student’s perceptions of the nature of science
   2.12 Psychomotor Skills Required by Students
   2.121 Students with special physical needs and limitations
   2.13 Prior Experiences
      2.131 With labs in general or with specific types of exercises
      2.132 With particular technical skills
   2.14 Student’s Psychological Nature
      2.141 Attitude
      2.142 Motivation
      2.143 Maturity/Responsibility
      2.144 Learning styles
      2.145 Confidence and Self efficacy
      2.146 Creativity
      2.147 Curiosity
      2.148 Interdependence and Independence

2.15 Classroom Dynamics (Relationships among students)
   2.151 Number of students in the class
   2.152 Grouping issues (arrangements, dynamics, etc.)
   2.153 Level of individual participation (opportunities for all to participate)
   2.154 Opportunities for cooperative learning and peer coaching

2.2 Student-Teacher Issues (relationship between students and teacher)

2.3 Teacher-Related Issues
   2.31 Teacher’s Role (Facilitator, Dictator, etc.)
   2.32 Nature of Questions asked Verbally
   2.33 Expectations of the Teacher
   2.34 Level of Approachability
   2.35 Knowledge (experience) of the Teacher
      2.351 Content knowledge (of a particular phenomenon)
      2.352 Curricular knowledge (where to get good labs)
      2.353 Pedagogical knowledge (how to instruct in the lab)

2.36 Teacher’s Psychological Nature
   2.361 Comfort Level
   2.362 Confidence
   2.363 Enthusiasm
   2.364 Values (Does the teacher value laboratory experiences?)
Applying an Environmental View of the Laboratory

The intention here has not been to produce the definitive list of laboratory variables. In spite of the care taken in the development of the list, this proposed classification scheme will certainly be amended as our knowledge about laboratory learning grows. Even in a tentative state, the view presented in Table 1 can be useful in three general ways; to further research into laboratory teaching, to impact teaching practice and related teacher education programs and affect assessment of both learners and practitioners in the laboratory.

In the realm of research, decades of commentary on laboratory teaching practice criticize the cookbook-like aspect of many exercises. Various studies of the laboratory have shown that it is effective to have students work first on the investigative component before class discussion of the phenomenon while other studies demonstrate that as the number of student choices increase, many students perform at higher levels. While these studies seem conclusive, what is missing is an examination of the extent to which their implications should be implemented.

For instance, in the interrelationship of variables found in the laboratory, while some students may certainly benefit and become empowered by having to make more choices in the laboratory. This suggestion may dissuade other learners because of their prior conceptions of what laboratory work should be or their lack of skills needed in a different environment. At the same time, the teacher variable comes into play. If teachers are not comfortable with their new role as a facilitator, classroom behaviors they apply may not support an increased level of student decision making. Therefore, from the perspective of research, it is vital that we investigate not just single variables but the effect that one aspect of the laboratory may have on others. In fact, many new research questions may be asked simply by looking at the issues contained in the classification scheme.

Practitioners too can benefit from an enhanced view of the laboratory as an environment. Dreyfus (1986) has shown how the same laboratory activity can be modified for learners of differing abilities by focusing on many of the issues presented in the taxonomy. For example, an exercise with several variables may be adjusted by having students concentrate on a single issue. Also, the written laboratory questions could be adjusted in difficulty by knowing something of the nature of the learners. Even extending the time available for the activity with some students can make a significant difference in the kind and depth of the learning that takes place. Only through knowledge of the variety of issues relevant to laboratory teaching can teachers make judgements about how to adjust particular activities to suit the goals they hold for laboratory instruction. Of course, with implications for practice also come implications for teacher education. Rarely is the laboratory discussed as a unique science teaching environment. Perhaps reference to the proposed taxonomy by methods instructors will provide motivation to include aspect of laboratory learning in programs designed to educate science teachers.

Finally, the assessment arena can be greatly enhanced by referring to the laboratory taxonomy. The finding that it is difficult to defend the laboratory based on research may be an indication that the wrong association of laboratory variables was applied in the design of particular activities or that incorrect student outcomes were examined. If laboratory assessment focused on the development of particular psychomotor skills, the improvement of scientific attitudes or even the enhancement of confidence, curiosity or independence, the laboratory experience may suddenly be seen as quite valuable. Unfortunately, these areas are rarely mentioned as goals for science instruction by teachers perhaps because teachers are unaware of the potential of the laboratory to develop these areas.

In conclusion, it is time that educators cease viewing the laboratory as simply another type of classroom. Classrooms can be complex environments in their own right, but the laboratory presents an even more intricate, involved and dynamic association of personal and physical factors. These factors must be taken into account by researchers and practitioners if the laboratory is to be studied and applied properly. Darwin concluded Origin of Species with the oft-quoted phrase, “[t]here is grandeur in this view of life . . .” (1986, p. 374). I would like to suggest that there is also a certain majesty to be found by examining the laboratory holistically. To paraphrase Darwin, an environmental perspective reveals the grandeur in this view of the laboratory.

HELPING STUDENTS UNDERSTAND THEIR OWN LEARNING THROUGH THE USE OF LOG BOOKS IN A SCIENCE CLASS

Nick Derry
Carey Baptist Grammar School Kew, Victoria
and
John Loughran
Monash University, Australia

Abstract

Students often see science as a subject that requires learning to simply be a matter of knowing, being able to use the right formula at the appropriate time, or being able to balance equations. Perhaps more than in other subjects, they also often see the teacher as the “font of all knowledge.” Because this view is often to the forefront of students’ thinking about science, they often undermine their own ability to think and learn in ways that science teachers themselves consider to be much more important. This paper is about how one teacher attempted to dispel the “I talk, you listen, do and learn” approach to science learning by introducing log books as a basis for the development of greater student responsibility for learning.

Introduction

Too often teachers experience a feeling of dissatisfaction with a lesson or a unit of work. Ideas and questions run through one’s mind: “Is there a better way of teaching this concept? I thought I explained it well but the students did not seem to understand it.” Dissatisfaction is felt as a sense of frustration or confusion about student learning (or the lack of it), and is exacerbated by assessment procedures that may not allow students to adequately demonstrate their understanding. The relationship between student learning and a teacher’s approach to teaching is central to professional satisfaction, yet little of the struggle to better relate the two is reported by practitioners. The tradition of working behind closed doors in one’s own classroom often hinders the free flow of professional knowledge amongst teachers. What many teachers view as good ideas or innovative teaching strategies are in fact much more, they are attempts to better relate teaching and learning. Promotion of these ideas should become more a part of professional dialogue so that our understanding and valuing of teachers’ professional knowledge is enhanced.

In this case the link between theory and practice was facilitated through a professional development in residence program (Loughran, 1994) and the incorporation of a Children’s Science approach to teaching (Driver et al., 1985; Osborne & Freyburg, 1985; Gunstone, 1990). The professional development in residence program was a way of ensuring that professional development was available to teachers at the school site. The science faculty of a school organised for a science teacher educator (second author) with a background in PEEL (Project for the Enhancement of Effective Learning, Baird & Mitchell, 1985; Baird & Northfield, 1992) to be available to work with them in their classes at times which suited them. As part of this work, both the PEEL project and a Children’s Science approach to teaching and learning became better understood by faculty members. This resulted in one science teacher in particular (first author) becoming actively involved in developing ways of ensuring that students accepted more responsibility for their own learning.

Reconsidering existing teaching

The 30 girls and boys who comprised the Year 9 class which was the focus of this study attended nine 40 minute science classes per two week cycle, all except one was a double period. The existing Year 9 science course was generally structured as individual units of work. The students had a booklet comprising worksheets and most of the information (theory and practical) that they needed for the unit.

The original Electricity Unit was more practically based than most of the other units the students had completed (Atoms and Molecules; Science and the Road; Body Balance; and Ecology). It was designed around introducing the students to circuits. As the unit progressed the circuits became more complex. One of the concerns with the format of the unit was that although the worksheets appeared adequate, there was no sense of conviction in the teacher’s mind that the students’ learning about electricity was being enhanced. The students followed the instructions but did not seem to be particularly engaged by the work; that “Aha, I get it now” type of response was lacking.
In essence, although the curriculum was well organised and structured, the students had become comfortable with a format which more often than not led them to think and act routinely rather than in a deliberate and purposeful manner.

Fostering student interest in a topic is important, especially while introducing a new topic. Paying attention to, and valuing students’ input and ideas is one way of doing this. The intention for the teaching in this unit was to use probes (taken from Osborne & Freyburg, 1985) to “unpack” the students’ understanding of electricity. By using these probes as a starting point, it was inevitable that the unit would become student-centred rather than teacher dominated. If the students’ interests, concerns and questions were to be taken seriously, then they had to be used to drive the unit. Their “need to know” would determine what would happen next. Lesson preparation would take on new significance, the teacher would have less control of the content sequence in lesson planning, but a much greater demand would be placed on the teacher’s ability to match activities to the students’ expressed need to know. A natural consequence of working from the students’ concerns was the replacing of the worksheets. The aim of the unit was for students to learn by their own “need to know.” Students used to using worksheets are aware that the answers to problems and what to do next can be found on the worksheets. Worksheets could therefore hinder the students’ own need to know, as they would take their cues from the worksheets rather than as a response to their own thoughts and ideas.

The use of teacher generated notes on the chalkboard following each investigation was also seen as inappropriate, as it would cause a reliance by the students on the teacher. This led to the idea of using a logbook as a means by which the students could record their own progress through the unit.

**Using logbooks**

In the logbook students were expected to record all of their observations, document their results, write their questions, develop their hypotheses and conclusions, and generally develop their understanding of the unit. It is important to stress that the aim of the logbook was not solely to replace teacher generated worksheets with student generated worksheets. Some teacher generated worksheets were used where “a piece of theory” was needed for the students’ investigations to continue. Examples included the use and function of the ammeter and the voltmeter. The logbooks were to be used to record every investigation and the questions raised in their minds during the investigations. Students were encouraged to record at the end of each entry what they had learnt that lesson, and what still puzzled them. As well as this, the logbook was to be used to document and describe in their own words new or unfamiliar terms in the form of a glossary.

The students’ logbooks were collected at the end of each lesson then distributed again at the start of the following lesson. The aim of this rather time consuming process was to encourage the students to document and think about their work during the lessons rather than writing up their ideas at a time distant from the experience. In writing up their thoughts, students had the opportunity to discuss investigations within small groups, sometimes including the teacher. There was also a whole class debriefing in which all students had the opportunity to share their results and ideas with each other. It was anticipated that this would encourage the students to think more carefully about what they were doing during a lesson as they were largely responsible for constructing their own notes. Also, knowing that their questions might be used to direct the learning in the next session, it was hoped that this would encourage free and honest questioning of concepts, and shed light on misunderstandings, in ways that were perhaps less likely in a teacher directed class.

The logbook entries were so interesting and revealing that the original notion of pursuing eight or so after each class soon grew to reading all of them. It was also apparent that through the logbooks many students were able to safely raise their concerns about not understanding the work. This was particularly important for those students who felt uncomfortable about verbalising their understanding in class debriefings.

**Log Books: catalyst for thinking**

The use of probes was a very important means by which the concepts already held by students on many aspects of electricity were able to be “unpacked.” The intention of the probes was to stimulate the students to explore their understanding of, and need to resolve, content dilemmas. Probes used in the first few lessons came from Osborne and Freyburg (1985). Those used in later lessons were devised by the teacher (first author). Through both classroom experiences and the students’ logbooks it soon became obvious that the production and use of probes involved the development of new pedagogical skills. Probes which were well written encouraged useful student enquiry, poorly structured probes added to student misunderstandings. As an unexpected advantage, the use of logbooks therefore aided in the development of new pedagogical
approaches, but it was through the open and honest questioning by the students that the logbooks really demonstrated their value by enhancing students’ learning strategies. The following examples demonstrate this point.

**Logbook A:** (referring to a probe from Osborne & Freyburg, 1985)

From experimenting with the (am)eters, I found that

A—is wrong
C—is wrong
D—is wrong

but I’m still confused about B. If the electricity current in the wires both go towards the bulb, then what happens to the electricity when it gets there? But, if the electricity flow is circular, then why is energy not being used up and current less like in C?

**Logbook B:** We found that all of the voltage supplied by the battery is used by the lamp, e.g., if the battery is 6V, the voltage will read 6V across the lamp.

**Logbooks C, D, E & F** (following group work activity and in response to “How do current and voltage change as the brightness of the lamp changes?”): If the light globe glows brighter, that means that there is more energy and more current in the circuit.

The questions they then wrote though were very interesting.

How does the battery know to send more energy?

What happens when we put in another light?

Clearly these examples, which are indicative of the group as a whole, demonstrate the value of logbooks as a way of genuinely accessing students’ thinking. Consequently, the possibility for the teacher to address students’ misconceptions or to work through particularly demanding conceptual principles in appropriate ways is enhanced. Also, through the various forms of dialogue between teacher and student, in the logbook and in the classroom, students’ metacognitive skills can be developed. Purposeful questioning in the quest for understanding can be recognised and rewarded both at the individual and the classroom level.

**Overview**

The impact of logbooks as a learning device was interesting. The students’ questions were the catalyst for many of the class’ activities and they appeared to be using their logbooks in a responsible manner. For some students they were a very useful learning tool, for others they were undervalued. This was mainly because not all students had the discipline (or desire) to record what they had done and learnt during a lesson. This was perhaps more a reflection on the teaching practices normally experienced than on the students themselves. Too many classes are still run along the traditional lines of the student being told what to think, what to do and what to write. It should therefore not be a surprise that when presented with a situation in which what they write is their responsibility that some find it difficult to make the transition.

The use of a logbook calls for particular learning skills which need to be addressed by both students and teachers so that they become a more acceptable and useful resource. Logbooks would be difficult to use if students are used to, or expect, the teacher to do the thinking for them. Teachers need to develop an atmosphere where reflection on practice and an interest in everybody’s ideas is the norm. Highlighting the use and value of metacognitive skills is important if students are to overcome the initial difficulties associated with organising their thoughts in a meaningful way on paper. Such skills can be developed through the use of techniques such as: telegrams—students write a sentence or two at the end of a lesson saying what they have learnt, or what still puzzles them; listing what I know about a topic—from a list of concepts/content taught, students comment on those they believe they have learnt/not learnt, the list can be teacher generated, student generated or both. These techniques help student learn how to record their thoughts and reflections. Once these skills have been initiated, students’ confidence in recording their thinking using a logbook can be continually encouraged.

After an investigation to look at energy in a circuit, and having already explored current, one student constructed a drawing and explained it, another developed an analogy, as the following demonstrates.

**Student A:** My drawing shows that there is current running through both wires (arrows) and the current remains the same throughout the circuit. With this current is carried energy (dots). When the energy comes to the globe it is changed into light energy and you see the globe light. The current goes back to the
battery to pick up more energy to take to the light.

Student B: The current is like a delivery boy who collects his energy, takes it to the light where it gets used and then he goes back to the battery for more energy and he does this repeatedly.

A number of the students who had not coped well with the worksheets in previous units were very taken by the logbook as a means of recording their work. Their understanding of the value of the use of log books was borne out by the fact that the majority of students did not feel that the logbook was appropriate for all topics. Many of the students could see that log books were useful as a communication tool with their teacher for their individual and small group based inquiries, but not all fully grasped the notion or saw the value in writing about their thinking and learning. However, they certainly noted that if a unit was more teacher centred, then a logbook was not as important to them because “the teacher would give them the right answer anyway; so why bother trying to work it out for oneself?”

From previous experience in teaching this particular unit the teacher considered that there was significant numbers of students who were disenfranchised by the topic. This was particularly the case for the girls. It was therefore interesting to observe how the use of logbooks allowed students to really take control of their own learning. The girls in particular were very enthusiastic. They proved to be very good at conducting their investigations, discussing results in both small and large groups, and documenting their thinking. A number of the girls came to have a significant input in the direction of their own learning and that of their peers as their questions were the catalyst for the teaching and learning in many lessons.

Conclusion

The students enjoyed learning in an environment where they had control over their learning. Many lessons seemed to instigate that `aha` response from students, perhaps illustrating how this particular approach to the topic had addressed and answered their questions. In the first four weeks of the unit in particular, the meaning of terms used outside the science classroom became better understood as they were introduced at appropriate times and in appropriate ways, rather than being thrust upon the students as purely propositional knowledge. Learning was seen to be valuable as it gave answers to questions posed as a result of reflection on the students’ everyday experience. A good example of this followed the investigations on current and voltage, and how the two changed in the two wires in the circuit used in the laboratory. A number of students then wanted to know how the electrical appliances they were familiar with only had one lead going to them. For a number of students the operation of this unit was really tapping into skills they did not know they had; metacognition.

For students to accept more responsibility for their own learning it is important that they be successful learners. Through the use of logbooks this success is able to be fostered as their understanding can be used to help shape the teaching experiences. Learning is also enhanced when the purpose for an activity is clearly understood by the learner. It is therefore important that this be explicit for the students, and can certainly be developed by the individuals through their logbooks, so that they are fully cognisant of the purpose of activities and that they can make informed decisions about their own actions (or inaction).

Perhaps one of the most telling lessons from this experience is that if students are to be more responsible for their learning, they need to value the learning experiences that they are confronted by. This is not a simple process, nor is it a quick process. However, if students are given the opportunity to explore their understanding of content in appropriate ways they are more likely to value the experiences. Despite the students’ apparent control of content in this instance, the content covered by them almost exactly matched that required by the curriculum for Year 9 science.

For many teachers it is often the case that there is an implicit need to be responsible for what their students learn. Therefore, if students are to be encouraged to accept more responsibility for their own learning then they need to value their learning, this happens best when the teacher’s practice matches the teacher’s beliefs. The use of logbooks is one concrete way of encouraging this.

For the teacher of these students, there was no doubt that through the logbook approach the students were more actively engaged in their own learning in comparison to previous groups. There has also certainly been an increased understanding of his own pedagogical approaches and the reasons that underpin them.

Cybercheck

This is a new journal for senior students and teachers. The emphasis is on science and society and, as such, is complementary to the ICASE/UNESCO initiative Project 2000+, scientific and technological literacy for all.

The journal will be published bi-monthly in printed form, but will be available also on 3.5 inch diskettes and through e-mail. Annual subscription is 50 pounds for the printed version, 60 pounds for electronic version. The first issue of the Journal has 40 pages.

A specimen copy of the new Journal has already been distributed to all members of ICASE. Individual subscribers to the ICASE Journal may obtain a sample copy by contacting the editorial office at Viale Aguggari 12, 21100 Varese, Italy (Fax: 39 332 236 997; E-mail: 100707.3432@compuserve.com)
Australian Joint Regional GASAT and IOSTE Conference

The international organisations Gender and Science and Technology (GASAT) and the International Organisation for Science and Technology Education (IOSTE) are holding a joint regional conference on December 5-8, 1997 at Curtin University's main campus in Bentley Western Australia.

Internationally, Dr. Jayshree Mehta is the president of both GASAT and IOSTE. It is, therefore, an opportune time for a joint regional meeting which will include the interests of both organisations and particularly the gender dimension of science and technology education.

GASAT

The aims of the international Gender and Science and Technology association are to:

- encourage research into all aspects of gender differentiation in science and technology education and employment;
- foster gender equality in science and technology education;
- foster socially-responsible and gender-inclusive science and technology;
- facilitate the employment of women into the fields of science and technology;
- provide a forum for dissemination and discussion of research and experiences of those working in the field;
- provide a support network for those working towards the objectives outlined.

Papers are invited that address any of these aims.

IOSTE

The International Organisation for Science and Technology Education was established to advance the cause of education in science and technology as a vital part of the general education of the peoples of all countries and to provide scholarly exchange and discussion in the field of science and technology education.

Papers are invited that have any of the following foci:

- alternative modes of delivery of science and technology;
- teacher education in science and technology that recognises and includes alternative modes of delivery;
- staff development for science and technology education;
- research in the teaching and learning of science and technology.

This conference will bring together a wide range of practitioners and researchers working in the areas of gender, science and technology education. Expressions of interest in attending and/or presenting a paper are called for. Flexible modes of presentation are encouraged. Abstracts and early bird registrations are due August 31, 1997.

Further details can be obtained from:

COOPERATIVE GROUP STRATEGY APPLIED TO ACTIVITIES
IN A POLYMER CHEMISTRY CLASS

Joaquín Palacios, Adolfo Obaya*
Facultad de Química, UNAM, Postgrado
Ciudad Universitaria, México 04510 D. F.
*FES-Cuautitlán, UNAM; Cuautitlán Ixcalli, Estado de México
MEXICO

Polymer Chemistry is a subject in the Chemistry Programs, students have a natural curiosity about Polymers materials, the materials that we all use in our everyday activities, such as poly(ethylene), PE, poly(styrene), PS, poly(amide)s are well known by the group and they are highly interested in their identification, production, characterization and peculiar properties.

Since there is a well spread misinformation about the contamination caused by polymers, we decided to clarify this point and emphasize in our classes, the beneficial aspects of the appropriate use of polymer in our community, so we thought that was important to test the cooperative group strategy in a polymer class with the main aim of improving the preparation of the chemical engineers in this topic.

The principal purposes of this project were:

1. To facilitate the study of the polymers science at undergraduate level.
2. To make the study of polymers more meaningful and close related to our everyday life activities.
3. To raise consciousness about the origin of raw materials used for the production of polymers, their chemical transformation and the necessity to recycle the polymeric product in order to maintain ecological equilibrium.
4. To discuss the economical implications of the great demand and consumption of polymeric articles.

Cooperative group strategy may be used to supplement other teaching methods. It involves students in small-group learning activities that promote positive interaction resulting in improved learning. In this cooperative learning, small heterogeneous groups of students work together to achieve individual and group objectives. The objectives may include both content and process skill outcomes. Additionally, by using well-defined roles, under the supervision of the teacher, students can develop social interaction skills.

As a result of its application cooperative learning produces positive effects on students who participate in it. In the affective domain, the strategy improves intergroup relationships among gender and stimulates the integration of social ethnic groups between normal and exceptional students (Slavin, 1991; Johnson, 1989; Kurfman, 1991).

The cooperative learning refers to a process in which the students working together in small groups, using social skills achieve academic objectives (Johnson, 1990; Kurfman, 1991). In this process the students realize that in order to reach their academic goals, the other students in the same group must also meet their goals (Slavin, 1990). This active participation enables students to practice interpersonal skills while they are achieving academic objectives.

Many studies (Johnson, 1989; Steinbrink, 1991) have shown that compared to other formats, cooperative attitude produces positive result in several domains. Researches (Jones & Steinbrink, 1988; Steinbrink, 1990) reported that higher achievement in their classes was observed when task in cognitive domain were
conceptually oriented. This orientation required problem solving and creativity, it involved higher level of the cognitive skills, and required the application of information to the real world.

According to other authors (National Council for Social Studies: NCSS, 1991; Steinbrink, 1990; Steinbrink, 1991), cooperative lessons should incorporate five essential components, those were incorporated during the development of our course.

As Steinbrink said, "the key to achieving positive results in cooperative activities is to divide the class in small heterogeneous groups, to develop specific task for each student in the group to perform, and to integrate these tasks into a teaching-learning sequence" (Steinbrink, 1991). For classes structured into group of four students, for example, the teacher would assign each group member one of the following roles: principal investigator, materials manager, the recorder-reporter investigator and maintenance director. Roles can be combined or divided as group size dictates. Stimulated by the positive literature reports in cooperative groups strategy we decided to use it, in a senior polymer chemistry class offered at the Facultad de Química of the National University of Mexico UNAM, in Mexico City.

**Methodology**

We methodology applied the cooperative group strategy to a class of 30 students enrolled in the Polymer Chemistry course that is offered every semester in the chemical engineering program. During sixteen week the polymer chemistry class met twice a week in a two hour session, along the semester. After a complete explanation of the cooperative group strategy (CGS), we asked the students to organize themselves in cooperative groups of the three, so a total of ten groups participated in this activities.

During the first week of the semester the instructor explained to the class the specific objectives of our project, these can be summarized as follows:

- To identify the origin of the raw materials used for industrial synthesis of the polymers.
- To become acquainted with the most important industrial processes used for the synthesis of polymers.
- To identify the most important variables related with the control of the polymerization process.
- To correlate the physical chemical properties of polymers with the final applications of this materials.
- To recognize the importance of the polymer's marked characteristics, the supply and demand.
- To evaluate the importance of polymers recycling.

The groups' first decision was concerned with the selection of a polymeric material that became important for a study, some of these materials are very familiar to the student since they are used in our daily community lives. Example of these polymers are: poly(ethylene) HDPE, poly(styrene) PS, poly(vinyl chloride) PVC, silicones, etc. Ten commercial polymers were chosen, see Figure 1.

**Figure 1.**

![Polymer Family Diagram](image)

In Figure 2, we try to emphasize the separation between the technical factors from the economic factors in our study. In the second session of the semester a list of the principal activities concern with the cooperative group were discussed with the class. We emphasized the importance of literature search, since no productive work can be initiated without a good knowledge of the state or the science for that subject, see Figure 3.
When the purification of the raw materials, the origin and quality characteristics are well understood, then the engineer is in a good position to undertake control of the production process. Once the monomers were purified and identified by means of spectroscopic test (IR, NMR, RI). The group synthesized the polymer. Activities such as literature search, monomer purification, polymer synthesis, characterization and identification, samples collection, final report and poster preparation were programmed along the semester on order to achieve the goals.

After the seventh week of the semester, the group concentrated attention in the search of several items fabricated with the material of study. Collection of five or more articles made of polymers were integrated. In order to facilitate this acquisition and to confirm the multiple application of polymers, the search was oriented principally around the house, the school and the office, articles used in our daily life activities, as examples we can mention: gears (PTFE), tooth brush (ABS), coffee cups (PS), decoration sculptures (PMMA), tires (NR). At the same time the students were involved in samples shopping, around one pound of ships of the polymeric material was collected. The samples and properties sheets were obtained through the local offices or large commercial producers.

Meanwhile we covered the topics of the current program in our regular sessions.

During the 14th week, the group became involved in the preparation of the final report. In the paper they included all the outstanding information gotten in the former activities. The information was concentrated on the form of: monomer and the polymer properties tables, polymeric reaction conditions and mechanism. Great importance was given to the selection of the appropriate polymerization technic. Engineering aspects of the reaction as the kinetic equation and type of reactor recommended were analyzed and asked to be included in the report.

In most cases the core of the paper was dedicated to the description and variables analysis of the industrial polymerization process. Questions concerned with the type of reactor and equipment required to separate and purify the polymer were analyzed.

The polymeric materials studied were classified according with their main application in five traditional families: engineering plastics, fibers, coating, elastomers and adhesives. The figures describing the consumption tendencies and the relation production-consumption were included. The principal national and international material's producers were identified.

One section of the report was dedicated to the presentation of examples of the practical uses for each polymer, pictures of items were included, most of the groups were oriented to the presentation of some spectacular applications, as the medical, aerospacial and telesat. See Figures 3 and 4.
The class decided to share this experience with the rest of the college community, so we organized a poster display in the main floor of building “B,” entrance hall of Facultad de Química UNAM. This place is frequently visited by the students and is the natural meeting place for our classes.

In a democratic way the class decided to call this event EXPO-POLYMERS. The class was organized in groups of six members. Each group had a special assignment. One group was appointed by the professor to the preparation of the show place, engineering activities concern with the electrical power supply, lights and general services. Another group was charged with painting and grooming the show area. A third group took the responsibility of preparing invitations and programs for faculty members, families and friends. One group suggested to have guided tours around the exposition, in order to present and discuss the information in a well documented manner, in this group each aide worked with a small group of five persons for periods of 30 minutes, the necessary time to go over the display. Another group was assigned to produce information about the event for the media, college newspaper articles. Colleges TV. One video with the most relevant moments of the opening session was prepared. The opening ceremony was attended by graduate studies dean and a large group of faculty members from the Chemistry and Engineering Departments. See Figure 5.

Conclusions

During sixteen weeks of the semester the class was very active. The cooperative spirit of the group was very high, this environment facilitated the communication with the professors, among the groups and in the groups. As a result we can say that our objectives were reached in a very productive way.

A more positive affective relationship among students and between students and faculty has been observed in the group, these concepts were shared by the classes working with cooperative strategy, as a result, a more positive psychological well being, greater self-esteem, self-sufficiency, social skills, coping skills, and general psychological health, was developed in the class.

The students comments were very favorable to the project. This was a life time experience that we want to share with others.

**SCIENCE & SOCIETY: TECHNOLOGICAL TURN**

*International Conference on STS, Japan*

*March 1998*

Topics include the following:

- Network Assessment of Science
- Transnationalization of Corporate Science
- Science and Technology in Asia
- MITI and Innovation Policy
- Cultural Studies
- Gender
- Social Epistemology of Science
- Implication of STS on Science Education
- Human Resource
- Knowledge Production Mode 2
- Technology and Media
- Japanese Studies on STS
- Post-Colonial Studies
- Expertisation and Public Awareness
- Medicine
- Religion and Science
- Science Education Policy
- International Relation in the Post-Nuclear Age

Invited speakers include the following:

- Michel Callon
- Deepak Kumar
- Brian Martin
- Rustum Roy
- Peter Weingart
- Sheila Jasanoff
- Morris Low
- Arie Rip
- Song Sang-Youg
- Robert Yager

To obtain the first circular or more information, please contact:

Conference Office

REGIONAL GUIDELINES AND PRELIMINARY TIME LINES

Step 1 June–July 1997

Regionalizing or nationalizing project material, for example possible translation, addition of local reply address, etc.

Step 2 August–September 1997

Copying and distributing the adapted brochure to all members of ICASE in the region and as widely as possible to any other interested people, schools, or education offices.

Step 3 September 1997–Early 1998

Encouraging and collecting as many names and addresses as possible of schools wishing to take part in the links scheme. Making a regional list or data base of the schools interested in joining the international science links scheme.

Step 4 Early 1998

Send to all interested parties or schools in your region who request links a Key Information Sheet and reply letter.

Step 5 April–June 1998

The ICASE Regional lists of those wishing to participate need to be centralized, matched and the links made. Executive Secretary, Jack Holbrook has offered to do this amalgamating of the lists and data bases.

Step 6 Any time after the link is made

Schools and links will forge ahead.

Step 7 Towards the end of 1999

Information from linked groups wishing to share their international Links Science/Technology Project would need to be collected, certificates issued, and the possible means of sharing the experiences carried out (for example possible exhibitions, news letters, posters, booklets).
Editor's Introduction

Across the world attention is shifting from pre-service teacher education within the confines of the college or university to the crucial phase of induction, the first year(s) of teaching when the teaching novice grows into the profession. Student teachers often complain about the irrelevance of pre-service education, teacher educators complain that in pre-service one can only teach survival skills and that students are not ready for more sophisticated teaching skills and methods until they have taught at least a year and then they are out of reach of the teacher educator as they have graduated. That is one of the reasons that pre-service teacher education itself is shifting from colleges to the schools. In UK pre-service students spend most of their time in the schools and their mentors (cooperating teachers) are their teachers more than their college advisors. Induction programs assist teachers in their first year(s) of teaching and try to put them on the track of life-long professional development (see Poul Klindt’s article about the Lesotho induction program in ICASE Science Education International of June 1994). Below Herbert Thier describes a comprehensive project on the West Coast of the U.S.A. In a later article he hopes to give information about first experiences.

******

The goal of this project is for beginning teachers to experience student teaching and the early years of teaching as the beginning of a long term growth and learning experience. For this to happen, we must change the way teachers are prepared for and function in tomorrow’s classrooms. The focus in this project will be the teaching and learning of science as an exemplar of an overall approach to more effective teaching in the elementary school. This project will be a cooperative effort between the Science Education for Public Understanding Program (SEPUP), developers of CHEM at the Lawrence Hall of Science, University of California at Berkeley, and the Institute for Educational Inquiry (IEI) of Seattle, Washington and its associated Center for Educational Renewal (CER) at the University of Washington. Overall responsibility for the design and implementation of the project will be the responsibility of Dr. Herbert D. Thier, Director of SEPUP, and his staff. Dr. John Goodlad, President of IEI, and his staff will be responsible for cooperatively designing field test models and helping to implement field testing of the project in five of its National Network for Educational Renewal (NNER) settings, and five additional sites to be chosen.

SEPUP/CHEM will provide the instructional materials to be used in the classroom by the participating teachers and will design, develop, and produce the materials and models for using them, which will be used by teacher educators in their work with pre- and in-service teachers. The cooperation of the IEI/CER and its associated National Network for Educational Renewal will provide the project with extensive input on models and approaches for using the instructional materials to be developed. In addition, this cooperative effort will permit the materials to be used at selected NNER sites. These sites are involved in a major national effort to establish new teacher education programs based on institutional commitment at all levels, including the full participation of education and arts and science faculty and deans plus the teachers and administrators from partner schools. These NNER sites are currently developing instructional materials and developing and
establishing pedagogic practices, particularly those related to the supervision of student teaching and associated experiences for future teachers.

**Project Goals and Objectives**

**Goals**

The goals of the Elementary Science Teacher Leadership project are:

1. Design, field test, and produce science teacher education materials (the ESTL guides) and approaches for using them that will contribute to improving the quality of elementary science teaching in the United States.

2. Further design, make available, and help put into practice cooperative models for including such materials in the wide variety of organized pre- and in-service elementary teacher development programs currently under way or planned in the United States.

3. Collaborate with professional groups such as the National Science Teachers Association (NSTA), the Association for the Education of Teachers in Science (AETS), and others to design and offer a series of Exxon Elementary Science Teaching Institutes. Institute participants will include university professors, school system leaders, and others responsible for designing and implementing elementary teacher development programs at the local level.

**Selected Objectives**

1. Select topics, format, and suggested models for the Elementary Science Teaching Leadership (ESTL) guides that will be developed by the project for use by elementary science educators.

2. Design, pilot, collect feedback on and revise two sets of five ESTL guides and suggested ways of using them as part of an overall approach to improving the ability of pre- and in-service elementary teachers to teach science and use science to more effectively accomplish their overall instructional goals for their classes.

3. Carry out national field tests of each set of five ESTL guides in conjunction with five selected IEI/CER/NNER sites and five other sites that include school systems participating in the Issue-Oriented Elementary Science Leadership (IOESL) Project.

4. Prepare all ten ESTL guides and the suggested models for using them for final publication, incorporating feedback, assessment results, and independent expert reviews. This will be done cooperatively with the ESTL Panel and the input from the IEI associates involved in the project.

5. In cooperation with the ESTL Panel and representatives of selected professional organizations design a seminar program for introducing teacher educators to the ESTL guides and their use in pre- and in-service elementary teacher education programs.

6. Conduct and collect feedback on a pilot Exxon Elementary Science Teaching Institute in Berkeley during the summer or fall of 1999.

7. Field test the project approach to developing elementary science teaching leadership by conducting three Exxon Elementary Science Teaching Institutes during the 1999-2000 academic year.

8. Use further feedback and evaluation of both the modules and the institutes to develop a long-term plan for offering the institute and for providing attendees with the ESTL guides and other project materials needed to effectively utilize the modules in their own teacher education programs.

**Please Note:** The editor would like to remind our member organizations and individual readers that all articles in Science Education International are available for reprint in your own journals. All copyrights are extended to members. This is a wonderful opportunity. Please consider starting an international section for your journal and use our fine articles to expand global awareness. All we ask is that you give credit to the author and the ICASE Journal.
PROMOTION FOR THE TEACHING PROFESSION

Ed van den Berg
Science and Mathematics Education Institute
University of San Carlos
Talamban Campus
Cebu City, Philippines 6000
E-mail: edberg@durian.usc.edu.ph
Fax: 63-32-346 4614

In many countries teaching has lost its glamour and teacher shortages have surfaced in science and even more so in a field like Physics. In some (not all) industrialized countries the glamour has gone due to more serious classroom discipline problems than before and salaries which have become less competitive. Even students from teacher colleges no longer become teachers automatically. In the 1980s many science teaching graduates in the Netherlands became teachers of computer courses in industry and business rather than school teachers. In many countries teacher colleges became polytechnics or universities. In developing countries the emergence of mass education (positive) has created a huge group of teachers and made salary increases or even compensation for inflation very difficult for governments. In many African countries teacher salaries have dropped considerably. Where before the leaders of independence and national heroes had been teachers (Julius Nyerere, former president of Tanzania; Kenneth Kaunda, former president of Zambia; others), now their sons and daughters would become anything but teachers. In quite a few countries corruption in the huge national Departments of Education has made classroom teachers particularly vulnerable and powerless. The result has been that only weaker and/or poorly prepared students go into teacher education leading to a considerable drop in competence. It should be emphasized that trends as described here are often cyclical, but with very long cycles. For example, complaints about the talents of recent teaching graduates might lead to higher salaries and then to higher status of teachers which might attract better students.

When designing our science teacher education project in the Philippines over two years ago, we (Philippine and Dutch colleagues) opted for prioritizing pre-service teacher education over in-service. For many years the production of teachers had been much less than replacement and expansion needs and many unprepared teachers had entered the profession somehow. For example, 90% of the Physics teachers and 80% of the Chemistry teachers in the Philippines are considered not qualified in their subject. Most Physics and Chemistry teachers come from other subjects such as Mathematics, Agriculture, and Physical Education and have been forced to teach Physics or Chemistry. We wanted to attract bright students into a profession that more and more only attracted weak students. Our Philippine colleagues believed that a promotion campaign and scholarships would do the job. We had some doubts whether that would be sufficient but they were right. We have had a promotion campaign for two years and about 35 scholarships each year and we have been able to attract 35 good students last year and another 35 this year. Among them are valedictorians (best students in their graduating class) and quite a few (about 30%) honor students who placed 2nd, 3rd, or 4th in their graduating class. For many students the scholarships are the only way to get into higher education, the scholarships contribute to upward mobility. In interviews these students have been able to convince us that they are really interested in teaching and not just in the scholarship. We will see how their motivation develops. However, there are also children of the middle class. Their parents consider teaching as a sure job while other professions (even engineering) have many unemployed.

Promotion campaigns have to work differently in different countries. In the box I included a sketch of our Philippine sales pitch and it has worked very well. In the early 1980s in Indonesia there was a scholarship scheme to overcome the shortage of science teachers. All over the country 1, 2, and 3 year Diploma programs were started with guaranteed placement as a teacher upon graduation. A new group of students entered college, those who could not afford a regular college program, but whose families dared to invest in a two year program with a guaranteed job at the end. We were able to select students from four times more applicants than we could accept. Nationally the program fared less well due to poor quality teaching and lack of quality control, but the programs did attract enough students. When later the worst teacher shortages were alleviated and government jobs upon graduation became a problem, the number of applicants quickly decreased. At present there is a serious oversupply of teachers in some heavily populated provinces in Indonesia. Yet
these experiences do show that in developing countries the proper incentives can generate a stream of good applicants for teacher education programs. Scholarships can do the job.

In the past Dutch students in university programs could take a bit of extra load for several semesters and get certified as teachers for the upper academic levels in high school. In the mid 1980s the system changed and required an extra year of study. Furthermore, education budget cuts were achieved by cutting salaries of beginning teachers and sparing the older and highly paid teachers. These older teachers had been hired in the 1960s at relatively high salaries when the economy was booming and participation in secondary education expanded rapidly. The low starting salaries were bad publicity for the profession. For several years no students entered physics teacher education. Then when the government offered graduates of selected science subjects (Math, Chemistry, Physics) half-time teaching jobs with full-time pay and paid for teacher training, students were coming although not in great numbers. The scheme had to be discontinued due to cost. Teacher colleges constitute another component of teacher education in the Netherlands. They educate teachers for junior secondary teaching. The colleges have tried all sorts of campaigns to attract students, but particularly in Physics and Chemistry, they have not been successful.

The status of the profession has been undermined by budget cuts and widely published classroom discipline problems. As elsewhere (e.g. Australia, UK), the Dutch teacher colleges have merged with other forms of higher education and have become polytechnics or 2nd tier universities.

What do we learn from this story? That the proper mix of incentives can attract good students into science/math teacher education but one does need the proper selection instruments and policies as well as a good educational program to realise the benefits of potentially good students. Also in industrial countries governments can “play” with the mix of incentives and disincentives, but it is more difficult to compete with well paying alternative employment and students are less “influenceable.”

Note to Member Organizations

Please ask your members to submit material to Science Education International. We are looking for:
• Teaching activities and lessons, especially for elementary
• Action research articles which talk to the practicing teacher
• Research articles which focus on practice, not research strategies
• Informal and nonformal articles which address “Things to do” in these settings

PLEASE INCLUDE PICTURES AND OTHER DRAWINGS OR GRAPHS.
Manuscripts may be sent to:

Lincoln, NE 68588-0355
USA
A PROMOTION CAMPAIGN

First we pushed the car with driver to the nearest gas station. Apparently he ran out of gas and money and had reached us on the last drop. Then we drove for 12 hours over a slow road with a lot of traffic until we arrived at a small (330 students) Catholic High School. The purpose of the trip was to advertise our teacher education and other science programs.

You cannot become mayor, big businessman, or President of the country without teachers! Even Jesus chose to be a teacher. This is how my Filipino colleague Malou Gallos started her speech to the students. The teacher profession has had a low status for some time. That is why it seemed necessary to use religious and secular heroes in the promotion. Some other golden statements: The most beautiful and handsome in the professions are teachers, because they have a two month vacation to rest and beautify themselves. Which other employer in the Philippines offers a two month paid vacation? (About 80-90% of the science and math teachers are women.) My colleague does not mention that most female teachers have families and perhaps just like herself do the laundry at 4:00 a.m. and the ironing and 22:00 p.m. However, the Filipino High School students react much less skeptical than Dutch students would have, but they certainly know that teaching is a lot of work for a limited salary.

Is being a teacher hard and tiring? Yes, shouts the class. Can you become a millionaire by teaching? No, shouts the class. Do you know that teachers have long and paid vacations? No, they did not seem to know. Do you know that the teacher does not only earn P2000 or 3000 but P7000 ($260/month)? Look at Mrs. Reyes (the chemistry teacher of the school), does she look poor? No, not quite, they seem to think. And I? No. And look at Dr. Ed, is he poor? No, shouts the class. One can read in their expressive faces: Such a foreigner with a fat salary . . . But he is a teacher, so becoming a teacher cannot be too bad. Who has parents who are teachers? Now, several students have. Well, they had the money to put you to school in this school!

We have been to many schools with her speech and my demonstrations. Now we have 35 students for the Physics/Chemistry pre-service teacher education program and we have been able to select from more than three times that number. All students have a scholarship, one half from the Philippines government, the other half from our project. All students have passed their first semester courses without major problems. The promotion campaign also resulted in about 60 new students for the regular Physics program (PDP project) while the annual intake had been two or three students for the last 15 years. This year Malou Gallos and her colleague, Cheryl Yap, were able to get 2000 students to take the exams for Government Science and Technology scholarships. Some of these students will come to our programs, others will go into engineering. Our challenge now is to offer these students good programs.
Calendar
1997-1999

June 21-24, 1997
International History, Philosophy and Science Teaching Group
North and South America Regional Conference
Calgary, Canada

A regional conference of the International History, Philosophy and Science Teaching Group will be held in June 21-24, 1997 at the University of Calgary, Calgary, Canada. The Dean of the Faculty of Education, Professor Ian Winchester, will be the conference chair. Although a regional conference, all members of the International Group, and others, are welcome to attend. Calgary is situated at the foot of the Canadian Rockies, near to the mountain resort of Banff. The conference programme will include an optional visit to the Rockies.

International and national groups that have interests in the role of HPS in science, mathematics and history teaching are encouraged to use the conference as an occasion to present their work and to consolidate networks.

Proposals for contributed papers, workshops, discussion groups, and exhibits of curricular and instructional materials related to the purposes of the conference are now being accepted. Four copies of the proposal or paper should be sent to Ms. Linda Lenz at the address below.

Proposals and papers should be sent to, and registration information can be obtained from:
Ms. Linda Lenz
Faculty of Education
University of Calgary
Calgary, Alberta
Canada, T2N 1N4

October 1-5, 1997
8th International Conference of ISATT (the International Study Association on Teacher Thinking)
Kiel, Germany

The Conference theme is “Teachers’ Work and Professional Development.” The work of teachers is changing due to systemwide policies, global economic and technical trends, equity issues and changes in the nature of school subjects. These trends place teachers in new roles. How do teachers respond? In times of change it is important to consider the implications for the individual, social and cultural development of the teaching profession. What now constitutes, “professional” development? What is the impact of research and curriculum development?

Registration fee will be 400 DM for nonmembers and 350 DM for ISATT members or students.

Information about the forthcoming conference are provided on the Internet:

January 8-10, 1998
ASEF Meeting
(More details to come.)

March, 1998
Science & Society: Technological Turn
An International Conference on STS
Japan

Topics to be discussed include the following:

- Network assessment of science
- Transnationalization of Corporate Science
- Technology and Media
- International Relation in the Post-Nuclear Age
- Science and Technology in Asia
- Implication of STS on Science Education, Science Education Policy and Human Resource

Among the invited speakers are: Michel Callon, Sheila Jasanoff, Deepak Kumar, Morris Low, Brian Martin, Arie Rip, Rustam Roy, Song Sang-Youg, Peter Weingart, and Robert Yager.

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Workshops on Creating STL Teaching Materials—
Lahore, Pakistan 4-8th April and Mar del Plata,
Argentina 19-22nd April, 1997
by Jack Holbrook

ICASE, in conjunction with UNESCO and the local STAs, ran two STL (scientific and technological literacy for all) teacher writing workshops, one in Lahore, Pakistan and the other in Mar del Plata, Argentina. In these workshops, participants from regional STAs and other institutions were introduced to the Project 2000+ philosophy on science education and the need to make science teaching in schools more student-centred and more relevant for the students. Stress was placed on the need for change, but with this change first coming from the teacher in the classroom.

(Examples of this material is on the ICASE website: http://sunsite.anu.edu.au/icase)

In groups the participants were invited to create materials of their own. These are now being edited and will be trialed in the school situation. The participants judged the workshops to be very useful and the Project 2000+ philosophy worthy of further consideration.

It is hoped follow up to these workshops can take place and further regional workshops of this nature initiated. Participants for the regional workshops should be well placed to assist STAs run local workshops of a similar nature. ICASE will be very interested to hear from STAs willing to host such workshops. Please contact the ICASE executive secretary.

One approach suggested for helping change was the creation of supplementary STL teaching materials. First a number of exemplars were introduced and the participants interacted with these at length. All exemplary material met the STL criteria set:

1. Student participatory
2. Relevant to the local society
3. Motivational for the students
4. Educational - promotes higher order learning and societal/personal skills
5. Based on constructivist principles
6. Promotes communications skills
7. promotes cooperative learning

10th ICASE Asian Symposium

The 10th ICASE Asian symposium was held 5-10th April 1997 at the University of the Punjab, Lahore, Pakistan. Over 200 participants from Pakistan and other Asian countries participated in this symposium on "empowering teachers to promote scientific and technological literacy for all in the 21st century." It emphasised the need to help teachers change their views about science teaching and to review student involvement. It pointed out that students and teachers reading the textbook is definitely not science.
I was once told "anyone can organise a symposium in a developed country, but it is a real challenge to do this in a developing country." It is thus with great pleasure that I report the 10th ICASE Asian symposium was not only successfully held in Pakistan, but that it was away from the capital and upcountry in the number two city, Lahore. The more than 200 participants mainly from schools, colleges and training institutes came from all over Pakistan and representative attended from ICASE member organisations in a range of Asian countries, from Japan to Iran.

It is no small feat to organise a symposium in Asia where many countries are among the most populous and classified as developing. ICASE is thus proud to have held 10th such symposium in Asia, beginning with the very first in India in 1977 and culminating in the 10th anniversary 29 years later in 1997. And not only did the symposium attract science teachers from the primary and secondary levels, but it was the largest meeting to be held at the University of the Punjab (according to the Vice-Chancellor) for many years and certainly the only such meeting in Science Education.

So far perhaps this is report is nothing special. But allow me to paint a picture of science teaching in some Asian countries. Imagine a class of 70-150 students with virtually no apparatus, maybe no laboratory and certainly very few chemicals. The curriculum changes from time to time, but the teaching remains the same. The teacher needs to cover the textbook !!! The textbook is king. The examination questions come from the textbook and if they do not, the students refuse to sit the examination, claiming it is unfair. And teacher opportunities for training, certainly in-service retraining, is very minimal. No wonder teacher morale is low and teacher absences high. No wonder student drop out is very large.

Yet the symposium was able to bring together enthusiastic teachers, teachers willing to pay a registration of 300 Rupees (5-10% of monthly salary), to spend 2-3 hours travelling home afterwards and to attend a symposium in an international language (English) which is a second language for all and which is presented in a variety of accents. But they welcomed the plenary sessions, complaining they wanted more question time. Enjoyed the presentations and workshops, especially any related to experimental work. Many overseas participants from STAs in other Asian countries were willing to offer demonstrations of simple experimental ideas—reflection inside water or any medium made visible by smoke or colloidal particles, movement on water testing whether eggs are raw or hard boiled, pressure change caused by the expansion of a volatile liquid to fire a simple cannon, changes in vapour pressure using the drinking duck and so on.

But if ICASE can take pride in itself in lending its name to this symposium, it is the Pakistan Association for Science Education (PASE) and to its symposium
convenor in particular, Hafiz Muhammad Iqbal, that thanks are due for the tremendous efforts undertaken to overcome so many constraints and see the symposium through to fruition. Funding was always in short supply and it may not be surprising to hear that the total cost of mounting the event is much less than US$50000, inclusive of airfares for 12 overseas delegates, conference bags, programmes, proceedings and refreshments of all during the symposium. All this from a man described by the Vice-Chancellor of the University of the Punjab as "a small man, with a big heart and a large mind."

2nd ICASE Latin American Symposium

The 2nd ICASE Latin American symposium was held in Mar del Plata, Argentina from the 22-26th April 1997. This was an extremely well planned and executed symposium attended by approximately 500 participants covering most of the Latin American countries. It was also the first ICASE symposium to be held in Spanish and the first to have instantaneous translation for some of the keynote presentations. The meeting was held on the theme—to improve scientific and technological literacy for all: a challenge for the year 2000.

This symposium went a long way to promoting Project 2000—the ICASE/UNESCO initiative to mobilise efforts by Governments and non-Governmental organisations (e.g. STAs, Teacher Education Institutes, Curriculum Development Centres, Universities) to rethink the purpose of science education and, looking ahead, suggest the direction of science education for the next millennium for all students—academically able and students with learning difficulties, girls as well as boys, science as an integrated, interdisciplinary subject or science separated as biology, chemistry and physics, science in well stocked laboratories and science where the society resources are all that are available. Project 2000+ provides a particular challenge to science teacher associations and this symposium was a start to encouraging the formation of professional STAs in the Latin American countries.

The success of the symposium is in no small way due to the dedication and efforts of 3 ladies—Marta Moyano the symposium organiser, Gabriela Inigo and Vilma Giannini. ICASE is very grateful for their efforts and wishes to congratulate them on their success. They have set a very high standard for the 3rd Latin American symposium (being planned for Chile in 1999) to maintain.

1997 CEFIC Award Winners

Geneva, 13 June 1997—On the occasion of the CEFIC, European Chemical Industry Council, General Assembly in Geneva today, Mr. Jürgen Dormann, CEFIC President, presented the 1997 “CEFIC Science Education Award” to Ms. Mona Gidhagen and her class of students from Ytterbyskolan, Ytterby, Sweden.

The Winning Team was selected by an International Jury from among 41 finalists from 18 European Countries. The winning “Daily Chemistry” project consisted of a study of everyday items as varied as auto products, cosmetics, detergents, iron and steel, medicines, metal packaging, paint, pulp and paper, soap and shampoo, etc. It focused on how chemistry plays an integral part in our daily lives.

Mr. Gunnar Uhlin, Headmaster, received the "Science Award" and a check for 5000 ECU, on behalf of the school.
The winning teacher, Mrs. Mona Gidhagen received a check for 1000 ECU and the “Excellence in Science Education Award” Diploma.

The Second Prize went to Mrs. Ann de Neef and Mrs. Hilda Jonckers of the Sint Theresia College Kapelle-op-den-Bos, Belgium for the “Clean but Green” Detergents testing project.

Two Third Prizes were given to: Mrs. Jana Dudrova of Masarykova Stredni Skola Chemicka, Prague, Czech Republic for the “Tyre production, use and recovery” project; and to Mrs. Alina Jaworska-Mattylla of the Technical High School for Builders and Carpenters, Poznan, Poland for the “Food packaging in Poland before and after 1989” project.

1997 CEFIC Science Award Winners

Scientific Literacy—An International Symposium

From September 9 to 12, 1996, the IPN (Institute for Science Education, Kiel, Germany) held a symposium on Scientific Literacy in Hamburg. The meeting was intended to be a dialogue between German-speaking and British and Northern American scientists.

The IPN has published the proceedings of the symposium and presented them at the recent NARST meeting in Chicago.

For more detailed information with program, list of participants and all abstracts please visit our symposium’s website: http://www.ipn.uni-kiel.de/work_e/a4/allgemein.html

The volume is available from IPN for US$20. To order a copy please send an e-mail to Dr. Wolfgang Graeber (wgraeb@ipn.uni-kiel.de), we will then post a copy and an invoice.

For more information, please contact:

SCIENCE ACROSS EUROPE—WHY IT WORKS!

Marianne Cutler
Science Across Europe
The Association for Science Education
College Lane
Hatfield, Herts AL10 9AA U.K.

Abstract

This paper gives a brief background to the development of the Science Across Europe (SAE) project and its aims. It investigates the elements which make the project innovative and different to related projects, as well as successful. Future developments are also discussed. The paper is relevant to teachers/advisers/trainers/inspectors and other school educators in the sciences, languages and humanities, including those with an interest in the use of the Internet in education.

Introduction

In response to the growing need for school educational materials in the 1980s, that focus on the applied nature of science, its relevance to society and in particular relation to the teenage community, a successful set of curriculum enhancing materials were developed in the UK, entitled Science and Technology in Society (SATIS). At an international forum during an Annual Meeting for the Association for Science Education, the possibility of developing these materials from their UK school base area was investigated—to bring a global dimension to education, for students to learn how people in different parts of Europe use science in their efforts to understand and solve crucial everyday issues—and so the project Science Across Europe was conceived in 1990.

From the beginning, Science Across Europe has evolved under the active partnership between the Association for Science Education and British Petroleum (BP), and it is this partnership that has been an integral factor in the success of the project.

Science Across Europe, with its resource materials, provides a forum for students to exchange facts and opinions of their own concern and interest with students in other countries and cultures. It is this exchange of information which makes the Science Across Europe project unique and stimulating to students.

The Aims and Objectives

Science Across Europe has developed the following overall aims from the beginning, as exemplified by Evelyn van Dyk (1996):

• to bring a global dimension to education by raising awareness of varying perspectives and ways of life of students in different countries;
• to raise awareness of the ways science and technology affect society, industry and the environment; and
• to provide opportunities for teachers and students to collaborate with those from other countries; and to develop communication skills, especially languages other than their own.

These aims have been categorised into socio-scientific, informative and affective education areas by Sinigalas and Turner (1997). They also fit into the pattern of changing emphasis in the classroom from teaching to student centred, hands-on learning, as indicated by Rutherford and Grana (1995) and the 1996 UNESCO report “Learning—the treasure within.” Educators find the project attractive as it fits current trends in education—science, the environment, languages and newer technologies (email and the Internet) all in one package. The Science Across the World web pages, the only global education web site in six languages were nominated as “Internet site of the month” in July 1997, by Access to Excellence in the USA. The project has also gained recognition by winning the Global Best Award in North America and the Aim High Innovation Award in the UK, both in 1996 for education and business linked partnerships.

The project encompasses the wider aspects of science and can be a useful means of teaching and assessing key skills, e.g. the "Drinking Water" unit has been used as the basis for the collection and processing of data for General National Vocational Qualifications (GNVQ) in the UK, under numeracy, communication and information technology (Taylor, 1997).

The project is recognised as a useful tool in gaining language skills, with the units written in at least 12 European languages. More than 50% teachers found an enhanced knowledge of other languages in their students (O'Rowe & Neill, 1996). The Association for Language Learners (ALL), working in consultation with SAE and the Centre for Information on Language Teaching and Research (CILT) has recently produced a guidance booklet (Language through Science) for language teachers using SAE materials. ALL aims to provide SAE training for language teachers in target European countries later in 1997 and 1998. This programme of training follows on from the successful SAE multinational in-service teacher training programme, which extended to more than 300 teachers, trainers and advisers from 15 European countries, under the European Union Comenius umbrella in 1996 and 1997.

The project provides materials for other positive cross-curricular links. Eighty-six percent of teachers found an increase in student knowledge of geography, 70% in "economic awareness" (O'Rowe & Neill, 1996).

The project can provide the basis and impetus for extended links and partnerships between schools. 30.2% of participating schools have developed additional collaborations, based on their initial contacts through SAE units (Sinigalias & Turner, 1997).

The number of schools in Europe has risen by 91% over the year 1995-6. At the time of writing, 489 schools are actively participating in the project from 22 European countries. There are 640 registered teachers undertaking 815 units; the most popular of which are "What did you Eat?" and "Drinking Water" accounting for 18.5% and 16.8% of the units purchased respectively. Eighty-six percent of teachers indicate that they are using or will use the materials again (Sinigalias & Turner, 1997).

An outline of the Units

The main method of achieving the aims in the European classroom is through a series of units, focusing mainly on environmental science topics. The topics, chosen for their application to school curricula, also fulfill the commitment of BP as a "responsible corporate citizen," as part of their international business strategy. The eight units available are: Acid Rain over Europe, Using Energy at Home, Renewable Energy, Drinking Water, What did You Eat? Global Warming, Domestic Waste and Road Safety; with Keeping Healthy ready for trials between February and April 1998. Schools wishing to participate in these trials should contact Science Across Europe before the end of January.

Each unit has been created at a specific writers workshop by a team of teacher writers from 15 European countries, together with BP Community Affairs personnel. It is this melange of experiences, cultures and expertise that is a key factor in the success of these materials. The following four elements to a unit must be satisfactorily completed before the unit is ready for translation into 12 European languages, and for trialling:

- The information to be exchanged must be relevant, stimulating and above all must highlight different perspectives, attitudes and resolutions to issues in different countries. Social and environmental scientific topics lend themselves best to these approaches, whereas the pure science curriculum topics would very often result in the exchange of the same, and therefore rather uninteresting data and other information;
- The units should contain wherever possible, practical and investigative work which may provide an additional stimulus to the text; this work should not require specialised equipment or facilities and therefore would be accessible to all schools;
- The units should be flexible to complement any school curriculum for students aged 14 to 19 years. The units which are translated into 12 languages, should have a cross-curricular appeal, with relevance to language and humanities teachers, as well as to teachers of science; and
- The exchange forms should raise discussion issues of interest and relevance to the student population, so that the exchanges or partnerships formed have the basis for a fruitful extension, beyond the duration of the unit.

All units have the same structure which includes an introduction to the topic, teachers notes, copyright-waived student material, a topic reference section and the exchange form.

In order to facilitate the exchange process, all schools are required to register with the project on an annual basis so that their contact details are entered onto a database of schools. The monthly updated database
is available on the Science Across the World web pages (http://www.hp.com/saw) and is also sent to each registered school three times a year. Information within the database is arranged by countries and includes contact details of the school and teacher, the unit(s) to be studied, the language(s) to be used in the exchange process, the ability and age range of the students, and the month in which the exchange of information can take place with other schools. This simple system enables teachers or students to select schools in desired countries using the same unit, in the same language at the same time as they are, so facilitating a smooth dialogue interchange via the exchange form.

Future Developments for Science Across Europe

As a result of recommendations in the above evaluations and discussions within the SAE team, the Science Across Europe project will be concentrating on the following—with a visible dissemination strategy, embedded in a national context if possible:

- Certain countries with small numbers of participating schools at present, will be targeted through a programme of teacher training. It is not the aim of the project to recruit maximum numbers of schools; rather to have viable overall numbers which are actively participating and benefiting from their involvement.

- Current individual country accreditation methods and possible methods of implementing SAE training courses within existing initial teacher training courses and in-service training courses, at national levels, is being investigated.

- The importance of end user/student evaluation is recognised and evaluation methods aimed at the student audience, for specific units are under development. The first student evaluations will be implemented during the trials for the Keeping Healthy unit, from February to April 1998.

The project wishes to thank Evelyn van Dyk, the former SAE project manager, John Hughes and Andrew Hunt, as former project directors for their comments.

ISSUES IN ELEMENTARY SCIENCE TEACHER PREPARATION:
A COMPARISON OF PROGRAMS AT HACETTEPE UNIVERSITY (TURKEY)
AND TEXAS TECH UNIVERSITY (USA)

Julie Thomas
Texas Tech University
and
Fitnat Kaptan
Hacettepe University

Is there a universal concern in the design and practice of elementary science teacher preparation courses? This article will trace the rationale and practice of a science methods course in Turkey and a comparable one in the United States. What are the similarities and differences of these courses? What can one professor learn from another?

Education Programs

Hacettepe University is located in Ankara, Turkey. The elementary teacher education program accepts approximately 45 students each year into a four year degree plan which includes a balance of learning experiences including general knowledge, field knowledge, and knowledge of teaching methodology. The area of general knowledge helps students acquire the consciousness and ability to recognize individual and social issues, seek solutions and contribute to the economic, social and cultural development of Turkey. Field knowledge consists of the knowledge of teaching principles and methods of courses taught in primary education institutions. Knowledge of teaching methodology consists of the knowledge of general teaching principles and methods. Elementary teacher candidates complete field observation in the 7th semester and practice teaching in the 8th semester.

Texas Tech University is located in Lubbock, Texas. Tech students must complete academic foundation courses before they can be admitted into the elementary education program. Thus, approximately 120 students are selected as juniors and must meet admission standards including a GPA of 2.7 or higher, high ethical standards, and English language proficiency. The program is based on a philosophy of reflective analysis, inquiry learning, rational decision making, and merged educational theory and practice. On admission, students join a cohort of peers and follow a strong, sequential, clinical, program based on reflective practice.

The Texas Tech program, just celebrating 20 years of service, is nearly three times the size of the elementary teacher education program at Hacettepe University which is in its sixth year of operation. Though both universities focus teacher preparation program on very similar philosophies regarding field experience, the Texas Tech program affords formal arrangements with elementary school partners while in Turkey, five hours of observation a week is left to university students to arrange themselves. Perhaps the major difference in program planning is limited access to elementary classrooms in Turkey.

Elementary Science Methods Courses

At Hacettepe University, the elementary science methods courses focus on science as 1) a body of organized information and 2) the systematic methods (i.e., observation and information collection) necessary to understand it. The course directs elementary science teachers to develop and interest in science; knowledge about the environment; problem solving and thinking skills; observation and experimental methods to understand scientific results and laws; and an understanding of the relationship between science and technology.

At Texas Tech University science is a way of learning about the natural world. Preservice teachers learn to understand that science in the elementary school
can be 1) developed from real world situations through the use of hands-on, minds-on lessons and should be 2) guided by new standards and current research regarding the teaching and learning of science. The science methods course is field-based and taken during the second semester of the junior year. In this course, Tech students spend a minimum of 15 clock hours teaching science lessons in elementary classrooms. They are expected to develop hands-on, inquiry-based lessons, to adapt lessons for children with special needs or diverse cultural backgrounds, and to apply technology when possible.

The methods course at Hacettepe is primarily lecture-based due to limited lab space and materials as well as limited access to elementary classrooms. Thus elementary teachers in both universities are encouraged to teach hands-on science, but students at Texas Tech actually experience hands-on model lessons and practice hands-on teaching with elementary students. Additionally, Texas Tech students have greater technology resources which include Internet and other relevant computer applications.

Methods Course Content

At Hacettepe University the science methods course focuses on the National Curriculum of Turkey, grades 4-5. In the first three years of elementary school, units of Social Studies and Science are joined together in a single Life Science course. At the 4th and 5th grade levels Science and Social Studies courses are taught separately. Fourth grade science units include Earth and Sky, Life Science (Plants and Animals), Healthy Environment, Matter, Light, Electricity, Energy (Solar, Water, Wind, Fuel, Recycling) and Nutrition. Fifth grade units include Human Body Systems, Ecology, Matter and Energy, Sound, Light (refraction, vision), Heat (sources, effect), and Electricity (static, current).

At Texas Tech, students become aware of the National Research Council Science Standards as well as the Science Texas Essential Knowledge and Skills (TEKS). These identify the standards for science teaching and learning in Texas and direct the science curriculum in every public school in the state. Specific processes and concepts are defined by grade level from Kindergarten to sixth grade. This methods course does not address all elementary science content, but lays a helpful foundation for wise decision making regarding elementary science teaching.

Science education in the fourth and fifth grades in Turkey is fairly critical since most Turkish citizens (55 percent) have completed their formal education by the end of fifth grade. In addition, junior-high-bound students are anxious to do well on the high school entrance exam as their score will determine which high school they may attend. For these reasons, elementary science teaching in Turkey strictly follows the National Curriculum. In Texas, elementary children are not tested in science. Elementary science is thought to lay the foundation for more content-based science learning in junior high and high school.

Instructional Format

Teaching methods and technologies used in Hacettepe University elementary science courses include concept mapping, cooperative learning, observation, discussion, demonstration, problem solving, hands-on activities, questions and answers, reading, fair project. Students learn to choose the most suitable method according to instructional objectives, ability level of the students, classroom conditions, available equipment, and experience, knowledge and ability level of teacher. Students also learn a variety of organizational techniques such as teacher-centered teaching when all activities (lecture, demonstration, etc.) are done by the teacher; student centered teaching in which activities are done by the individual student; teacher-as-guide, when the teacher directs individual students or group work.

Elementary teachers are required to prepare a series of plans—annual plans, unit plans, and daily plans. Annual plans provide an overview of the school year and unit plans indicate the details of the course content, and the teaching plan. Daily plans explain the course activities and how they will be applied. Detailed and successful daily plans include specific content; instructional objectives; a list of visual and audio equipment, books, and teaching aids; and evaluation of learning. Evaluation is one of the most important processes of the teaching and learning process and includes a measure of achievement as well learning needs. Curriculum plans must include special, national events defined by the Ministry of National Education since all Turkish elementary teachers are expected to do some activities related to these events. Special weeks (related to social studies and science) include: Food Conservation and Nutrition, Turkish Standards, Energy Conservation, Forest Week, Museum Week, Healthy Heart Week, and Environmental Protection Week.

Teaching methods at Texas Tech University focus on hands-on, inquiry. Students participate in model lessons from a variety of print resources as they become familiar with the science processes of thinking and problem solving. Lessons include mini-lectures but are
primarily organized as active, small group or whole class experiences. Students prepare a unit plan which includes ten daily lesson plans. Significant components of the teaching unit include necessary teacher background knowledge, a plan for authentic assessment, and connections across the elementary curriculum (i.e., math or reading).

By way of comparison, the instructional format at Hacettepe University is defined by the Ministry of Education. The program teaches future teachers what they will be required to do to implement the National Curriculum. The Texas Tech program introduces future teachers to a teaching model that will enable them to teach science in a self-contained classroom. Additionally, Tech students have the opportunity to connect a variety of resources to merge specific science content to appropriate elementary learning. Tech students are encouraged to recognize the creative teaching opportunities in this process.

Materials and Equipment

In Turkish elementary schools, all text books are chosen by the elementary teachers. For this reason all teachers should know some selection criteria. Textbooks must help to teach all objectives that are described in curriculum, present correct information, be appropriate to learning and understanding levels of students, encourage students toward reading, observation, and research. Additionally, elementary teachers are encouraged to other materials like methods books, encyclopedia, periodical teacher books, curriculum book, etc.

Learning how to select and use science equipment makes the teaching and learning process most effective. Equipment knowledge necessarily includes awareness of natural materials, models, dramatizations, exhibitions, computer software programs, educational TV programs, slides and films, radio programs, resource people, and written documents.

Technology equipment used in elementary science courses are designed and developed by Ministry of National Education Course Equipment Development Center. The Science Course Equipment Kit consists approximately one hundred different materials and is distributed to elementary schools by the Ministry of National Education. Educational films radio programs for all levels of education are developed and distributed by the Film, TV, and Radio Education Center. Also a Department in Ministry of National Education is responsible for the production of software for computer supported instruction, but preparation and usage of these programs are not common.

At Texas Tech University students are introduced to state-adopted elementary science text books as well as six ancillary science teaching curriculum resources. One of these includes membership in the National Science Teachers Association. This membership entitles students to receive a professional elementary teaching journal. Computer access allows students to exchange e-mail, explore Internet, and experiment with instructional materials such as CD's and computer software. Students are encouraged to select, develop, and use a variety of meaningful learning experiences in science for children.

Texas Tech students have access to a wide variety of teaching resources and materials. At Hacettepe University, students have fewer resources to choose from. This is one reason the science methods course is lecture-based; very few books about teaching science are written in the Turkish language and students do not have access to computers or Internet.

Conclusion

It seems that there is a great similarity in the foundational structures of the science preparation of elementary teachers at Hacettepe University and at Texas Tech University. We teach in different countries and realize different funding opportunities, different graduation expectations, and different teaching resources.

Hacettepe University (as well as the general Turkish system of education) suffers considerable limitations. Realizing this, the Turkish government is currently generating system-wide changes in teaching and teacher education. Considerable change is beginning at Hacettepe as well as in the country of Turkey. The Elementary Education Department is continuing to find better ways to educate teachers and improve the science methods course. Also, the developing Elementary Education Department of Hacettepe University is aggressively increasing education projects to increase the department budget. New budget money will be used to enrich the department’s facilities in the areas of lab equipment, computers and computer software, Internet connection, and textbook packages.

Compulsory education in Turkey will soon be increased from five years to eight years. This means the elementary science methods courses will change,
and there will be more time for hands-on activities which enhance and develop thinking skills. Another important change is that collaboration between university faculties and practice schools is increasing. This will increase the possibilities of field experience during methods courses.

In connection with the National Education Development Project (NEDP), selected education faculty have been sent to the United Kingdom and the United States to observe and collect information about other teacher education systems and methods courses. This project will eventually support the development of improved methods course textbooks and materials.

By comparison, Texas Tech University is a partner in the National Science Foundation (NSF) funded Texas Statewide Systemic Initiative (Texas SSI). Tech is also seeking to improve elementary science teacher preparation and currently focusing on improvement of the required 12 hours of science content courses. The intent is to develop science courses to meet the specific learning and teaching needs of elementary teachers. Thus, both universities are engaged in change—local change and national change. It is interesting to realize we are guided by similar philosophies though limited by different political and economic parameters. Still, the shared comparison of university programs lends insightful opportunities for personal as well as institutional growth.

Making Curricular Connections in the K-8 Classroom

_Summer Institute jointly sponsored by the National Science Teachers Association and National Council for the Social Studies_

**July 25-28, 1998**
Northern Arizona University
Flagstaff, Arizona

Join teacher leaders in this unique participatory institute on curricular integration featuring science and social studies. Working sessions based on presentations by nationally-known experts will provide opportunities for dialogue and application. Topics for exploration include: multiple intelligences, standards-based practices, service learning, performance-based assessment, thematic instruction, project-based learning, planning and managing integration, issues oriented learning, and literature connection.

DEMYSTIFYING CONSTRUCTIVISM: SPONTANEOUS AND GENUINELY
CONSTRUCTIVIST TEACHING IN DISADVANTAGEOUS CONTEXTS

M. E. W. Juca
University of Fortaleza, Brazil
and
R. Maskill
University of East Anglia, England

Abstract

In the last two decades, constructivism applied to education has been recognized as a potentially better way to deal with teaching and learning. A review of literature appears to show that, particularly in developing countries, teachers working in natural settings use practices that do not reflect constructivist teaching. A qualitative study was carried out in the Northeast region of Brazil (a poor and problematic area) to investigate whether constructivist teaching practices are evident in everyday lessons in state primary schools. Surprisingly, some teachers were found to subscribe to and use genuinely constructivist methods. The theoretical background, methodology and implications of this finding are presented and analysed.

Introduction

Constructivism is emerging as the new orthodoxy in science education. Nevertheless, as Nussbaum (1989) emphasized, constructivism is not monolithic. Consequently, it is important to define and characterize a constructivist approach in education, in order to give a theoretical basis for any research. Our approach has been mainly based on ideas developed by Gilbert et al. (1982), Posner et al. (1982), Driver et al. (1985) and Fensham et al. (1994). These authors emphasise ‘the active pupil reaching out to make sense of events, engaging in the construction and interpretation of individual experiences.’ For teaching to be appropriate it must complement this process.

From a synthesis of the ideas put forward by the researchers cited above, a profile of a constructivist teacher was constructed and is summarised.

The constructivist teacher will:

1. use student’s ideas to plan lessons (the teacher should have a prior awareness of the ideas which pupils bring to the learning situation);

2. use pupils’ ideas in the development of the lesson, as it happens (the teacher should use of teaching techniques which involve challenge to, or development of, the initial ideas of the pupils).

The genuinely constructivist teacher will assess, discuss, test and constantly use pupils’ ideas when leading learners to an understanding of new scientific concepts, laws and principles. With this description of constructivist teaching, the problem investigated by the present study can be stated by the following question:

Is it possible to find primary science teachers who already use this approach in ordinary situations? More specifically, is it possible to find constructivist practices in spontaneous ‘good practice’ (or does constructivist teaching need external stimulation and expert advice)?

A review of the literature indicated that the majority opinion is that spontaneous constructivist practice was unlikely, even in developed countries (Eaton et al., 1984; Hendry & King, 1994; Hewson & Hewson, 1983; Sequeira et al., 1993). In developing countries, such as Brazil, the context is even less conducive to the development of constructivist practices: state schools are badly equipped and teachers have to deal with crowded classes and a great heterogeneity of students with respect to age, ability and level of motivation.
There are reports of projects which have developed constructivist teaching practices. Tasker et al. (1980) and Scott (1987) described the implementation of projects at the University of Waikato, New Zealand, and at the University of Leeds, England. In both cases, a team of researchers helped teachers to implement constructivist approaches at their classes. Some of the teachers involved concluded that, at the beginning, the process is time consuming and very difficult. After some trials, which were followed by evaluation, the results showed that the constructivist methods were practicable and did improve students' meaningful learning. Jofili and Watts (1995) evaluated a kid of intervention into teachers' professional development and concluded that teachers involved in the project (from northeastern Brazil) faced many difficulties trying implementing constructivists approaches in their lessons but were very committed to continuing despite adversity.

If constructivist teaching practice could be found in disadvantageous contexts, which have not had the intervention of external support from research teams, it will have fruitful implications. Other teachers could be encouraged to adopt constructivist practices with confidence that they are practicable. Local examples are always more convincing than theories developed elsewhere.

Methodology and Results

The research was designed, loosely, within the specifications of a case study (qualitative approach). Individuals were to be studied and described as they taught their lessons. Three research instruments were developed: a personal interview, a method of classroom observation (the main instruments) and a questionnaire. The latter instrument was applied only to test the results on a bigger sample of Brazilian primary science teachers.

The science topic “The Law of Floating Bodies” was selected as the topic to contextualize the questionnaires and the interviews ‘questions with which to search for teachers’ ideas about constructivist teaching practices. This topic involves the teaching of a kind of knowledge which is usually classified as functional or procedural—it is knowledge which is actively used in daily encounters with the ordinary physical environment. Pupils are familiar with and deal frequently with things which float. As a consequence, the related knowledge might be very difficult to develop since ideas which have learned from this real experience may differ from the scientifically more “correct” knowledge which is to be taught.

The topic also involves the teaching of abstract and complex relationships (proportionality) among basic concepts (mass and volume). This is recognized to be a challenge for teachers and certainly will call for careful teaching. Also there is in the literature much research (since Piaget in 1929) describing children’s ideas as well as teachers’ efforts to teach the topic of floating bodies in primary school.

The research instruments were validated and adjusted in two pilot studies, the first one in England and the second one in Brazil. In England, the instruments were applied to nine science teachers working in four state schools. In Brazil, they were applied to five teachers and to five educationalists. The results obtained in the pilot tests indicated that the instruments were reliable and were ready to be used in the main study.

The main study involved twenty-four state primary science teachers, selected at random from eighteen state and city schools, in the city of Fortaleza, the capital city of the State of Ceara in northeast Brazil. It was decided to observe lessons taught to sixth graders (mean age around 12 years old) as this is about the age at which the law of floating bodies is taught. The teachers were observed usually for two lessons of fifty minutes each and they were interviewed immediately afterwards. The questionnaire was sent to a different randomly selected sample of teachers of sixth grade and was answered by forty-seven state primary science teachers.

The basic designs of the interview, classroom observation and questionnaire schedules were as follows. The results will also be described and analyzed.

1. The interview

This presented four teaching strategies representative of traditional practices and four typical of constructivist practices. The teachers were asked to analyze the practices and give their opinions about their use. The answers were recorded as “partly,” if the teacher subscribed to strategies from both categories, “yes” or “no” in each case, if he/she totally accepted or refused either of the two categories. From twenty-four interviews, nine (37%) were labeled “partly,” eleven (46%) subscribed to the constructivist strategies and seven (29%) to the traditional ones (some teachers totally selected more than one category).

A question then asked how the teacher normally introduced a new concept. Many ideas followed from this question. Five teachers described completely constructivist approaches and refused traditional ones.
They claimed that normally start lessons from students’ ideas and continuing using their ideas on the further development of the lesson.

Another question asked for the teachers’ reactions to wrong answers by pupils to teacher questions. The same five teachers said that they normally rephrased the questions in order to allow students to think more deeply and restructure their answers. Other teachers said that they ask another student to correct the answer, or alternatively give the “right” answer themselves.

The last question asked the teachers to suggest an ideal way to teach “The Law of Floating Bodies,” given ideal conditions. The five above mentioned teachers suggested an experimental approach (as did some of the other teachers). One of the teachers from the group of five said that she would use the same sort of lesson as she normally did except that she would use more material resources to enrich the learning experience.

2. The classroom observation schedule

This was constructed around two dimensions of classroom activities which might show constructivist teaching in action. The first was a checklist of four teaching activities that might be observed in classrooms which were considered to be representative of constructivist practices from literature descriptions of the approach. These practices were assessing, discussing, testing and applying students’ ideas in a variety of different ways. The second dimension was ordinary strategies for developing activities in class—oral and written questions, homework, small group work, demonstration, hands-on experiments and others. The results show the existence of these two dimensions in varied proportions in the observed lessons of the twenty-four teachers, teaching sixth-graders. The five previously mentioned teachers developed all of the four specified categories (assessing, discussing, testing and applying students’ ideas). Other teachers only use some of them.

The results also show that small group work was a very common strategy (and is one of the most important strategies according to constructivist researchers specially the Vygotskyans) and that only one of the teachers was able to develop hands-on experiments. This teacher taught in the only of the observed state schools that had a proper laboratory.

From the interview and classroom observation results, each teacher was classified as traditional or constructivist. This classification showed that from twenty-four teachers five (21%) subscribed and behaved (while teaching) in a constructivist way. Sixteen (67%) teachers subscribed and adopted traditional approaches and three (12%) were classified as “mixed” because they subscribed and adopted some traditional as well as some constructivist approaches.

3. The questionnaire

The questionnaire presented seven teaching strategies, varying from traditional to behaviourist, including some typical discovery learning approaches. The teachers were asked to analyze and give opinions about each of them. The results of the questionnaire (answered by forty-seven Brazilian state science teachers) showed that 28% of teachers explicitly subscribed to teaching practices based on the use of students’ ideas and which are broadly constructivist in approach.

Although information about student achievements were not part of the present research, some indirect data was available. This might give some clues about the profiles of students taught by some of the teachers. Students of five of the teachers belonged to the sample selected for interview and observation commonly entered projects in the Science Fairs held in the state. Three of these teachers have been classified as genuinely constructivists. The level of independence, criticism, originality and high level thinking skills possessed by pupils who contribute to the Science Fairs is often remarkable and it is interesting to speculate that these qualities have been fostered by the constructivist styles of the teachers, or perhaps that teachers who use a constructivist style are also able, by whatever means to stimulate their pupils. Not too much should be lead into this finding, though it is interesting that not one of the traditional teachers had pupils who entered for the Science Fairs.

Conclusions

In summary, the basic question posed at the beginning of the work can be positively answered. Some Brazilian state primary science teachers did use genuinely constructivist lessons in very unhelpful contexts. These teachers have had no in-service training courses emphasizing constructivist practices, nor did they learn about these things in their initial training (the majority of the teachers had been teaching for more than 10 years and, in any case, the teacher training curricula in Brazil are very out of date). These findings were surprising for the following reasons:

1. According to our review of the literature, the spontaneous constructivist practices should not have
happened; even in projects supported by teams of researchers, teachers had difficulty implementing and continuing constructivist practices in normal classroom settings.

2. Brazilian state teachers work in very problematic contexts. The social and economic background of their students is usually poor. The number of students per class (often more than 50) is high if compared to European and North American schools. There is a great heterogeneity of ages in each class. Material resources, such as textbooks and any kind of equipment, are often non-existent.

One interpretation of the findings is that constructivist practices come, especially in unhelpful circumstances, not from theoretically contrived new practices but naturally from common sense, internal epistemology (including a care for students), professional and political commitment. Appleton and Asoko (1996) described a teacher’s progress toward using constructivists’ approaches in his teaching some time after an inservice activity and concluded that the extent to which the teacher used teaching principles based on constructivism was influenced by his views of science and of learning, how he usually planned his teaching, and his confidence in his own understanding of the topic.

Maybe the observed Brazilian teachers who used constructivist methods valued and used the students’ ideas in lessons because of a common sense of good teaching which naturally causes them to constantly seek to know their students’ progress and to be in touch with their students’ development. This will happen, with some teachers, whatever the classroom circumstances. With other teachers, whatever the entreaties of researchers and curriculum developers, change may be difficult to bring about.

From these results we believe that a better way to bring about ‘constructivist practice’ may be to sensitise teachers to the good, natural qualities of their common sense approaches to the pupils, most of them also present in the majority of lists of prescribed constructivist practices. Together with some theoretical underpinning of the constructivist ideas in Education with support and encouragement for teachers to reflect on their own practices, this may be a more effective way to develop constructivist features to classroom practice. Local examples presented and discussed in short inservice training programmes might also be useful.

It is possible that the development of constructivist teaching may be being retarded by the weight of theory and suggestion of newness which inevitably accompany newly developed and well researched teaching approaches. Perhaps if constructivism were demystified and placed in the context of common sense good practice, then it might be easier to foster. As Joffili and Watts (1995) concluded, constructivism may not be the only, or the best, way of working in certain situations and circumstances but in this very moment it provides an excellent opportunity for changing both teachers’ thinking and behaviours and children’s conceptions in the classroom.

Science for the Millennium

Key Information Sheet
International School Science Links 1999—Project 2000+

Science Links
There are many schools already involved in linking and there are several different types of links, e.g., through letters, e-mail, fax, visits and exchanges. As we near the year 2000, ICASE in conjunction with ASE (UK) felt that it would be an ideal opportunity to build on existing links and to encourage the formation of new ones between schools in different countries. In this way we would be making a contribution to Project 2000+, the international project working towards achieving scientific and technological literacy for all.

Why get involved?
A link provides an ideal way to widen the horizons and increase the motivation of pupils. To get to grips with a scientific problem, share ideas and findings can enrich a science curriculum, and can also provide the opportunity to find out more about another culture. This will promote international communication and understanding between schools and cultures as well as providing lasting friendships.

Ideas for science links.
You are free to choose any topic, of interest to the two schools. It is helpful if the theme enriches the science experience of both schools by giving a wider context for study of the topic and also links school science with pupils' everyday lives. For example, possible topics might be nutrition, balanced diets, environment—local pollution, energy use, useful chemical reactions (soap making, fermentation baking).

How long should the project last?
There is no definite time scale and different approaches may need different times. There are no hard and fast rules!

What happens when the project is completed?
Tell us what you and your partner school have learned. You can do this in any appropriate format, e.g., in poster, a short video or tape, a science report. This should be sent to Jack Holbrook at ICASE or the ASE (UK). All participants will receive a certificate and in the year 2000, there will be an international ceremony to celebrate the work achieved through the links. Schools which produce the best project links will be invited to participate. We would need to hear of your project and link before December 31st 1999 if you wish to be considered for an award. However we believe that your greatest award will be the pleasure of the link process as you work with your partner school.

INSERVICE SCIENCE COURSES FOR PRIMARY TEACHERS:
IMPLEMENTATION OF DIFFERENT TYPES OF
INSERVICE TRAINING COURSES IN FINLAND

Dr. Tuula Asunta
Department of Teacher Education
University of Jyvaskyla, Finland

Abstract

The effects of six differently organized primary inservice training courses on teachers motivation, anxieties, hands-on working skills and needs of support were studied and the areas in which teachers needed most support were evaluated. The total of 140 primary teachers attended workshops lasting from six to nine hours. Both written and verbal evaluation were used in assessing these workshops. Teachers found, with no exception, the inservice training very important. This study shows that, above all, primary teachers felt they needed more continuous support in the area of improving their knowledge and understanding of the subject, especially in the area of chemistry and physics. They also wanted more practice in experimental, problem solving oriented hands-on activity planning as well as the knowledge of availability of necessary classroom equipment and materials. Primary teachers felt quite lost about progression in scientific concepts and the appropriate content of science curriculum in different primary levels.

1. To support teachers motivation and self confidence and reassure them that they can facilitate good science education in their classrooms.
2. Help teachers improve in subject matter competencies and instructional skills.
3. Get teachers aware of simple hands-on activities they could use in primary classroom and the use of simple household materials in science teaching.
4. To heighten knowledge of availability of the necessary classroom science equipment and supporting materials.
5. To reassure teachers on that teaching of science should arise out of the children’s spontaneous curiosity.

Learning in science is a product of the interaction of attitudes, ideas, concepts and process skills. Pupils’ attitudes towards science have been widely studied (Canary & Seabold, 1994, German, 1988) as well as children’s ideas and concepts concerning science (Driver et al., 1985, Driver et al., 1994). Ideas and concepts are formed by children as a result of a variety of influences and process skills ability can be developed through practice. While knowing all that, we should realise that through primary science we need to help children to understand first of all their immediate environment. We need to pick the phenomena that we talk about as near of children’s own world as possible. That is why topics used during these inservice training courses concentrated on simple household materials, simple electrical circuits, light, colours, food, water, etc. We should also keep in mind all the time that, no matter what subject we teach, learning is always the process of developing and teachers need all the time to build up the strong relationship with his/her pupils (Bullough & Giltin, 1995) and should feel empowered (Bell & Gilbert, 1994).
Goals

The following goals were addressed:

1. development of positive attitudes toward science teaching and learning;
2. help primary teachers to find science teaching motivating and make them aware of the great variety of integration possibilities;
3. strengthen teachers self-confidence and familiarity with the basic science equipment and available materials;
4. give teachers experiences with hands-on activities and knowledge that no special equipment are actually needed to teach science in primary level;
5. address the conceptual understanding of science as a process rather than a set of facts;
6. give some content advice; and
7. creation of science learning groups through computer net.

Planning

The workshops were administered through the County Governments and arranged by the Department of Teacher Education together with local subject teachers. The primary concern was to help teachers develop instructional strategies using simple mainly "home made" equipment and usual household materials for teaching science on primary level. In each workshop teachers received the workshop book, that included all hands-on activity instructions used during the course.

During four years, six primary inservice training workshops were arranged in four different places (Heinola, Jyvaskyla, Kuopio and Vaasa). Two workshops were held in Jyvaskyla and Vaasa in two year period. The total of 140 primary teachers were attending these courses (20 - 30 in each course). One workshop lasted usually from six to nine hours.

Personnel

The instructional personnel varied in different sessions. In each workshop there was a professional science educator present and additionally:

a. in first workshop no other leaders
b. in second workshop two area subject teachers
c. in third two student teachers
d. in following three workshops 2-6 area subject teachers and one primary teacher (biology, chemistry, physics and mathematics).

Notices were sent through the local County Governments and in one case through the University.

The participating teachers represented all types of school districts and different types of primary schools. Some came from so called "village schools" where one teacher teaches both levels one and two and the other one both levels three and four. Some teachers came from the ordinary primary school where one teacher teaches one class. The attending teachers had masters degree in education and were qualified for primary teachers. Most of them had not attended any science education class after high school and some had attended only one compulsory chemistry class during three years high school period. In two courses both primary and secondary level teachers of the same regions were present and worked together as a team.

Contents of the courses

The importance of teaching meaningful, hands-on activity oriented science in the primary levels and the ways that can help doing that were the leading thoughts when carrying out these inservice training courses.

Through all the workshops much attention was paid to the emphasis of encouraging teachers to use children's natural curiosity—their basic nature of questioning things—as a basic power resource and stimulator. Teachers were continually reminded that no matter what teaching methods they would be using they should give children more time to think, why he/she is doing what he/she is doing and why is the teacher asking him/her to do so. Learning science is a process that needs time to go on and children should be allowed to use their knowledge systematically, solve problems and make decisions. They should be encouraged all the time to rely on their own experiments and results and make them aware of, that some phenomena they can only understand based on their further experience. Pupils should also understand that there can be different answers to the same problem and that all the answers can be as good. The value of the answers depends on the pupils explanations and how well they can argue their own decision.

Teachers need to develop positive attitudes and reflective assessment to reach the demands that children of this generation will be setting for them. During all these inservice training courses much attention was paid to the co-operative group work. It is going to have an important role in future classroom allowing teachers more time to observe and challenge pupils directly. Activities used during these courses were designed to motivate teachers to include more science contents in their teaching, develop self-confidence, alleviate science anxiety and promote hands on experiences.
All six inservice training courses were based on process-oriented, problem solving activities and group work. Specific topics included: hands-on science activities, process skill activities, questioning strategies and innovative planning and use of home-made equipment for different purposes. The scientific concepts taught during these inservice training courses were very simple ones, example: acid-base, indicator, solubility, saturated, density, volume, pressure, warmth, light, colour, electricity, energy etc. During each workshops adequate discussion breaks that enabled teachers to express questions and realise common concerns were provided. Each workshop enabled each participants to leave with ready-to use materials. Arranging some of these workshops in local elementary schools brought them closer to teachers everyday life and assured them that the requirements were not so demanding as many of them had thought. During the last hour of each workshop teachers evaluated the course, gave the feedback and reflected their own contribution in their learning process.

Comments about teachers implementation the ideas—that they had learned during the course—into the classroom were asked by interviewing some of attendees afterwards. Several teachers attended courses in different years. Registration fees varied depending on the County Government support. The amount of teachers who wanted to attend was related to the amount of the registration fee. This was actually obvious, because the money that the schools have for inservice training per teacher in academic year is approximately 600 Fmk.

The effect of using different lecturer combinations on the learning of teachers

It goes without saying that, if there is one or two teachers for 20 students, this affects learning. It is not however necessarily so that in a usual classroom the pupils will learn more if there are more teachers present, actually it can be just in opposite way. In these inservice training workshops it was however noticed that if there were more than one instructional persons at present during the workshop period, teachers felt more free to ask them help. There was not very much difference if there were subject student teachers or subject teachers present. It did not seem to make much difference ether whether there was one primary teacher and one or more subject teachers present during workshop. Only thing that really mattered was that there were more than one teacher around: "It is nice that there are more than one person to ask." "Different teachers that are responsible for different experimental 'stops' save a lot of our time, because we can have answers to our problems right away."

The materials

A workshop book including these inservice training hands-on activity course material, has been developed and some have been published as a separate book (Asunta, 1993) or integrated in the material for secondary and high school levels (Asunta & Little, 1995; Bader et al., 1995; Asunta & Hakkarainen, 1996). All participants received the written material in the beginning of the workshop. During each workshop there were different hands-on activity books and materials available for teachers to see. Also informational material concerning equipment and supporting materials were available.

Teachers’ feedback

Both written and verbal evaluation was asked after each inservice training workshop. First the teachers were asked to think over themselves answers for questions concerning:

1. their own expectations of the course content and what were they anxious about;
2. why they attended the course;
3. if the contents of the course was 'right' (ratio of introductive lesson and experimental period);
4. what they think they learned;
5. how did they help their own learning; their own commitment;
6. how were they going to use the knowledge that they got during the workshop, in their own classroom;
7. what they were the most excited about;
8. what more support they would need in this area;
9. which were their own strength, where were they skilled of; and
10. what they would think is the meaning of hands-on activity on pupils science learning.

Expectations and anxieties

Most teachers expected to receive from the course both 'hins' for primary science teaching and some new thoughts about what should be dealt with in primary level science. Many teachers wanted to become more familiar with this—as they themselves expressed it—'new and frightening' area. They felt they should know so much more to be able to teach chemistry or physic contents for their pupils. Over half of them expected to get some help for their routine work at school. Some of them mentioned they wanted some knowledge what is going on around the world in this area: "I would like to know how primary science is taught in other countries."
Some other things mentioned were: ‘learn some new methods,’ ‘something new to take into the own classroom,’ and ‘to get more self confidence.’

The reasons for attending the inservice

The reasons why most teachers attended the course were mainly the same as their expectations, i.e., to learn some new things, curiosity, to find out which type of scientific experiments would be useful on primary level, interesting topic, to get some new ideas. Some teachers also mentioned that they felt they needed to find some new ideas to refresh their own classroom teaching, because they had taught so many years without having a chance to attend any inservice training course. Also some mentioned that they were just interested to find out what the topic “Creative science for primary level” had to offer.

About the course content

Teachers’ answer to this question varied depending on how much time for lectures was included in these workshop courses. Most teachers did not like it if more than two hours lecturing was included in an eight hour workshop. Such an answer was not unexpected because the inservice had been advertised as workshop courses and because the course only lasted one day. However, teachers also felt that a lecture providing some background information was necessary and that the whole course should have lasted at least two whole days. In one workshop when there was an equal time reserved for lectures and experimental work, teachers gave the feedback that too much time was spent for lectures. The contents of hands-on activity part varied a little from course to course. In each workshop there were however both demonstrations and experiments for teachers to learn. No meaningful difference was found in teachers feedback concerning the contents of the courses.

What teachers think they did learn?

Many teachers said that they learned just what they had expected to learn: some new things on primary science area. Some mentioned they had learned logical thinking, and positive attitude towards science. A few teachers mentioned that they had had fun and they would think children would feel the same way after having a chance to do things like they had been doing during the workshop:

“I learned how to do some experiments that would interest primary children.”
“I can try almost anything as far as I do have enough skills and I know my pupils well enough.”

“There are a whole lot of scientific experiments that I can use even in the first grade.”

How did they help their own learning?

Many teachers either could or would not answer to this question, many questions, tried many new things even being a bit afraid not to know how to manage and been interested:

“I have been curious.”
“I put my own spoon into the soup.”
“I was a good listener.”

Do the teachers think that the knowledge they got will be transferred to their own classroom?

Almost all of the participants thought that they would be using some of the activities in their own classroom:

“I am positive.”
“I will remember not to give children ‘the right answers’ and reserve more time for discussions.”
“I really hope I have enough courage after this course to use all these applications in my own classroom.”

Many teachers said that they will try to develop their own teaching so that it would include more hands-on science activities.

What were they most excited about?

The demonstrations which the teachers considered the most exciting were: “floating potato,” “oil and water,” “how to get a boiled egg to an Erlenmeyer and back without breaking it,” and “the liquid rainbow.”

The experiments that teachers preferred were: “starch from potato,” “indicators from the nature,” “make your own sheet of paper with flowers in it from recycled papers,” “potato that is excited,” “eggs with different colours,” and “who left the note.”

Many problems that were presented to teachers during workshop also made them excited. For example the activities: “what makes rainbow?” “why is wet sand darker than dry sand?” and “why does not the light go through your hand but only makes a shadow?”

An example of demonstrations and experiments used

Floating potato

Teachers were presented a high glass with some liquid in it. In the bottom half the liquid was red and in
the upper half colorless. There was the potato floating just in the middle of the edge of these two colours. Teachers were asked to think over what was the explanation for this. They were also asked to think over if there were more than one possible explanation and what previous knowledge pupils should have before they are capable to answer this question.

**Indicators from the nature**

Teachers were asked to study, for example, which of the following flowers and berries can be used as an indicator: tulip, violet, wood sorrel, white oxeye, blue wild pansy, blueberry, priether, lingonberry and cranberry juice.

Because microwells and very familiar household materials such as orange, citron, applejuice, cocacola, coffee, vinegar, baking powder, etc. were available, teachers could very well figure out what to do. Only in few cases it seemed necessary to advice teachers what the word 'indicator' means and how they can use just the ordinary household materials to test if some plant is an indicator or not.

Science educators designing the workshops in the future should be aware at least the following:

**What more support did the teachers think they would need?** When teachers were asked what would be the areas where they would need more support, they mentioned first of all the following:

a. more information about the availability of necessary classroom science equipment and materials;
b. more knowledge about easy hands-on science activities and scientific knowledge behind those activities;
c. more knowledge about what science-topics should be included in teaching in different primary levels;
d. inservice training for improving the subject matter competency especially in the area of chemistry and physics;
e. practice in experimental, problem solving oriented planning and advice to improve the instructional skills; and
f. availability of suitable, simple activities they could use without danger and with sometimes quite unlimited knowledge of chemistry and physics.

**What is the opinion of teachers on a meaning of hands-on activity on pupils science learning?**

One teacher had answered to this question: “Can there be any learning without doing?” Most teachers thought that pupils learning only happened through their own experiences, through doing experiments. So they thought it is really important to try to use as much hands-on activities as possible at school:

“Knowledge can become internal only through active working.”

Teachers also thought that hands-on activity has an important meaning for pupils future learning. Some teachers had evaluated that 70% of the knowledge (OF WHOM?) is coming through ones own active participation. Many of them were of the opinion that different phenomena such as the rainbow and how it is generated can be understood through experiments:

“Only by doing, one can really remember.”

“The creative thinking can be developed only through active experiences.”

“It is all the world for science learning.”

“It is fundamental part of learning.”

**Results and discussion**

The attitudes and concerns of primary teachers were very similar: they all cared about their pupils and were aware of possibilities of science teaching to support learning process. They suffered the lack of knowledge on innovative teaching strategies and resources. Almost without exception they felt that the intensive workshop promoting understanding and practicing different types of science instructions can have effective results in their classrooms. They felt that the mixture of theory and practice integrated together as they were in these workshops should be continued as time to time repeated meetings. Most of the teachers had the feeling that they were, after the workshop, much more motivated to use hands-on activities to get pupils interested in science. Some teachers also felt that the course had supported only a little their subject matter competencies but a lot of the development of positive attitudes towards science.

The teachers reported that during the workshop they had suddenly realised how “everything has connection to everything” and that science really can be supportive subject for many other subjects:

“The teacher made me realise that science is a small part of a big never stopping process that is life and made me really aware of its importance in understanding this process.”

According to the feedback most teachers felt more free to ask if there were more than one instructor available during workshop. It seemed also that the content of the
in-service courses should mainly be based on active hands-on activities. Teachers want to do as much as possible themselves to get practice:

"I feel so safe to try new activities when there are some people around that I can rely on."

"I want to carry out as many experiments as possible, because if I am familiar with the experiments then it is easier for me to teach my pupils to do them."

As odd as it can sound, it has become obvious according to these six in-service training courses, that the knowledge of our primary teachers, when we are dealing with some very basic concepts of science, is very chequered. For example the scientific meaning of acid-base concept is not at all clear for them. There were few teachers who did not know if pH-value two means acidic or basic conditions. I do not doubt that it has been taught to most of them thoroughly when they were pupils at school, but no matter what, it has not become an internal concept.

Interviews and questionnaires indicated that even one in-service training course can substantially improve primary teachers’ self confidence on being able to teach some science for children and motivate them to learn more about science themselves. Also their understanding of some science concepts was improved.

Inservice had also an activating effect on teachers. During social communication processes created during workshop they learned a lot from each other. Some of them decided to build up the networks with other teachers to support each other. After the first two workshops run several years ago there are still some active teachers who communicate regularly.

It seems obvious that this type of workshop has so many good points that they should be regularly repeated events. There are always many teachers who want to attend the workshops whenever they are available and there would be even more, if the schools would have more money to support their teachers to attend. None of those teachers who attended these six in-service training courses told that they came because their employer forced them to because they themselves wanted to. The fact is that many teachers had been teaching 10 to 25 years without being able to attend even one in-service training course though they had wanted to. Many teachers were still doubtful how much hands-on activities they could try at school because many schools are not at all equipped for teaching science. Even the leader of the course tried to make teachers convinced that with very basic equipment would make science teaching possible, many teachers had a feeling that because their basic knowledge is quite weak it would not be so easy to create simple experiments.

Our primary teachers are confident that the best way of learning is by doing. It means that also us teacher trainees should follow that philosophy. We should compensate as much theory as possible with active participation and conversation: give a chance for us all to learn together.

**key words:** primary science activities, in-service teacher education, material development, problem solving oriented primary science workshop

Bell, B., & Gilbert, J. (1994). Teacher development as professional, personal, and social development. Teaching & Teacher Education, 10(5), 483-497.

In February 1997 the Open University (OU) was awarded a Queen’s Anniversary Prize for Higher Education. This award, established within the national honours system, was in recognition of the launch and successful development of a new pre-service teacher-training programme, the Postgraduate Certificate in Education (PGCE). The citation accompanying the award included reference to the international interest and significance of the programme and the contribution being made to the training of teachers in mathematics, science and technology.

The award was the culmination of a five-year project that has established innovative applications of open and distance learning to teacher training. In this article I want to explain something of the origins of the OU PGCE, the way the programme is structured, and the relevance of the experience to initiatives being developed elsewhere in the world.

Britain, like many countries, has a shortage of teachers in certain key subject areas, most importantly in mathematics, science and technology but also in modern foreign languages, and even music. In the late 1980s a number of us in the OU began to examine the extent to which experienced adults would be interested in a teaching career. Two market-research exercises, one of which was government-funded, showed some astonishing results. First, amongst graduates in their mid-thirties there existed a high level of interest in switching to a teaching career. Second, the secondary subject areas they were most interested in teaching were mathematics and science. Amongst those interested in teaching at the primary phase, a significant proportion have degrees in mathematics, science and technology.

A new seam of potential teacher recruitment had, therefore, been identified; the average age of potential entrants was thirty-three, and their subject backgrounds were radically different to those who chose to become teachers straight from university. The challenge, however, was to find a flexible and part-time training route. Most potential applicants, for professional and personal reasons, could not attend a full-time course, and the vast majority lived a long way from the few part-time pre-service courses geared to the needs of mature entrants.

In 1992 government funding was received to develop a full range of primary and secondary PGCE courses. The plan was to cover most of the UK and also some overseas countries, particularly within the European Union, where many UK nationals based near English language-medium schools wished to qualify to teach.

The programme was launched in January 1994 and now recruits over a thousand students a year. As predicted, science is the most popular secondary subject, and half of all primary entrants have degree backgrounds in mathematics, science and technology. These entrants also have substantial vocational experience that significantly enriches the teaching population as a whole. International interest has been shown, not only in the programme structure, but also in the research and experience in drawing teachers from the more mature stratum of the population.

The programme is run over an eighteen-month period from January in one year to July in the next. This allows those graduating to obtain a teaching post at the beginning of the autumn school year. The course is divided into three stages and within each there is a period of full-time experience in schools. Potential applicants nominate schools when they apply and regional OU staff verify their suitability.
All students are provided with a wide range of resources covering all aspects of teacher preparation and their specific phase and subjects areas. The experience in schools, the OU resource packs, and a number of OU-edited readers and other set books are all linked in to the student's study guide. The programme has a common overall framework within which the primary and secondary and the different subject areas develop distinctive themes. The framework is a key support to the overall quality-assurance system that underpins each aspect of the course and the ongoing evaluative procedures that annually feed into course review.

The course team took some important initial decisions in developing the programme. First, any reading of activity set for students had to relate directly to experience in schools. We did not want a theory/practice divide. Second, the course team designed a 'curriculum of activities' for each of the programme. Students' experience in school was, therefore, planned to develop progressively. Experienced teachers in the school play a mentor role and facilitate the completion of the full range of prescribed activities. Students also have the support of a locally based OU tutor who provides individual and tutorial support and helps in the running of a series of day schools.

A development that has attracted widespread interest is the provision of a computer for each student. As with many open- and distance-learning programmes, the large numbers create economies of scale that allow initiatives which are impossible in a conventional institutional setting. Students acquire personal IT skills and can practise with software appropriate to classroom use. The most interesting use, however, is for interpersonal communication. Using conferencing software called 'First Class', students are linked to each other, to their tutors, and to a range of electronic subject conferences. They have the opportunity to share ideas and problems, exchange teaching plans and resources, and communicate with central OU academics on all aspects of the programme. A genuinely electronic PGCE 'village' of activity simulates the sort of informal exchange found on a conventional campus. End-of-course surveys have shown that students value this aspects of the programme more than any other.

Experience to date has shown that a course recruits well and has a low drop-out rate. Students are also every bit as successful in finding a teaching post as those graduating from conventional institutions. Every student takes to their place from employment an end-of-course profile, developed from their own course-assessment portfolio, which gives guidance on the sort of further professional development needs an OU PGCE graduate would have.

A great deal has been learned from the first few years of the programme. I have been hugely impressed by the enthusiasm and commitment of our students. Perhaps one of the biggest problems has been to persuade people not to work too hard! Inevitably, those who have made the decision to enter teaching rather late in life take the requirements of their course very seriously.

The programme does have wider international significance and members of the Centre for Research in Teacher Education at the OU, who have produced the course plan and resources, have responded to invitations to visit many countries. I would highlight the following points in this respect. First, it is quite clear that the demands for pre-service, retraining and in-service training of teachers are growing in all parts of the world. The 'bricks-and-mortar' institutions that were developed to respond to teacher-education needs in the twentieth century cannot possibly meet this demand in the twenty-first. Some form of open, flexible learning is essential. New interactive technologies provide new forms of open learning and these are likely to be adapted by 'campus-based' as well as 'open' institutions. Some convergence is already taking place.

Secondly, however, in the context of teacher education, much more attention needs to be given to the school as a 'site' for learning. Too many open- and distance-education programmes have wholly neglected this crucial experiential dimension. The OU PGCE has shown how practical experience can be integrated into course design, allowing the potential not only for teacher development, but also school improvement. Staff from the programme have taken this message to countries and continents as diverse as Albania, Pakistan and South Africa. These are issues of concern for teacher education of global dimensions and, although the precise way this is worked through will vary from one educational system to another, the dissemination of experience on an international scale is already proving of great benefit to those involved.

For further information, including details of all the OU PGCE resources for public sale, write to:

Pre-service teachers obviously are required to master the basic concepts of their subject. In addition they are made to study general education subjects such as “foundations,” some cognitive psychology and social psychology, classroom management, etc. and then there are “science teaching methods” courses. In many institutions such courses are taken by pre-service teachers from various science disciplines and so the content and experiences in these courses are not very specific for any particular discipline. In some institutions (most teacher education programs in the Philippines) there may only be general teaching methods courses where all disciplines (also social science) are mixed. In others (such as most universities in the USA and Australia) teaching methods are taught to majors of four or five different science disciplines. So in many programs and countries the opportunities to pick up craft knowledge about teaching a particular subject are limited. What could this craft knowledge consist of? Facts about safety precautions in certain demo and lab experiments, knowledge about various alternative ways of explaining a particular Chemistry of Physics concept, knowledge about analogies which could be used, tricks for improvising, general ideas about how to use predict-observe-explain demonstrations for maximum learning and concrete physics and chemistry examples, ideas for role plays to simulate transport of energy in electric circuits, knowledge about applications of particular concepts in everyday life and in technology, ideas for inserting humor and variation in lessons about solubility or atomic physics, suggestions for contacts with industries, etc. Where can one find such knowledge? Well, in science textbooks, in laboratory manuals, in teacher manuals for textbooks, Internet, etc. However, this craft knowledge is highly scattered and it takes teachers a whole life of collecting to build up their resource files. In the following I would like to present several books which are either very useful in developing such craft knowledge in teaching methods courses (1 and 2), or which are dense sources for craft knowledge for the practicing teacher (3-7). The books are not expensive and should be in any science teacher education library. The book that best addresses the questions posed above is number 5, the four volume publication of the American Chemical Society. The book that will be most used by the classroom teacher, might be number 4, Tik Liem’s now famous collection of over 400 demo’s with everyday materials.

In UK pre-service teacher education has shifted from college-based programs to school-based programs. Pre-service students now complete a Bachelor’s level academic program in their discipline and then study for their teacher certification (Diploma of Education) while being based at a secondary school rather than in a university. So all activities for the completion of the Diploma of Education are carried out in and around the secondary school classroom. Learning to Teach Science has been written for activities the pre-service teacher can carry out during school practice (student teaching). It is a book for student teachers and their mentors, yet most activities could be carried out in more conventional pre-service teacher education programs. Monk and Dillon compiled and edited teacher education activities produced by their well known colleagues of King’s College in London. All activities are formulated in terms of what the pre-service teacher (Student Teacher) is supposed to do. All activities have a common format: Student Teacher’s Brief, Objectives, Instructions, followed by some necessary information. In the text preceding the Student Teacher activities, there is often also a Mentor’s Brief consisting of instructions for the teacher who supervises the Student Teacher. That teacher is called Mentor. In other parts of the world various terms are used: Tutor, Cooperating Teacher, Supervising Teacher, etc. Examples of activities are: Directed Activities Related to Text (DARTS) where Student Teachers construct activities which help pupils to study and process science texts (applicable in any country); activities with concept maps and relational diagrams; analyzing investigations for openness; techniques for guiding pupils in open investigations; pupil’s development of inquiry or research skills where Student Teachers go through student reports and notice qualitative differences and compare those with the levels of investigation defined in the UK National Curriculum; planning, organizing, and managing a class practical as
part of a lesson; planning and managing a demonstration with questions and answers; incorporating historical material in a lesson; using video’s; etc. The activities are grouped into the following chapters: **Observing Science Teachers at Work**, **Activities for Pupils**, **Planning and Managing**, **Science Investigations**, **Communicating Science**, **Science and Knowledge**, **Science and People**, **Progression in Pupil’s Ideas**, **Assessment**, and **Progress and Potential**. All of this is preceded by a chapter for the Mentor. Most of these chapters include 6-8 activities which each require quite a bit of Student Teacher time (one or more days). So there is a lot of choice. Some activities, such as planning a laboratory lesson, contain checklists which might be useful to experienced teachers as well.

The activities only contain minimal background readings for the student teachers. Yes, the book does have a bibliography which refers mainly to books. I would have preferred a bibliography with references to articles in teacher journals, or even still having some traditional reading material included in the chapters to make the book more “self-contained.” For example, reading material on the art of questioning, on science processes, on assessment, etc. Nevertheless, the book contains a wealth of activities and students themselves could be tasked to do research and find background readings. For example, on concept mapping and on cognitive conflict and predict-Observe-Explain demonstrations one might well take chapters from **Probing Understanding** (see below). The chapter on **Progression of Student Ideas** has a strong Piagetian streak, no doubt inspired by King’s College Philip Adey who has done extensive work on using science teaching to develop student thinking (CASE program) and has delved deeply into Piaget and other European psychologists. Children science and alternative conceptions are included in the chapter, but, of course, students will have to go to the extensive literature in books and teacher journals to gain a basic knowledge of popular student alternative conceptions in their subject.

Going through the activities, the pre-service teacher will build up quite a bit of craft knowledge. However, the Mentor and the university supervisor should really see to it that the pre-service student seriously builds up the craft knowledge base and does not just “go through the activities.”

During the five years I was training teachers in the Netherlands (1991-96) I used to give this book as a present to graduating Physics teacher education students, except that I gave this present many months before graduation so that I could still give assignments based on the book. The authors of this book are professors and former science teachers from Monash University in Melbourne, Australia. As the title suggests, the authors are very much concerned with understanding and the various chapters discuss different methods of “probing” understanding, methods the authors used in their research. However, these same methods can also be used for “teaching” understanding as they can focus student attention on their own understanding and “exercise” their understanding. The book contains chapters on concept mapping, Predict-Observe-Explain demonstrations (an outstanding chapter!), Interviews about Instances, Interviews about Concepts, Drawings, Fortune Lines, Relational Diagrams, Word Association, and Question Production. The Predict-Observe-Explain (POE) chapter is my favorite. White and Gunstone provide a very nice introduction to POE’s as they call them. Many readers might wonder what fortune lines are. Well, in a story the “fortune” or luck, or whatever of main characters can go up and down. Students are asked to graph the fortune of main characters across the story and such fortune lines will show their understanding of the story, or lack of it. So fortune lines are more appropriate as a technique for exploring student understanding of literature than of science. The other techniques are solidly placed in science. The book is an ideal guide for teacher and student teacher for getting into the heads of their students and studying their preconceptions and conceptual development. Unfortunately it is often quite difficult to get student teachers to pay attention to their students’ conceptions. The first concern of my students in the Netherlands was always classroom control and the next lesson. In those cases where I was able to get student teachers into a little study of student conceptions through diagnostic tests and interviews, the student teachers got quite excited.

This well known physics text for non-majors, meaning students who do not go into engineering or science, is a beautiful resource for teaching ideas. The book is full of examples, links of physics with the environment and every day life, nice pictures which say more than 1000 words, etc. Hewitt does not belong to the “club of misconception researchers” but he artfully touches on all the crucial and subtle conceptual difficulties of students. Even expert readers and teachers might have trouble with some of the conceptual subtleties, but then there are the nice explanations. We ourselves are using the book as a textbook for teacher.
education students coming from the Philippine 4-year secondary school to get a sound grounding in concepts and a wide basic knowledge of applications in everyday life before they move on to the more abstract and calculus-based physics of the typical college texts such as those of Halliday/Resnick and Young.

What can a teacher get from this book?

- hundreds of everyday life examples (see Figure 1);
- hundreds of nice, clear, and attractive explanations;
- hundreds of conceptual exercise questions where Hewitt puts his finger on most of the conceptually sensitive points;
- many ideas for simple demonstrations, such ideas can be found in the text, in pictures on the side of the text (see examples), and quite a few of the conceptual exercise questions at the end of the text can be investigated in simple demonstrations or lab work;

Figure 1. Examples' from Hewitt's Conceptual Physics

The fact that the book is so widely used and now in a 7th edition suggests that by now most errors must have been caught. My colleagues and I found some awkward explanations here and there, but on the whole we like the text very much and get ideas from it. What one does not find in the book are the computational problems we in Physics are so used to. There are many other sources for such problems (any physics textbook), so this is no great disadvantage. In short Hewitt's book should be on the shelves of every teacher all over the world and in the hands of everyone studying to become a Physics teacher. Support materials are available, but in spite of requesting them six months ago, nothing has arrived. Last week I discovered that this was due to the acquisition of the Harper Colling College Division (the original publisher of the book) by Addison-Wesley. There should be a rich store of additional craft knowledge in these support materials (test items, answers to questions in the text, transparencies, lab manual).

This is the ideal source for POE demonstrations. There are more than 400 demos, each described in a handy format, one page per demo with a drawing for the set-up, a few lines of procedures, and most importantly: questions for discussion with students and an explanation. Almost all demos can be done without special equipment and have more or less counterintuitive results. Pupils and student teachers love them, in the Netherlands as well as in the Philippines and Indonesia where I used an early 1980 version of the book for 10 years. Here in the Philippines this book is our main source for our demonstration circus in schools and for peer teaching practice of teacher education students. The book can be ordered directly from the address above or from the NSTA. The price is $40 or $45 dependent on the number of copies ordered, that is US$ 0.10 per demonstration, there are few other things one can do for 10 cents that provide the same amount of fun and satisfaction!

The four volume set Chem Source might well be the best source for craft knowledge for chemistry teaching. All popular topics from junior and senior secondary chemistry syllabi have their own chapter. Each chapter consists of the following parts: Content in a Nutshell, Place in the Curriculum, Central Concepts, Related Concepts, Related Skills, Performance Objectives, Worksheets for Laboratory Activities both in Student Version and with (extensive) Teacher Notes, Demonstrations, Counterintuitive Examples and Common Student Misconceptions, Metaphors and Analogies, Pictures in the Mind, Group Discussion, Tips for the Teacher, History: On the Human Side, Humor: On the Fun Side, Media, Links and Connections (Within Chemistry, Between Chemistry and Other Disciplines, to the Contemporary World), and References. And finally Masters for Transparencies including cartoons (Figure 2). In short, Chem Source constitutes a beautiful knowledge base for chemistry teaching. Chem Source comes loose leaf to be inserted into binders. Let a new teacher start from there and then expand that base by inserting articles from chemistry education journals and other sources and the result would be a lifelong resource. I wish there were equivalent projects in Physics, Biology, and Mathematics which would integrate various knowledge sources as neatly as ACS has done for Chemistry.

Figure 2. Cartoons from Chem Source

Obviously not everything can be put in. The sections about misconceptions are very useful but more in-depth study would require going to articles in journals. Similarly, the content in a nutshell does not and cannot replace a textbook, and the demo's and labs included are but a small sub-sample of what is possible. What I missed were test items, it is surprising that those are missing. However, ChemSource is a great start and resource for any new and practicing teacher.

The book has a long history in spite of its recent publication date. It grew out of a "consumer Chemistry" course taught in the early 1970s to non-science majors. The book represents the author's "craft knowledge" developed over a period of twenty years. Like many of the textbooks nowadays, each chapter has a clear structure with different components.

A discussion of the chemistry principles is prefaced with a demonstration utilizing sample equipment and household chemicals. The demonstration is then revisited after the discussion. The text includes questions to help students check their understanding of a section, worked examples of exercises and problems, a running glossary of the key terms and a short section titled Perspectives that looks at the implications and applications of the concepts. Each chapter ends with some thought-provoking exercises that show the interrelatedness among chemistry, society, and values.

The purpose of the author is primarily to teach chemistry. This is done in the context of familiar everyday materials and experiences. In most of the book the context is the means to the end of understanding chemistry. In the last several chapters, such as a chapter on proteins, the chemistry becomes the means to understand everyday issues such as nutrition. The book is a very helpful resource for teachers who want to prepare lessons that can trigger students' interest and awareness of the chemistry around them. It is worthwhile to have the book in the school library and in the resource room for any science teacher education program.

7. Chem Matters CD-ROM version 1.0. American Chemical Society, 1155 Sixteenth Street, N.W., Washington, DC 20036, U.S.A. Price: $54.95 for a single user and $84.95 for a network or library.

Now this is really a resource where chemistry is used as a means to an end to understand things in life.
Chem Matters contains many chemistry related readings on a single CD-ROM disk. You want to teach about acids and give examples from fruits, look for the oranges article. What about chemistry, drugs, and zombies? A very interesting article reports over 10 years of anthropological and chemical research. Chem Matters is a popular chemistry magazine for high school students which has published a great variety of articles: Bubble Gum Chemistry, Ice Cream, Crazy Candies, the chemistry of Post-it Notes™, Biodegradable Bags, Liquid Crystals, Soap, etc. Thirteen years of four issues a year has been put on CD with a handy search system. As with all CD-ROMs, reading from a screen is not as pleasant as reading from paper, but it is handy to have so much information on a little disk and to have the ability to search. One can also order back issues of the magazine, both the first five years and the second five years of the magazine are available for $30 each.

THE UTRECHT/ICASE SYMPOSIUM

June 3th - June 5th, 1998
Utrecht University, the Netherlands

The Utrecht/ICASE international symposium on science education will be held at Utrecht University as a follow-up to our very successful symposia at Dortmund University. Like the Dortmund Symposia, the Utrecht symposium will be organized in cooperation with the International Council of Associations for Science Education (ICASE).

The key theme of the conference will be:

Bridging the gap between theory and practice:
What research says to the science teacher

• The purpose of the conference is to bring together researchers from different countries to present and discuss new results in the field of education in chemistry, biology and physics.

• No conference fee will be charged. All participants are expected to obtain their supports by themselves.

• 40 minutes are allotted for the presentation of the paper, another 40 minutes for the discussion. The medium of the conference will be English.

• Invited lecturers include: George Bodner (USA), Diane Bunce (USA), Bao-tyan Hwang (Taiwan), Mercè Izquierda (Spain), John Oversby (UK), Arminda Pedrosa (Portugal), Iris Pigeot (Germany), and Hans-Jürgen Schmidt (Germany).

• ICASE have committed themselves to publish the contributions as proceedings. The abstract should be limited to 1 page (including references) and send in on diskette (and print) before September 30, 1997.

The National Research Council, Washington, DC

Abstract

This article introduces the National Science Education Standards and suggests that the Standards can be used as a mechanism for bridging formal and informal science education. Based on a review of the literature on student learning and educational effectiveness of science museums, specific science content from the Standards is outlined as potentially useful in informal settings for increasing student learning.

The National Science Education Standards

The release of the National Science Education Standards (NRC, 1996) was an important first step in identifying the goals for achieving scientific literacy for all Americans. The National Science Education Standards define the science content that all students should know and be able to do and provide guidelines to assess the degree to which students have learned that content. The Standards detail the teaching strategies, professional development, and support necessary to deliver high quality science education to all students in grades Kindergarten through grade 12. The document includes standards for:

- science content
- science teaching
- assessment in science
- professional development for teachers of science
- science education programs
- the science education system

The science content standards recommend less emphasis on the following:

- Knowing scientific facts and information
- Studying subject matter disciplines (physical science, life science, and earth science) for their own sake
- Separating science knowledge and science process
- Covering many science topics
- Implementing inquiry as a set of "process skills"

and more emphasis given to:

- Understanding scientific concepts and developing abilities of inquiry
- Learning subject matter disciplines in the context of inquiry, science and technology, science from personal and social perspectives, and the history and nature of science
- Integrating all aspects of science content (life science, physical science, and earth science)
- Studying a few fundamental science concepts
- Implementing inquiry as instructional strategies, abilities, and ideas to be learned

Bridging the Gap between Formal and Informal Science Learning

Achieving scientific literacy has become the national goal for education in many countries. Although admirable, the goal represents a challenge for the formal system of education. If nations are going to achieve scientific literacy, they will need to recognize the
importance of a combined effort of both the formal and informal education communities. In the words of Honeyman, "This is a time when we need to forge partnership between both formal and informal science education sectors." (Honeyman, 1996, p. 30). The position we present in this article is that the National Science Education Standards (NRC, 1996) represent an essential linkage for these two systems in the United States. People learn science from a variety of sources, for a variety of reasons, in a range of different ways (Wellington, 1990). These variables reflect earlier questions posed by Collins and Bodmer (1986) about the dynamics of science learning:

Do individuals get most of their understanding of science from school, from television, radio and newspapers, from their jobs, from leisure activities, from magazines and books, from museums and libraries, from special events designed to promote understanding of science? What is the balance between these sources for different segments of the public, and what should the balance be? (p. 103).

Outside the formal setting, science learning can take place in many environments including science centers and museums, natural history parks, geological sites, zoos, botanical gardens, and nature centers. Informal science learning is difficult to define, particularly when trying to determine its relationship to formal science learning. The literature identifies two frameworks for considering the relationship of formal and informal science learning. The first type draws a sharp dichotomy between formal and informal learning (Wellington, 1991). This approach, however, does not take into account the varied characteristics of informal learning, for example, visits to science museums can be voluntary or compulsory, structured or unstructured, integrated into the school science program or occasional, sequenced or unsequenced. The second type of framework is a hybrid approach, which includes both formal and informal learning (Crane et al., 1994):

Informal learning refers to activities that occur outside the school setting, are not developed primarily for school use, are not developed to be part of an ongoing school science curriculum. However, informal learning experiences may be structured to meet a stated set of objectives. Informal learning activities may also serve as a supplement to formal learning or even be used in schools or by teachers. (p. 3).

Hofstein and Rosenfeld (1994) adopted this hybrid approach to highlight the distinction between learning context and learning method. In the past, it was assumed that the compulsory school science context was tightly linked with formal learning methods. Hofstein and Rosenfeld suggested that this linkage is artificial and could also be harmful to the pedagogy of science teaching since what students learn in science cannot be limited to what is learned in schools. Thus, they suggest, learning contexts and learning methods should be mixed in order to provide a good blend of learning experiences. In particular, compulsory school contexts should include informal learning experiences.

What Influences Students Learning?

On the basis of syntheses compiled from thousands of research studies in education, Walberg (1991) suggested that the following model of nine constructs appears to increase learning:

Student aptitude
- ability, and prior achievement
- developmental stage
- motivation

Instruction
- the amount of time students are engaged in learning
- the quality of the instructional experiences

Psychological environments
- home
- school and classroom
- peer groups outside school
- media and other informal learning environments

By estimating the size of the contribution to learning of each element, Walberg found that ability, development, motivation, amount, and quality of instruction are essential for learning. It is suggested that both formal and informal settings contribute to, and influence the development of, these elements and thus will enhance learning overall.

The Educational Effectiveness of Science Centers and Museums

While recognizing science centers and museums potential for enhancing student motivation—a critical contributor to learning—this article focuses on the cognitive aspects of learning in these informal settings. The literature was reviewed with the following three key questions in mind:
• What do students learn from science museums?
• What is the most effective context in which to conduct a visit to a science museum or center?
• What can science museums do to increase motivation to learn science and to expand the repertoire of instructional techniques?

Learning and Time on Task Increase With Interactive Exhibits in Museums

Laetsch, Diamond, Gottfried and Rosenfeld (1980) asserted that about twenty million students\(^1\) took field trips to science centers, museums, and other informal learning environments each year in the United States. Often, these visits occur without much consideration as to why and how they should be conducted. In the past, the question of what students will learn from a visit to a science museum was rarely posed (Koran & Baker, 1979). Many of the studies focused on the affective components of the visit namely, the interests in and attitudes toward the science museum in general and certain exhibits in particular. For example, Atkin stated, “The goal of museums at that time was to fascinate, stimulate interest, and evoke feeling of wonder. The focus was on the dramatic and visual.” (Atkin & Atkin, 1989).

However, in the last 20 years, with the expansion of our knowledge of how students learn, and how to effectively assess this learning, and the increase in research supporting constructivist models of learning, there has been more interest in studying learner behavior in a nontraditional museum-type setting (Kubota & Olstad, 1991). A review of six studies (summarized by Falk, 1983) suggests that significant cognitive learning of science can and frequently does occur during museum visits. Falk also reported that scientific knowledge acquired on a field trip may be remembered for a long period of time.

Beier and McRobbie (1992), in Australia, found that students developed an understanding of the concept of sound via a hands-on investigation in an interactive science museum. They also found that students who already had an understanding (prior knowledge) of the

---

1 A current best estimate of student services (including taking field trips, outreach programs, and school enrichment programs) extrapolated from data in Invisible Infrastructure by Inverness Research Associates, and from interviews with selected museums and other informal science institutions is computed to be closer to, or even exceed 70 million. This calculation is based on the estimated number of informal science learning centers hosting field trips (967), a range of attendance figures for field trips from 10,000 to 400,000, and a knowledgeable estimate of an average of 75,000 school children annually per site.

concept of sound as a vibration or wave were most likely to have major changes in their level of understanding.

In the United States, a series of studies based on behavioral psychology was conducted by Fehr and Rice (1988) and Fehr (1990) in California. Their work focused on the concept of light, i.e., vision, image formation, shadow formation, and color. They found that meaningful learning occurred when the students were engaged in hands-on activities with interactive exhibits. These findings support previous research by Screven (1975) who found that the more interactive the exhibit is the greater the attraction and holding power (time spent near the exhibit), and the greater the cognitive gain.

In their investigation of learning at the Lawrence Hall of Science, Their and Lynn (1976) found that interactive exhibits were better at fostering scientific reasoning skills than were more passive exhibits. Visitors are able to test their understanding of ideas as they interact with phenomena and with each other in hands-on exhibits and program activities in science centers (Honeyman, 1996).

In summary, the literature reviewed found that there is a direct and positive relationship between the interactivity of an exhibit, the time spent near the exhibit, and the amount of learning that will result. (See also Falk, 1983; Koran et al., 1986; Boisevert & Siez, 1995; and a comprehensive review of 20 research studies conducted by McLaugherty & Rennie, 1992). However, while some important insights have been gained from these studies, the literature on museum learning remains scarce due to the difficulty of identifying, isolating, and controlling the relevant variables which impact informal science learning.

Reducing Contextual and Cognitive “Novelty” Increases Learning

The question of when and in what context the visit to the museum visit is conducted relates to studies by Falk and Balling (1982), and Kubota and Olstad (1991), in which they discuss the psychological aspect of informal events. They refer to this phenomena as environmental novelty. They found that due to the novelty of an informal event or environment, students did not learn expected concepts. These studies demonstrated that the ability of students to conduct activities during field trips depends on their familiarity with the field trip setting. When the novelty was reduced through vicarious exposure (i.e., slide show presentation) to the site, the field trip was more educationally effective (Kubota, 1985).
Orion and Hofstein (1994) suggested that the novelty of the environment consists of three factors: 1) the cognitive novelty, i.e., experience with the concepts and skills which students will deal with during the informal event; 2) geographical novelty, i.e., acquaintance with the new environment; and 3) psychological novelty, i.e., experiences with out-of-school events. The most important factor for this discussion is the cognitive novelty.

It is suggested that that familiarity with the scientific concept underlying the exhibit will reduce the cognitive novelty of the visit (McLafferty & Rennie, 1992; Finson & Enchos, 1987; Orion & Hofstein, 1994). This is, in fact, a call for integrating the visit to museums or science centers with current and previous experiences in school science. Providing students with relevant material prior to the visit will enhance cognitive experiences on the site and increase understanding of the relevant scientific concepts.

In summary, when the informal setting is familiar to students and when tasks at the exhibit are clear, structured, and related students' experiences in formal settings, the informal learning experience can be extremely effective.

Science Centers Motivate Learning Through Varied Experiences

In the teaching of science, curriculum material and instructional strategies should be tailored to the abilities and aptitudes of different students. The overall objective is to create a learning environment which allows students to interact physically and intellectually with instructional materials through hands-on experiences and through minds-on and inquiry-oriented activities. A recent review (Walberg & Hofstein, 1994) presented evidence that instructional techniques in science should be matched to the learners characteristics and needs in order to maximize the effectiveness of the teaching and learning process. These findings call for varying the instructional techniques utilized in science education. In this context, the contribution of science museums should not be overlooked. Science museums could provide a significant component to the wide repertoire of learning modes and instructional techniques used in science education. Educators capitalizing on the thematic, interactive exhibits, the demonstrations, or the discovery-focused labs might concur with Screven (1987) that:

Informal learning in museums and science centers involves a different set of conditions than learning in schools . . . in general terms museum environments are better suited to effectively communicate general notions about science as a process, new ways to look at and to think about things, ways to explore, discover, ask questions, learning that simple things can be complex and complex things can be simple, learning to learn, learning that learning can be fun, that science can be fun, and perhaps most important of all, stimulating greater self-confidence with science topics and activities.

It is also suggested that using informal events in the context of school science will fit nicely with Walberg's model for increased learning. His model includes the amount of instruction, the quality of instruction, as well as in-school and out-of-school learning environments. These constructs, according to Walberg, will also enhance students motivation to learn science. Wellington (1991) suggests that the first step in the development of scientific literacy is to raise students motivation. Science museums should be considered a partner in this endeavor. Screven (1987) addresses the issue of motivation and notes that learning experiences in informal science settings are different than school-based learning.

It is likely that museums are better suited to improve motivation and attitudes toward science and providing frames of reference for dealing with science topics . . . (in museums) learners are mostly voluntary. What learning takes place is self-paced, self-directed, nonlinear, visually oriented, and motivated mainly by intrinsic interests like curiosity, exploration, manipulation, fantasy, task completion, and social interaction . . . the informal environment requires approaches that are different from what you can get away with in schools. More emphasis must be given to the intrinsic motivations of visitors that can insure attention, effort, and proper exhibit usage. Freedom of choice and movement must be maintained.

Many informal science institutions have taken the step to link with schools and to build relationships grounded on the National Science Education Standards. To enlarge the picture, making this a reality in all communities, requires teachers and informal science institutions to "construct the bridge" between formal school learning and informal science learning. To achieve increased science learning both partners should meet to consider the following:
• varying the context of learning, i.e., including some informal experiences within the formal education program,
• actively involving students in the learning experiences, i.e., hands-on and minds-on activities,
• familiarizing students to the setting, i.e., reduced environmental novelty or time to adapt to the new setting,
• varying the instructional techniques, i.e., an instructional model with different strategies used
• capitalizing on intrinsic student motivation to learn

In summary, informal science education settings, as science-rich, experiential, learning-contexts, can complement and serve schools in achieving the full potential of science education as envisioned by the National Science Education Standards. The following discussion explores additional strategies for achieving a comprehensive formal-informal relationship, recognizing and encouraging other opportunities that might arise.

Using Content Standards in Science Museums and Science Centers

The content standards in the National Science Education Standards elaborate what students should know and be able to do as a result of their educational experience (Bybee, 1997a, 1997b). In general, these standards state that as a result of inquiry-oriented activities, students should develop an understanding of fundamental concepts and abilities. We suggest, that in order to link formal and informal science education, the content standards guide both the teachers in establishing learning outcomes for field trips and the exhibit designer or educator in creating exhibits and programs. The following content standards may be of particular interest to informal educators: science as inquiry; science and technology; science in personal and social perspectives, and history and nature of science.

Science as inquiry

Science as inquiry is an essential component of scientific literacy and subsequently of school science programs. It includes abilities necessary to do scientific inquiry, and understandings about scientific inquiry in all three grade levels (K-4, 5-8, 9-12). As a result of their science studies, students will be able to ask questions, plan and conduct scientific investigations, think critically, construct and analyze alternative explanations, and communicate scientific arguments. The essential outcomes of science as inquiry include cognitive abilities using logic and evidence in formulating and revising scientific explanations, recognizing and analyzing alternatives models, and communicating and defending scientific arguments (Bybee, 1997a, 1997b). This vision of science education calls for dramatic change in school science teaching. Yet, in some science museums and in science centers, inquiry happens every day and thus could constitute a valuable resource to complement formal science education. The Exploratorium in San Francisco is such a science center (Oppenheimer, 1975).

Science and technology

In recent years, the integration of science with its respective technological applications has become an important component in science education. In the Standards, the similarities and differences between science and technology are clarified to include: the development of students abilities associated with technological design and the understanding of science and technology. The Standards provide students with opportunities to develop decision making abilities regarding science concepts and its technological applications in a societal and personal context. Museums that integrate science with technology, for example, the Museum of Science and Industry in Chicago, could contribute significantly to students understanding and abilities. The main achievements of these centers for science and technology have been to relate science and its technological applications to the objects that people see and use in every day life.

Science in personal and social perspective

A contemporary vision of scientific literacy includes connections between scientific knowledge necessary for decisions students and adults make about personal and social issues. For example, the content standards for science in personal and social perspectives for grades 9-12 includes the following knowledge and understanding:

• personal and community health
• population growth
• natural resources
• environmental quality
• natural and human-induced hazards
• science and technology in local national and global changes

It is suggested that these abilities and knowledge will help students fulfill their obligations as future citizens both socially as well as personally. The Human Body Discovery Space (HBDS), in Boston's Museum of Science, contains a variety of interactive exhibits on topics related to human biology and medicine. This
museum includes exhibits on cholesterol, human growth, match calcium content food, medicinal herbs, examples of fat content food, amount of blood in ones body, pulse and electrocardiogram, senses, insulin and glucose control and clinical chemistry (Boisvert & Slez, 1995). These are fairly complicated issues to be introduced in the formal setting of science education and the contribution of the museum in this area should not be overlooked.

**History and the nature of science**

Contemporary science developed from its history and advanced knowledge through established rules of conduct, such as using empirical evidence, applying logical arguments and allowing skeptical criticism. The content standards on history and nature of science presents science as a human endeavor: the limitations of science, the contribution of individuals to our current scientific knowledge, the interactions and interdependencies between science and society, and the fact that science is fundamentally a human enterprise. There is no doubt that science museums can play a significant role in illuminating these aspects.

**Summary**

In this article we have suggested that science museums and centers play an important role in reinforcing some of the goals of the National Science Education Standards. The Standards could help science museums and centers in strengthening their roles and relationships with schools and teachers within their local communities and in helping to increase students’ achievement in science. Recently, there has been a constant call for bridging the gap between formal and informal science education. We suggest that the National Science Education Standards could provide a solid and reliable bridge to connect this two entities.

CEFIC—THE EUROPEAN CHEMICAL INDUSTRY COUNCIL ON THE INTERNET WORLD WIDE WEB

Brussels, 10 July 1997—CEFIC has been developing its own home page and site on the Internet for quite a while. It feels it would now be useful to alert Journalists and all those interested in the chemical industries’ activities on the international scene, about access to CEFIC through the Internet World Wide Web.

http://www.cefic.be/

JUST TRY IT AND SEE FOR YOURSELF!

NEWS RELEASES SPEECHES POSITION PAPER ISSUES
ECONOMIC INFORMATION/STATISTICS BROCHURES
LINKS WITH MEMBERS, ETC.

The CEFIC Internet site is being regularly updated and extended.

Later this year, a “CEFIC PRESS ROOM” will be created where the Press Releases, upcoming Press Meetings, European Press Officers Directory etc. will be grouped into one chapter on the CEFIC site.

Should you wish to receive press information electronically, please send your e-mail address to Marc Devisscher.

December 6, 1997
Chemical Modelling Conference
Bulmershe Court, University of Reading

The Modelling in Science and Technology Research in Education Group (MISTRE) is an international group of teachers and university tutors investigating the role of models in science and technology education.

The Chemical Modelling Group is part of the MISTRE Group focusing on how models are used in the teaching and learning of chemistry. Membership is open to anyone who wishes to contribute and share in its work.

Workshops
The workshops will explore delegates' own understandings of each theme. They will also include informed input on each theme, based on the range of models available and the sorts of models used in teaching in schools.

Discovering models
This interactive session will cover some practical methods of studying models in typical classrooms. Delegates should then be able to use some of these methods to carry out research with their own classes.

The theme for schools will be: Oceans

July 5-10, 1998
CONASTA 47
Northern Territory University, Darwin

Science Education—Beyond the Horizon

The 1998 conference will be hosted by the Science Teachers Association of the Northern Territory (STANT Inc.). The conference is designed to provide a forum where all science educators; whether in primary, secondary, senior secondary or teacher education, have an opportunity to reflect and examine the important issues confronting education today and in the future. Issues of a geographical, cultural, political and technological nature centering on student learning will feature throughout the conference program. The sub-themes will give all interested in science education the opportunity to reflect on their practices and gain insight into what is waiting for us "beyond the horizon."

It is planned that prominent Australian and international educators, as well as experienced and enthusiastic classroom teachers will provide a stimulating environment where keynote addresses, seminars, workshops, discussion groups, forums and excursions allow professional enlightenment.

Further details are available from the conference website at:

March, 1998
Science & Society: Technological Turn
An International Conference on STS
Japan

Topics to be discussed include the following:
- Network assessment of science
- Transnationalization of Corporate Science
- Technology and Media
- International Relation in the Post-Nuclear Age
- Science and Technology in Asia
- Implication of STS on Science Education, Science Education Policy and Human Resource

Among the invited speakers are: Michel Callon, Sheila Jasanoﬀ, Deepak Kumar, Morris Low, Brian Martin, Arie Rip, Rustum Roy, Song Sang-Youg, Peter Weingart, and Robert Yager.

Making Curricular Connections in the K-8 Classroom
Summer Institute jointly sponsored by the National Science Teachers Association and National Council for the Social Studies
Northern Arizona University
Flagstaff, Arizona

Join teacher leaders in this unique participatory institute on curricular integration featuring science and social studies. Working sessions based on presentations by nationally-known experts will provide opportunities for dialogue and application. Topics for exploration include: multiple intelligences, standards-based practices, service learning, performance-based assessment, thematic instruction, project-based learning, planning and managing integration, issues oriented learning, and literature connection.

International Consortium for Research in Science and Mathematics Education (ICRSME)
7th Consultation
St. Clair, Trinidad

The International Consortium for Research in Science and Mathematics Education (ICRSME) is holding the 7th International Consultation from February 26 - February 28, 1998 in St. Clair, Trinidad. St. Clair is in the Port of Spain metropolitan area. The meeting will be co-hosted by the science and mathematics education community of Trinidad & Tobago and The Ohio State University represented by Donna Berlin and Arthur White in Columbus, Ohio. The program will provide opportunities to share favorite ideas and programs, make new friends and renew old friendships, get some much needed vacation time, pick up some new ideas and refine some collaborative research and development projects.

International Conference for Environmental Educators
Pretoria, South Africa

Vista University and the University of South Africa (UNISA) would like to extend an invitation to educators to attend this international conference for environmental educators. The conference seeks to discuss the holistic role of environmental educators at universities, colleges of education, non-governmental organisations as well as those in business and industry.

Theme
There has been a growing realisation that environmental problems cannot be solved without keeping social, economic and political aspects in mind. The contrast between the so-called western and pre-modern worlds, often referred to as the first and third worlds, was highlighted during the Earth Summit in Rio. It is essential that these “worlds” work together to address environmental problems. Environmental educators at post-school level need to adjust their education programmes to address EE in both worlds and so work towards a global solution. The conference aims to discuss the role of these educators and to seek answers to questions such as: Are there different approaches to

EE in western and pre-modern worlds? How could strategies be co-ordinated to both?

Science Education International is the Quarterly Journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Happy New Year

Third European Science Festival
Dr. Boris V. Boulybash
State Technical University of Nizhniy Novgorod
Kovalichinskaya Street, 57-41
Nizhniy Novgorod, 603 155, Russia
shein@cht.fci-nnov.ru

For the last two years (1996 and 1997) the educational project 'European Science Festival (Science of Europe in Language and Culture)' has been realized in Nizhniy Novgorod (Russia). The authors of the project want the key goal of the Festival to be the demonstration of the European cultural diversity through the diversity of the national visions of Nature. The Festival competitions and contests make the students and the teachers from secondary schools of three Russian regions acquaint with the 'great persons, great books and great ideas' of European science and demonstrate its sociocultural context.

The First Festival (Science of France in Language and Culture) was devoted to the 400-ds anniversary of R. Descart, the Second Festival (Science of Netherlands in Language and Culture) — to the 300-ds anniversary of the Great Embassy of Peter the First to the Netherlands. The Second Festival was sponsored by the Embassy of Netherlands in Russia. In the May of 1998, the Third European Science Festival is planned to be held; thematically we intend to deal with the Science of Germany and Russia in Language and Culture.

We are sure that our educational project promotes the students' interest in science development and science itself. Besides, we expect that the Festival will stimulate the students to participate in the dialogues between science and humanities. We are willing to establish contacts with foreign partners who are ready to participate in our project.

STL Science Teaching Materials

In response to the call to promote Scientific and Technological Literacy for all (STL), ICASE has seen its role to help teachers and has undertaken a number of initiatives. These will be reported at the ICASE General Assembly.

One initiative, ran over the last 2 years by ICASE, with the help of UNESCO, has been a number of regional, writing workshops on creating STL teaching materials. The materials created so far will be displayed at the ICASE General Assembly in Liverpool, January 1998.

ICASE is concerned that science curricula are changing around the world to meet the ever increasing developments in science and technology, but little attention is paid to helping teachers modify their approach in line with changing emphases. There is a growing realisation that before curricula change, teachers need to be helped to rethink the goals of science education and the impact of this on their teaching strategies. One way to do this is to develop teaching materials in line with developments, but to do this with teachers so that they can gain 'ownership' as they reflect on the change. The ICASE writing workshops have had this objective.

The materials developed are supplementary to the textbook and other teaching guidelines and can be used in the classroom at the discretion of the teacher. All the materials:
Research on Science Teaching and Learning

This is the latest ICASE publication with the proceedings of the 5th International Seminar held in the University of Dortmund, Germany June 1996. There are 15 research papers and discussion reports ranging from gender issues to students’ conceptions. Copies of this publication may be obtained from the ASE Bookselling Department, ASE, College Lane, Hatfield, AL10 9AA, UK. The price of the book is 15 dollars or 10 pounds plus 25% for postage and packing.

Declaration made by the President of ICASE

On behalf of delegates of the Second ICASE Latin American Symposium, Mar del Plata, Argentina, April 1997:

‘We, the participants of the Second ICASE Latin American Symposium, affirm:

• that science and technology education can have a profound impact on the individual as well as the society at large;
• that science and technology education can help students towards a better understanding of themselves and their environment; and
• that, in order to be fully effective, science and technology education must become more relevant to the local context, promoting an action perspective in relation to the needs and issues which impact on the quality of life at the individual and societal levels.

We call upon governments and educational organisations—formal and non-formal—to stimulate and support action which will lead to scientific and technological literacy for all across the Latin American region.’

Globalisation of Science Education Conference

The following represent excerpts from the ICASE President’s opening remarks at the Globalisation of Science Education Conference, Seoul, Republic of Korea, May 1997:

“One behalf of the International Council of Associations for Science Education, I welcome you to the International Conference on Science Education and the wonderful city of Seoul. The theme ‘Globalisation of Science Education: Moving toward worldwide science education standards’ is a timely one. It recognises the global nature of the challenges and issues...
that confront us as science educators. There are remarkable similarities in what needs to be done in our respective countries despite our different cultural identities. This conference highlights the fact that we are not alone as we seek to encourage changes and developments in educational policy and practice which will provide a science education relevant to all.

ICASE is a networking organisation with over 130 member science teacher associations and educational organisations around the world. The theme of this conference describes the very essence of ICASE as we work with our members and various international bodies around the world to develop a quality education in science for all. Therefore, it is with a great deal of pleasure that ICASE is co-sponsoring this event.

The task of improving science education for all, however, is a huge task and much needs to be done. The task can only be achieved through collaboration and partnerships. We need to find ways to mobilise and martial the resources, skills and talents of individuals and organisations, not just from the formal education sector, but also from non-formal agencies. This, too, is a particular focus of our agenda this week.

My thanks to the co-sponsors—the Ministry of Education, UNESCO and the Korean Min-Jok Leadership Academy—for their support of this important event. I would like to pay tribute to the Korean Educational Development Institute and its staff for their efforts and skills in organising this conference.”

ICASE Distinguished Service Award to Dr. Robert E. Yager

During the opening of the ‘Globalisation of Science Education’ Conference, Seoul, Republic of Korea, May 1997, Dr. Robert E. Yager was presented with the ICASE Distinguished Service Award by ICASE President, Brenton Honeyman.

“It is my very great privilege to acknowledge an individual who has been selected to receive the ICASE Distinguished Service Award—the highest ICASE award honouring the achievements of an individual in the field of international science education. This individual joins an illustrious group of science educators who have each made their own remarkable contributions to science education at an international level. I am pleased to announce that the 1996 ICASE Distinguished Service Award is to be awarded to Dr. Robert E. Yager.

Dr. Yager’s career as a science educator spans a period of more than 40 years—a period in which science education has been characterised by significant and far reaching changes and developments. Throughout this exciting period of re-defining science teaching and learning, Bob Yager has been a prominent figure in inspiring new thinking about how best to engage students in experiences of understanding science in the context of their everyday lives. It is his clear vision of science as it relates to technology and to society that has been the driving force underlying his outstanding efforts to promote science curriculum so that it moves out beyond textbooks and classrooms to connect with the demands and challenges that people face in the context of contemporary society.

The remarkable achievements of Dr. Yager, the Professor of Science Education at The University of Iowa, have been recognised by the conferral of many USA awards, including the Distinguished Service to Science Education award by the National Science Teachers Association, the Presidential Award by the National Science Supervisors Association, and the Governor’s Science Medal for Science Teaching. His high standing in the educational community has been recognised through his appointments and elections to prestigious US educational organisations and projects.

His talents and contributions are well known beyond his own country, however. He is in high demand as a speaker, contributor and consultant in many, many countries throughout the world. His prolific writings have been appreciated by countless students, teachers, researchers and administrators in many regions of the world, and have been a significant catalyst for change in educational practice—particularly in the area of STS (science-technology-society) education. It is a fitting tribute to the high international regard in which Dr. Yager is held, that he has been appointed as the organiser of this important conference on the theme of ‘Globalisation of Science Education: Moving Towards Worldwide Standards.’

In addition to acknowledging his extensive accomplishments, I would like to refer to his outstanding qualities as a person. Bob continues to be a source of inspiration to all of us involved in science education. Classroom teachers, teachers-in-training, educational researchers and administrators alike, through our contact with this man, have been encouraged and enriched as a result. His genuine interest in and commitment to facilitating the work of those involved in science education at all levels have left a special mark on all of us.
Therefore, it is with great pleasure that I present the 1996 ICASE Distinguished Service Award to Dr. Robert Yager in recognition of his outstanding contributions to international science education."

Professor Rosalind H. Driver (1941-1997)

Rosalind Driver died at home at 6.30 p.m. on Thursday 30 October 1997, as a result of her cancer.

Rosalind Driver became one of the most pre-eminent figures in science education of her generation. She was a major figure on both national and international stages who attracted considerable interest and respect from science education researchers and science teachers. Throughout her professional career she displayed an enduring passion towards science education and took very seriously the responsibility of trying to improve our understanding of what is involved in teaching and learning science and, indeed, what might constitute an education in science.

Educated at Nottingham High School for Girls, she went on to study at the University of Manchester where she gained an upper second in physics, a subject whose intellectual demands and rigour were always a source of great fascination and interest for her. It was at this time that she met her future husband, Geoff.

After completing her degree, there followed a period of several years teaching which ultimately led her to the University of Illinois to work with Jack Easley as a research assistant on a project examining the cognitive behaviour in children. It was this work that was to lead to her Ph.D., awarded in 1973, on the representation of conceptual frameworks in young adolescent science students.

Her thesis presented an argument that was radical at the time. Students everyday knowledge of natural phenomena was viewed as a coherent framework of ideas based on a commonsense interpretation of their experience in living in the world, rather than as misunderstandings or mistakes. These findings, published in an article in Studies in Science Education in 1978, were to offer a new language to describe children's thinking. No longer were their ideas naive notions but alternative frameworks or interpretative models. Furthermore, she argued against the dominance of the Piagetian stage theory of development. Instead, together with Easley, she proposed that children's cognitive development may be more like a series of Kuhnian paradigm shifts, new ideas about a phenomenon replacing older ones. She argued that children's learning was dependent upon existing ideas about a phenomenon, rather than being limited by a child's developmental stage. Through this work, Rosalind Driver became one of the main progenitors of the constructivist movement that was to dominate science education throughout the 1980s and into the 1990s.

In 1974 Rosalind Driver was appointed as a Lecturer in Physics and Science Education at the University of Leeds. Her interest in research soon led to an appointment as the senior research fellow (1977) and then Deputy Director (1979-82) of the Assessment of Performance in Science Unit (APU), a major research project to document student achievement in science during the years of compulsory secondary schooling in England and Wales.

However, her most influential work stems from her period as Director of the Children's Learning In Science Project (1982-1989) and the Children's Learning In Science Research Group (1990-1995). The CLIS Project, funded by the UK government, was established to investigate possible reasons for the poor performance of students in science that had been identified by the APU. The early work of CLIS drew upon work described in her seminal book, *The Pupil as Scientist?* (1983, Open University Press). For many teachers, this volume provided an introduction to the work of Ros Driver. Teachers changed their perceptions of children's learning, and started to respond to children's thinking more directly in their teaching. Moreover, written in a simple and clear style, the book was a reflection of Ros's view that research can often be of practical relevance to the classroom science teacher and underpin curriculum development. Consequently, it is no surprise that Ros Driver's name became so well known amongst science teachers in the UK (and elsewhere).

The work of the CLIS project was firmly based on a collaborative effort between CLIS researchers and science teachers from the West Yorkshire region. In developing the CLIS in the Classroom teaching materials as many as fifty teachers were involved in three working groups over a period of two years. Ros Driver was at the heart of the activity, always welcoming teachers to the university, always appreciative of their efforts, always intent on talking and thinking through how theory might inform classroom practice. Through this work teachers became involved in reflecting on their own practice, in developing new teaching approaches, in attending conferences, in running workshops for
various audiences, in studying for higher degrees in education. Professionally, these were liberating and exciting times.

The work of the CLIS project led to many more important publications, in particular an edited volume (with Andree Tiberghien and Edith Guesne) aptly entitled *Children’s Ideas in Science* (1985, Open University Press), and further valuable packs for teacher professional development. By the mid-1980s, scholars from all over the world were beating a path to Leeds to work with Ros Driver and her colleagues. The standing of her work was recognised in 1986 by her appointment to a Readership, and then in 1989 when she was appointed as Professor of Science Education at Leeds. Her growing reputation led to a increasing number of appointments, in particular, to the UK National Science Curriculum Working Group, and a growing number of invitations to present her work, both nationally and internationally. In 1995, she was appointed Professor of Science Education at King’s College London, following the retirement of Paul Black.

In a very real sense Ros Driver saw research as a team enterprise and was always keen to encourage and support those that she worked with. The delight of working with Ros was the sheer passion and enthusiasm that she brought to whatever project she was working on. Endowed with the gift of being not only an eloquent speaker, but also a good listener, she took an avid interest in colleagues ideas and work, always willing to argue the point, but always offering the reassuring support so vital to sustain research work through the many dark hours and difficult periods. Moreover, she led by example a positive maelstrom of energy and hard work that carried those who worked with her in its wake, gaining their highest respect and commitment. It was also this interest in her colleagues, both in the UK and abroad, that led to a wide national and international network of friends and colleagues. A Canadian colleague recently wrote of what she had learnt from Ros’s work: “when I read her writings or when I listen to her talk, I learn a way of being, a way of doing research, of talking about it and a way of talking to people. . . .”

Ros was instrumental in working with science educators in Europe to establish the European Science Education Research Association (ESERA). The Association, inaugurated at the European Conference on Research in Science Education held at Leeds in April 1995, now holds a biennial conference which alternates with a summer school for Ph.D. students in science education. She was delighted to be able to attend the First Conference of the Association in Rome, two months before she died, and once again to meet and discuss her work with many old friends.

During the 1990s, the focus of Ros Driver’s work shifted towards explaining progression in conceptual understanding through cross-sectional studies. In addition, students conceptions of the nature of science and promoting scientific literacy became more prominent in her work and she extended the scope of her work to look at students learning of science at the undergraduate level. A feature of Ros’s approach to research was a willingness to develop and extend her own theoretical perspectives, recognising issues not addressed in earlier work, rather than defending an existing position for the sake of it. She was the lead author of a number of influential publications in science education such as Constructing Scientific Knowledge in the Classroom (Educational Researcher, 1994) and Young People’s Images of Science (Open University Press, 1996).

Whilst at King’s College, even though troubled by the onset of cancer, she succeeded in gaining funding for a series of seminars to explore the shape of the future science curriculum with leading science educators in the UK; a proposal to investigate pupils’ and parents views about the science curriculum, and in August heard that she had been successful in a proposal to explore and develop the skills of argumentation in school science. A crowning moment in her career was the award this year by the National Association for Research in Science Teaching (NARST) in Chicago of the plaque and citation for Distinguished Service to Research in Science Education. Those of us who were there will remember the enthusiastic standing ovation that this well-deserved award received from the science education research community.

If we are to be judged by what we leave behind for future generations then Ros Driver’s work in changing our understanding of what it means to teach and learn science must be regarded as a considerable and enduring contribution. For those of us that knew her professionally, her death prompts particular sadness in that she still had so much to offer. We shall all miss Ros’s energy and enthusiasm, her scholarly interests and wisdom. We shall miss her warmth, humanity and friendship.

Ros is survived by Geoff Driver, her husband of 34 years, and her son, Robert.

EXCAVATING SCIENCE EDUCATION: SOME REFLECTIONS FROM ARCHAEOLOGY

Alan E. Wheeler
Institute for Educational Development
The Aga Khan University
Karachi, Pakistan

Abstract

Adopting an archaeological perspective may be fruitful when examining the historical remnants, pillars, and foundational basis for much of current thought and practice in science education. The process of attempting to uncover the past and trace early forms of current science education involves the collection of both intellectual and physical evidence and is not unlike the archaeologist’s quest to more fully understand the nature, scope, and belief systems of ancient civilizations. In a Kuhnian sense (1970), the mental and physical strata of previous civilizations correspond to paradigmatic shifts in science education which are useful in characterizing the level and movement of science education thought in western society. Several incongruent features and practices, referred to here as Science Education Artifacts (SEAs), identified from this archaeological stance, are discussed in light of a more authentic and alternate conception of scientific practice. In order to treat the identified SEAs as true historical relics, all traces of their persistence in current science teaching practice will have to be eradicated.

Introduction

The inspiration for this paper came during a visit to several antiquity sites and ancient ruins in Western Turkey, the location of two of the seven wonders of the ancient world. While it is hard to isolate a particular moment in time when the idea for viewing science education form an archaeological stance actually occurred, it was definitely there as my wife and I wandered about the ancient acropolis of Pergamum overlooking the Aegean Coast. Active excavation is ongoing at Pergamum under the supervision of an Italian team and much of the large, open amphitheater, the impressive library, which rivaled that of Alexandria, the agora, and some main features of the main temple have been restored. The technology behind the piped in, gravity powered, water system from higher sources several kilometers away rivals that used in nearby villages today. Still much is left to one’s imagination of what the city must have been like during the first century A.D. Similar feelings abounded as we toured other sites of antiquity: Troy (Troas), Heliopolis, and the far more extensive excavations at Ephesus, begun over a century ago.

At such places, it is difficult not to reflect on what life must have been like during the height of grandeur of these ancient past civilizations and what little really remains today for observers to base their opinions on? What valid insights can one actually extract, from such ruins—the miscellaneous relics, columns, and limited artifacts that have survived the pillages, archaeological expeditions, lootings, and, (probably more significantly) the major earthquakes that have occurred over millennia? In many ways our insights into the daily life and the nature of civilization in ancient times comes about only partially from the physical evidence one encounters directly or from those on display in archives and museums. Major understandings are also a function of the knowledge, practices, beliefs and values that have withstood the ravages of time and humankind. These are the more enduring qualities of past civilizations that lie at the essence of the particular society which have contributed so much to the overall betterment of humankind.

I believe the archaeological metaphor is an apt one when examining the historical layers and foundational bases underlying much of current thought and practice in science education. This process of attempting to uncover the past nature and foundational basis of current science education, focuses more on mental fragments but the process is not unlike that of the archaeologist’s overall quest to more fully understand the nature, scope and belief system that characterizes ancient civilizations. In a Kuhnian sense (1970), the mental and physical strata of previous civilizations correspond to paradigmatic shifts in science education which are useful in characterizing the level and movement of science education thought in western society.
Learning About Science

Hodson (1994) makes a useful distinction in science education by identifying three major elements which make up the field:

1. **Learning science**, which refers to the acquisition and development of the conceptual and theoretical knowledge in science;

2. **Learning about science**, which is directed towards developing an understanding of the nature and methods of science, and an awareness of the complex interactions among science, technology, society and the environment; and

3. **Doing science**, which entails engaging in and developing specific disciplinary expertise in scientific inquiry and problem solving.

This paper is directly towards learning and teaching about science and how many of our pedagogical conceptions and assumptions about teaching and learning have changed dramatically over time. Indeed the contention is that, for the field of science education in general, changes in practice have been profound. So much so, that, even assuming an archeological stance, the science educator of today is hard pressed to even recognize or to be able to uncover the essential remnants and basic structural foundations of current constructions in science education. On the other hand, there is distressing evidence that for some science teachers, little or no fundamental change has occurred in learning and teaching about science over the years. Hopefully, those who tend to be ‘methodologically bound’ to a more traditional science teaching position are both few in number and non-influential in effect. However, in the context of many lesser developed countries, there is considerable evidence to indicate that much of science education is still heavily influenced by an ‘older,’ outmoded transmissional view of teaching and learning. This traditional view only serves to perpetuate certain stereotypical and outdated views of how science works and what scientists actually do (Wheeler et al., 1992). These distortions are harmful for, in addition to grossly distorting the nature of science, they may well serve to turn off students from entering science related careers.

Consider the following passage taken from PSSC Physics:

It [physics] is like a great building under construction . . . some parts are pretty well complete, and both useful and beautiful, others are only half done. Still others are barely planned. New parts will be started and completed by the men and women of your generation, possibly by you and your classmates. Once in a while, a finished room in this structure known as physics is found unsafe, or no longer large enough for new discoveries, and the room is abandoned or rebuilt. *But the great foundations are well laid and stand on pretty firm ground. These remain unchanged though changes go on above them.* (1976, p. 3)

The implicit message in the above passage is indicative of what I am referring to as an ‘older’ view of science, one in which the overall objective of science is to finish constructing *the* building. While new rooms can be modified or added, little or no consideration is given to alternate designs for the structure, other possible venues for science to occur, the human face and texture of science, and the idiosyncratic, serendipitous, and often highly intuitive dimension of scientists. One gains the strong impression that the same architectural firm was successful in tendering for the construction of all science education building during the 1960’s and 1970’s! Other excavations in science education throughout this period yield strikingly similar foundational features.

Science Education Artefacts

There are several incongruent features or practices associated with learning and teaching about science which quality for entry into the permanent archival collection as legitimate ‘artefacts’ of science education. Some of these artefacts are easily excavated, others are far more difficult to uncover. All, however, are inconsistent or incompatible with more current conceptions of practice in science education.

**ONE—THE ‘BLANK SLATE’ ARTEFACT**

This incongruent feature or artefact refers to the heavy reliance placed on observation as an objective and reliable means to scientific knowledge. It often manifests itself as the oft-quoted phrase in the science classroom, “the mind is a tabula rasa” and assumes that scientific observations are truly independent from the observers and are reliable across different observers. It qualifies as a legitimate artefact in science education since it is now apparent that we filter and decode observations based on our previous experiences, prior knowledge base, beliefs, and expectations. Far from being ‘blank slates,’ our minds are laden with existing constructs which serve to accommodate, and assimilate incoming stimuli. Attaching meaning to these stimuli
is a complex and idiosyncratic process. For example, whether you see an elegant vase or two old men, or an old or young women in Figure 1 depends more on the brain’s interpretation of the incoming images than on any physical phenomenon. According to Barlex and Carre (1985) our existing conceptual framework plays a critical role in determining how and what we observe. “We do not see things as they are, we see things as we are.”

Figure 1. An elegant vase or two old men?

Interestingly, if the incoming stimuli are incompatible with our existing conceptual framework, the result may be an optical illusion (Figure 2). Here the effect is often a disturbing or irritating one as the image does not mesh well with our expectations.

Once changes occur to our mental constructs, they in turn affect future perceptions. Once you are first able to see the alternate images embedded in Figure 1 for example, you will experience little difficulty in discerning both images in the future. The point here is that nothing has changed in the incoming stimuli, hence the change must have taken place be in the observer and the way in which the world is now perceived. Hence it is important in science education to acknowledge the extent to which our perceptions are personally constructed and to teach students how to observe and interpret what they perceive.

Figure 2. Optional Illusional

TWO—THE ‘LAST BRICK’ ARTEFACT

The earlier reference comparing the process of science to the construction of a building is indicative of the ‘last brick’ artefact in science teaching and learning. Viewing science teaching and learning as ‘bricklaying’ accepts that science is a precise, and highly objective process. Presumably adherents to this position, believe that if the bricks are placed according to the architectural blueprints, the process will eventually lead to some ultimate truth when the last brick or cornerstone is set into place. Like Kuhn’s complacent period of normal science, only minor construction refinements or modifications are allowed to the overall structure. These only serve to house additional equipment or to provide additional space to carry on the expanding process. Like many ancient Roman and Greek buildings, classical houses of sciences were built for permanency and aesthetics. This ‘last brick’ artefact held great appeal for many as it appeared to lend a degree of credibility and authority, and hoped for longevity to the scientific community.

However, the study of archaeology is resplendent with the ruins of past civilizations who operated solely under this model of ‘normal science,’ unable to accommodate to the cracks in the building’s foundation, the inevitable unsolved and unexplained problems that accompany the constant growth of scientific knowledge.

As Kuhn (1970) reminds us, science does not proceed by consolidation alone, but through successive phases of revolution and consolidation, whereby established paradigms are superseded during ‘crisis’ periods by dramatic and revolutionary processes. Like the study of archaeology, excavations in science reveal discontinuous layers of conceptual thought over time.

Figure 3. Paradigm Shift

It is interesting to reflect on the degree of resiliency under Kuhn’s model of science in relation to the ‘science educator as archaeologist’ metaphor. Like the golden years of earlier civilizations, the life-span of a particular paradigm is measured largely by it tolerance for unexplained anomalies, and other refutational evidence
brought in by people of other emerging nations. If such incoming evidence is not critically damaging to the existing paradigm, the 'civilization' adjusts by modification and development to these incoming changes and pressures. If, however, incoming ideas prove insurmountable to existing thought, then science theories, like civilizations, may decline or be overthrown. These transitions can occur through either peaceful or revolutionary means. Theories are resilient because they can absorb or assimilate abnormalities in many ways. If they are not the case, science educators would have to be constantly shifting theoretical positions or paradigms. Kuhn has further argued that competing paradigms are often also incommensurate. That is, they involved different ideas and concepts or they use them in different ways. For example, consider concepts like time and space. These same words, used in a Newtonian sense, convey very different meaning when used in the context of the Einsteinium paradigm. Presumably this incommensurate feature applies in archaeology as well. That is, when attempting to ascribe meaning and value to certain precepts held by different people, the time period and development level attained by the culture, must be taken into consideration.

THREE—SEPARATE SHARD ARTEFACT

There is little doubt that considerable insight into past civilizations has been amassed through the meticulous and painstakingly slow process of attempting to fit the many pieces of the archaeological puzzle together. Clearly however, the archaeologist's skill and knowledge base about the nature and origin of the excavation under examination is instrumental in making sense of the many pieces of evidence, which frequently consists of small shards of pottery and glass. The interpretation and meaning however, placed on the many archaeological finds, are made possible because of the theoretical background and training of the professional archaeologist.

The 'separate shards' artefact in science teaching manifests itself when the processes of science, like observing, classifying, measuring, etc. are treated as if they were discrete, generic, and theory-independent processes. The separate shard approach does not recognize that it is impossible to engage in these processes independently of content. As in the 'blank slate' artefact, the manner in which one observes, classifies, hypothesizes depends largely on one's theoretical understanding. As noted by Hodson (1994),

... we are not teaching students to observe, classify, measure and hypothesize per se. They can already do that perfectly well. They have been doing so since long before they came to our science lessons, and continue to do so every day in their lives outside the laboratory.

What we are teaching them is a firm understanding of the scientific notion of these processes which are theory-specific. Scientific observation is theory—impregnated and all observations should be validated by reference to a theory base. To teach science by treating these processes as separate entities or shards of evidence is an artefact of science education which should be permanently laid to rest.

FOUR—'VALUE-FREE' SCIENCE ARTEFACT

The Kuhnian notion that science advances through a complex communal process whereby ideas of particular scientists eventually become accepted as scientific knowledge in itself negates the idea that science can ever be value free. It is the psychological, emotional, and political turmoil that scientists engage in that eventually give rise to paradigmatic shifts. These factors, also impact on a wider scientific community. Hence simplistic accounts of theory acceptance and rejection, found in many earlier science textbooks, do injustices to both students of science and what they read about scientists themselves.

Summary

This paper examined certain parallels that appear to exist between the field of archaeology and science education in an attempt to identify outdated features in the study of the teaching and learning of science. Any analogy of teaching and learning unavoidably encompasses some oversimplification and is unlikely to take into account all the complexities involved in the teaching and learning process. However, the science education artefacts presented here are reflective of earlier eras which gave rise to them. Ironically, in spite of their inapplicability to current practice in science education, it is evident that such artefacts are highly resilient and can still be found in many science classrooms today. Hence, before they can be treated as true historical artefacts, total classroom eradication would have to be assured.

In summary, it is important to remember that all archaeological artefacts are, by definition, a result of human endeavor, and hence reflect both human achievement and fragility. In the context of science education, we often forget this human aspect, and the extent to which all science is a result of human activity, built up over centuries by the views, attitudes and prejudices of real people.

Call for Papers for the Second China-U.S. Conference on Education

If you are interested in expanding our professional network and interacting with counterparts in the People’s Republic of China we invite you to submit a paper or to attend as an interactive participant.

The Steering Committee invites papers for presentation at concurrent and poster sessions. Applicants must address one of the following topics:

QUALITY OF PERSONNEL: Preparation and development of administrators, teachers, or teacher trainers, leadership, professional standards and responsibilities, teacher/student relationships, and personal characteristics.

QUALITY OF STUDENTS: Preparation of students to live successfully in their local and in the global community, required knowledge and information base, assessment and personal characteristics.

QUALITY OF PARENTING: Preparation for the parenting role, recognition of parents as first and life long teachers, building school/home relationships, parents as school partners, and personal characteristics.

QUALITY OF CURRICULUM: Preparation, selection, and integration of new curriculum, elimination of irrelevant and outmoded subject matter, required technology and training, integration of curriculum, and assessment.

Papers must not exceed one page double spaced, using 10 point pitch.

Include:
- presenter’s name
- title
- organization/institution
- mailing address (including 9-digit zip code)
- phone number, fax number, and e-mail address
- grade level - K-12, college/university

Presenters are responsible for their travel and expenses related to the Conference.

For more information visit our website at: http://www.goodnet.com/~global or contact us directly by phone: 602/943-3922, FAX: 602/943-4458 or e-mail: global@goodnet.com.
SCIENCE EDUCATION DEVELOPMENTS IN TURKEY

Lütfullah Türkmen

General History of Turkey

Before coming to Anatolia (Asia Minor), many of the Turkish people were newly converted to Islamic religion from their native religion (Shamanism). By the 13th century, most parts of Anatolia were colonized by Turkish people and in 1299, they established the Ottoman Empire lasting more than 650 years. The Ottoman Empire collapsed in 1922. The educational system of the early Ottoman Empire was composed primarily of religious schools supported by the Ministry of Religion. In addition to these religious schools, which were affiliated with the Mosques, there were a few palace schools designed to prepare the state-men. However, in 1839, as a result of western influence, the first major system-wide change in the educational system occurred. With proclamation of the Republic of Turkey in 1923, the national educational system was expanded to include military and technical schools and more closely emulated school systems in European countries. For example, all educational institutions were brought under one umbrella by the Unification of Education Law passed in 1926. As a result of this law, still effective today, duality was eliminated and replaced with a more western and secular system (Cahill, 1984).

Turkey has an area of 780,576 sq. km. and geographically forms a bridge between Europe and Asia. According to 1997 statistics, the population is almost 63 million, 99.8% of which are Muslim and the remaining two tenths of one percent are composed of ethnic minorities, such as Jews and Christians. The workforce is dominated by agricultural related jobs, but is decreasing every year, and being replaced by industrial and service sector positions. The World Bank classifies Turkey as a half-industrialized developing country (growth rate approximately 8% per year). The per capita income in 1995 was around 3,000 US dollars (OECD, 1995).

Educational Developments After 1923

According to Ayas, et al. (1993), the Turkish Science education developments after 1923 can be divided into two phases—before 1960 and after 1960. In recent years, it has been difficult to see stable governments in Turkey and this causes changes in the educational system every three or four years. However, the early Turkish education system showed the most stable period and shaped the education system. During these years, many famous foreign educators, such as John Dewey, Kuhne, and Omer Buyse, etc., were invited to Turkey (Basgoz & Wilson, 1968). Their findings were discussed by Turkish educators and many of their suggestions were applied. The most influential foreign educator was John Dewey whose comments directed Turkish educators to prepare their own curricula based on Turkey’s needs. During the 1950’s, aims and objectives of Turkish education system were revisited again with the primary goal of increasing literacy and reaching out to everyone in the country. Especially in the elementary science curriculum, the basic focus was to teach basic science concepts and make elementary pupils understand and find connections in their daily life via science courses. However, it is difficult to say the same thing for middle school and high school science curricula. In fact, how these objectives were accomplished is not clear. Despite foreign educators’ suggestions, the science curriculum continued to use textbooks as a source of science curriculum and did very little to meet regional and local needs.
After 1960

There has been a world-wide deviation to science education starting in the late 1950's. One contributing fact was the technological competition between West and East during the cold war era. When Russia launched the first space craft, it focused its attention on science education, especially in the USA. This led to the formation of new USA science curricula, such as PSSC, the CHEM study, and BSSC in the USA. The effects of these new curricula innovations influenced Turkish science education curricula, but it did not go beyond simple translation of these curricula. These translated versions were made available, but the new American curriculum implementation was not totally successful throughout the country. In fact, the Ministry of National Education of Turkey (MEB) and the Turkish Scientific and Technical Research Institute (TUBITAK) made a great effort to adapt the new science curricula, such as opening a science lab classroom for every secondary school complete with local supplies.

Although the Turkish education system has been centralized since 1925, these imported curricula created a dichotomy in the nation’s schools. Many continued to use the so-called classical science curricula while other secondary schools were implementing the modern science curricula (BSSC, the CHEM study, etc.). This dual system in secondary science education continued until 1985. Finally, in that year these translated and adapted science programs were mandated by the Ministry of Education (MEB, 1985; Turgut & Pekgoz, 1976; Turgut, 1990), but continued to fall short of the need for educational reform.

Here are some points why these science curricula were not successful in Turkey. First of all, the American curricula were prepared for the USA, a technologically advanced country. There has been similar complaints concerning these curricula in other countries who also attempted to adopt and implement these curricula (Fensham, 1988). The Turkish education system and society were simply not ready for these curricula, especially the science teacher preparation component. Keep in mind that one of the most important aims of the Republic of Turkey has been to reach the level of the other westernized nations. After 60 years, perhaps physically Turkey appears to be a westernized country, but the same thing can not be said of their underlying philosophy and beliefs. Turkish society still depends upon traditions, religious customs, and strong family values, especially in rural areas. During the implementation of these curricula, teacher preparation both in service and pre service were ignored. For example, until 1975, elementary school teachers were prepared in Teacher Training Senior High Schools. Later, it was changed to two-year junior teachers’ college. High school and junior high school teachers were coming from three-year colleges, and a few from four-year university college programs. Also, during the 1970’s, wide-spread student unrest, especially in teaching institutions, slowed the integration of the adopted science curricula in those institutions (Turgut, 1990). Consequently, the majority of Turkish science teachers were not prepared to teach the new curricula. For instance, in the author’s high school physics course, the teacher was not capable of teaching the course or using the lab equipment. In addition, this imported curriculum was very difficult and because the material was written with another culture in mind, it was near impossible to find daily applications of the curriculum. To make things worse, the Turkish Scientific and Technical Research Council (TUBITAK) funded and cooperated with the Ministry of National Education, but withdrew its support in 1980, thus leaving the Ministry of National Education without the required funds, and technological and scientific supports needed for implementation (Turgut, 1990).

Other problems arose as a result of the translation process. When the curricula and textbooks were translated by Turkish science educators and scientists, a vocabulary problem surfaced because few scientific words of the Turkish language could not meet the scientific vocabulary of English language used in the textbooks. Thus, science educators and translators used the original English word or some other Turkish words previously used by students during their early education and having completely different meanings. The results of process confused students’ concept development and scientific understanding (Ayas, 1993).

The adopted biology curriculum received a great deal of attention by society, and voters mandated that politicians change the biology curriculum or remove some parts of the curriculum, especially in evolution sections found in the 11th-grade modern high school biology text book. Like in the Bible’s Old Testimony, the Quran, the holy book of the Islamic Religion, refers to creationism and mainstream Islamic philosophy states that “Man is created by the God as he is.” This controversy began in 1985 and resulted in a new high school biology curriculum prepared by a special curriculum committee including biology teachers from high schools, biology faculties from science colleges, and other curriculum specialists, and published in the official newspaper of the Ministry of National Education (Tebildir Dergisi) (MEB, 1985). This new high school biology curriculum covers creationism as well as Darwinian evolutionary theory. It was an effort to create peace between socio-religious values and scientific approaches. However, according to the National Basic
Education Law legislated and passed in 1973, one of the main aims of the Turkish education system is to have students gain scientific understanding. Supporters of this new curriculum surplant this mandate by claiming that creationism should be considered a theory just like the evolutionary theory.

As mentioned in the early part of this paper, since the 1960’s the major problem in the Turkish education system has been political stability because of changing governments and education ministers every two or three years. Many times, this results in unfinished attempted changes as each new education minister promotes a new agenda. For example, during the educational ministry of Avni Akyol in 1991, a new high school credit course system was created, only to be replaced with another system three years later by another minister of education, Nevzat Ayaz in 1994. Although these changes affect high school curricula including science, few of these changes are aligned with current worldwide accepted reform. Generally, these changes focus on course objectives and minor revisions. Therefore, the nature of high school science curricula in Turkey continues to reflect teacher centered programs, textbook and a heavy content base. From the students’ and teachers’ point, the purpose of science textbooks and curricula is to prepare students for higher education university entrance exams. For this reason, few see a need for science education to develop process skills or present concepts in their daily life. That is why many high school students see no practical value in these science courses except as preparation for the university entrance exams. There are three major goals for Turkish secondary science curricula. These include: 1) an understanding of scientific facts and principles for every citizen graduated from high school; 2) the development of good health habits; and 3) a basis of scientific knowledge and skills for university education (Cahill, 1984). It seems that science curriculum change efforts ignore especially the first goal.

**Primary Science Education Developments in Turkey**

Primary education, or basic education, refers to K through 8 grades in Turkey. Until recently, primary education was under three different school systems, such as pre-primary level, first level basic education for 1st through 5th grades, and second level of basic education for junior high or middle schools, grades 6th through 8th. However, in 1997, the extension of compulsory education from 5th grade to 8th grade brought two different schools under one school system called primary schools. With these changes, the following administrative school systems were abolished: middle schools, junior high schools, junior religious high schools, and Anatolian junior high schools which teach science and math courses in a foreign language, such as English, German, or French.

Possibly because of the complexity of the primary school system, the curriculum changing efforts are even less apparent than in secondary science education. For more than 20 years, the same science curricula and textbooks with minor changes were published by the Ministry of National Education for use in the nation’s schools. However, in 1992, in order to be ready for the last legislative changing, primary schools science curriculum was prepared as one part, and in 1992, was published in the official newspaper of Ministry of National Education. Until 4th grade, the first three years of science are taught as a combination of social and environmental sciences four periods every week, and is called life science. The curriculum changes of 1992 did not cover the first three grades because of this dual emphasis (MEB, 1992).

Stated in the introduction of this new curricula were the reasons for these changes that “it is required to bring science curricula under one curriculum because of the extension of compulsory education from five years to eight years, the elimination of usage and uncomtemporary knowledge behind the century, the introducing of new concepts and methods, the scope and sequence of curriculum without repeating the same objectives” (MEB, 1992). This science curriculum mainly covers the universe and the earth, energy and substance, living organisms, and our natural resources. Some of the earth science concepts of this new curriculum were moved to the primary science curriculum despite the social science emphasis.

The significance of this new primary science curriculum is that it was prepared under the supervision of science educators, curriculum specialists, primary school teachers, and university science faculties; and was built on the experience of previous elementary and middle school science curricula. Therefore, it is easy to see the contemporary science education notions in the curriculum. For example, the mentioning of the nature of science and the scientific method as a way of learning and teaching has been included in this new curriculum. As a result of this new primary science curriculum, the purpose of learning science has been expanded to not only prepare students for the next level of school, but to prepare scientifically literate citizens who are able to use scientific facts in their daily life and understand basic concepts by using simple locally suppliable materials (hands-on science). Moreover, in spite of social and religious controversy in teaching evolution in schools, this curriculum prepares students for the natural selection and evolution science objectives they will find in their 8th grade science classes.
The Developments and Changes in Science Teacher Education

Along with changes in science curricula, teacher education, particularly science teacher education, has also attempted to make changes. The Turkish education system has from the beginning faced major problems preparing quality teachers to serve and teach in the nation's schools. First of all, the demand for quality teachers outweighs the number available, especially since the westernized educational reform movement. Even though many Turkish governments have attempted to improve teacher preparation programs, many times they simply create temporary solutions, such as allowing high school graduates or college graduates to become teachers without training. These stop gap solutions have been brought about due to higher demands and rapid population growth. This approach first occurred in the early 1940's by opening elementary school teacher training in senior high schools. These were boarding schools whose students were selected by exams and came mainly from villages, rural areas, and poor families. For this reason these schools were called Village Institutes—"Köy Enstitüsüleri"). Their graduates were teaching science courses as well as other courses in elementary schools. Middle and high school subject teachers of this period, including science teachers, were allowed to teach after three years of college. In addition to these education colleges, art and science college graduates who wanted to become teachers were also allowed to teach in high schools. In 1975, teacher training senior high schools were abolished and replaced with two-year junior elementary teacher training colleges. In 1978, all three-year education colleges were converted to four-year teacher training colleges. With these changes by the Ministry of National Education, teacher preparation was extended to the college level. Also during this time many elementary and middle school teachers, who had not graduated from these colleges, joined in service teacher training programs in order to complete and reach other teachers graduate levels. In 1982, with the university reform, all junior education colleges and other education colleges were put under the university system. And, in 1992, the number of training years was increased from a two-year to a four-year for elementary school teachers. This significant change ended the difference between the elementary school and high school teacher training period.

In spite of some significant changes in the development of science teacher preparation as well as in other subjects, many teachers still lack necessary subject knowledge and specific subject area teaching methodologies. According to National Educational Basic Law, in order to be a teacher, every teacher candidate has to have: 1) a field of specialization, 65% of total course work; 2) general cultural knowledge, 11% of total course work; and 3) a professional area concentration; this includes courses in teaching methods, measurement and evaluation, educational administration, psychology, and sociology. In addition to teachers' college graduates, college of science and art graduates who take the professional area courses as an extra option can be science or other field area teachers (Cahill, 1984; and MEB, 1995). Lastly, due to a shortage of science educators in teachers' colleges, method courses are general in nature, covering all fields but not specific to elementary and/or secondary science teaching. Therefore, since 1993, many master and doctorate students have been sent to the USA and UK through the National Educational Development Project (NEDP) supported by the World Bank (Thomas & Kaptan, 1997).

The next reform in Turkish teacher training calls for all teachers' college graduates to have a masters degree. With the change of compulsory education from five years to eight years, Turkey faces a tremendous elementary school teacher shortage. Again, the short-term solution has been to allow some college graduates whose major is not teaching to be appointed as elementary teachers (MEB, 1995).

Conclusion

Our history of educational reform is not unlike many of our neighboring countries. Change at a national level is a long-term process. We must not lose sight of the progress made while continuing to work for additional improvements.

SCIENCE & SOCIETY: TECHNOLOGICAL TURN
International Conference on STS, Japan
March 1998

Topics include the following:

Network Assessment of Science
Transnationalization of Corporate Science
Science and Technology in Asia
MITI and Innovation Policy
Cultural Studies
Gender
Social Epistemology of Science
Implication of STS on Science Education
Human Resource

Knowledge Production Mode 2
Technology and Media
Japanese Studies on STS
Post-Colonial Studies
Expertisation and Public Awareness
Medicine
Religion and Science
Science Education Policy
International Relation in the Post-Nuclear Age

Invited speakers include the following:

Michel Callon
Deepak Kumar
Brian Martin
Rustum Roy
Peter Weingart

Sheila Jasanoff
Morris Low
Arie Rip
Song Sang-Youg
Robert Yager

SCIENCE EDUCATION IN BRUNEI DARUSSALAM: EFForts TO COMMUNICATE SCIENCE TO STUDENTS

Dr. Hassan Hamid Tairab
Universiti Brunei Darussalam

Introduction

At a time when most countries started to take serious look to the status of science education in their curricular, educators in Brunei Darussalam are no exception. Since the introduction of science education eighty years ago, various efforts have been put forward to place science education firmly in schools. Nowadays, science is taught at almost all levels of education with increasing demands on teachers to make various initiatives to promote students' interest in and attitudes to science. Such initiatives coupled with the government derive to continuously update and implement plans to derive awareness of the contribution of science and technology to the development of the country, is believed to be of paramount importance to future interest of the country in order to meet its needs. Realising the importance of role of science and technology for future generation, currently the government is implementing a programme called Brunei Era of Science and Technology by the year 2001 (BEST 2001). It is a comprehensive and coordinated derive designed to help its people take an interest in science and technology and enhance student appreciation of the role of science and technology in the development of the country. It is being spearheaded by the Ministries of Development through its seventh national plan. The plan outlines the significant role of various sectors including education to prepare the nation to the challenges of the future.

In this article, the role of Brunei Association for Science Education (BASE) in deriving various efforts to promote science and technology is highlighted hoping to share such efforts and initiatives with other regional and national organisations in order to strive for more excellence and cooperation among individuals and educational organisation. It is also hoped that ideas similar to those generated by Brunei science students will be generated in other counties. In Brunei, it is believed that education and the pursuit of excellence is something that Brunei Darussalam is very much aware of (Ministry of Education, 1992) and consequently many efforts have been carried out by the educators to sustain national interest.

Education System in Brunei Darussalam

Education system in Brunei Darussalam comprises government schools and colleges and non-government schools. All children enter school system at the age of five, stay at the pre-school level for one year before proceeding to the first year of primary education. They spend six years of schooling at primary level. The primary level consists of lower primary (Year One to Year Three) and upper primary (Year Four to Year Six). All children will sit for a public examination before they proceed to the secondary education. The secondary education lasts seven years with the first three years as lower secondary, two years as upper secondary, and another two years as higher secondary which is commonly known as Advanced level. Students will sit for public examinations at the end of each level. After completing their secondary education, students with relevant credentials (i.e., Advanced Level passes) can proceed to higher education at local higher institutions or abroad.

Science is taught formally at Year Four including health science but students may be exposed to non-formal science at an earlier stages. At all levels and to ensure high quality education, the Ministry of Education lays down curriculum guidelines for pre-school, primary and secondary education guided by its national education policy.
Science curricular are continuously reviewed and revised to ensure quality with special emphasis on science being taught as activity-oriented particularly at primary level. Resources and facilities for modern science teaching are given priority by educators and therefore most schools are well equipped. Such as environment has provided teachers in general and science teaches in particular with challenges to strive for better teaching and learning. Hence, as part of these derives Brunei Association for Science Education (BASE) was formed twenty years ago to contribute to the promotion of science and technology education in the country.

**Brunei Association for Science Education**

BASE, Brunei Association for Science Education (BASE) is an umbrella for science educators formed in 1978 purposefully for promotion of science education in the country. Specifically the association aims to contribute towards the improvement of the teaching of science and technology in all levels of education to all children. As a professional organisation it also aims to promote exchange and sharing of ideas among its members through meetings and discussion of issues related to science and technology. In this regard, BASE has exerted numerous efforts to establish links with other professional organisations. Since its formation twenty years ago, BASE has developed close links with international organisations such as International Council of Association for Science Education (ICASE) and the Association of Science Education in the United Kingdom (ASE). Regionally, BASE has also established close relationships with its counterparts in Singapore and Australia.

Since its inception in 1978, BASE organises various activities for the purpose of promoting science and technology in Brunei Darussalam. Perhaps the most significant contributions are those which incorporate student activities. Two of the most important activities are the Science and Technology Week and the National Science Camp which are both student-based activities whereby hands-on-experiences are shared by students through individual and groups involvement in carrying out scientific projects.

**BASE Science and Technology Week**

Science and Technology Week is an annual event which incorporates all student-based innovative activities. It aims to stimulate student imagination and increase creativity and scientific participation among students. So far BASE has organised 19 weeks since 1978. Each year all student activities will be based on a theme to reflect the emphasis given to the role of the chosen theme. For example, the theme for 1996 week was 'Information Technology in Science Education' which included activities designed to bring about awareness in students as to the role of science and technology in the development of the nation. The 1997 week which marks 20 years of existence of BASE, carries the theme of 'Science and Technology Education for the 21st Century.'

Prior to and during Science and Technology Week, students are involved in broadly three kinds of activities, namely scientific quizzes, essay writing and exhibitions displaying individual or group projects designed by students. Scientific quizzes start earlier during the academic year as part of the extracurricular activities during which students compete at regional levels before being selected to represent their school nationally. The aims of this activity are to enhance student general scientific knowledge and promote scientific attitudes.

**Science Essay Writing**

Science essay writing is designed to promote creative writing related to science and technology and to uncover communication skills among school children and to inspire greater love for books and the desire for reading in students. In so doing it is hoped that it will propagate in children the idea that science is an intrinsic part of their culture and environment. Essay writing activity is designed for students in lower secondary (14-16 years old) and up to tertiary level. Students’ work will be judged by teachers appointed by BASE management committee and those which judged to be of outstanding nature will receive prizes and will be certified.

**Young Scientist Badge Award**

This activity is designed for students at primary level to supplement the activity-oriented learning approach being implementing by the science teachers in primary schools. Children may carry out an activity or any project of scientific interest under minimal supervision of their teachers. It is hoped that this activity which involves personal interaction and construction of knowledge by children will encourage and develop children positive attitudes towards the study of science at an early age and thus, promote more active approach to science. The activity is guided by science teachers as facilitators using a pre-planned strategies printed in a card which is similar to a log book where the student has to follow certain instruction to be able to complete the activity. An example of an activity card is shown in
Table 1. It is similar in nature to the ‘Stepping into Science Project’ run by ICASE since 1988 and the young scientist scheme operated in Singapore. Points are awarded on satisfactory completion of each activity. When sufficient points have been acquired, the pupil qualifies for the badge which highlights the participant achievement.

Table 1
Activity Card for Young Botanist Badge Award (BASE, 1996)

1. Make a simple plant press.
2. Make a collection of pressed leaves of ten different identified trees.
3. Produce the silhouette (shadow) of a tree.
4. Take a series of photographs of different trees to show the similarities and differences of particular part of the tree. Drawing may be accepted.
5. Design a flower-bed for your school and name the plants you intend to use.
6. Put up a display of dried plants in your classroom.
7. Raise 5 plants from cuttings (vegetative propagation).
8. Use leaves and paint/crayon/felt pens to make an attractive picture.
9. Make a collection of 5 different ferns.
10. Draw 5 different kinds of pollen grains. You may use microscope or lightscope.
11. Observe and make drawing of three different aquatic plants.
12. Draw and identify the flowers of 20 different types of flowering plants grown locally.
13. Make a bottle garden.
14. Keep at least 2 different types of plants growing indoors using improvised containers. Bring healthy specimens to show your classmates.
15. Photograph the growth of a flower from bud to seed/fruit.
16. Make a collection of 20 different types of plant seeds and display them attractively in a box.
17. Make a map to show the sites of the different trees in your housing estate. Name the trees.
18. Write a poem or imaginary story on flowers/trees/plants.
19. Put up a bulletin board on some aspects of plants (e.g., a display showing different methods of seed dispersal, useful plants, poisonous plants, . . . etc.)

Tasks associated with the activity card can be interpreted as follows:

- When the activity asks for a drawing or photographs, the pupil has to make a series of drawings or photographs sequentially to show the scientific principle(s).

- When an activity involves a visit or need further observation by visits, this can be done by arranging a class field trip to the site(s).

- Pupils are encouraged to present their work either in English or Malay language.

- When the activity needs experimentation, advice or consultation is available from teachers who normally act as facilitators.

Statistics for these activities were impressive. More and more children are given opportunities to practice their knowledge and skills and taking responsibility in their learning. For example, a total of 362 students from 14 primary schools participated in the young botanist badge award in 1996 and 131 students for the science essay writing competition. For science quiz statistics showed that 19 secondary schools were included in the quiz (BASE, 1997).

The National Science Camp

The national science camp is an annual activity organised by BASE during school holidays and run for 4 to 5 days. Students are selected from all government and non-government schools with some selected teachers. The aim of the camp is to provide students with opportunities to explore scientific phenomena and to involve in an interactive and inspiring environment that will encourage promotion of individual, personal and educational development. For 1996 camp, a total of 65 students selected from 31 schools participated in a 5-day activities (BASE, 1997).

For 1997 activities, a number of new initiatives designed to bring about more students' participation in science-related activities have been put forward. For example, 1997 science and technology week includes a scheme whereby secondary school students involve in carrying out small-scale research projects with the aim of developing investigative ability and skills of students. An example of such research project is given in Box 2. Pedagogical philosophy behind such project which are entirely student choice includes:

- Students will learn new ideas as they research aspects of the problem under investigation from texts, teachers and other adults at hand.
- School science to some extent has become more pure and conceptually demanding and has less
concerned with children experiences. Such projects will blend students’ experiences with school science and thereby making it more meaningful and understandable.

- Students will develop and increase their ability to communicate their ideas in a more scientific approaches.

- Develop positive attitudes to science and technology and be able, for example, to appreciate that learning by doing science can be fun.

- When students initiate their activities, and take responsibility for carrying the projects by making decisions and solving problems, they develop a sense of ownership which is a central feature of effective learning (Watts, 1991).

The derive behind all these activities, of course besides fulfilling its professional role as educational organisation, BASE has come to a realisation that for Brunei students to be prepared to function in their future, they need to be equipped with the knowledge and skills which enable them to fulfill their role in an increasingly technology-oriented world. It is becoming evident that perception of science education has to move from its traditional look to a more progressive ways that consider evidence of learning. Kuch (1997) emphasises that students must be partners in their education by taking active rather than passive role. In so doing they will be able to show evidence of learning by being able to discuss and share scientific and technological issues related to themselves and their environment. The kind of projects that BASE has been carrying out since its inception has brought about significant changes in student perception of science. We often hear students commented on how science is boring and hard to understand. Though so far no systematic studies have been carried out to assess student attitudes to and perception of science in relation to BASE activities, students often remark that their participation not only giving them opportunity to learn science in a naturalistic environment but also help them to develop friendships, cooperation and independence.

PMB 1087, Apapa, Lagos NIGERIA

and

Ben B. Akpan
National Secretariat
Science Teachers Association of Nigeria

Why Topic Study?

Topic Study was created at Jordanhill in Glasgow to meet the needs of teachers seeking to integrate their teaching, rather than sticking within subject boundaries. It has transferred successfully to many education systems, in many countries. We believe it offers a remarkably fresh and effective way for delivering Environmental Education.

At heart, a Topic Study asks the teacher and learners to join together in imagining a context, somewhere where something can happen. Together they describe it, draw it, and write about it, explaining it as best as they can. They learn about the "models" of the world they and others have in their heads. Sharing ideas, questioning each other’s ideas, leads to the ideas being changed and improved. The topic is not static. A story is told. So changes occur. The teacher can make things happen. The children must then work out what best to do. A Topic Study is exciting and fun. Children say “It's better than work,” but will spend endless time and effort on it. They feel a sense of “ownership.” It is their Topic, the teacher is seen by them as the one who “only makes suggestions.”

Two Theories of Education

One model of education sees it as teaching, where the teacher does the thinking and the work and the pupil simply memorises. The child’s head is thought of as an empty bucket waiting to be filled. The teacher carefully prepares the knowledge into parcels and throws these at the child. Sometimes a parcel would miss, sometimes it would be caught by the bucket. Even if the parcel was in the bucket it could fall out when the child was playing or messing about. Some children’s buckets are full of holes and the parcels just fall through.

At the end of the teaching, the teacher sets a test. For every parcel of knowledge the pupil can find in his or her head they get a tick. For each one they have lost, they get a big red cross.

Active Learning

The other model of education considers that children’s heads are not empty. There is a brain inside. The brain helps the child interpret the world by creating models of what the world is like. The role of the teacher becomes one of changing and improving the models children already have in their heads. Much as we, the teacher, sometimes feel the desire to do so, we are not able to get inside the child’s brain. We can’t poke in our fingers and sort out their ideas. We have to get the ideas out. We must help them share their models with us.

There are four ways of bringing out the models:

Talk—they tell us about their ideas
Show—they show us things, with actions
Write—they put their ideas in words on paper
Draw—they use all the kinds of drawing skills.
Text 1 A Dying Planet

The Earth was dying. The forests were gone, the sea polluted, and fish driven to extinction. Now the crops were failing because of soil loss, changing weather patterns, and new and unexpected disease. Global warming was unstoppable. Millions if not billions faced a slow death by malnutrition, starvation, or genocide, as social order broke down. Those with power and money looked for an escape. Could they use their wealth to survive? One solution was to seek new lands but there were none left . . . on Earth. They paid scientists to search the skies for a new planet. One where they could, given time, recreate Earth. The search was successful. There was a suitable planet. The problem was that it was so far distant that it would take 250 years to reach. Or, as scientists could be very exact about these things, 248 years, 34 days, and 6 hours! The problem was to design and build space ships which could make the voyage. Teams of scientists were selected to advise and help.

Text 2 Space Convoy

The huge space ships were designed as modules which could be joined in space held together by passageways like the spokes and rim of a great wheel. Each module was similar but adapted for its particular function. Space ship Nigeria had modules for Energy and power, Recycling and recovery, a species bank, accommodation, education, health, passengers in hibernation, workshops, entertainment, and a command centre. At the centre of the wheel was the life support system. Plumbing and other services were visible on the outside of the modules. So each module was easily recognised. Inside, the walls and rooms were arranged to suit the function of the module. Each module was allocated to a separate design team, so that all would be ready by the launch date. If the deadline was missed by one module, the whole spaceship would never leave earth orbit.

Text 3 The Crew and Passengers

Many more people wanted to go than there were places for. Committees were set up to determine the criteria for selection. There were two categories; crew and passengers. The crew would be there because their skills were essential for the success of the voyage. They would also need to be replaced when they became old and useless.

The passengers included the rich and powerful. They decided that they needed others to make life on the new planet a success. Some passengers would come abroad “alive” some in deep sleep at low temperatures, and some frozen in the deep freeze in the hope that they could be revived. The organisers asked groups to draft proposals for the selection criteria. A consensus would be established.

Text 4 Life’s Necessities

Life on board the ship would not be much fun. Luxuries would not be allowed; only the necessities of life. Although this rule was established early in the planning, it became clear that different teams and people had different ideas. A plan had to be found to develop a list which all could agree to. They asked for suggestions, seeking one page summaries from each team. If no better suggestion came up, then each would create its list then present it to the others, who would accept or reject items. The finished combined list would still need to be shortened.

Text 5 Sourcing Necessities

Even simple “everyday” items are the result of many activities, indeed a chain or “tree” of processes. The organisers knew that the spaceship would be too far away for help, so they had to make sure they forgot nothing that could endanger the voyage. They approached consultants and found that “backtracking.” Each item selected as an “essential” was considered. Its parts were identified, and sourced. But where in turn did these parts come from? How had they been made? Where had the factory, the raw materials, and the energy come from?

Experts said that everything could be traced back to minerals and elements and energy sources, usually the sun. As an example to explain the process, they selected the ball point pen. It was made of three kinds of plastic, a brass writing head, a tungsten ball, and filled with ink. How had these parts been made, with what techniques, what resources and what energy. They put their heads together and thought.
Text 6 Energy Sources

The importance of the Sun was a matter of concern. It would only be a few months before the ships were too far from the Sun to be able to harvest its energy. A portable source of energy was needed. All fuels were considered. Whatever fuel system was to be used, they would have to take care not to be wasteful. Scientists told them that energy did not disappear, it was never destroyed; just converted into other forms and spread out. “Using energy” was a process which took stores of energy and scattered them. The organisers asked if the scientists could think of ways to recover the energy for use, like they could recover the metals and plastics and other materials. It was difficult for the scientists to explain this. Why can’t the scientists recycle energy?

Text 7 Sustainable Life Support System

Once the energy source had been decided upon, the teams of scientists were asked to submit designs for the core of the spaceship—the sustainable life support system. The message from the ecologists was this. Simple systems can easily swing out of balance and need very close monitoring and control, yet complex systems seemed to be able to create stability from their very complexity.

The choice, therefore, was to create a computer monitored and controlled simple system, with all the risks, or to establish a complex ecosystem transplanted from earth. Was there any other way?

Text 8 Space Pirates

There had always been rumours that there were other convoys in space. These had been poorly designed and their life support systems failed to meet the needs of all who boarded. Fighting had broken out, and so the rumour went, a ruthless group had seized control. They had stopped trying to make their spaceship work, and instead had adapted them for attack. They prowled through space, seeking defenceless spaceships to plunder, so that they could survive themselves. Unknown to everyone was a new danger. After the convoy had left, the rich who had been rejected, the drug lords, and other criminals of the world, had designed attack ships. These were on their way.

Text 9 Memories of Earth

In the school, the children who had been studying Earth history were asked to write an imaginary poem describing what living on Earth might have been like.

The structure they used was a sense poem. The teacher gave them headings:

- see
- smell
- touch
- fear
- hear
- feel
- do
- wish

When the class or groups had come up with good expressive phrases, the teacher rubbed out the first two words on each line. Now, they had a poem.

Text 10 Messages to Earth

After many years of journeying, the crew decided that they should send messages to Earth. They wanted to say that they had learned to live with limited resources, never wasting materials or energy, and making sure that they recycled everything. They thought it was right that those on Earth should be told. Now they realised that Earth was itself a spaceship traveling through empty space with no hope of help from outside. The “crew” of Earth had to make their spaceship work.

Text 11 A Message from Space

Earth had not done well in the years since the spaceships left. The message was too late. There was no-one who could do anything, for it was a question on individual survival. There was no hope, no-one to tell, all was lost. The stinking hulk of the once beautiful Earth would forever drift in space. It need not have been so. The message from space could have been learned in time. What are the implications globally, nationally, locally and individually of the message from space? Select a part of another group’s message and write a response to it under the four headings.

GROUP REPORTS

Editor’s Note:

As a sample of just how powerful a teaching tool this approach can be, the authors have included an outline of topics and ideas generated by groups as they actively engaged each of the previous Topic Study scenarios. These thoughtful reflections could serve as guidelines for your own groups. But please remember that the authors are NOT suggesting that these or any specific responses are "correct." It may be useful to either ignore these "other group" conclusions or use them as simply a helpful suggestion list that you draw upon for groups who are having difficulty generating their own ideas.
Text 1: A Dying Planet

Design of Spaceship
- Suitable raw materials
- Eco-balance
- Suitable source of energy
- Recycling facilities
- Modulation of temperature
- Alternatives to non-environment friendly materials

Text 2: Space Convoy

A list and specifications of the requirements for each module should be prepared.

Text 3: The Crew & Passengers

Crew
- qualified and skilled
- sound health
- relatively young
- able to train and pass on the knowledge and skills

Passengers
- Good health
- Ability to endure low temperature
- Rich and influential
- Scientists
- Industrialist
- Sportsmen and women

Text 4: Life's Necessities
- Water
- Suitable Power Supply
- Ventilation
- Drugs
- Friendly Eco-Environment
- Exercise and games facilities
- Transportation
- Balance Diet
- Adequate Accommodation
- Textile production
- Security
- Entertainment
- Education

Text 5: Sourcing Necessities
- Water—Water cycling materials required
- Suitable Power Supply—Suitable source of energy; Oxyacyetylene for welding
- Drugs—Petrochemicals and Medicinal plants
- Textile Production—Cottage Industries
- Education—Books made from the vegetation
- Friendly Eco-Environment—Suitable Environment; Vegetation
- Generally: Source of the Necessities in Text 4 are the target of this text

Text 6: Energy Source
- Solar: Solar Batteries = Electrical energy = Re-energise the solar battery
- Fuel: Coal, Crude oil, etc.
- Steam Engine: Water (Cycling plant) Steam energy (power the Engine)—Water—Steam
- Nuclear Energy: Nuclear batteries from radioactive materials
- Solar: Potential energy (plant through photosynthesis) -> Chemical energy (Organism) -> Heat -> Plant (chemosynthesis)

Text 7: Sustainable Life Support System

Complex Ecosystem
- Transplanting of plants
- Water Cycling
- Suitable Conditions
- Balanced Ecosystem
- Suitable Energy Source
- Adequate Water Supply
- Good Cooling System

Computer Monitored & Controlled
- Human resource to compliment computers
- Trained personnel to monitor & control system inside spaceship
- Trained personnel to control materials, e.g., security
- Control room—Computerised

Note: High level of risk involved here.
Text 8: Space Pirates

- Appropriate Defence System
- Will Power
- Manpower
- Anti-missile gadget
- Facilities modified to perform many functions
- Modified Radar System
- External magnetic field to shield the spaceship
- Formation and training of an army
- Computerised Signals Department

Text 9: Memories of Earth (by one group)

- The picture of an eco-balanced Earth.
- The sound of rivers flowing and cries of animal.
- The sweet aroma of beautiful flowers, green and lush vegetation.
- The radiant heat of the sun.
- The sample of the remains of the Earth.
- The things that are eco-friendly.
- The calamities caused by ozone layer depletion and global warming.
- For a new Earth that is eco-friendly.

Text 10

Dear Inhabitants of Spaceship Earth,

Messages to Earth

It gives great pleasure to write you our experience in our Spaceship. Over our long journey, we have learnt that it is possible to live with limited resources, never wasting materials or energy and making sure that every resource is recycled.

However, realising the state where we left the earth, we believe that more damage will have been done by now. However, the earth should not lose hope but rather should be thinking on how to remedy the situation and we hereby offer the following suggestions:

1. Environmental monitoring agency: You should now set up a lush powered and result-oriented agency that will monitor the utilisation of your natural resources. It should be well funded to enable it to perform.

2. Food: There should be no wastage of food. Excess food should be preserved. Every inhabitant needs to be well educated on how to do things.

3. Balanced Ecosystem: The inhabitants on the earth should ensure that there is a balanced ecosystem.

To ensure that this is done, for every tree pulled down, there should be a replacement. And this applies to other resources like animals and fish, etc.

4. Water: Ensure that you recycle your water. This was already being practised in developed countries before we left. The idea should be sold to the developing countries.

5. Health: To prevent sickness and diseases ensure that your inhabitants take balanced diet. However, in order to take care of the sick ones, ensure that you have well trained medical personnel (doctors & nurses, etc.)

6. Education: Studies on Environmental Education should form an integral part of your education at all levels so that every individual will learn to take good care of his or her environment.

7. CFCs: As a matter of urgency you should find alternatives to the synthetic materials which lead to increase of CO2 production and depletion of ozone layer.

8. Earth population: The inhabitants on the earth should monitor population growth and if possible limit the number of children per family.

We wish you speedy recovery.

Yours Sincerely,

(Signatures by group members)

Text 11

Global Implication: Over population, food shortage, CFC accumulation, disease, UV emissions, Desert encroachment, high temperature, high CO2 build-up.

National Implication: Overpopulation, high mortality rate, disease, inadequate housing, ecological problem, food shortage.

Local Implications: Means of livelihood threatened by deforestation. Overcrowding, poor ventilation, under employment, increase in crime rate, poor health conditions.

Individual Implications: Skill problems, psychological problems, bush burning, malnutrition, health hazards, social problem.
Non-formal and Informal Science Education

Section Editor
Andrea Anderson

ava825@aol.com

This section focuses on the interface between non-formal, informal, and more traditional formal science education. Articles expose the world of out-of-school and public science experiences.

Defining How and Why the History of Science Might be Included in Informal Science Learning Opportunities

Eric J. Pyle
West Virginia University

An appreciation of the entire span of history cannot be arrived at by an audience simply by reciting a sequence of historical events. A sequence begs the question: whose history? whose culture? whose language? whose discoveries? Since science and technology play such a large role in our current society, the history of science (HOS) and technology is of particular interest. At the same time, institutions with an interest in education are under increased pressure to represent a variety of cultures, ethnicities, points-of-view, etc. How then can the individuals responsible for the organization of education operationalize larger, more inclusive agendas without being divisive or seeing only narrow slices of history?

A question we might ask is why bother to include the HOS into science museum exhibits and other informal learning experiences? A simple answer might be modeled along the lines of the posters that show a drawing of the Milky Way galaxy, with a small arrow pointing to a rather small star, labeled, You Are Here. Audiences exposed to and shown their position with respect to the HOS have an opportunity to create a context for their own current relationship with science. Understanding how science evolved and its future directions may help people construct meaning from their own journeys with science.

The intent of this paper is to serve as a starting point for discussions that intend to define the mechanisms and rationales (the how and why) for the inclusion of the HOS in the construction of informal and nonformal science learning opportunities. These opportunities might range from a bulletin board or learning center in a classroom to a museum exhibit or television show, but the intent remains the same—an opening for dialogue to emerge between the producers and the consumers of such a learning opportunity.

Approaches to the History of Science

In considering how the HOS might be presented in an exhibit, several approaches are available that might reach out to and 'grab' a particular segment of the audience. Briefly, they are:

- Milestones and Artifacts
- Historical Figures as Exemplars
- Cultural
- Interpretive Entity
- Linear Sequencing

Each of these approaches is outlined below, along with a brief comment on the advantages (or occasionally, disadvantages), opportunities, and considerations offered by each approach. Caveats to the application of these approaches are presented in the final section of this paper.

Milestones & Artifacts

One approach to including the HOS in an exhibit is to examine history as a sequence of milestones or artifacts. An artifact is examined from the perspective of the motivation and thoughts that the artifact developer experienced. A human face is placed on technological innovation by concentrating on the developer of a process, an invention, or a procedure and how he or she worked within (or outside of) his or her culture. Milestones should highlight lesser known inventions and inventors, especially those of women and minorities. Doing so allows the display to go much beyond the commonly known exemplars, such as the assembly line (Ford), the light bulb (Edison), or vulcanized rubber (Goodyear). Patent applications can be used as "mini case studies" in examining the innovation from the perspective of the developer as the project progressed from its inception to the granted patent number.
A larger case study of an artifact might consist of a portfolio for an innovation. Such a portfolio would consist of: (a) the inventor and his or her social context, (b) the relationship of the innovation across contexts (e.g., the hearing of a voice with respect to the way a telephone works), and (c) relationships that forge links across unrelated or marginally related field, (e.g., Olympic competitions and precise electronic controls). Each component within the portfolio can serve as a "jumping-off point" to whatever other dimension an exhibit developer wishes to explore. Care must be taken, however, to avoid a fetishism of invention (Barber, 1952), such that the product is taken for the process, overlooking the context in which the actual work occurred. As James Burke stated somewhat facetiously in The Day the Universe Changed, "Isn't science wonderful? . . . Scientists make gadgets, don't they?" (Burke, 1985). Scientists may make gadgets, but might do so, for reasons or, by using methodologies that others might find unfamiliar.

**Historical (and not so historical) Figures as Exemplars**

The use of historical figures as exemplars in expressing the HOS is closely related to the use of milestones or artifacts. The difference lies in a focus on the developer, not the artifact produced. An attempt should be made to re-contextualize the visitor into the atmosphere that the figure worked within, including motivations and influences on the individual, including more entrepreneurial influences. The approach goes further, suggesting possible consequences of the work, both positive and negative. For instance, the individual scientists that developed high-yield rice plants for the third world did not consider the cumulative effects and costs of increased pesticide use (the indigenous insects found the plants very tasty). The result was that after years of encouraging local farmers to use the new plants, rice yields actually decreased, causing famine and disease.

One view that must be combated is the separation of the individual from his or her culture. The view of science in the early 20th century was that a pure science exists free of social factors (Barber, 1952). The list of scientists motives covers the whole range of human desires and aspirations (Lilley, 1948-49, p. 385). The notion at issue is not whether the mind guides action, but whether the mind determines the selection of the list of culturally acceptable thoughts and actions (Harris, 1979, p.60). Scientists are not appreciably different from others within a culture; they reflect the mores of their culture. For example, many 18th Century authorities found Linneas work objectionable, as he classified plants based on their reproductive parts, using anthropomorphic analogies (Schiebinger, 1996).

Another consideration is the level or stature at which the figure is presented (Brush, 1974). Is the figure to be presented as a high exemplar, well above the norm and thus at an unattainable level, or more a more humble, "just like me"? Each viewpoint has the potential for alienating a certain portion of the audience, either by scaring them away, or by diminishing the figure to the merely ordinary. A careful balance between them must therefore be maintained.

**Cultural**

History of science may be approached through the cultural dimension, which offers an ethnic or cultural perspective about a sequence of events or development of objects. This approach can take on one of two forms. The first of these is an ethnocentric approach, from which one ethnic group developed or used some technological innovation at the expense of another ethnic group, or systematically suppressed another culture’s innovations. While ethnocentric viewpoints might be seen as perhaps destructive in general, they do have the advantage of the “outsider’s” point of view, a viewpoint which many visitors might identify with.

A second aspect of the cultural approach is the suggestion that ancient cultures had developed knowledge and understandings of some basic scientific principles that equal or rival those of today, based largely on the interpretation of myth and metaphor in ancient texts. Such knowledge was subsequently lost or perhaps suppressed. This approach can be seen as largely conjectural, depending on an exhibit developers definitions of culture and interpretations of myth. Barber (1952) suggests that it is an error to assume that science and empirical rationality are modern, western developments. The biases of dominant societies, toward earlier or other societies, have overlooked the nature of the innovations because, perhaps, they were the development of other peoples or marginalized populations.

**Interpretive Entity**

Another way to incorporate the HOS in exhibits is to show it as an interpretive entity. What is done for exhibit development in this approach is to examine well known and understood phenomena, especially the HOS that are constant across time and are evocative, such as meteorologic events. The task is then to document the transition from a myth-based to a science-based description of that phenomenon. The myth-based views
assumes that there is some meaning, perhaps divine, within an event. The science-based view assumes that the event is an impersonal expression of physical laws. Such assumptions are not confined to the ancient or distant past, such as the myth-based explanations of the AIDS epidemic as divine punishment for particular lifestyles.

The distinction between the myth-based and the science-based interpretations lies in the desired outcome of inquiry: do we wish to understand the will of the gods or a comprehension of events causing the phenomenon? The answer to this question becomes the difference between “why?” and “how?” The difference is embedded in the social context of what audiences consider an acceptable line of questioning. What is to say that a myth-based line of inquiry is any less valid to the culture it is embedded in? As Goldstein and Goldstein (1978) emphasize in their example of the behaviors of witch doctors, “how?” is often an inappropriate question, not because it is wrong, but because it is seen as irrelevant. What passes for “normal science” (Kuhn, 1962) is deeply ingrained into the culture of the audience. If, then, the goal of an exhibit is to increase the appreciation of and motivation for scientific inquiry, the exhibit developer must consider both the “myths” and the “science” of the target audience of an exhibit. Only then can the exhibit act as a gateway to self-motivated inquiry.

Linear Sequencing

The HOS in an exhibit can also be developed as a more traditional linear sequence of history. Given a broad scientific concept, such as light or sound, the exhibit would trace the development of our understanding along or at specific time referents or periods, such as: (1) the Greek legacy, (2) the Middle Ages, (3) the Scientific Revolution, (4) the Enlightenment, (5) the 19th Century, and (6) the 20th Century. Specific innovations or discoveries within these time periods could be demonstrated. Individuals and their work can be highlighted in each period, emphasizing the research tradition of the time period with respect to the broad concept. For instance, improvements in instrument making in the 16th and 17th centuries allowed for more accurate and precise measurements of phenomena. These improvements in instrumentation arose from the needs of the scientific research itself (Barber, 1952). Thus the context of discovery becomes especially relevant in the exhibit design.

This approach has the disadvantage of being chronological and temporally dependent. It also has the distinct disadvantage of presenting only one culture’s developmental periods. The entire exhibit would have to be restructured for each culture’s history. To overlay cultural periods on a single time would have the potential to overload the visitor, who would then “vote with his [or her] feet” (Fayard, 1991) and walk away from an exhibit so crammed with information.

Caveats

All too often, it is easy to overlook some of the darker or less palatable aspects of history for fear of alienating an audience. A constructive postmodern approach to the HOS calls for the inclusion of as many of the aspects that surround a particular event or innovation as is possible. These aspects include both positive and negative effects. One of the legacies of the modern age with respect to science has been an air of optimism regarding technological advance (Barber, 1952). From the development of antibiotics to putting a person on the Moon, the general public has been of the opinion that science and technology can solve or surmount any problem, from the life-threatening to the purely mundane. Exhibits in museums have tended to reinforce and promote this point of view. In a practical sense, however, if a goal of science education is to promote scientific literacy for all (AAAS, 1989; NRC, 1996), then it is important for an exhibit developer to include as much information as possible for the audience to make informed decisions on scientific issues. Outlined below are three approaches to representing the rest of the story.

Scientists’ Behavior and Science Education

An important caveat in the presentation of the HOS is the contention that how scientists actually behave may not establish a good model for students to follow (Brush, 1974). If the intention of including the HOS in an exhibit is to educate the public in how scientists work and thus provide a methodological framework, we do science a great injustice by diminishing its true nature to one standardized approach. Science and history have the potential to ‘do violence’ to each other by the inclusion or exclusion of particular temporal and social contexts (Brush, 1974). As a result, science education produces ‘anecdotes’ that are only marginally “history”.

Whiggism

From an educational viewpoint, any exhibit including the HOS must contain information on cultures within the dominant culture (SciTrek, 1993). The rationale for this inclusion is to prevent the promotion of a whig version of the HOS (Brush, 1974). A whig
presentation of the HOS has the exhibit developer judging the accomplishment of scientists of the past by today's standards, removing the context that such scientists worked within. For example, it is tempting and quite easy to brand pre-Copernican astronomers as being ignorant of how astronomical motion took place, when in fact these same astronomers used the best available information, as they understood it, to arrive at their models. The whig view presents scientific forbears as persons to be pitied or looked down upon because they just weren't as good as us. Bowler (1989) goes on to describe whig history as, an invented past, since factual discoveries [are] interpreted within the conceptual scheme that satisfied cultural demands of the age (pg. 3). Progress can be slowed by villains but never halted, as purposeful development is inevitable (Harris, 1979).

Technological Revenge Effects

With the dawn of the postmodern age, the darker side of the advance of science has been exposed. With Rachel Carson's *Silent Spring* (1962), the down side of technology, through the use of pesticides, was made all too apparent. Recently, a bleaker picture of our future has been portrayed by Laurie Garrett in *The Coming Plague* (1994). Humanity's expansion into new environments, the increased mobility of humans, and the widespread use (and misuse) of antibiotics and medical equipment has promoted the emergence and diffusion of new and deadlier diseases. Extreme elements of the lay population seem all too willing to assign responsibility for such problems to scientists.

Tenner (1996) has summarized these down-sides as revenge effects, such that the application of science and technology to problems has unintended consequences. According to the revenge viewpoint, technological advances have had the effect of: (1) increasing unpredictability in life, and (2) demanding more, not less, vigilance on the part of the users of the advances. For example, widespread prophylactic use of antibiotics has had the effect of selecting for superbugs, or multiple drug resistant (MDR) microbes (Garrett, 1994). The overall reduction in acute health care problems, many of them previously fatal, has increased the cost of health care by allowing people to live to an age where chronic health problems, such as cancer and heart disease, are much more common (Tenner, 1996). The revenge effect need not, however, remain a constant. The modern approach to problems was one of brute-force. Overcoming or preventing revenge effects in a postmodern world requires greater finesse, attacking problems from the side (Fayard, 1991) or turning potential problems to our advantage. In short, to carry on and survive, we must substitute brains for stuff (Tenner, 1996, p.275). For the dark side of science and technology to be constructive and informative, therefore, it must be represented in exhibits by solutions and their quest, not in terms of problems and their effects.

Conclusions

Science, regardless of the culture in which it progresses, is a cultural and historical universal, in the absence of a more acceptable means of knowing (science for all). To urge, however, that the viewpoint of scientific observers is one among an infinity of equally valid viewpoints surrenders our intellects to total relativism (Harris, 1979, p.45). Cultural relativism (science of all) does harm by offering an ideology which promotes fanatics that seek to tear down destroy rather than build up.

Including the HOS in a display requires a representation of the needs and expectations of the audience. Each approach to the inclusion of the HOS outlined above has the potential to reach a segment of the potential audience, but each segment must come to expect that its needs would be met. As compared with the scope of history and science within a formal educational setting, informal and nonformal approaches have the potential to reach a much broader audience and retain that interest. So if we wish for individuals to know where *You Are Here* is in history, they should do so in awe of and not in fear of the totality of history.

Editor's Comment:
As you read this wonderfully creative approach to the introduction of the Periodic Table, please feel free to change specific items to make the activity fit your student's culture. Also remember that ICASE copyright policy allows our members to reprint this and other articles in local journals.—Ronald J. Bonnstetter, Editor

You're a young element out on your own and need a place to live. You've heard that Mendeleev Tower on Periodic Plaza is a really great place to be—plush accommodations, hot and cold running electrons, sauna, workout area, the whole nine yards—but there's one catch. The management is very selective about the elements they rent to; some would say they're extremely picky. "We here at Mendeleev Towers are very concerned about relationships among our renters. You have to be in sync with your neighbors, you know, no personality clashes, no squabbles, just perfect harmony. Here is your renter's application. Before you are selected, we must have a complete personality profile before we can place you in just the right room. Yes, we select it for you because we know just the kind of elements that fits in. Oh do include your family pedigree; we have to know what kind of element you are. We cater to a very select clientele, you understand." The manager hands you a lengthy list of questions with a family personality profile request that would choke a moose. You roll your eyes at the prospect [the manager rolls them right back].

This task is overwhelming! So you gather a few of your closest associates and prepare to tackle the monumental catalogue of questions. You consider dividing them up between you in order to meet the manager's deadline (hint, hint).

(The following refers to the application form on page 33.)

Name: (well, that seems simple enough, but this "Meaning or Origin of Name" is really odd)

Chemical Symbol: (identifying mark for your doorbell; must be short, one or two letters)

Electron Configuration:

Valence Electrons: (isn't that getting rather personal?)

Temperament: (the manger's cryptic explanation was something about how hot you can get before you get boiling mad) and the second explanation was concerned with you when you are just a puddle of emotions—something about melting:

Rationality:—"How dense do they think I am? Of course I'm a rational element!!"

Country music preference: (what? you say—"well, the last place I lived, the guy upstairs always doing this hideous stuff he called music, but I swear it sounded like a cat fight") [At this point, your friend accused you of being extremely electronegative, only liking polka and accordion music. Those with + electronegativity are true connoisseurs of country, whereas those who have a negative value can't tell if the singer was Garth Brooks or Mel Brooks (and they don't care either!!!!)]

Now for the really personal stuff.

Waist size: (you scoff: "Is that before or after lunch??") Your other friend pointed out that they need to know your radius, both covalent and ionic, to make sure you fit through the custom-designed doors)

Mass: ("We have found that by arranging our clientele by increasing atomic mass has resulted in the most structurally sound environment")

Occupation: (what is it that you do to be a useful member of elemental society? What can you make of yourself?)
Hobbies:  (what do you do during those creative moments when you aren’t at work; be inventive!)

Date of discovery:  (well, I’m still waiting for my star on the sidewalk, but … I first showed my face on … )

Where discovered/Place of origin:  (not under a cabbage leaf! not at Graumann’s either!)

Discovered by:  (Oh, yeah! the doctor that assisted at your delivery.)

Family habits (Personality traits/chemical properties):

What kind of question is that? Who wants to know about Auntie Cesium, anyway? Just because she doesn’t do well with water … oh, I suppose that’s to determine who gets to use the hot tub … but I don’t have any idea why they have to know about grumpy old great uncle Boron—his stories put you to sleep. And then there’s those snobby Noble gases … Ow! [Your friend slapped you siller.] “They want to know if your family has any embarrassing habits like trading electrons with just anyone or if someone has been a real tightwad, keeping all their electrons for themselves and not sharing. That sort of thing.”] Oh. How am I going to find that out? Interview all my relatives? [you ask yourself, wishing you’d written down the life stories of all your relatives at the last holiday feast when Uncle Boron rattled on and on and on and on]

You suspect that this might be a involved section and would be very important to the manager. Since you don’t know your relatives very well, living so far away from them and all, that you split up the skeleton seeking among your associates, so they can help in the detective work. [another big hint]

Relations with neighbors:
(By this time you are wondering if this is more trouble then it’s worth. “Why can’t we all get along? Sharing electrons between elements is the only way to go,” you utter under your breath, but realize that not all elements share your feelings. “Yup. Some of them are just looking for a good fight and are only in it for the electrons they can grab.”)

Color Preference: (“Studies show that our elements prefer to live in rooms decorated to match their own true colors”)

**Neighborhood Preference:** After all your research, you have decided on the section of the Tower you’d most like to live. Where is it? Who are your intended neighbors?

You decide that you are going to need some kind of edge if you are going to get a spot in the Tower, so you send a couple of your associates to check out the neighbors. What kind of elements are these anyway? What kind of skeletons are in their closets? Do any of them have any unseemly family habits? And what about the guy upstairs?

***************

**Back to the Real World—translation and directions**

In your group, you will have the opportunity to investigate the family background of an element, and submit a completed application with answers to all the questions above. The “manager” will provide some background reference information on you and your “relatives.” Many of the questions can be answered with information in your textbook. Encyclopedias and other library material may also be found useful. Or if you choose, you could check out one or more of the **Various Periodic Tables on the Internet**:

In a minimum of three paragraphs, describe why you desire to relocate in Mendelev Towers and where you think you would best fit. Please include a description of the outlook you would bring to our unit, as well as how your presence here will benefit all of the current clients. Feel free to add anything you find unique about yourself that would be interesting to us, especially any recent newsworthy items. We are especially proud of our clients with celebrity status!
Book Review

SCIENCE, MATHEMATICS AND TECHNOLOGY EDUCATION & NATIONAL DEVELOPMENT CONFERENCE
HANOI, VIETNAM. 1997

Darrell Fisher and Tony Rickards
Editors

This unique conference provided an intellectually challenging and culturally enriching experience for science and mathematics teachers, teacher educators, researchers and administrators at the primary, secondary and higher education levels from around the world. Over 100 participants from 14 different countries had an opportunity to interact and exchange innovative ideas, research findings and practical implications in the traditional fields of science, mathematics and technology as well as new areas of international significance related to the conference theme.

The book contains over 50 papers that were presented at the conference on recent research and practical implications in science, mathematics and technology education covering the following areas:

Research Methods  Curriculum
Teaching  Learning Environments
Equity  Assessment and Evaluation
Teacher Education  Education Technology
Learning  History & Philosophy of Science

The book would be useful for mathematics, science and technology researchers, teachers and postgraduate students.

For details on how to order copies of the book please contact:

Tony Rickards
Doctoral Student & Research Assistant

Opportunity for USA-China Links Program

With the rapid changes in China’s economy, Chinese educators face extraordinary challenges as they work to educate 1.4 billion people. The Beijing Institute of Education has asked us to connect more than 100 elementary and secondary schools with schools in the U.S. through our U.S.A.-China Links program. We are seeking schools to become partners with Chinese schools.

We encourage you to share this information with colleagues and students in your area and throughout your network. For more information visit our website at http://www.goodnet.com/~global or contact us directly by phone at 602/943-3922, FAX: 602/943-4458 or e-mail: global@goodnet.com.

Thank you

President, Global Interactions
TEACHING ETHICAL ASPECTS OF SCIENCE

Patrick Fullick and Mary Ratcliffe
Editors

Increasingly, as our knowledge of science advances, it raises questions about both the ethics of scientific investigation and its uses. The importance of the relationship between science and ethics has been known for centuries, but the discoveries and technologies of the late twentieth century require decisions in increasingly complex areas such as genetic screening, human reproduction and global warming.

For those involved in science education this has led to a demand for practical advice on teaching the ethical aspects of science. A new book edited by Patrick Fullick and Mary Ratcliffe of the University’s School of Education aims to address this need and to encourage an awareness of the ethical dimensions in both the conduct and use of science.

Entitled Teaching Ethical Aspects of Science, the book is an outcome of the School of Education’s Science, Ethics and Education Project, which was established to produce practical advice for teachers. The project, which has funding from the International Council of Scientific Unions, has brought together the expertise of curriculum developers from around the world.

The authors emphasise the distinction between providing and analysing evidence (that is when science operates) and acting on that evidence (when ethics operates). The role of ethical analysis in dealing with science-based personal and social issues is also highlighted.

In his preface to the book, project director Professor Kelly writes:

Scientific discoveries have led to technological applications which have immense social and personal implications. Global change, human genome research, reproductive technologies and nuclear technologies are examples of such current topics of concern. They beg questions both of social policy and personal attitudes and behaviour.

The answers lie in science—to determine what we can do. Technology, economics and socio-cultural issues will also need to be considered; but, as crucial, is a consideration of ethics—to aid us in determining what we ought to do.

As well as containing curriculum materials that can be used to illustrate and develop themes concerned with ethical aspects of science, the book aims to stimulate awareness of ethical analysis as a rigorous mode of thought and to prevent discussion of moral aspects of science-based issues being merely a diffuse gathering of opinions.

The material will prove useful to science educators around the world in examining this important aspect of the conduct and use of science.

PROFESSIONAL DEVELOPMENT INSTITUTES FOR 1998

Science and Mathematics Education Centre (SMEC), and the National Key Centre for Teaching and Research in School Science and Mathematics, Curtin University, Perth, Western Australia announces its Professional Development Institutes for 1998

During 1998, the National Key Centre for School Science and Mathematics will offer TEN more of its highly successful professional development institutes for science, mathematics and technology educators.

Six institutes will be held in Australia and four will be held in overseas locations. Details of institutes are available at http://www.curtin.edu.au/curtin/dept/smeg/institut.htm

Brief details are listed below:

1. Learning Environments in Science, Mathematics and Technology Education
   Associate Professor Darrell Fisher, Curtin University of Technology

2. Special Topic: Writing a Thesis Proposal
   Associate Professor Darrell Fisher, Curtin University of Technology

3. Constructivist Approaches to Teaching and Learning
   Dr. Peter Taylor, Curtin University of Technology
   24-28 February 1998, National Kaohsiung Normal University, Kaohsiung, Taiwan

   The Key Centre is collaborating with the National Kaohsiung Normal University in the provision of this institute.

4. Classroom Climate in Science, Mathematics and Technology Education
   Professor Barry Fraser, Associate Professor Darrell Fisher, Curtin University of Technology
   22-26 June 1998, Universiti Brunei Darussalam

   Jointly sponsored by the Sultan Hassanal Bolkiah Institute of Education, Universiti Brunei Darussalam, this institute will be held in conjunction with a conference on science, mathematics and technology education at Universiti Brunei Darussalam during 29 June-2 July.

5. Teaching Science for Understanding
   Professor Sandra Abell, Purdue University, USA
   13-17 July 1998, Curtin University of Technology, Perth, Western Australia

6. Action Research for Science, Mathematics and Technology Teachers
   Dr. John Wallace, Dr. Peter Taylor, Curtin University of Technology
   13-17 July 1998, University of the Northern Territory, Darwin, Northern Territory

   The Key Centre is collaborating with the University of the Northern Territory in providing this institute.

7. Assessment and Evaluation in Science, Mathematics and Technology Education
   Professor Leonie Rennie, Professor Barry Fraser, Curtin University of Technology
   27-31 July 1998, Wright-Patterson Air Force Base, Dayton, Ohio, USA

   The Key Centre is collaborating with Miami University, Ohio, USA, in providing this institute.

8. Leadership and Professional Development in Science, Mathematics and Technology Education
   Dr. John Wallace, Curtin University of Technology
   14-18 September 1998, Department of Education, Community and Cultural Development, Hobart, Tasmania

9. Constructivist Approaches to Teaching and Learning
   Dr. Peter Taylor, Curtin University of Technology
   14-18 September 1998, Curtin University of Technology, Perth, Western Australia

10. Improving Teaching and Learning in Science, Mathematics and Technology
    Professor David Treagust, Curtin University of Technology
    Professor Reinders Duit, University of Kiel, Germany

    The Key Centre is collaborating with the Auckland College of Education in providing this institute.

    Dr. Bruce Waldrip
    University Planning, Institutional Research & Science, and Mathematics Education Centre & Faculty of Education
    Curtin University of Technology
    GPO Box U1987
    Perth 6845 Western Australia

    Phone: (08) 9266 2168 or 9266 7643
    Fax: (08) 9266 2547 or 9266 2503
    Email: b.waldrip@educ.curtin.edu.au
FIFTH INTERNATIONAL HPSST CONFERENCE
Pavia University
September 15-19, 1999

The International History, Philosophy and Science Teaching Group is holding its Fifth International Conference at Pavia University, northern Italy, September 15-19 (Wednesday -Sunday), 1999.

The 1999 conference is being held in conjunction with the European Physical Society’s Interdivisional Group on History of Physics and Physics Teaching. This group has been meeting biennially since its first conference at Pavia University in 1983. The joint conference will contribute to local celebrations of the bicentenary of Alessandro Volta’s creation of the battery at Pavia University in 1799.

The conference will follow, and overlap with, the 4th European Physical Society’s Conference on History of Modern Physics. A joint session of the two conferences will be held on the Wednesday.

Part of the conference will be held at the Centro di Cultura Scientifica ‘A. Volta’ on the shores of Lake Como, and underneath the Italian Alps. The non-profit Centro is devoted, in part, to educational and interdisciplinary aspects of science.

CONFERENCE PAPERS

The International Group is concerned to promote the improvement of school and university science teaching by making them informed by the history, philosophy, and sociology of science and of education. It has a particular interest in bringing these spheres of knowledge into teacher education programmes, and in applying considerations from the history and philosophy of science to theoretical and pedagogical issues in science education, including science education research.

Scope. Papers dealing with theoretical or pedagogical issues in science teaching. Thus historical and philosophical papers are welcome provided effort is made to bring out the educational dimension or implications of the research.

Publications & Deadlines. The conference organisers hope to continue the practice of earlier conferences and provide Conference Proceedings to all attending the conference. It is also anticipated that some scholarly journals will run special issues devoted to papers being given at the conference.

Because of production schedules, papers to be considered for journal publication (after standard review processes) need to be submitted to the organisers by May 1st, 1998. Papers for conference presentation and for inclusion in the Proceedings, need to be submitted in their final form by May 1st 1999.

The Preliminary Notification should be completed as soon as possible, and prior to submitting a paper. Papers will be reviewed as they are received, thus the earlier they are submitted, the earlier acceptance decisions can be communicated.

Submission. Papers should not exceed 5,000 words in length. Four copies, along with a disk version (Mac or Apple), need to be submitted by the above deadlines (May 1, 1998 for preconference journals; May 1, 1999 for conference presentation and inclusion in Proceedings). An ‘About the Author’ statement should also be included, taking the form of: Present Position, Education, Major Publications and/or Research Interests and/or Teaching Responsibilities.

Format and Style. Papers are to follow the format and style used in the Group’s journal Science & Education. Pay particular attention to title (bold), author (capitals), address (italics), Abstract (70-100 words), headings (capitals, not underlined and not in bold), and bibliographic conventions. Detailed guidelines, along with Permission to Publish forms, will be sent on receipt of attached Preliminary Notification. Papers must comply exactly with style guidelines in order to be considered for publication in either journals or Proceedings.

Conference Organisation. The chairperson of the local organising committee is Professor Fabio Bevilacqua of the Physics Department, ‘A. Volta’, at Pavia University. He and colleagues have been working since 1983 on ways of informing science teaching through use of the history and philosophy of science. They have created the multimedia Pavia Project Physics course which embodies history of science, and is framed on philosophical ideas about theory development and testing in science, and on considerations of how children learn science. An International Advisory Committee will assist with conference planning and programme content. School teachers and graduate students are especially encouraged to attend and contribute to the conference.

Please return as soon as possible to:

Science Education International, Vol. 8, No. 4 December 1997 37
May 2-10, 1998
National Science Week 1998
U.S.A.

The theme for schools will be: Oceans

July 5-10, 1998
CONASTA 47
Northern Territory University, Darwin

Science Education—Beyond the Horizon
The 1998 conference will be hosted by the Science Teachers Association of the Northern Territory (STANT Inc.). The conference is designed to provide a forum where all science educators; whether in primary, secondary, senior secondary or teacher education, have an opportunity to reflect and examine the important issues confronting education today and in the future. Issues of a geographical, cultural, political and a technological nature centering on student learning will feature throughout the conference program. The sub-themes will give all interested in science education the opportunity to reflect on their practices and gain insight into what is waiting for us “beyond the horizon.”

It is planned that prominent Australian and international educators, as well as experienced and enthusiastic classroom teachers will provide a stimulating environment where keynote addresses, seminars, workshops, discussion groups, forums and excursions allow professional enlightenment.

Further details are available from the conference website at: http://www.topend.com.au/~stant/conasta.htm or write to:

March, 1998
Science & Society: Technological Turn
An International Conference on STS
Japan

Topics to be discussed include the following:
• Network assessment of science
• Transnationalization of Corporate Science
• Technology and Media
• International Relation in the Post-Nuclear Age
• Science and Technology in Asia
• Implication of STS on Science Education, Science Education Policy and Human Resource

Among the invited speakers are: Michel Callon, Sheila Jasoff, Deepak Kumar, Morris Low, Brian Martin, Arie Rip, Rustum Roy, Song Sang-Youg, Peter Weinart, and Robert Yager.

January 8-10, 1998
Enhancing the Teaching of Science
The Association for Science Education (ASE) Annual Meeting
The University of Liverpool, U.K.

• 280 Talks and Workshops
• 300 Exhibitors
• 40 Science Lectures
• 10 Social Events
• 20 Visits
• 90 Courses

June 3-5, 1998
THE UtreCHT/ICase SYMPOSIUM
Utrecht University, the Netherlands

The Utrecht/ICASE international symposium on science education will be held at Utrecht University as a follow-up to our very successful symposia at Dortmund University. Like the Dortmund Symposia, the Utrecht symposium will be organized in cooperation with the International Council of Associations for Science Education (ICASE).
The key theme of the conference will be:
**Bridging the gap between theory and practice: What research says to the science teacher**

For more information, please contact:
Dr. Onno de Jong, Chairman
Utrecht University
Department of Chemical Education
Princetonplein 5 3584 CC Utrecht
The Netherlands
Fax: +31302537494
E-mail: O.deJong@chem.ruu.nl

**July 25-28, 1998**
**Making Curricular Connections in the K-8 Classroom Summer Institute jointly sponsored by the National Science Teachers Association and National Council for the Social Studies**
Northern Arizona University
Flagstaff, Arizona

Join teacher leaders in this unique participatory institute on curricular integration featuring science and social studies. Working sessions based on presentations by nationally-known experts will provide opportunities for dialogue and application. Topics for exploration include: multiple intelligences, standards-based practices, service learning, performance-based assessment, thematic instruction, project-based learning, planning and managing integration, issues oriented learning, and literature connection.

**February 26-28, 1998**
**International Consortium for Research in Science and Mathematics Education (ICRSME)**
**7th Consultation**
St. Clair, Trinidad

The International Consortium for Research in Science and Mathematics Education (ICRSME) is holding the 7th International Consultation from February 26 - February 28, 1998 in St. Clair, Trinidad. St. Clair is in the Port of Spain metropolitan area. The meeting will be co-hosted by the science and mathematics education community of Trinidad & Tobago and The Ohio State University represented by Donna Berlin and Arthur White in Columbus, Ohio. The program will provide opportunities to share favorite ideas and programs, make new friends and renew old friendships, get some much needed vacation time, pick up some new ideas and refine some collaborative research and development projects.

**March 23-26, 1998**
**International Conference for Environmental Educators**
Pretoria, South Africa

Vista University and the University of South Africa (UNISA) would like to extend an invitation to educators to attend this international conference for environmental educators. The conference seeks to discuss the holistic role of environmental educators at universities, colleges of education, non-governmental organisations as well as those in business and industry.

**Theme**
There has been a growing realisation that environmental problems cannot be solved without keeping social, economic and political aspects in mind. The contrast between the so-called western and pre-modern worlds, often referred to as the first and third worlds, was highlighted during the Earth Summit in Rio. It is essential that these “worlds” work together to address environmental problems. Environmental educators at post-school level need to adjust their education programmes to address EE in both worlds and so work towards a global solution. The conference aims to discuss the role of these educators and to seek answers to questions such as: Are there different approaches to EE in western and pre-modern worlds? How could strategies be co-ordinated to both?

Science Education International is the quarterly journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

Compiled by Jack Holbrook (Secretary), Brenton Honeyman (Past President) and Robin Groves (Editor, SEI)

The Seventh ICASE General Assembly was held in Liverpool, UK on 6/7 January 1998. This was the first full meeting of ICASE since 1993, and this edition of Science Education International contains several items and reports from that meeting.

New Constitution for ICASE

Members at the ICASE General Assembly in Liverpool voted to accept a new ICASE Constitution. This was the culmination of a two year period of review of ICASE operations, involving consultations with all executive officers and member associations. The General Assembly expressed its appreciation for the careful process of consultation between the Executive Committee and member organisations. The Executive Committee would like to thank member organisations for their support and, in particular, the executive team members who developed the new constitution – John Anderton, Dennis Chisman, Anna Garner, Jack Holbrook and Brenton Honeyman.

The new constitution provides for an increased role by ICASE member organisations in the governance of ICASE, and more efficient management by and clearer accountability on the part of the members of the ICASE Executive. It provides for an executive structure ready to incorporate a permanent secretariat should this become financially viable. The new constitution has reduced the period between General Assemblies from four years to three years.

Copies of the new ICASE Constitution can be obtained from the ICASE website <http://sunsite.anu.edu.au/icase> or by requesting a printed copy from the ICASE Executive Secretary, PO Box 6138, Limassol, Cyprus.

New ICASE Executive Committee

The ICASE General Assembly in Liverpool elected a team of new and continuing officers to the Executive Committee for the next term of three years.

Management Committee

Ms Anna Garner (previously President-Elect) was instated as President (1998-2000). At the time of her election to the position of President-Elect in 1993, Anna was the President of the Icelandic

Anna Garner (ICASE President, Norway), Cheng Donghong (CAST, China) and Jack Holbrook (ICASE Secretary, Cyprus)
Science Teachers Association. Since then, Anna has played a key role in several science education projects and events across Europe, including the highly successful CEHC-ICASE Industry-Science Education Symposia. During her term as President-Elect, Anna completed an extensive revision and update on the ICASE Guidebook for Science Teachers Associations, contributed to the development of the new ICASE Constitution, spearheaded ICASE’s involvement in the 1999 Schools Links Project, and played a leading role in many other ICASE initiatives. She now resides in Norway, teaching at the Red Cross Nordic United World College in Flekke.

Mr Brenton Honeyman (previously President) became Past President (1998), a position that, under the new constitution, ceases one year after the General Assembly. Brenton lives in Canberra, Australia and is the International Programs Manager at Questacon, Australia’s National Science and Technology Centre.

Ms JoAnne Vasquez was elected as the new President-Elect (1999-2000). Under the new constitution, this appointment commences one year after the General Assembly. JoAnne Vasquez works at the Science Resource Center, Mesa Public Schools, Arizona, USA and is the Retiring President of NSTA.

Dr Jack Holbrook was elected to the position as Secretary (1998-2000). Jack, previously a Vice President and Executive Secretary of ICASE, will continue to provide the secretariat services under the terms of the new constitution. The office of the Secretary is in Cyprus.

Mr Patrick Whittle was elected as Treasurer (1998-2000). Patrick, an experienced international education consultant based in the UK, brings to the ICASE team an extensive background in working with science teacher associations in developing countries in Africa and Asia.

Executive Committee
The Executive Committee comprises members of the Management Committee and the following regional representatives elected at the General Assembly:

African Representative: Chief Bassey Albert Nyong, Nigeria
Asian Representative: Dr Janchai Yingprayoon, Thailand
Australasian Representative: Mr John Anderton, Australia
European Representative: Ms Miia Rannikmae, Estonia
Latin American-Caribbean Representative: Prof Marta Cristina Moyano, Argentina
North American Representative: Dr Joe Peters, USA

Bob Lepischak CASE, Canada, JoAnne Vasquez (NSTA, USA) and Brian Atwood (ASE, UK) following the election of ICASE Officers at the General Assembly.

The following standing committee chairpersons were appointed by the Executive Committee to serve on the Executive Committee:

ICASE Journal: Mr Robin Groves, Australia
Pre-Secondary Science: Dr Sue Dale Tunnicliffe, UK
Finance Development: Mr David Standley, UK
Publications and Communications: Joseph Depireux, Belgium
Project 2000+: Dr Jack Holbrook, Cyprus
Ad Hoc Committees

Several Ad Hoc Committee Chairpersons were appointed by the Executive Committee. These are non-Executive Committee positions:

Safety Project: Dr Kenneth Russell Roy, USA
Secretariat Project: Mr Dennis Chisman, UK
1999 International School Links Project: Ms Caroline McGrath, UK
International College of Science Education Project: Mr John Anderton, Australia
International Consultancy Network Project: Mr Brenton Honeyman, Australia

Contact addresses of Executive Committee officers are listed on the inside front cover of this journal. Contact details are also published on the ICASE website <http://sunsite.anu.edu.au/icase>.

New ICASE Journal Editor

The ICASE Executive is pleased to announce that the editorial team of Science Education International will be led by Mr Robin Groves, an Education Consultant based in Perth, Western Australia. Robin has had a long and distinguished involvement in administering science teacher association activities at local, national and international levels. He has considerable experience in science education publishing through his involvement as Feature Papers Editor of the Australian Science Teachers Journal and producer of several science education publications. He was appointed as the founding Executive Director of the Australian Science Teachers Association in 1991 at the time of establishing a fulltime national secretariat and held this position until 1997. Robin is now undertaking a range of education consultancies.

Thank you to Dr Ron Bonnstetter and to his editorial team who have most capably produced the ICASE Journal during the past four years. Their efforts have been significant, not only in terms of the amount of time they have freely given to this task, but also in terms of what Ron and his team have chronicled for the professional benefit of readers and the member organisations of ICASE. This quarterly journal continues to be a high profile vehicle for communicating science education thought and practice throughout the world and we are indebted to Ron Bonnstetter and his team for their outstanding contribution.

First meeting of the newly elected ICASE Executive Committee. January 1998
It is important to record the outstanding efforts of two leading ICASE Executive Committee members whose roles are changing in 1998.

Dennis Chisman

Dennis Chisman can be considered as the ‘father of ICASE’. Although the origins of ICASE can be traced back to a UNESCO regional workshop on integrated science teaching held in the Philippines in 1970, ICASE was formally established in 1973 at the University of Maryland, USA. At that time Dennis was appointed as the first Executive Secretary and Treasurer, a position he held through three ICASE General Assemblies until 1985. From 1985 until the Seventh ICASE General Assembly recently concluded in Liverpool, UK, Dennis continued on the ICASE Executive Committee as the appointed Honorary Treasurer. All in all Dennis has been an ICASE officer for 24 years, a feat unlikely ever to be matched in the future. Dennis has not cut his ties completely, however, as he continues to work for ICASE by chairing an ad-hoc committee to explore setting up an ICASE secretariat.

Dennis’s unparalleled experience and wisdom will be sorely missed by the ICASE Executive. He was directly involved in setting up all ICASE General Assemblies and in getting the series of hugely successful ICASE Asian Symposia off the ground with the very first, held in Delhi, India in December 1977. Dennis played a major role in planning and running two major international integrated science conferences in the 1970s, both sponsored by UNESCO. The first was held in Oxford, UK in 1975 and was concerned with the evaluation of integrated science education and the other, in Nijmegen, Netherlands on trends in integrated science.

Dennis’s involvement on the international science education scene continued through the 1980’s, not only for ICASE events, but also for other large international events in which he succeeded in involving ICASE. He was very much involved with the ICSU CTS conference in Bangalore, India held in 1985 on science education and future human needs, with editing New Trends in Integrated Science, Vol VI, a UNESCO publication arising from an integrated science seminar in Australia in 1988, and in being treasurer to chemical education conferences in York, UK in the 1990s.

Many ICASE member organisations exist in the developing world and maintaining communication with all member organisations was undoubtedly a major task. Dennis handled his very time-consuming task voluntarily and often initiated follow up matters at his own expense. There can be no doubt that ICASE is where it is today, in no small part thanks to the enormous dedication and hard work undertaken by Dennis.

Brenton Honeyman

Brenton Honeyman steps down as ICASE President after four years at the helm, when he took up the challenge of leading ICASE into new vigorous times. This followed a very successful four years as the ICASE Journal Editor where he pioneered Science Education International and set it up as a truly recognised international science education journal. The amended ICASE constitution, agreed upon at the last ICASE General Assembly, is a major example of how Brenton has guided Executive Members and member associations towards a new direction and set ICASE up as a more professional organisation with clear goals and involvements.

Under Brenton’s leadership ICASE has pioneered major links with Latin America and succeeded in helping member associations there to publish a first ICASE Journal in Spanish. ICASE has also become firmly associated with Project 2000+, as UNESCO struggles with its internal financial difficulties, and Brenton has taken this message around the world, none more so than in the STS conference organised by KEDI in Seoul, Korea in 1997 and the 2nd ICASE Latin America Symposium in Mar del Plata, also in 1997.

Brenton also helped to establish ICASE links with UNESCO at the primary education level and ran a very successful workshop in Kingston, Jamaica developing primary science education materials.
Extracts from the Executive Secretary's report at the 7th ICASE General Assembly

by Jack Holbrook

(a) ICASE Membership

At the General Assembly membership was stated as 148 member organisations.

From these figures you can see that ICASE continues to grow as countries in Eastern Europe start to form Associations and ICASE makes contact with organisations in Latin America.

The fastest growing category continues to be institution members (77% growth).

(b) Communication

With this great increase in membership, communication continues to be, as is to be expected, problematic.

An increasing aid to communication over the last four years has been email. Much correspondence between Executive Committee officers is in this manner and it is hoped this can be extended to ICASE member organisations as well.

(c) Conferences, symposia and workshops carrying the ICASE name, held since 1993

6. STL Teaching Material Workshop, in conjunction with UNESCO and PASE, Lahore, Pakistan, April 1997.
7. 10th ICASE Asian Symposium, Lahore, Pakistan, April 1997.
8. STL Teaching Material Workshop, in conjunction with UNESCO and Club de Ciencias lAlbert Einstein, Mar del Plata, Argentina, April 1997

d) World Activity Day/Week

Since the last General Assembly, an Activity Day was held in October 1993 and an Activity Week in October 1995. Both were geared to involve students in projects and were welcomed in some countries. Certificates were awarded to participating schools.

e) ICASE International Distinguished Awards

The 9th Award, mentioned in the last General Assembly report and awarded to Professor Sam Bajah in 1993, was presented in Nigeria at the 1994 annual meeting of STAN.

The 10th ICASE Award was given in 1994 and presented in 1995 to Dr Hans Jurgen Schmidt at the 1995 annual meeting of MNU. In 1996, the 11th Award was made to Professor Robert Yager and presented in Korea in 1997. No award was made in 1997.

f) ICASE Stepping into Science Project

This project for primary science continues to be promoted through the ICASE primary science newsletter. More details about the development of this project are reported in the minutes of the General Assembly sent to each ICASE member organisation.
(g) Publications since the 1993 General Assembly

It has become increasingly difficult for ICASE to continue publications to its members and the earlier series of commemorative issues and yearbooks has now ceased in favour of a quarterly newsletter and a primary science newsletter.

Regional ICASE newsletters were produced in Europe (three issues) and in Africa (one issue) and sent to ICASE member organisations in these regions to keep them abreast of news and developments.

The following publications, carrying the ICASE logo, have been produced since 1993.

ICASE Books

Reports of Workshops/Symposia

Documents Produced for UNESCO under Contract

(h) New Projects

By far the major initiative taken by ICASE to follow up Project 2000+ is an attempt to operationalise scientific and technological literacy for all (STL) in the classroom. With Project 2000+, ICASE has taken the lead and is now wishing to persuade STAs on the future direction for science teaching.

The Project has initiated concern for STL teaching materials. ICASE has run four STL workshops in the last two years, all with UNESCO and a local member association partner. These workshops have aimed to:
1. Promote an STL philosophy befitting the 21st century in which the purpose of teaching science subjects is clearly addressed.
2. Create STL teaching materials that can be used directly in the classroom.
3. Provide in-service training to the workshop participants on STL by means of the hands-on creative activity of writing materials.
4. Stimulate subsequent piloting of the materials in the classroom (worldwide if applicable).
5. Consider the dissemination of the materials and the initiation of other workshops promoting the STL criteria.

A major difference with STL materials is that in
science lessons, teaching science concepts is essential, but not enough. Making lessons interesting is important, but not enough. Promoting student-centred teaching is important, but not sufficient. Also needed in science lessons are the development of personal skills, social values and the scientific method. All of these constitute science teaching for the 21st century in striving for STL (scientific and technological literacy for all).

(i) ICASE - 25 years

Finally, it is worth mentioning that this year marks the 25th anniversary of ICASE. ICASE was founded in 1973 at a seminar in Maryland, USA. Most of the founding members associations continue to be members of ICASE.

Extracts from the Honorary Treasurer’s report by Dennis Chisman

Every year since ICASE was established has been difficult from the financial point of view. 1997 is no exception. Although the 1997 account shows a positive balance, there are still outstanding bills to be paid, including the cost of the General Assembly meeting in Liverpool and the printing of the December issue of the journal.

The incomes for subscription from all categories of members in 1997 amounted to about US$13,000, which is less than 1996 (US$15,500). Income from UNESCO contracts was $21,500 for 1997. About half of this was contracted for a Project 2000+ steering committee meeting in May. Most of the balance was for the development of a Resource Kit.

The reality is that the total income from members' subscriptions and journal subscribers is just enough to pay for the direct costs of printing and posting the journal and for the direct costs for the Executive Secretary and the Treasurer in the day-to-day running of ICASE. Without grants or contracts from UNESCO or elsewhere it would be impossible to meet even modest expenses of the officers and the Executive Committee for regional activities or for international meetings. There has not been a full meeting of the Executive Committee during the last four years because of financial constraints.

The real costs of running ICASE are much greater than those shown in the official statement of accounts, since many of the Executive Committee and the officers contribute directly or indirectly, personally or through their organisations and employers, considerable sums to support the work of ICASE. In addition ICASE has received generous support from member organisations such as the ASE (UK). For example the ASE printed and posted all four issues of the STEP newsletter in 1997.

Questacon – The National Science and Technology Centre in Australia has generously supported the President with office facilities and support.

The subscription rates for members in all categories and the subscription rates to the journal and the primary newsletter have not changed significantly in recent years. There is a case for raising the rates and the following are recommended for 1999 onwards:

Associate members: As for full members up to 1000 members; thereafter US$50 less.

Institution members: US$150

Company/Foundation members: No change

Journal subscription: US$25 Individual (UK£16)

US$50 Library (UK£32)

These rates were duly adopted by the Executive Committee at its meeting following the General Assembly.
An abridged version of the ICASE President's Report to the 7th ICASE General Assembly held in Liverpool, UK, 6 January 1998

By Brenton Honeyman, President of ICASE (1993-97)

Introduction

To all members of the Executive Committee and to all the individuals and organisations who have contributed to the work and development of ICASE and its activities during my four years of office, I wish to express my sincere thanks. As a voluntary organisation, ICASE continues to make a significant impact not because it has huge resources but because it involves dedicated people who are willing to contribute generously of their time, talents and skills.

The years 1993 to 1997 have been significant in the growth and development of ICASE. 1993 marked the twentieth year of ICASE, providing us with an opportunity not only to review and celebrate past achievements, but also to consider how best this worldwide organisation might move forward and build upon these accomplishments.

In establishing a Development Plan, the ICASE Executive Committee identified five major areas for development.

1. Profile and image of ICASE: to establish ICASE as an advocate for science education in the global community, working with its members to enhance the quality of science and technology education for all.

2. Policy development and operations: to develop policies and operational procedures to facilitate existing programs, and to more effectively address and respond more effectively to new challenges.

3. Financial base: To strengthen the financial base of ICASE so that the Council is able to fulfil its programs.

4. Enhancing support for ICASE members: to expand existing services, and to develop new services to meet the evolving needs of member associations, institutions, centres, foundations, companies and individuals with an interest in science education; to initiate research and development projects relating to anticipated future needs of ICASE members.

5. Human resources: to identify and involve science educators and others in assisting the Council to carry out its initiatives; to develop support links with other international non-governmental and governmental organisations.

This report covers some of the highlights made in relation to these areas of development.

Profile and image of ICASE

The International Forum on Scientific and Technological Literacy for All, held in Paris in July 1993, had just concluded as the last General Assembly met to consider the focus and direction of ICASE during its next term of office. As a key initiate of Project 2000+, ICASE pledged that it would continue to play a key role in stimulating and supporting follow-up action in this worldwide program. The goals of Project 2000+ were seen to closely reflect the rationale which had led to the formation of ICASE twenty years previously, and so ICASE was in a position of readiness to raise awareness about this global venture and to plan programs to provide much needed direction and interpretation on how member science teacher associations and science education institutions, and even individual teachers within their classrooms, might contribute to scientific and technological literacy (STL).

Accordingly, ICASE joined with its Project 2000+ partners (UNESCO, The World Bank, UNICEF, UNDP, UNEP, Commonwealth Secretariat, ICSU, IOSTE, GASAT and WOCATE) to work towards the challenge of realising STL for all children, youth and adults. Progress to date, however, has largely been due to the individual efforts rather than the combined efforts of Project 2000+ partners. A meeting of most Project 2000+ consortium members in May 1997 made some progress to revitalise a consortium approach, and agreed that a more regular forum for consortium members to plan and review initiatives would help to regain the momentum of Project 2000+.

ICASE has, through its enthusiastic commitment to this global project, gained the highest respect of the international community for its capacity to provide quality programs to support the curriculum reform efforts of many countries. One of the most exciting developments has been in the area of workshops that involve local educators and curriculum officers in the production of classroom resources based on the need to enhance scientific and technological literacy.

Following the success of a pilot workshop in Vanuatu to develop activities for trialling in local primary and secondary classrooms, ICASE has organised and led several workshops to familiarise teachers and curriculum developers with curriculum approaches.
congruent with STL goals.

Regional ICASE conferences and symposia in Asia, Latin America, Europe as well as ICASE contributions to international and regional meetings in Africa, Asia, Australasia, Europe, North America and Latin America have all played their part in strengthening the profile and activities of ICASE.

Policy development and operations

The Executive Committee has carried out a review of its structure and operations. A revised constitution has been developed by John Anderton and members of the Executive Committee, paving the way for an increased role by ICASE member organisations in the governance of ICASE, and more efficient management by and clearer accountability on the part of the members of the ICASE Executive.

One of the most pressing needs is to establish a permanent secretariat for ICASE. The Executive has been exploring options to establish a secretariat base with at least some of the costs met by another professional organisation, an industry body or an inter-governmental organisation.

In order to contain expenditure, only one meeting of the full Executive Committee was held – in Lancaster, January 1995 – between General Assemblies. A number of mini-executive meetings have been held in conjunction with various conferences to enable a few members of the Executive to focus on particular agenda items, thereby keeping the momentum flowing on major projects.

During this term, there has been a growth in the use of the internet by Executive Committee members to maintain contact, communicate updates on their projects and share ideas. The internet is becoming an important tool for keeping ICASE operations and projects on the move and provides our most affordable option yet to traverse the great distances around the globe.

Financial base

Funding to support ICASE operations comes from three major sources:

1. Membership and journal subscriptions: While celebrating a growth in membership, ICASE continues to have to find ways of coping with the challenge of providing services to members who, often for understandable reasons, are not able to arrange payments for subscriptions. The ICASE Journal, while continuing to be very much appreciated by library and individual subscribers, has not yet attracted sufficient subscriptions to be fully cost recoverable. Yet, the ICASE Journal has the potential to earn useful additional revenue to support other areas of ICASE activity.

2. Project funding grants from organisations such as UNESCO and the Commonwealth Secretariat: Whenever such project funds become available, ICASE officers work in a voluntary capacity so that ICASE can retain the administrative fee component of the funding grant. Such grants are critical to maintaining the operations and activities of ICASE. The levels of these grants are never sufficient to outsource expertise beyond ICASE officers at normal consultancy rates; hence the workload always falls to those ICASE officers or individuals who are willing to carry out such projects voluntarily. Grants from a number of local, national and international organisations contribute greatly to the success of ICASE Regional Symposia, often enabling a wider participation from across the region.

3. In-kind contributions from organisations and individuals: The Association for Science Education has kindly met the cost for printing and distributing the ICASE Primary Newsletter 'Stepping into Science'. Organisations such as the ASE and NSTA provide support for ICASE officers participating in their national meetings. Other organisations provide in-kind support in terms of office facilities and services to support the operations of ICASE officers.

One of the special aspects of ICASE, as a voluntary organisation, is that its officers and those who work within the organisation are strongly motivated to do whatever they can for the benefit of the organisation and its members, often giving generously of their time and even their own finances to ensure that ICASE continues to be as effective as possible.

This spirit is no better demonstrated than in the life of Sheila Haggis, who was acknowledged for her outstanding contributions through the award of the ICASE Distinguished Service Award. Sheila had been instrumental in the establishment of ICASE in 1973 and had been active in the establishment and support of so many science teacher associations throughout the world. Sadly, Sheila passed away in 1995 as a result of an illness she kept to herself. From her estate she bequeathed an amount of
£10,000 to ICASE. It is through such generous and selfless support that ICASE was founded and continues to flourish. The Executive is considering how best to use this gift from Sheila Haggis so as to perpetuate her memory.

Strengthening the financial base of ICASE is essential if we are to accomplish the ambitious agenda before us. There is much potential to build on emerging partnerships with business and industry, and to strengthen our links with UNESCO and other international bodies in order to facilitate the work of ICASE.

Enhancing support for ICASE members

ICASE continues to maintain member services such as the ICASE Journal. Ron Bonnstetter and his team deserve our special thanks for capably taking on the task of producing Science Education International, the quarterly journal of ICASE and a key publication in sharing science education ideas and perspectives from around the world. Similarly, Sue Dale Tunnicliffe, Norman Lowe and their team continue to make a valuable contribution to the support of primary science education through the production of STEPS International, the primary science newsletter of ICASE.

Sue Dale Tunnicliffe and a network of primary science educators continue to conduct workshops and share resources at conferences and gatherings of teachers of primary science, and to support the Stepping into Science Award Program for students. Through these programs, ICASE is making a strategic effort to support countries in their development and implementation of primary science.

Several new ICASE publications have been produced including Primary Science Activities Around the World: Sourcebook 1, Proceedings of the Eighth ICASE Asian Symposium, Proceedings of the 1994 Seminar on Problem Solving and Misconceptions in Chemistry and Physics, and the Proceedings of the 1996 Seminar on Research on Science Teaching and Learning. ICASE facilitated the production of the Science in Space teaching units by the ASE, and prepared manuscripts for the production of two UNESCO publications – a monograph on Scientific and Technological Literacy Within Formal Schooling, and a resource kit on Teaching Materials for Scientific and Technological Literacy. ICASE is

ICASE display stand at the 1998 ASE Annual Meeting, University of Liverpool, UK.
very appreciative of the substantial work that has been undertaken by its Executive Secretary, Jack Holbrook, in relation to these publications.

In 1996, ICASE established its own site on the World Wide Web. In addition to providing contact details for ICASE officers and member organisations, and information about ICASE and its programs, the website provides a place to publish resources for science educators. Web-based publishing provides a much less expensive alternative to print-based publishing, and it is likely that ICASE will use this medium more and more to provide access to publications and resources on-line. The website can be located at <http://sunsite.anu.edu.au/icase>.

Anna Garner, President-Elect, completed an entire revision of the ICASE Guidebook for Science Teacher Associations. This resource provides a most useful framework to assist in the formation of new science teacher associations or in the review and restructure of existing associations.

One of the pleasing developments already mentioned is the increasing activity of ICASE in leading workshops to develop curriculum materials consistent with the goals of Project 2000+. One of the key strategies in such workshops has been to involve practising teachers and, where possible, officers of the local science teachers association. This type of activity has served to enhance the skills of teachers and officers of science teachers associations and to encourage curriculum development agencies to involve practising teachers and local science teachers associations.

On the occasion of the 1997 ICASE Latin American Symposium held in Mar del Plata, Argentina, a Spanish Edition of the ICASE Journal was produced. A 1998 Spanish Edition is currently being prepared. This initiative is a particularly important one for ICASE to maintain and further develop. It recognises the necessity for an international organisation to operate beyond the English speaking context.

ICASE has been successful in extending its outreach directly to students through the 1995 ICASE World Activity Day coordinated by Bob Lepischak, Past President, and the regional representatives. ICASE has cooperated with the ASE in establishing the 1999 School Science Links Year in which schools in different countries link to work on common projects. Anna Garner, President-Elect, and the regional representatives have helped to set up this program.

**Human resources**

As already mentioned, ICASE continues to rely on the strength of its major resource – the willingness of individuals to commit their time and skills in order to further the work of ICASE.

ICASE continued to recognise special contributions to international science education through the ICASE Awards Program. The 1994 ICASE Distinguished Service Award was presented to Professor Dr Hans Jurgen Schmidt of the University of Dortmund, Germany during the German Science Teachers Association (MNU) annual meeting in Nuremberg in April 1995. The 1996 ICASE Distinguished Service Award was presented to Dr Robert E. Yager at the opening of the "Globalisation of Science Education" Conference, Seoul, Republic of Korea, May 1997.

In addition to past and present members of the ICASE Executive Committee and ICASE Award Winners, it has been especially encouraging to learn of a growing number of individuals, many of whom are very experienced in conducting international projects, who are expressing interest in contributing to the work of ICASE. I certainly hope that ICASE will be able to tap such offers of assistance and to coordinate projects in such a way so as to involve many more individuals outside of the Executive team.

One proposal, which the new Executive will be considering, is to establish an international consultancy group, comprising experienced science educators and researchers who could be involved in a range of educational consultancy projects (both small and large). It is proposed that the international consultancy group is registered with educational agencies around the world and that for its role in managing this group, ICASE receive administration fees.

I am particularly encouraged by the enthusiasm in Latin America to develop a strong ICASE program in that region following the very successful ICASE Latin American Symposium in Mar del Plata, Argentina. I am confident that this will be a major growth area for ICASE in the coming years and will bring additional talent to work towards ICASE goals.

**In conclusion**

As we look to 1998 and beyond, the challenges include:

- Developing mechanisms to provide more
direct, practical support to initiatives within ICASE regions, particularly the African region and the Pacific region

- Continuing to develop partnership programs with large associations, several of whom have very successful international programs within their own organisations

- Expanding ICASE services beyond the English speaking world into regions where French, Spanish and other languages are the major means of communication

- Continuing to provide a leadership and advocacy role for educational reform which seeks to develop scientific and technological literacy for all

- Finding ways to better mobilise the expertise and resources of ICASE members (including institutions of informal learning) in order to increase the effectiveness of ICASE programs

- Increasing the revenue base of ICASE and finding alternative, more cost-effective means to provide services for members

- Establishing a permanent secretariat for ICASE

My sincere thanks to those who have made space in their busy lives in order to support the work of ICASE. Both those within and outside the organisation acknowledge the herculean contributions that Jack Holbrook, Executive Secretary and Dennis Chisman, Honorary Treasurer have continued to make to ICASE during this term of office. Their work has been well supported and complemented by the other officers – Anna Garner as President-Elect, Bob Lepischak as Immediate Past President, Ron Bonnstetter as Journal Editor, Sue Dale Tunnicliffe as Primary Science and Technology Officer, John Penick as Special Projects Officer, Maris Silis as Policy and Development Officer and Claude Gadbois as French/Spanish Liaison Officer. The work of the regional representatives is worthy of special mention – these officers are the key people who provide an ICASE presence throughout the major regions of the world. My special thanks, therefore, to Isaiah Ikobi (Africa), Janchai Yingprayoon (Asia), Alicja Wojtyna-Jodko (Europe), Jose Chamizo (Latin America/Caribbean), Kenneth Roy (North America) and John Anderton (Australasia-Pacific). I know that there have been many others who have supported these officers – too numerous to acknowledge here. This team effort has made the last four years a most exciting period of development for ICASE and for me personally – thank you to each one.

While several officers have indicated that they are not standing for a position on the new Executive Committee, I would like to take this opportunity to mention one of these – Dennis Chisman. I single out Dennis because his involvement with ICASE spans a longer period of dedication and service than any other; in fact, Dennis Chisman has been a key figure in ICASE since its very inception. Many have aptly dubbed him as the ‘Father of ICASE’. It is a daunting prospect to consider an ICASE organisation without Dennis Chisman being involved. I am hopeful that, although Dennis will retire from the key roles he has held for 24 years with ICASE, he will find room in his very full life to support one or two projects and thereby continue to participate. On behalf of ICASE and its officers – past and present – I express our sincere appreciation and respect for the remarkable contributions that Dennis Chisman has made in building and shaping what today is a mature, diverse, active, effective and highly respected organisation.
SCHOOL LINKS INTERNATIONAL 1999
Celebration of School Science

Join hands across the world by sharing your science with a school from a different culture. Simply work on a similar theme and tell each other what you learn. Then join in our ‘Celebration of School Science’ by telling us about it. We'll help with contacts and ideas. So don’t be left out!

All participants will receive certificates. The best group will be part of an international ceremony.

This project is being organised by the Association for Science Education (ASE) in cooperation with ICASE and UNESCO. For further information about how you can become involved in this project, contact:

Obituary

ICASE is saddened to learn of the death of Dietrich Blandow. The worldwide profession involved with education about technology, taken in its broadest sense, has unexpectedly lost one of its pivotal international colleagues. On March 2, 1998, Professor Dietrich Blandow died peacefully in the presence of close colleagues in Erfurt, Germany. Dietrich Blandow will be remembered for his scholarship and many professional contributions as well as for his hallmark personal characteristics of energy, dedication, mentorship, friendship and caring. Most recently we remember Professor Blandow’s outstanding and influential international presence championing technology education. The ideas in his many publications, including edited books and a multitude of articles and presentations represent an ongoing contribution to technology that we can build on for years to come. Strategic vision, systematic analysis and creative configuration of innovative solutions are hallmarks that cut across most of Dietrich Blandow’s major achievements. It may be that this is best exemplified by his founding of the World Council of Associations for Technology Education (WOCATE), in consort with colleagues from Australia, the USA, and Greece, and his subsequent nurturing of it to NGO status with UNESCO.
The primary school curriculum: policies of environmental education in Bangladesh

Quazi Afroz Jahan Ara
Assistant Professor, Institute of Education and Research
University of Dhaka, Dhaka-1000, Bangladesh

Curriculum development is a continuous process in any education system. So in a young country like Bangladesh, where education was neglected in the past, efforts have been made following its independence from Pakistan to alter the curriculum and syllabuses. These changes have been and are being made to have them harmonise with national goals and aspirations as well as changing needs and education. In the past, though some aspects of environmental education have been accommodated within the formal curriculum, there was little or no attention given to conservation skills. Neither was concern accorded to environmental awareness or to an appreciation of the total environment. Thus the acquisition of knowledge, skills and attitudes able to conserve and enhance the quality of the environment were neglected. The overall position was accordingly seen as unsatisfactory and an opportunity to develop a spirit of enquiry regarding appropriate forms of environmental education was sought.

Though the term environmental education was introduced during the mid 1960s, the ideas of environmental education matured internationally only after the Tbilisi Conference in 1977 (SEEC 1990).

The need for environmental education at all levels of education furthermore was stressed in the "International Strategy for Action in the Field of Environmental Education and Training" held in Moscow in 1987. So far, however, the actions of the International Program have mostly focused on incorporating environmental education in the formal education systems of UNESCO’s Member States (OECD 1993).

Thus, an urgent need was felt to incorporate environmental education topics at various levels of school education.

As a result, in 1975, the National Curriculum and Syllabus Committee (NCSC) was constituted to develop curricula and syllabuses up to pre university level of education. It followed that environmental education was accommodated in the formal education system up to junior level in 1977.

In Bangladesh one of the broad objectives of environmental education is to help children understand the environment, adapt constructively to it and contribute to its survival and development. Every child will be able to live in harmony with nature by understanding how it works. In pursuit of this goal, environmental education was introduced in schools from primary to junior level.

The curriculum and syllabi prepared by the National Curriculum and Syllabus Committee (NCSC) for primary (Grades I-V) and junior secondary (Grades IX-X) levels were introduced phase by phase between the years 1978 and 1983.

The primary curriculum included for the first time environmental education subject matter under the name of Environmental Studies which is interdisciplinary in nature. In this subject the elements of both natural and social sciences have been incorporated in such an integrated manner as the learners are exposed to their immediate environment from the very beginning of their life.
The principal aims and objectives of environmental education at primary level are, in short, as follows:

- to make the child aware of his environment in a simple manner and his position in it;
- to arouse interest in pupils towards all living and non-living objects around him;
- to develop skills for understanding and learning about the environment through scientific enquiry;
- to develop the competency of using the environment with a sense of balance and proportion;
- to develop social behaviour and discipline;
- to develop and foster a sense of patriotism, fellow-feeling and universal brotherhood;
- to include in him moral and spiritual values and develop an aesthetic sense;
- to promote physical development and help from the habit of healthy living;
- to develop a willingness to work individually and in groups and to form a positive attitude towards manual labour;
- to create a consciousness for maintaining and protecting the environment;
- to foster and develop a positive attitude towards the environment.” (Ali 1990)

Children at primary level are generally curious, imaginative and creative by nature. So the principal aims and objectives of Environmental Studies at this level are to help the young children to increase their power of observing things, expressing experience, taking decisions and thereby developing a positive attitude toward nature and society. Children will be able to understand their immediate environment by using natural elements and objects within the environment. On a small scale, they will observe their environment from which they will be enabled to solve problems related to the environment which they face in their everyday life. In the classroom they will participate actively, arousing their curiosity and leading to them enquiring about their environment. In order to attain all these objectives and to develop in young children skills and attitudes towards the environment, Environmental Studies has been introduced at primary school level.

Science Across the World remakes its website

A working example of how the Internet can bridge language and cultural differences has been given a facelift after two years in the field and a rising popularity among schoolchildren in 46 countries.

The Science Across the World programme, coordinated by the Association for Science Education in Britain, was one of the first to incorporate a website into an education programme. The programme aims to raise awareness of science and technology issues in society, industry and the environment. The Internet was used initially to allow teachers and students to send information to other schools.

But there is much more to the new site. It is easier to navigate and more visually appealing. Ease of navigation and speed of download are key features. There are no spinning logos: instead there are resource areas, with discussion forums and news sections to contribute to. Nor is it all dull text. Video clips are available. And the whole thing is available in six languages - English, French, German, Italian, Portuguese and Spanish.

Those who dream of using the Internet in schools might like to check how its done in Science Across the World. There are 1 200 schools world-wide using the BP-sponsored programme, and in the last six years it embraces schools in Africa, the Asia-Pacific region, Europe and North and South America.

Encouraging the use of practical work in primary schools

Sue Fisher
Institute of Teacher Education, Kyambogo
Kampala, Uganda

When primary teachers in The Gambia were asked why little or no practical work was carried out in primary science lessons three standard reasons were regularly offered in all earnestness. The first and most common was that they had no equipment, the second was that there was not enough time and the third that the classes were too big. Whilst the third does sometimes present some daunting challenges it is suggested that the real reasons for so little practical work were not quite as simple as those stated.

Availability of equipment

It is certainly true that the majority of the primary schools in The Gambia, especially in rural areas, have no standard equipment designated for science practical work. But, with the exception of perhaps magnets, no formal equipment is required before teachers are able to carry out a whole range of activities with their classes. At the same time these would cover most of the topics required in the syllabus. There are many opportunities for improvisation from materials in any of the local environments. What was lacking was recognition of the need to do practical work, the stimulus for ideas for improvisation and a background of experience of such activities on which to draw. Access to large quantities of materials might present a problem at times. However, with limited equipment a demonstration, well handled, would be better than no activity at all and sometimes this may be the appropriate teaching strategy.

Improvisation

Setting aside the lack of recognition of the importance of practical work for the moment, those teachers who have a good foundation of theory need some stimulus to get them started. It was found that once teachers were presented with some activities at a workshop, using local materials, and experienced using them, then they began to have their own ideas about other local materials which might be an alternative or even better for a particular purpose. At the beginning of the first term a week’s workshop was run for a group of teachers with this as a major theme. At the end of term when the teachers returned for further in-service training they all brought examples of improvisation. Many of the teachers had used an excellent variety of materials and showed considerable imagination. Both natural and man-made products had been pressed into service. One teacher proudly announced that he had had a much better idea than the original for making a model of pulleys and levers using common tomato paste tins rather than card from a box of tea.

Application

However, even when stimulated the teachers do have to have an idea of the ultimate purpose of an activity and an idea of how this may be achieved. This means a reasonable understanding of the concepts and principles behind the topics being taught. When asked if anyone knew how to show pupils a spectrum without using a prism one teacher demonstrated how he used a mirror and a dish of water (much simpler than the example in the book) but he couldn’t actually explain what was happening. He had achieved the result by observation and trial and error but at other times this may be an inhibiting factor to improvisation. It was therefore necessary to go...
through as much of the syllabus as possible carrying 
out the recommended activities (however simple) and 
suggesting others and discussing materials, theory 
and the relevant teaching points. Four separate weeks 
were used to cover, among other things, the topics of 
water, air, soil, and matter and energy (including 
light, heat, sound, electricity and magnetism). It was 
said that discussion on teaching plants and animals 
was not so necessary, though there was many a grade 
two lesson in a classroom surrounded by bush where the ‘parts of a plant’ were studied by means of a 
drawing of a hypothetical plant on the blackboard! 
After due consideration the teachers agreed that lack of 
materials was not the fundamental problem.

Use of Time

It cannot be denied that practical work takes time. 
Teachers frequently state that there just isn’t time to 
do activities. By this they usually mean that there is 
not time in class. There is the perception that 
activities are peripheral to the real job of learning. 
The syllabuses in many African countries, including 
The Gambia, are certainly entirely content based. 
Pupils must learn all the facts and spew them out in 
the exam.

Firstly, teachers had to be persuaded that doing 
practical work leads to greater understanding and 
hones learning, both of which are beneficial to the pupil 
in the short and the longer term. Secondly, the 
teachers’ time management needed to be significantly 
improved. Teachers had to be encouraged to be 
punctual, well prepared and have the class ready as 
simple starting points to managing time. Thereafter 
the need for good planning and management of the 
activity was stressed as being critical alongside a 
well trained class.

This naturally led to discussion of the problems of 
planning and preparation. Undoubtedly these take 
some of the teacher’s non teaching time and 
disincentives abound. In many cases there was very 
little motivation as a result of poor school leadership, 
lack of recognition of teachers’ efforts, conservative 
attitudes of the administration, other responsibilities, 
delay in payment of salaries and low salaries. In 
addition some teachers failed to accept the principle 
that they were primarily there for the benefit of the 
children. Several of these were government matters 
but others had to be tackled at the more local level of 
the region and the school. Time itself was not the 
problem.

Class size

In many situations the class size is an inhibiting 
factor especially in the lower grades of primary. 
Classes of 60 to 100 or more need special handling 
but the use of group work, for example, may still be 
achieved. In many cases, however, it is not the size 
itself but lack of teaching experience, concerns about 
discipline and class control, the organisation and 
planning of activities, noise levels and the perception 
of others that real work is not being done that inhibits 
the teachers. It is a fact that, despite legislation 
against it, the stick or plastic tube rink is still the main 
means of establishing and maintaining discipline in 
many primary classrooms. It is feared that once the 
situation of the teacher at the front with his or her 
stick of office to hand and the pupils in ranks facing 
the front (albeit squashed onto benches or mats on 
the floor), is broken then all discipline will be lost. 
Managing pupils in groups, talking, moving around, 
using water or soil or candles etc. presents a far 
greater challenge to the teacher. But this was thought 
to be so whatever the size of the class.

Lack of Confidence

To return to the question of recognition of the 
importance of practical work mentioned in the 
beginning. It is suggested that it is in fact lack of 
confidence which, though not stated, plays a major 
part in the reluctance of teachers to engage in science 
activities in primary schools. By this is meant lack of 
confidence in:

i. the importance and efficacy of practical work, 

ii the individual’s ability to carry it out in his or her 
classroom.

The importance and efficacy of practical work

Many of the teachers in The Gambia had studied at 
school, passed their exams and got where they were 
without the benefit of the practical work under 
consideration. They had, however, read and written 
about the various activities and could often quote 
examples for examinations. A major task was to 
induce confidence in the importance and efficacy of 
doing practical work at all. The most convincing way 
to do this was for the teachers to experience some of 
the activities for themselves. (A group of science 
teachers training to be tutors in Primary Colleges in 
Uganda were asked the one most significant occasion 
when they had learnt something in science. All but
one quoted an activity or experiment in which they had participated that had made all the difference to their understanding. The exception quoted the lesson where the teacher explained the 'mirage' effect on the hot tarmac road outside. Where opportunities for teachers to participate in and be encouraged to carry out activities existed then confidence in the importance of those activities soon grew. Too many instances occurred during workshops, where a teacher's face lit up as theory was shown in practice or teachers became totally absorbed in following an activity through, for this to be disputable.

The majority of teachers themselves were thus convinced. It was a short step to persuade them that such pupil centred teaching had value. Following this, as part of the course, the teachers were required to try out practical work with their classes. This led naturally to the second aspect. There still remained the need to persuade the teachers to 'risk' doing activities in class.

The individual's ability to carry out activities in his or her classroom.
Several obstacles stood in the way.

i. the lack of basic scientific knowledge of the teacher;

ii. the teacher's poor professional competence;

iii. concern over discipline;

iv. perceptions of hierarchy in the classroom; and

v. concern for the marginally higher noise level, likely fluidity of class structure and resultant possible censure from the senior staff.

Scientific knowledge and professional competence (i) & (ii) varied with individual teachers and were sadly weak in many cases. However, a start could be made through the in-service workshops. Besides going through the syllabus much emphasis, as might be expected, was put on planning, preparation and good classroom organisation. It was also decided that the teachers should be provided with user-friendly activity sheets, showing experiments and activities by means of very simple drawings with the text reduced to a minimum (7 or 8 words). Further basic information and hints for management were to be found on the back. In many cases these sheets were pictorial representations of activities mentioned in the text of the teachers' guides but which were often not read and rarely carried out.

A major concern was that of maintaining discipline (iii). Many teachers had few ideas as to the variety of ways in which discipline could be maintained and they needed help and encouragement to take any risk. The perceptions of hierarchy in the classroom (iv) presented an associated problem. The teachers strongly believed that they should know all the answers and always be right. This is a view shared by most of the pupils. Any weakness in these areas would result in loss of respect and loss of discipline. Rigidly controlled chalk and talk lessons would avoid most challenges, whereas activity based lessons could present teachers with unexpected situations and unpredictable questions thus possibly exposing them as less than omniscient. Changing these attitudes will be a long term operation but an effort was made to begin the process.

Finally, should the teacher be prepared to accept the slightly higher noise level resulting from pupil discussion and the greater activity in the classroom, there was concern about and experience of censure from the Head and senior teachers (v). It was found that it was essential that the head teachers be kept informed of what was being expected of the teachers by way of changing methodology and that they be encouraged to support it.

Conclusions

Whilst provision of equipment, time management and class size all represent obstacles to teachers doing practical activities they were in many cases a screen hiding the underlying lack of confidence of many of the teachers. Tackling the reasons for this was something that the teachers could not do by themselves. In-service courses and subsequent follow up and support were a means by which the teachers of the Gambia were helped and are continuing to be helped first by expatriates and now by Gambians. Those who benefited from training were expected in turn to help their school colleagues. It is to be hoped that the pre-service training will also make every effort to continue to promote and foster the importance of child centred learning and practical science activity in primary classrooms thus complementing the in-service work.

The Gambia is a small country with a relatively small population. The task in other parts of Africa is far greater and no less important, as many of the features discussed here are common to other African countries.

ICASE Distinguished Service Award

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

A listing of past award recipients can be found on the ICASE Website at <http://sunsite.anu.edu.au/icase/i_awards.html>

Nominations for this award must be forwarded by member organisations of ICASE. For full details of how to forward nominations, contact:
Dr Jack Holbrook, ICASE Executive Secretary,
ICASE Secretariat, PO Box 6138, Limassol, Cyprus
Email: icase@logos.cy.net
The teacher’s role in inquiry-centered experiences

JoAnne Vasquez
National Science Teachers Association, USA

Introduction

It started with a simple laser beam on the ceiling. The lesson objective of teaching was: that the angle of incidence is equal to the angle of reflection. Once the kids illuminated the invisible beam bouncing off the mirror with chalk dust, they were snagged. From that moment, they began to develop their own question. They soon became fascinated by the discovery that by manipulating the laser, they could then manipulate the angle. Students became empowered by their own curiosity. As they began to develop their own questions, they started creating obtuse, acute, and right angles. They took the lesson to a different ‘plane’ by predicting if they used mirrors to become part of the beam, where would they line themselves up? The real investigations started, and it became real inquiry when the students took ownership of the investigation and started asking, ‘what would happen if …?’

The way students develop an understanding of a topic is by interacting with the content. Students’ interactions are part of the total learning process. Those skills that allow teachers to be good leaders of inquiry are the same skills used by the students. Teachers need to become responsive to how children learn. They must then give students permission to take ownership of the lesson once they are engaged. Often, teachers feel uncomfortable when the student comes up with a different answer from the one that teachers thought they would choose. This can be a moment when the teacher has to “let go” and then become the true ‘guide by the side.’

Over the past decade, the groundwork has been laid for new classroom approaches that encourage students to become active learners. It is imperative that we help all students learn to employ higher-order thinking skills. Higher-order thinking is defined by Lauren Resnick as nonalgorithmic: complex; amenable to multiple solutions; involving nuance judgment; which can employ multiple criteria for constructing meaning (Resnick 1989, 3). In contrast to previous theory, current views about learning and teaching emphasize “that higher-order skills must suffuse the school program from kindergarten on and in every subject matter” (Resnick 1987, 3). These higher-order thinking skills encourage children to become effective readers and to develop their mathematical skills, both of which are important for learning science.

The previously dominant view of instruction as direct transfer of knowledge from teacher to student does not fit the current perspective. The present view of learning places the learner’s constructive mental activity at the heart of all instructional exchange. This view does not mean that the student is left to discover everything for themselves, nor that what they discover and how they choose to describe and account for it are left solely to them. Instruction must provide experiences and information from which learners build new knowledge. Instruction helps to focus those processes so that the resulting knowledge is both valid and powerful.

The laser activity represents “content selected to meet the interests, knowledge, understandings, abilities, and experience of students” from the National Science Education Standards (NSES, 1996, Teaching Standard A, 30). Also included in this activity are the NSES Teaching Standards B: Teachers of science guide and facilitate learning. In doing this teachers:

• focus and support inquiries which interacting with students;
• orchestrate discourse among students about scientific ideas;
• challenge students to accept and share responsibility for their own learning;
• recognize and respond to student diversity and encourage all students to participate fully in science learning; and
• encourage and model the skills of scientific inquiry, as well as the curiosity, openness to new ideas and data, and skepticism that characterize science. (NSES, 1996, Teaching Standard B, 31)
What are the characteristics of a teacher who is using an inquiry instructional approach?

These characteristics of inquiry-based teachers should apply to all classrooms, not just to those teaching science. You would see teachers as the following:

- encouraging and accepting students’ autonomy and initiative;
- using raw data and primary sources, along with manipulative, interactive, and physical materials;
- when they are framing tasks, using cognitive terminology such as classify, analyze, predict, and create;
- allowing student responses to drive lessons, shift instructional strategies and alter content;
- familiarizing themselves with students’ understandings of concepts before sharing their own understanding of those concepts;
- encouraging students to engage in dialogue, both with the teacher and with one another;
- encouraging student inquiry by posing thoughtful, open-ended questions and asking students to question each other;
- seeking elaboration of students’ initial responses;
- engaging students in experiences that pose contradictions to their initial hypotheses and then encouraging discussion;
- allowing time after posing questions;
- providing time for students to construct relationships and create metaphors; and
- nurturing students’ natural curiosity. (Brooks & Brooks 1993, 102-18)

What is the teacher’s role in inquiry-based instruction?

In inquiry-based, student-driven investigations, teachers direct only a part of the action. In ‘real’ science, there is no absolute authority to supply an answer that scientists can’t find for themselves. No absolute authority can lend a hand by hinting to scientists that their investigation is on the right track or reassuring them at the conclusion of their efforts by confirming or rejecting the results. The students’ progress is enhanced if the teacher doesn’t give them the answer or even tell them in detail how to get the answers. This is an intrinsic part of modelling the process of doing science.

Teachers enter the teaching profession because they have a desire to communicate knowledge. The temptation to supply the answer is sometimes very strong. For a teacher to stand there and be only a ‘guide by the side’ while watching a student make an obvious mistake is very hard to do. It is the teacher who preserves through this period of time that reaps the rewards of their silence. The students find it is OK to make mistakes. The bodies of knowledge they construct in making the mistake is the important product of the investigation.

Teachers in an inquiry-based lesson must act as facilitators and resources. They are to create the environment which is safe for the investigations to take place; they impart conceptual knowledge, mathematical and technical tools, and general guidelines at optimal moments. Teachers are to select learning experiences and adapt and design the curricula to meet the interests, knowledge, abilities, and backgrounds of their students.

If teachers find that their students have little or no experience with experimental approaches, they may then begin with nothing more than a simple question. For example, “How can you make the laser beam bend?” would be a good question to begin with on the lesson using the laser. As the students become more sophisticated in their discovery, you could then pose the question, “How many ways could you come up with to make the laser beam bend around the entire classroom?”

While teams of students are working on the problems, the teacher is available to provide resources and responses to calls for clarification. Students, working together as a community of learners, are able to build and reflect on one another’s ideas. They will demand evidence from their peers, challenge the facts and pose other points of view (Jones and Fennimore 1990, 17). After the investigations are complete, the teacher will be there to moderate the discussion as groups of students share and critique each other’s findings. The teacher can then help the students make connections between their experiments and their knowledge of scientific concepts.

This all sounds very simple. But it is not. The teacher must learn to give up much of the initiation of action during the day. Teachers must surrender some degree of control over the class’s activities. Close attention is then paid to the quality and depth of students’ learning, and the assessment of the students’ progress can be time-consuming and difficult. Both the teacher and the student will need to participate in the ongoing assessment of student performance.
The biggest reward for the teacher when they choose to become facilitators of their students’ learning is seeing their students develop as independent learners. The students themselves will also feel this satisfaction. They will learn to believe in what they are doing as well as take the responsibility for constructing their own learning. Most of all they will be acquiring the skills necessary to make them independent thinkers.

**What are the limits on the freedom to explore?**

The challenge for teachers is deciding how much freedom to give their students to explore. The students need to spend some time exploring the topic and posing questions, but soon they must decide when to focus on their investigations. Teachers must provide as much guidance as necessary to ensure that all students acquire the expected knowledge, skills, and understandings.

Among the principal reasons for maintaining some structure in the classroom is ensuring that the significant scientific concepts are introduced. Those concepts are clearly delineated in the NSES document. The lesson using the laser was designed to teach concepts about light and the angle of incidence is equal to the angle of reflection. The true inquiry came when the students began to pose their own questions and structure their own investigations. Once the students have been introduced to the inquiry mode and experimental design they can easily take ownership of the investigation. Although the teacher has surrendered some control over the classroom, they are still there to focus the students back to the desired learning outcomes of the lesson.

Teachers also recognize early on that they will not cover as many topics as some of their colleagues. But they are committed to ‘less is more’ to ensure that their students thoroughly know, understand, and are able to do that science to which they are introduced.

**Teachers talking to teachers**

If the teacher is to develop an inquiry approach to their teaching methods they must take a fresh look at the materials and resources available to them. Familiar instructional materials such as textbooks, written problem sets, and reference books cannot be relied on to provide the needed material for their investigations.

Developing materials for student investigations is not an easy task. Many teachers gather materials via creative collaboration with their colleagues. By using the Internet, many teachers find themselves able to develop lessons from material taken from the World Wide Web sites and then turn around and share these lessons with others via the Internet. The beauty of this lies in the fact that teachers are able to take another teacher’s lesson and adapt to their own learning environment. This method of sharing is becoming one of the fastest growing means teachers have to bring innovative ideas and experiences into their classrooms.

**Assessment in an inquiry-centered classroom**

One of the biggest concerns from administrators and parents, and the most difficult to maintain, is the types of assessment necessary to demonstrate that learning has taken place in an inquiry-centered classroom. Teachers have to be responsible for continuous assessment strategies in their classroom. This requires the employment of an array of methods. These can involve asking the students to:

- generate rather than choose a response;
- actively accomplish complex and significant tasks; and
- solve realistic or authentic problems.

Such achievement in classrooms is assessed through:

- exhibitions;
- investigations;
- demonstrations;
- written or oral responses;
- journals; and
- portfolios.

Elements of this approach to assessment can easily be identified in the NSES. “Making assessment decisions through meaningful, complex tasks embedded in instructional activities” is an ongoing responsibility of the teacher (NSES, Assessment Standard D 1996, 84). Assessment is not a separate activity.

An inquiry-based curriculum does not isolate skills and facts. Rather, it emphasizes both through meaningful, complex tasks embedded in increasingly challenging environments. Materials and content are structured so that students gradually regulate their own learning. This approach ensures learning competence and confidence. Self-assessment of progress by both the individual students and groups is a very powerful result of an inquiry-based approach to learning science.
The National Science Education Standards contains the road map for exemplary science teaching and learning. Master teachers recognize inquiry as one of the many instructional strategies encouraged by the NSES. In order to meet the needs of students, teachers must feel confident in their abilities to recognize and implement different pedagogical approaches.

Inquiry extends beyond merely teaching the processes of science. The new vision on inquiry requires the student to combine processes and scientific knowledge as they use scientific reasoning and critical thinking to develop their understanding of the natural world.

The path that the teacher travels to become skilled at using inquiry in their classroom is not an easy one. If we were to make an analogy it could be learning to drive a car. When you are a beginning driver, driving looks like the most wonderful skill you could ever acquire. The first time you sit behind a wheel, however, you find out driving may not be as easy as it looked from the passenger seat. As the driver, you have to control the car, evaluate road conditions, estimate distances etc. After a few months of driving, performing all these tasks simultaneously begins to feel very natural.

Like learning to drive, all teachers learn to lead the inquiry-based science lessons by developing questioning techniques and management skills, and by providing materials and resources to foster their students' learning. They also must develop the assessments that match this type of instructional approach. Like driving a car, when all the elements come together in an inquiry-based lesson, the teacher will have that moment of "Ah-ha!"

Science, Mathematics and Technology Education and National Development Conference
Hanoi, Vietnam, 1997

A book reporting on this conference has been prepared by Darrell Fisher and Tony Rickards (eds). The book contains over fifty papers that were presented at the conference on recent research and practical implications in science, mathematics and technology education covering the following areas: research methods; teaching; equity; teacher education; learning; curriculum; learning environments; assessment and evaluation; education technology; history and philosophy of science.

For details on how to order copies of the book please contact: Tony Rickards, Doctoral Student & Research Assistant, Science and Mathematics Education Centre, Curtin University of Technology, GPO Box U1987, Perth, WA 6845, Australia

Supporting change of science and technology teacher preparation in the Asian region

Lucille C. Gregorio
(UNESCO, Thailand)

The paper has an Asian bias, as the ideas are drawn from discussions with science teachers and educators who were sent by Member States to participate in regional workshops organized by UNESCO Bangkok. The presentation starts with an overview of the situation in the region, emphasising the education reforms taking place as influenced not only by socio-economic developments more so by advances in science and technology. These reforms have implications on the preparation of science and technology (S&T) teachers. The paper points out the demands for the S&T teachers, the role they have to play, the competencies and skills required and the need for changes in the science and technology teacher preparation programs. The 'pointers and recommendations' of the Delors report are presented, as these are found to be relevant to the quality improvement of science and technology teaching and learning.

Overview of the situation in Asia

The education reforms undertaken by countries of Asia in order to prepare for the 21st century, are influenced by the socio-economic developments and the specific awareness of the need to cope with the challenges of change, brought about by the advances of science and technology in all aspects of political, social, moral and economic life of their people, among other reasons. The reforms in the educational structure include re-orienting, reshaping, 're-engineering' the curriculum, the professional development of teachers, school administrators and other school personnel, the evaluation and assessment strategies, the school supervision, administration and management, the strengthening of institutions, the conditions of work and other areas of education. Although science education always had a recognized place in the school education of the countries, shortfalls were recognized in the program, which needed reorientation. These shortfalls are the focus on specialised disciplines e.g. physical science, biological science, environmental science, etc, the emphasis to prepare students for higher education and to become specialists in specific areas and the absence of linking to technology and the world of work as well as the exclusion of ethics and social responsibility.

Conceptual changes have been attempted in the teaching of science. In 1983, the 'Science For All' program was initiated in the region. At that time, science education aimed to produce an appropriately equipped workforce and also aimed to produce citizens who would be comfortable with, and able to benefit from, science learning. Whilst acknowledging that the concept was relevant to lifelong learning, and trying out many strategies in science teaching such as
‘learning by doing’, ‘activity approach’, ‘inquiry approach’, ‘child-centred approach’ etc., which were attempts in the right direction and could be considered as the outcome of past experiences in science teaching, most students were turned away from science. It was because science teachers attempted to move their students into the world of science, especially in the world of the research scientists - which were noted to be far removed from the everyday world. But the blame should not be on the teachers, as they learned all these things during their preparatory work in science teaching. As it is said, “teachers teach the way they were taught”.

Aware of these shortfalls, UNESCO in partnership with UN agencies and other intergovernmental organizations and NGOs initiated Project 2000+: Scientific and Technological Literacy for All, which is aimed to revitalise and reform science and technology education at all levels. The project recalls the World Declaration on Education For All (Jomtien, 1990) which recognized that “sound and basic education is fundamental to the strengthening of higher levels of education and of scientific and technological literacy and capacity and thus to development of self-reliance”. The project further recalls the worldwide concern for the environment and for the quality of human life, put forward in Agenda 21 of the UN Conference on Environment and Development (Rio Summit, 1992). One area of reform demanded is on teacher preparation. Thus this paper discusses the needed change in the preparation of science and technology teachers.

The demands on science and technology teachers

The teacher as an agent of change plays a pivotal role in the teaching-learning process. It has been said that “no education system can rise too far beyond the level of the teachers in it” (Roy Singh, 1991). Though teachers are faced with lots of constraints - some of which are those related to handling large classes, meagre resources to manage; handling new inputs in the curriculum without adequate training, examinations, etc., they are expected to fulfil their tasks effectively, in transacting the teaching-learning process. The demands on teachers, especially on those teaching science and technology, are very high.

The tasks are enormous - to prepare the learners to face real-life situations, and not only for the examinations but for life; to be made alert about the changes taking place in the immediate environment, the scientific and technological developments, the social, cultural, and behavioural aspects of life; to acquire skills and competencies like making a point in a conversation, making adjustments, processing information, behaving properly in a group etc. There are also demands to enable the learner to react to situations with rationality and scientific temper; foresee the future environment, newer technologies and their impact, and identify such elements as are likely to contribute to it significantly.

With the tasks identified the science and technology teacher is expected to observe his or her own way of working, analysing his or her reactions so he or she could adjust her/his teaching approach, style, habits and even personality based on the background and behaviour of the learners and modify his/her teaching methodology or style accordingly; appreciate the necessity of not only teaching but also interacting and listening to the learners; mobilise resources and utilise these appropriately according to the needs of the teaching-learning process; evolve a teaching methodology to adapt to the changing situation, using appropriate language, update with new knowledge and information, upgrade with new skills and competencies, including assessing and evaluating the learner’s performance, in terms of relevance and quality of learning. These expectations can only be fulfilled by the teacher if she or he believes that there is more than transfer of knowledge as a professional obligation. Furthermore, the status of teachers also has to be improved.

The various roles of the science and technology teacher

The S&T teacher has to be provided with opportunities in order to be able to promote science and technology education and in performing various roles.

Curriculum developer
The S&T teacher gets involve in curriculum renovation, even in a highly centralised education system, to develop a curriculum which relates to real-life situations, design locally relevant activities, utilise local resources and encourage the learners to bring in to the classroom their life experiences. He or she designs and organizes in-school and out-of-school activities, mobilise community expertise to assist the school and improvise equipment whenever necessary.
Innovator and motivator of learning
The S&T teacher designs science activities and mobilises resources from the environment or makes use of low-cost or no-cost equipment. As motivator of learning, good examples are set, he/she makes learning rewarding and interesting, generates curiosity, explains natural phenomena, provokes learners to be more inquisitive and gets involved as an active partner in the learning process.

Life-long learner
The S&T teacher has to be a life-long learner, by continuously updating and upgrading himself or herself, with new knowledge and skills. He or she also learns from his/her pupils through interactions, questions and interventions in the learning process. The rapport of pupils with the teacher could also be converted into potential instruments of evaluating his or her own learning.

Community collaborator
The S&T teacher serves as a resource person for the community, as well as counsellor of parents regarding their children. To perform this role, the teacher has to understand the existing socio-economic and cultural scenario and the possible impact of scientific and technological changes in order to prepare the community to accept not only those changes which would provide short-term gains but also lasting benefits. A close working relationship with the school and the community has to be established which would mean mutual accountability. This relationship would contribute to the effective functioning of the school.

Evaluator
The S&T teacher requires an in-depth understanding and adequate preparedness of the objectives of evaluation, to prepare the learners for life, to evaluate their interest, attitudes, values and ability in decision-making, their manipulative, laboratory and life skills and their understanding and analysing of concepts.

The competencies and skills of the science and technology teacher
To meet the demands to perform the above roles, the S&T teacher would demand new skills and competencies. In Project 2000+ teachers need diverse teaching-learning experiences in order to develop concepts and skills that are flexible and applicable to a variety of situations. They should be exposed to opportunities to allow divergent thinking required to anticipate problems and identify strategies to find alternative solutions. The competencies and skills required are described as follows:

Process skills
The basic skills required to develop the learner’s scientific and technological capabilities include: observation, use of space-time relationships, classifying, using numbers, measuring, communicating, predicting and inferring. The integrated basic skills are needed for the development of higher-order skills such as information processing and utilisation, creativity, problem-solving and decision-making.

Information processing and utilisation
Information is growing so rapidly that it has become impossible for the teacher to be a ‘know-all’ individual. The competence of the S&T teacher in information processing and utilisation is necessary to identify and locate sources of information, establish necessary opportunities to procure these and then sort out and identify relevant and appropriate materials.

Creativity
Scientific and technological developments, reaching every member of society, provide ample scope for identifying creativity-oriented situations. All children are endowed with the inherent talent of creativity. S&T teachers, therefore, should take advantage of this gift by providing creativity-nurturing activities. Probing, analytical, open-ended questions would not only lead to solutions but also permit full scope for the learners to formulate alternative solutions confronting everyday life.

Managerial and entrepreneurial skills
More often, a primary and secondary school teacher works under constraints of lack of resources and teaching-learning materials. In many instances, there is also a lack of opportunity in updating his or her knowledge and upgrading his or her skills. But to a school child, the teacher is a fountainhead of knowledge, a role model and mobiliser of resources, thus the teacher has to be a good manager and entrepreneur.

Decision maker
Decision making requires accurate and adequate information. The science and technology teacher is expected to help the learner present information, possibilities and alternatives objectively to resolve issues affecting people’s quality of life.
The need for change in the S and T teacher preparation programs

The educational reforms in member countries have resulted in perceptible changes in the objectives, structures and contents of science and technology teacher preparation programs. The following objectives are being suggested:

- to develop a holistic understanding of the nature of science and technology;
- to acquire a sound scientific and technological literacy and appreciate the social and ethical aspects of science and technology;
- to analyse critically the science and technology curriculum in terms of content, activities and applications;
- to plan and organise suitable activities, and mobilise resources;
- to design, identify and implement teaching-learning strategies aimed at developing scientific and technological skills and competencies;
- to relate learning experiences and activities to the cognitive level of the learner;
- to design and organize activities to help children with special learning needs e.g. slow learners, physically and mentally handicapped, the gifted and the talented;
- to encourage learner-centred, activity-based, participatory, cooperative activities;
- to utilise learning experiences from real-life and the immediate environment of the learner, and which could be obtained by the teacher and learner working together;
- to develop suitable monitoring, assessment and evaluation strategies, and be attentive to feedback for remediation;
- to improvise, handle and utilise low-cost teaching-learning aids to make the learning experiences and environment interesting especially to the learner;
- to appreciate the use of educational technology and be able to use it in the teaching-learning process;
- to familiarise and get updated with educational changes taking place;
- to equip oneself to act as interpreter of new ideas and technologies for the benefit of the learners and the community members;
- to find the relationships of science and technology with health, agriculture, industry, environment, food and nutrition and other aspects of living;
- to use scientific knowledge in correcting misconceptions, false beliefs, prejudices and practices; and
- to develop decision-making skills and utilise these in real-life situations.

The changing times have enhanced the roles and responsibilities of science and technology teachers. It is therefore necessary that teacher training institutions take due cognisance of the changing scenario and provide a kind of science and technology education which must meet the new challenges. While pre-service training of teachers is very important, equally significant are the in-service programs which can really update the teacher, and keep him or her abreast of new developments, particularly in science and technology relevant to the community. The teacher has to be all the time ‘aware and alert’. Apart from formal training, the teacher’s interest, aptitudes and creative abilities would contribute to the efficiency and effectiveness of his or her teaching. He or she has to possess first of all rational and scientific thinking to make his or her teaching dynamic.

The responsibility for training of teachers does not only lie on what the government can offer. The community and society are equally responsible to meet the new challenges.

Recommendations

In the report of the International Commission for the 21st Century (Delors Report, 1996), the role of the teachers and the need to improve their training, status and conditions of work are stressed. The report has emphasised ‘learning throughout life’ as one of the keys to meeting the 21st century - based on four pillars of learning. These are: Learning to be, Learning to know, Learning to do, and Learning to live together - learning to live with others.
Based on the four pillars, ‘pointers and recommendations’ have been proposed, which are relevant to the quality of science and technology teachers. These are classified and summarised as follows:

- the psychological material situation;
  - vary from country to country,
  - upgrading of their status is essential if ‘learning throughout life’ is to fulfil a central function in the advancement of our societies and the strengthening of mutual understanding among peoples,
  - their position as master or mistress in the classroom should be recognized by society and they should be given the necessary authority and suitable resources.

- the concept of learning throughout life;
  - leads straight on to that of a learning society, a society that offers many and varied opportunities for learning, both at school and in economic, social and cultural life,
  - the need for more collaboration and partnerships with families, industry and business, voluntary associations, people active in cultural life, etc.

- teachers’ imperative requirement to update knowledge and skills;
  - their professional lives to accommodate the opportunity, or even the obligation, for them to become more proficient in their art and to benefit from periods of experience in various spheres of economic, social and cultural life;
  - to be provided with many forms of study leave or sabbatical leave.

- the teacher is faced with his or her own responsibilities and professional duties, but;
  - teamwork is essential, particularly at the secondary level, in order to improve the quality of education and adapt it more closely to the special characteristics of classes or groups of pupils.

- the importance of exchanges of teachers and partnerships between institutions in different countries;
  - such exchanges and partnerships provide an essential added value not only for the quality of education but also for a greater receptivity to other cultures, civilisations and experiences.

all these lines of emphasis to be a subject of dialogue, or even of contracts;
- with teachers’ organizations which go beyond the purely corporate nature of such forms of collaboration,
- over and above their aims of defending the moral and material interests of their members, teachers’ organizations have built up a fund of experience which they are willing to make available to policy-makers.

With these views put forward, we hope to receive support for the improvement of the science and technology teacher preparation programs in the region.

Note to Member Organizations

Please ask your members to submit material to Science Education International. We are looking for:

- Teaching activities and lessons
- Action research articles which talk to the practising teacher
- Research articles which focus on practice, not research strategies
- Informal and non-formal articles which address 'things to do' in these settings

Please include photographs, pictures and drawings

Evaluation of clientele impact of science exhibits

Vivien M. Talisayon, PhD
College of Education, University of the Philippines
Diliman, Quezon City, Philippines

An impact evaluation model across time and clientele groups was used to evaluate exhibits of two Science Centres in Metro Manila. Immediate impact on majority of grade school to high school students, based on questionnaire and interview data, was great interest in science and science career choice. Short term and long term impact indicated lower student percentages. Student quiz performance was average. Experts highly rated exhibits’ alignment to national goals. Students preferred manipulative exhibits producing sound, light and motion.

Introduction

The Science Centres evaluated in this study are the Philippine Science Centrum and Science Works, both located in Metro Manila. The Centres were established by the Philippine Foundation for Science and Technology, a non-profit private organisation that aims to promote science and technology among the youth. Established in February 1990 with the support of the Department of Science and Technology, the Science Centrum is the first Science Museum in the country. It showcases nearly a hundred interactive exhibits in science and mathematics. Science Works is a satellite of the Centrum created in May 1993 particularly for children, ages three to twelve. The Centres aim to stimulate children’s curiosity and interest in science.

The evaluation sought to determine the attainment of the objectives of the Centres based on perceptions and observed behaviour of its clients – children (ages three to sixteen), teachers, principals and parents or adult companions of the child. It focussed on the influence of one or more visits to the Centres on the students’ science learning, interest in science, subsequent science-related activities and career choice. It also studied the students’ behaviour at the exhibits, their exhibit preferences and clients’ perceptions on admission cost. The study aimed, too, to identify characteristics of best-liked exhibits and describe trends in student clientele size and composition since the establishment of the Centres. Experts’ ratings of the exhibits’ alignment to national goals were also obtained.

Evaluation Framework

The impact evaluation model developed and used in the study (Fig. 1) shows impact across time and clientele groups. The model built on the short-term and long-term impact model used in a 1987 evaluation study of the Singapore Science Centre (Talisayon and Talisayon, 1987).

The clientele in focus in this study is the group of children from preschoolers to high school students. Perceptions of the other groups – parents or adult companions, teachers and principals were mostly in relation to exhibit impact on the students. Experts were also included as clients, because they rated the exhibits while viewing them. The experts’ ratings were based on national goals, specifically, the Science and Technology Agenda for National Development, Philippines 2000, of the Department of Science and Technology (Quiason and Quiason 1995).
Across time, the impact was categorised as immediate (during the visit – as the students interacted with the exhibits and as they left the Centre), short-term (within one or two years after the visit) and long-term (after two to four years from the visit). Measures of immediate impact were children’s behaviour at exhibit; their science learning, interest in science, exhibit preference and career choice immediately after exhibit viewing; and exhibits’ alignment to national goals. Short-term and long-term impact was measured in terms of science learning, interest in science, exhibit preference, career choice, perception on admission cost and performance of science-related tasks.

**Figure 1 Evaluation Framework of the Study**
Methodology

Evaluation design

Employed in the study is a five-stage impact evaluation design, as follows:

Stage 1 Identification of Impact Receivers and Environment

The impact receivers or clientele groups were identified (Fig. 1) with the children as the clientele in focus, based on the objectives of the Centres. Due to time constraints, Metro Manila was selected as the impact environment. Since the Centres are in Metro Manila, it is also the immediate impact environment.

Stage 2 Setting of Time Frame and Assessment Points

Three time frames and, consequently, three assessment points were chosen for immediate, short-term and long-term impact (Fig. 1). The years of existence of the Centres were considered.

Stage 3 Determination of Impact Measures Using Evaluation Models

The models used in this study were those relating to evaluation of attainment of objectives, inputs (e.g., student perception of interest in science prior to visit), processes (e.g., behaviour at exhibit) and outputs (e.g. short-term and long-term) and unexpected outcomes.

Stage 4 Simultaneous Data Collection

Due to time limitation in data collection, data were obtained simultaneously from visitors representing different time frames.

Stage 5 Quantitative and Qualitative Data Analysis

Trends were analysed and impact compared across time and student clientele groups. Frequencies, percentages and mean scores were qualitatively compared.

The Sample

The sample consisted of students and schools to which the research team had easy access in the allotted three month (August – October 1995) data gathering period. Involved in the study were 1445 students from 16 elementary schools (15 private schools, one public school) and 948 students from 12 high schools (9 private schools, 3 public schools) in Metro Manila.

Three science education experts from the Department of Science and Technology rated the alignment of exhibits with national goals in science and technology.

The Instruments

Table 1 shows the instruments developed and used by the research team for the students and experts. A total of fourteen instruments were constructed for different clientele groups for the two Centres for three time frames.

*Table 1. Some Instruments for Impact Measures*
The Exhibit Observation Form focussed on the condition of the exhibit, the number of visitors' verbal and non-verbal reactions to exhibits, including repeated viewing. The exit questionnaire (given at the Centres) had nine questions for grades 1 – 4 and eleven questions for grade 5 to high school students. The school questionnaire for students, administered in school by teachers, had fourteen questions each for grades 1 – 4 and grade 5 to high school. The questionnaire was administered orally to grades 1 – 3 pupils. The interview schedule (6 – 12 questions, depending on the respondent's age) and the school questionnaire for grade 5 to high school asked students to describe in sentences or pictures how the visit affected them.

Other instruments were the School Interview Schedule for Teachers (17 questions) and the School Interview Schedule for Principals (8 questions). The interview schedule was given at the Centre, mostly at the Science Works, to preschoolers, parents, teachers and other adult companions of children visitors. All questionnaires and interview schedules asked for suggestions to improve the Centres.

The written quiz consisted of ten items for grades 1 – 3, administered orally; fifteen items for grades 4 – 6; and 30 items for high school. These were based on the written explanation/description accompanying the exhibit. The reliability coefficients (Cronbach alpha) of the revised quizzes were 0.63 (grades 1 – 3, 60 students), 0.61 (grades 4 – 6, 180 students) and 0.56 (high school, 1st – 4th year, 100 students).

The instruments were pre-tested. The quizzes, questionnaires and interview schedules were tried out in a public elementary school and in two high schools, one private and the other public. Revisions were minor, like inserting Filipino translation for questions and using simpler words for lower grades.

The exhibit rating scale used by the experts was a five-point scale where '1' meant 'not at all aligned' and '5' represented 'perfectly aligned'. Rated were 90 exhibits of the Centrum and 50 exhibits of the Works.

To supplement the Exhibit Observation Form, behaviour at the Centrum exhibits of two groups of student visitors was also videotaped. For the trends in clientele profile across time, data were obtained from admission records.

Major Findings

The results given in this paper are limited to student data and experts' ratings.

Student Client Profile Trends

The number of visitors of Science Centrum increased at an average rate of 24% per year for 1990 – 1994, with the highest increase (46%) from 1991 to 1992 and lowest increase (8%) from 1993 to 1994. On the average, 70% of the visitors in 1990 – 1994 came from private schools, 59% from Metro Manila, about 50% were elementary school students, 46% were high school students and only 4% were preschool students.

In 1994 – 1995, 88% of Science Works visitors came from private schools and 85% from Metro Manila; 43% of the visitors were preschool students, 43% grade school students and only 14% high school students.

Career Choice

An immediate impact of the visit to the Centrum or Works was that the majority of grade school students (69%) and high school student (57%) replied that their visit made them want to be a scientist or engineer. The percentage decreased to 50% (grade school) and 35% (high school) within one to two years after the visit for another group of students. For a third group of students, the percentage slightly increased to 55% (grade school) and 42% (high school) two to four years after the visit.

Science Learning

More than 50% of the visitors from elementary to high school indicated that they learned 'very much' from the exhibits immediately after viewing them and 'much' one to four years after the visit. However, their performance in a written quiz on the science and mathematics concepts of the exhibits was average: 51% for Grades 1 – 3, 46% for Grades 4 – 6 and 44% for High School.

A high performance level in the quiz was not expected by the Centre management in view of the limited goal of stimulation of curiosity and interest in science among children. The Singapore Science Centre management held a similar view of the impact of a science museum on children (Talisayon and
Talisayon 1987). Besides, time spent in the centre per visitor was about an hour for 50 to 90 exhibits. Research on concept learning indicates that learning takes time. However, it is interesting to note that the majority of the students felt that they learned very much or much after the visit.

**Interest in Science.**

Majority of the student visitors expressed interest in visiting the Centrum or Works again. For those who just saw the exhibits, the percentages were 74% for grade school students and 66% for high school students. The percentages increased within one to four years after the visit to 86% for grade school students and 82% for high school students. For the same period, 89% of the grade school students and 96% of the high school students wanted their friends to visit the Centrum or Works.

Immediately after the visit, the experience increased the visitors' interest in science 'very much' for elementary school students (72%) and high school students (69%). The percentage for 'very much' decreased to 54% (grade school) and 49% (high school) within one to two years after the visit. Two to four years after the visit, the perceived increase in interest in science due to the visit was 'much' for 53% of elementary and high school students.

Immediately after viewing the exhibits, 77% of elementary and high school visitors found the exhibits interesting and 21% considered them useful. Another measure of interest in the exhibits was the number of students who talked to their family and friends about the exhibits after the visit – 88% of grade school students and 95% of high school students within one to four years after the visit to the Centrum.

**Alignment to National Goals**

On the extent to which all the exhibits – content, skills required and attitudinal impact – are aligned with the Science and Technology Agenda for National Development, Philippines 2000, the experts gave an average rating of ‘3.98’. The high mean rating was perhaps partly due to the involvement of the technical staff of the Department of Science and Technology in evaluating exhibit development proposals of the Centres for funding by the Department.

Exhibits receiving ‘5’, the perfect rating of alignment, included the phosphorescence, plasma sphere, laser, coloured shadows, Bernoulli blower and lego. These exhibits were also best liked by students.

**Exhibit Preference**

Based on behaviour at exhibits (e.g. biggest number of viewers, repeated manipulation, animated talk, smile or laugh), questionnaire and interview data, the best liked exhibits were those involving three or more senses. These exhibits were not only manipulative, they produced sound, light and motion. Such characteristics support the findings of an earlier museum evaluation study done by the author (1987).

**Admission Cost**

A great number of visitors (64%) thought that the admission cost – P20 (Us$1.00 is about P26) for the Centrum and P75 for the Works – was reasonable. For maximum entrance fees that student visitors were willing to pay, the amount receiving the greatest percent response were P20 (24%), P50 (19%) and P100 (12%).

**Visitors’ Suggestions**

Suggestions from different clientele groups included improvement of facilities and increasing the number of exhibits. One recommendation was to have the accompanying description or explanation of the exhibits also in Filipino besides in English. Some students suggested having exhibits in the Life Sciences.

**Conclusion**

The rated alignment of the exhibits to national goals is high. A continuing effort to increase the number of exhibits with perfect alignment rating is needed. These exhibits which involve as many senses as possible are also best liked by students.

The Centres attracted mainly students from the private schools in Metro Manila, elementary and high school students for the Centrum and preschool and grade school pupils for the Works. Admission fee may be a factor. There is a need for wider campaign for visits to the Centres among public schools in and out of Metro Manila, perhaps considering fee waiver or subsidy and locating private and public subsidy sponsors.
Majority of the student visitors expressed learning very much immediately after a visit to the Centre, although the performance in the quizzes was only average. The low reliability of the quizzes can be improved in a future study, for example, by increasing the number of questions. Longer exposure enriched by explanations of science concepts can be explored for best liked exhibits.

Science teachers and school administrators can consider the major finding that the immediate impact of the exhibits for majority of the grade school and high school student visitors is to make them want to be a scientist or engineer and to increase ‘very much’ their interest in science. That the percentages for a science career choice and high interest in science dropped within one to four years after the visit is worth noting. An unexpected outcome is that percentages in science career choice and interest in science at different time frames are higher for grade school students than those for high school students. Reasons for the differences can be studied.

How can the Centres’ immediate impact of students’ choice of a science career be maintained in the science classroom? How can science classes sustain, if not enhance, the students’ high level of interest in science immediately after a visit to a Centre? How can schools have the same joy and wonder of learning of learning science as in the Centres? These questions may be addressed by teachers and researchers alike. As an educator, Joseph Galdon, puts it “Learning begins in wonder, or it does not begin at all”.

Acknowledgment
The study was commissioned and funded by the Philippine Foundation for Science and Technology through its executive director, Leticia M. Zerda. The research team, headed by the author, consisted of Cynthia Balbin, Ma. Lourdes Baybay, Eva Baquirin, Rosemary Bumatay, Usha Chander, Haydee Farrol, Mona Lisa Intong, Zosima Panares, Cornelia Soto, Ma. Lourdes Torno, Zenon Abao, Ma. Corazon Huelar, Emelina Montaos and teresa Hernandez. The science education experts were Dr. Violeta Arsiaga, Dr. Estel Ogena and Dr. Vicenta Reyes. The research team acknowledges with many thanks the cooperation of the students, teachers and administrators of the elementary and high schools involved in the study.

1998

June 1 - 5
UNESCO-ASE Science Education Workshop
Location: Weybridge, UK
Contact: Caroline McGrath, The Science Centre, The Runnymede Centre, Chertsey Road, Addlestone, Surrey KT15 2EP, fax: +44 1932 570 161, email: <caroline@sci-ence.demon.co.uk>

June 3 - 5
Utrecht-ICASE International Symposium
Location: Utrecht University, Netherlands
Contact: Dr Onno de Jong, Chairman, Department of Chemical Education, Utrecht University, Princoenplein 5, 3584 CC Utrecht, Netherlands, fax: +31 3 0253 7494, email: <o.dejong@chem.ru.nl>
This conference follows on from the very successful series of symposia at Dortmund University, organised in association with ICASE. The theme will be 'Bridging the gap between theory and practice: what research says to the science teacher'.

July 5 - 10
CONASTA 47 Conference
Location: Northern Territory University, Northern Territory, Australia
Contact: Mr Stephen Zander, CONASTA 47 Secretariat, PO Box 778, Nightcliff, Northern Territory 0814, Australia, fax: +61 8 8999 6976, email: <conasta47@topend.com.au>
Science educators at primary, secondary and tertiary levels are invited to the 47th Annual Conference of the Australian Science Teachers Association, featuring keynote presentations, seminars and workshops on the theme 'Science Education: Beyond the Horizon'. See the conference website for further information: <http://www.topend.com.au/~stant/conasta.htm>

July 5 - 9
SCICON 98 Conference
Location: Nelson, New Zealand
Contact: SCICON Conference, PO Box 1254, Nelson, New Zealand, fax: +64 3 546 6020, email: <scicon@confer.co.nz>
Join science educators from across New Zealand and beyond for the 11th Biennial Conference of the New Zealand Association of Science Educators, NZASE. See the website for more information: <http://nzase.org.nz/scicon.htm>.

July 9 - 12
ASERA 98 Conference
Location: Casuarina Campus, Northern Territory University, Northern Territory, Australia
Contact: Mr Bill Palmer, ASERA 98 Conference Organiser, Faculty of Education, Northern Territory University, Darwin, Northern Territory 0909, Australia, fax: +61 8 8946 6151, email: <palmerew@darwin.ntu.edu.au>
The 29th Annual Conference of the Australasian Science Education Research Association will provide a forum for the discussion of science education research issues. See the conference website for further information: <http://www.ntu.edu.au/faculties/education/asera98/asera98.htm>.

July 14 - 18
Second China-US Conference on Education
Location: Beijing, China
Contact: Conference Secretariat, fax: +1 602 943 4458, email: <global@goodnet.com>
This conference focuses on four themes: Quality of personnel, Quality of students, Quality of parenting, Quality of curriculum.

July 25 - 28
NSTA-NCSA Summer Institute
Location: Northern Arizona University, Flagstaff, Arizona, USA
Contact: NSTA Conventions Department, 1840 Wilson Blvd, Arlington, VA 22201-3000, email: <conventions@nsta.org>
Join teacher leaders in examining the theme 'Making curricular connections in the K-8 classroom'. Topics for exploration include: multiple intelligences, standards-based practices, service learning, performance-based assessment, thematic instruction, project-based learning, planning and managing integration, issues-oriented learning, and literature connection. See the website for further information: <http://www.nsta.org>.
August 5 - 7
International Conference on Learning Science in Informal Contexts
Location: Questacon – The National Science and Technology Centre, Canberra, Australia
Contact: Kayt Watts, Conference Secretariat, PO Box 3182, Manuka ACT 2601, Australia, fax: +61 2 6239 7948, email: ingenue61@bigpond.com.au.
Organised by Questacon as part of its tenth birthday celebrations, in association with the Centre for Public Awareness of Science at the Australian National University, this conference will be the first of its kind in Australia. It will enable researchers and educators from science centres, museums, zoos, botanical gardens, wildlife parks, schools and tertiary institutions to share their views on learning science in response to the growing interest in the role that informal learning plays in increasing people’s understanding of science. See the conference website for further information: <http://sunsite.anu.edu.au/Questacon/conference.html>.

September 3 - 5
International Conference on Science and Technology Centres/Museums
Location: China Science and Technology Museum, Beijing, China
Contact: Mr Ou Jiancheng, International Conference Secretariat, China Science and Technology Museum, 1 Bei San Huan Zhong Road, Beijing 100029, China, fax: +86 10 6237 9378, email: <cstm@ihw.com.cn>.
This international conference is being organised in conjunction with the First Conference of the Asia Pacific Network of Science and Technology Centres and focuses on the theme of ‘Science and Technology Centres and Museums: Educating and Enlightening the People’. The conference will provide a forum for science and technology centre/museum professionals from across the world to share their ideas on how centres of non-formal and informal learning can promote scientific literacy for the general community. See the conference website for further information: <http://www.cicsst.org.cn/bicstcm’98>.

September 24 - 27
International Working Seminar of Scholars for Technology Education
Location: George Washington University, Washington DC, USA
Contact: Prof. Dr. Michael Dyrenfurth, President, National (USA) Association of Industrial and Technical Teacher Educators, 105 London Hall, Technology & Industry Education, University of Missouri-Columbia, Columbia, MO 65211, USA, fax: +1 573 884 4095, email: <pavtnike@showme.missouri.edu>.
The National Association of Industrial and Technical Teacher Educators, the European Society for Technology Education and the World Council of Associations for Technology Education invite you to participate in an international seminar on the theme ‘Outcomes of Technology Education for 2000+: A Focus on Learning: Models, Criteria and Demonstrations of Applied Learning and Assessment Methodologies’. The following themes present an opportunity for the seminar participants to structure their remarks: subject centered and/or interdisciplinary orientations for technology education; what are the key outcomes/benefits that result from participation in technology education; which learning and assessment theories are significant with respect to becoming competent in technology; what are the standards and models for technology teacher education; how can persons with special needs be better served and how can the diversity and inclusiveness of technology education be enhanced. See the website for further information: <http://unesco.uneb.edu/wocate>.

November 5 - 7
Annual Conference of the Science Teachers Association of Ontario
Location: Toronto
Contact: Jon P McGoey, c/o John Paul II Secondary, 1300 Oxford Street East, London, Ontario N5V4P7
email: jmcgoey@quark.physics.uwo.ca
Information is on the website at <www.stao.org>
Calendar

November 18 - 22
European Researchers in Didactics of Biology Conference
Location: University of Goteborg, Sweden
Contact: Dr Fred Brinkman, Secretary, IDO Vrije Universiteit, Amsterdam, Netherlands,
email: <fg.brinkman@ido.vu.nl>

1999

January 7 - 9
ASE Annual Meeting
Location: University of Reading, Reading, England
Contact: ASE Annual Meeting, The Association for Science Education, College Lane, Hatfield, Herts AL10 9AA, fax: +44 1707 266 532,
email: <asehq.telme.com>
The theme of this meeting is 'Science Education in the Computer Age'.
The Annual Meeting of the Association for Science Education attracts science educators from around the world. Don’t miss the substantial program of plenary addresses, papers, seminars, workshops, visits, displays and functions which makes this event one of the largest international gatherings of science educators. Following on the success of the 1998 ASE-ICASE-IOSTI International Seminar, a similar international seminar is being planned to precede the 1999 ASE Annual Meeting from 4 January.

March
ICASE NVON International Seminar
Location: Netherlands
Contact: Miia Rannikmae, ICASE European Regional Representative, Department of Science Didactics, University of Tartu, Lai 40 Tartu EE 2400, Estonia,
fax: +372 7 465 813
email: <miia@queenie.lai.ut.ee>

March 25 - 28
NSTA National Convention
Location: Boston, Massachusetts, USA
Contact: NSTA Conventions Department, 1840 Wilson Blvd, Arlington, VA 22201-3000
email: <conventions@nsta.org>
Join science educators from across the USA and around the world in a huge program catering to the needs of elementary/primary and secondary teachers of science and tertiary science educators. See the website for further information: <http://www.nsta.org>.

September 15 - 19
5th International HPSST Conference
Location: Pavia University, Italy
Contact: Dr Enrico Antonio Giannetto, Dipartimento di Fisica 'A Volta', Universita di Pavia, Via A. Bassi 6, 27100 Pavia, Italy, email: <volta99@pv.infn.it>.
This conference is being held in conjunction with the European Physical Society’s Interdivisional Group on History of Physics and Physics Teaching. The joint conference will contribute to local celebrations of the bicentenary of Alessandro Volta’s creation of the battery at Pavia University in 1799. See the website for more information: <http://www.cilea.it/volta99>.

October 4 - 8
3rd ICASE Latin American Symposium
Location: Curitiba - Parana State, Federal University of Parana, Brazil
Contact: Department of Educational Methods, School of Education, Federal University of Parana, Rue General Carneiro, 460 2o. Andar, Curitiba - Parana, CEP 80 060 - 150, Brazil.
Phone / fax: + 55 41 264 3574
Email: gioppoc@educacao.ufpr.br
The 3rd ICASE Latin American Symposium will be hosted by the Brazilian Association for the Advancement of Science - Parana Section, and will attract science educators from across the Latin American region and beyond.

2000

April 6 - 9
NSTA National Convention
Location: Orlando, Florida, USA
Contact: NSTA Conventions Department, 1840 Wilson Blvd, Arlington, VA 22201-3000.
email: <conventions@nsta.org>.

July 19 - 21
ICASE-CEFIC European Education-Industry Seminar
Location: University of York, York, UK
Contact: Miia Rannikmae, ICASE European Regional Representative, Department of Science Didactics, University of Tartu, Lai 40 Tartu EE 2400, Estonia,
fax: +372 7 465 813,
email: <miia@queenie.lai.ut.ee>.

ICASE Homepage: http://sunsite.anu.edu.au/icase
Science Education International is the quarterly journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

First Nepal Scientific and Technological Literacy Workshop

During one week in March a small but enthusiastic group of Nepalese science teachers met to learn about the UNESCO/ICASE Project 2000 + initiative. Then groups evaluated some of the STL materials developed in the region and elsewhere, before developing their own materials relevant for Nepal. The eight scripts produced are currently being edited for trial in Nepal secondary schools. They include titles such as: *Allow me to breathe comfortably*, *Improved kerosene lamps*, *Pineapple shaped wastebins*, and *The Naulo gaun free sweet story*. These units are very appropriate for use with the new upper secondary Science and Environment curriculum in Nepal, which has a strong emphasis on applications of science in the local community. In Nepal the Centre for Literacy Enrichment in Environment, Science and Technology (CLEST) has defined STL as the ability to understand and relate basic scientific knowledge and skills to everyday life and community needs in one’s own environment. CLEST seeks to promote relevant and meaningful environmental science education in schools and community with an emphasis on practical and personal involvement. For this reason Dr Sharada D Maharjan became involved in organising this first national workshop (previous ones had all been regional) with the help of Ms Annette Gueyva (UNESCO, Bangkok), Dr Jack Holbrook and Patrick A Whittle (ICASE). The workshop could not have taken place without the generous and practical support of Little Angels School, Kathmandu, where it was held. During his visit Dr Holbrook addressed two other meetings of science teachers, one to highlight trends in chemistry teaching at the secondary / higher secondary interface and another to explain the role of ICASE in promoting scientific and technological literacy. It is hoped that the Nepal STL approach will be replicated in other countries. It is expected that, in due course, copies of the trial materials and a report of their evaluation will be made available. Enquiries for further information about the first Nepal STL workshop, and its outcomes, should be addressed to Dr S D Maharjan, CLEST, PO Box 1007, Kathmandu, Nepal.

Update on the ICASE Website
http://sunsite.anu.edu.au/icase

Check out the contact details of more than 140 member organisations of ICASE! Each member organisation with its own website is requested to send details so that a link can be established from the ICASE website.

Find out about the worldwide scientific and technological literacy project called Project 2000+. Exemplars of curriculum materials which have been developed in Project 2000+ workshops conducted by ICASE, will be progressively added to the site as a resource for science teachers.

For further information or to send updates for inclusion on the ICASE website, contact:

Brenton Honeyman
ICASE Past President
Email: brenton.honeyman@questacon.edu.au

ICASE Distinguished Service Award

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

A listing of past award recipients can be found on the ICASE Website at <http://sunsite.anu.edu.au/icase/l_awards.html>

Nominations for this award must be forwarded by member organisations of ICASE. For full details of how to forward nominations, contact:

Dr Jack Holbrook, ICASE Executive Secretary,
ICASE Secretariat, PO Box 6138, Limassol, Cyprus
Email: icase@logos.cy.net
Feature Article

Language and Literacy: a problem for America’s science classrooms

Dr. Randy Yerrick and Dr. Paul Vellom
Assistant Professors of Science Education
East Carolina University and the Ohio State University

Introduction

Most countries of the world hold their visions for education in high regard and science education plays an increasingly important role in defining the success of a national educational system based upon student achievement. Despite the international comparisons and studies of curriculum, teaching, and learning, we contend there are implicit school structures which promote inequity through the use of science content and instruction. Further, we contend that many of these structures fall along lines of language and ethnic boundaries and it is rare that any educational system avoids bias steeped in based language, ethnic, racial, or economic differences. We offer our critique of American schools to provide helpful insight to teachers, researchers, and reformers of national systems who struggle with deeply rooted cultural divisions or who may send students to American schools which have repeatedly demonstrated commitment to change but struggle against the harsh realities of social agendas at work in schools.

American science education reform calls for students to practice the “habits of mind” of scientific communities. Ideally, in a reformed classroom, students interact like scientists and act according to what scientists value as a group. At the same time, teachers are currently being challenged to prepare their students to construct and reflect upon scientific knowledge as opposed to simply receive it (AAAS, 1989, 1992, & 1995; NRC, 1996). The American Association for the Advancement of Science argues (AAAS, 1989) that science “must consist of more than the provision of correct answers” recommending that,

“Science teachers are now assuming greater responsibility for helping females and minorities learn to succeed in these fields (as well as mathematics). With concerns of domestic equity and international competitiveness, science educators must help ensure that all students have equal opportunity to succeed in science-related endeavors.” (AAAS, 1989, p. 166).

Equity and National Standards

Current United States’ science education reform rhetoric reflects a rethinking of what school science should be and promotes a revised version of what it means for students to act in ‘scientifically literate’ ways and practice the ‘habits of mind’ of scientific communities. Further, the evolution of science education reform over the past three decades has been more inclusive than earlier efforts. According to current reform documents (AAAS, 1989; NRC, 1996) ‘all Americans’ can and should learn such implicit values and practices of science regardless of their background or experience.

Included also in current reform vision are the pedagogical recommendations that teachers treat scientific knowledge tentatively, provide students with opportunities to reason using evidence, and help students work collaboratively in groups. Each of these key elements is a valuable component of scientists’ work, reflecting their interactions as members of a scientific community.

The student-centered, problems-based approach to the practice of teaching conveyed in the National Science Education Standards (NSES) intends to give students practice in kinds of real scientific experiences.
The NSES have been developed using a variety of perspectives to reconceptualize the national definition of scientific literacy. These include: 1) constructivist notions of learning and teaching (von Glasersfeld, 1989; Tobin, Tippins, & Gallard, 1994; Driver, Leach, Millar, & Scott, 1996), 2) evolving philosophical representations of the nature of scientific thought and activity (Duschl, 1990; Lemke, 1990), and 3) ethnographic, anthropologic, and socio-linguistic interpretations of thinking, speaking and acting members of a scientific community (Gee, 1989; Michaels & O’Connor, 1990).

**America’s school literacy has been historically prohibitive**

Current reform efforts in the U.S. are the first of their kind and unique in vision from those of the past. The largest science education reform effort in our nation's history was meant to produce the best and brightest scientists in a post-Sputnik era of international competition and commerce (DeBoer, 1991; Duschl, 1990). It is only recently that Americans have grown dissatisfied with the products of elitist visions for schools and their tendency to exacerbate differences between lower- and higher-achieving students. In light of growing discrepancies between majority and minority students' achievement in science, selection of science as a major, and placement into science-related vocations, increased national attention is drawn to the role of schools in promoting fair and equitable learning environments.

The United States is certainly one of the few countries espousing a standard of scientific literacy for all. But our allegiance is somewhat divided and threatens our ability to achieve what we hold up for ourselves as an ideal. Social pressures have molded our schools to serve certain beliefs and social values. For example, we believe that schools should be places in which all students have equal and unfettered opportunity. In opposition to such a belief, Americans also expect their schools to reward students differentially according to their degree of hard work and demonstrated achievement. Rarely is there public discussion of such discrepant egalitarian v. meritocratic beliefs which compete within our schools (Apple, 1979). Unlike other countries which have adopted a focused vision for scientific literacy, and have also accepted the consequences that relatively few students will actually acquire such practices, the United States continues to wrestle with privileging a relatively small percentage of its citizens with discourse which earns them power in society.

American schools have adopted certain structures to deal with such fragmented ideologies in the hope that the illusion of equal access will satiate public opinion—at least the powerful public. One such structure is ability grouping or tracking. To accommodate diversity of all kinds, American schools began to sift and sort the mass influx of students immigrating to this country at the turn of the century (Cohen, 1984; Oakes, 1985 & 1990). Only recently have scholars' critiques of these tracking systems taken center stage in educational reform. Decisions made on behalf of the minority students by parents, teachers, administrators, and evaluators often carry profound socio-economic consequences, without clearly explicating the assumptions upon which they are grounded (Bowles & Gintis, 1976). Some researchers' voices challenge the very assumptions upon which decisions are made (Goodlad, 1984; Cohen 1984; Oakes, 1985 & 1990) and argue that most assumptions are, at best, over-generalizations based upon minimal information, and at worst, overt exercises to reproduce existing societal structures and imbalances. Many scholars argue that without explicating the assumptions used to track, group, or otherwise prescribe educational efforts, great disparities will continue to be propagated in the access to different kinds of knowledge (Anyon, 1981; Oakes, 1990 & 1995; Willis, 1977). Feinman-Nemser, McDermid, Melnick, & Parker (1989) contend that grouping serves the needs of a powerful few, arguing that,

"While many parents and teachers believe ability grouping and tracking enables schools to address the individual needs of a child, research..."
raises questions about the purposes—as well as whose purposes—these practices actually serve.” (Feinman-Nemser et al, 1989, p. 10).

Ability grouping is a school structure promoted as a means to assist students, but instead provides a means to simply manage a more complex problem. It is a problem that will not likely be soon resolved until America recognizes the skewed nature of competing internal ideologies.

Identifying and grouping children through language.

Implicit in the NSES are certain notions of constructivism (von Glasersfeld, 1989; Tobin, Tippins, & Gallard, 1994; Driver, Leach, Millar, & Scott, 1996; Duschl, 1990; Lemke, 1990). In incorporating these notions of constructivism as a means for better understanding the cognitive processes involved in learning, many science educators have become advocates for broad notions of scientific literacy. However, these notions of scientific literacy become problematic when its ideas are not clearly articulated or fully understood by researchers, administrators, and teachers.

In their present form, the NSES provide no arguments or compelling evidence that would encourage teachers or administrators to reflect critically on how well their students are learning, on how relevant the curriculum is, on the lack of ethnic and gender diversity in their advanced science courses, and on the socioeconomic impact of discouraging diverse learners to pursue science-related careers (Rodriguez, 1997, pp. 31).

In short, if things are working smoothly for teachers or administrators, they see little need for change. For example, if a teacher of Advanced Placement physics notices a difference in the ethnic composition of his/her applied general science class, s/he may construct or adopt a variety of rationales for why this may seem normal or even appropriate.

While separating children into ability groups by race or ethnicity is often frowned upon, it is a more esoteric decision to place students into ability groups based upon their ability to speak English fluently. Despite the flawed assumption that intelligence and primary language are one and the same, students are often assigned special classes in school and are pulled out of regular classes for special help on the basis of their control (or lack of control) over the dominant discourse. In some cases, students’ home-based discourses actually served as detriments to their school success, participation, and ultimate membership (Au, 1980; Heath, 1986). It would be quite a different matter if schools were identifying ways in which home-based and school-based discourses could best be mapped for future scientific inquiry, engagement, and ultimate success. Schools instead use such language labelling and grouping to privilege those students who are already privileged. As Michaels and O’Connor (1990) have eloquently stated, “If you don’t come to school already controlling elements of the discourse, it never gets unpackaged for you.” (p. 24)

Venues which promote stratification, and seeds for change

Tracking is a complex and deeply imbedded practice in American schools, and both recent and past research has shown that it occurs for both organizational and social reasons (Oakes & Guiton, 1995; Garet & DeLany, 1988; Kerckhoff, 1976). Studies of the relationship between high and lower tracks and students’ career aspirations have shown that lower tracked students are significantly more likely to believe that they are suited for working-class jobs, rather than scholarly or professional positions (Rosenbaum, 1980).

Intertwined with these findings must be the current relationships between social class and access to school knowledge, particularly as illustrated by Anyon (Anyon, 1981). Students from lower SES schools tend to experience knowledge as disconnected, discrete pieces of information, and are less likely to see what they learn in school as relevant or important in the world in which they live. And, many students in lower track classes in middle-SES schools have similar experiences.
So, how do the children of recent immigrants fare when they enter American schools, especially in terms of tracking in a system where higher tracks provide access to (and in fact often support the development of) the dominant discourse? Oakes and Guiton, in their 1995 study of three California high schools, provide two examples of common barriers:

"Curriculum prerequisites were partly responsible for limiting less successful students' course taking opportunities. Foreign students at Coolidge faced difficulties in meeting college admissions requirements because they had to complete ESL courses before moving into college-prep courses. At highly competitive Washington, the screening process for college-prep science was stiff." (p. 15).

Within this example, we can see that both the structure of the curriculum and the social structure of expectations served to limit non-native language students' access to the higher tracked classes. In essence, the system served to direct students who faced challenges with language into the lower and middle track classes, where what is learned is less likely to be empowering to them in career and school endeavors, and which represents less robust images of complex subjects like science. We are confident from the multiples of examples in this research tradition, and from more recent discourse-based studies of science classrooms, that the trend illustrated here is widespread in American schools.

We draw upon the current research from Haitian immigrant (Ballenger, 1994; Warren, Rosebery, & Conant, 1989) and Hawaiian children (Au, 1980) to assist us in our understanding and work with local rural black populations. Mexican migrant workers, and poor, at-risk Caucasian children who attend the public schools we serve. We intend by no means to trivialize the plight of any one group or to generalize that the problem is the same for each group in each school. Rather our intent is to use examples from our and others' research to draw attention to regular school events and artifacts of tracking that might otherwise be obscured. The following represents an insider's critique of school structures and recommendations couched in our own teaching, service, and research.

Explicit and Implicit Curricula

We maintain two concerns regarding the explicit and implicit curricula offered to ESL students and other students falling outside of the college-prep track. Specifically these are: 1) the treatment of and access to knowledge, and 2) the explicit guidance students receive around standard course offerings.

Traditional science curriculum is highly compartmentalized and linear in its structure. If students have not entered in on the bottom level at the right juncture, then there is little opportunity for students to enter the higher level science at any point in their high school career. In addition, if students struggle with any one of the core courses offered, they risk falling out of favor with the rest of the system on the basis of incomplete pre-requisites.

The nature of knowledge that students have access to in different classes is quite varied. By way of example, consider the disparate definitions held for skills, competencies, and attitudes between two extreme student groups. Curricular and assessment artifacts reveal that groups of advanced placement students are expected to value sustained lines of logical thought, to invent and construct multi-faceted proof, improve themselves through competitive norms, and to thrive in a performance-based venue (such as the annual AP test). These explicit outcomes, and even the more tacit ones, differ from those held for lower track students. Curricular documents reflect the value of learning basic skills and performing computations. Concerned teachers look into the eyes of alienated youth and hope these students can learn to buy into school long enough for it to "pay off," that students may "make something of themselves," and become productive citizens in "what they are good at", and perhaps even learn to adapt in difficult family and social environments. In this way, the implicit as well as explicit curricula convey to students others' beliefs regarding their abilities and continue to maintain definitions of student skills and content competencies filled with
implicit social, political, and economic factors that shape the lives of children.

When teachers describe to us their school offering five or more different levels of biology, we can usually guess where the students who struggle with English are placed. What is alarming to us is that students who have been directed to take a more general science course quite often are receiving little additional assistance in mastering the content and language in the context of that class. These students may also carry a collection of other courses prescribed to them based upon a counselor’s direction which include Home Economics, Masonry, and other vocational courses. The school science curriculum is rigid and unforgiving for students who cannot keep pace or balance across all upper level core courses. In addition, counselors may serve as the gatekeepers of the system steering unwelcomed students away and reinforcing a homogeneously upper echelon. A strong illustration for us is the racial imbalance as we walk across the hall (or sometimes to the other building) from the homogeneously sorted accelerated students and see a collection of minority students who have an entirely different membership within the school—the same schools that label poor, black children minorities even in the contexts in which they are by far the majority—clearly an indication of the power of a dominant school discourse and the conformity it demands.

Redefining science curricula in the lives of all students is essential. Benchmarks (AAAS, 1992) is but a beginning for describing a new set of science standards for a variety of students and levels of understanding. Accepting the view of literacy implicit in the NSES implies new criteria for understanding and measuring scientific literacy. Adopting NSES signals a radical departure from traditional understandings of what it means to teach and learn science. Indeed, what is being called for here, is the intentional scaffolding and teaching of the discursive practices of science. In other words, achieving scientific literacy will require spaces where students and teachers engage in meaningful social practices which reflect those of scientific communities. Talking and doing science is culturally specific and must be learned as such.

Science Teachers

Traditional ways of assessing instruction have been to examine mainly how smoothly a particular lesson has progressed, and how well the teacher has handled managerial aspects of teaching. In classrooms in which there are many types of activity structures (e.g.: group discussion, lectures, group work, projects, laboratory experiments) teachers need to understand and know how to convey the rules for participation. These activity structures have built-in sociolinguistic patterns that are not always explicit. Many teachers who are reflective about their practice can easily recount innumerable examples of struggles with ESL students or other students in lower track classes. While teachers may have been socialized to equate struggles with failure, these same instances can provide insight into teachers’ practice. Classroom conflict can be an opportunity for teachers and their students to learn something explicitly about one anothers’ differences. In doing so, teachers not only gain the knowledge to anticipate potential points of conflict, they establish a place in which negotiation and true cooperation can begin.

Classrooms must be places where meaning is negotiated, but must also be places where the rules for obtaining those meanings are negotiated. Teachers should engage other teachers in critical examinations of their own learning experiences and teaching practices, and how these are related to their conceptual framework of what the teaching and learning of science is about. Teacher research becomes an important tool for accomplishing this an alternative learning experience for teachers to experience the above endeavor. Providing resources and rewards to teachers without structuring obstacles will not be sufficient to develop wide-spread successful scientific classroom communities.

Teachers are not always prepared in their teacher education programs to address diversity or issues pertaining to ESL students, nor are they experienced in learning science
in the way they are expected to teach. Teachers need some meaningful and rich ways of understanding concepts for themselves as well as delving into, for example, students’ conceptions and ways of assessing students’ learning. Teachers need the assistance and input of a variety of specialists and institutions in order to be successful with ESL students. Teachers are overburdened by a system that has failed not only students but them as well. Because of the lack of support offered and the challenges associated with teaching students homogeneously sorted based upon their failure in school science, few veteran teachers volunteer to teach such classes. The result is the passing of enormous responsibility to teachers of minimal experience with a marginal understanding of available resources and support for language assistance.

Community

Finally, we implore communities to work together for resolving the local biases manifest through cultural and historical practices. We must all consider ourselves in need of cultural enrichment. Floden, Buchmann, and Schwille (1994) contend that all homes are culturally impoverished, arguing if is good for minority students to learn English, then English speaking students would be equally enriched by learning another language. Floden et al call upon educators everywhere to intentionally and earnestly “break from experience,” for it is the commonality of everyday experience and our comfort within it that enslaves us.

The belief that good schooling requires continuity is an invidious myth. Breaks are necessary for all children to think and act with a sense of method and ideas that reach beyond the immediate. (Floden, Buchmann, & Schwille, 1987, p 494)

Communities need to help their schools understand the importance of finding science in the lives and talk of its children and how to best link up through issues based education or other types of partnerships. As demonstrated by many past and present efforts (Au, 1980; Ballenger, 1994; Heath, 1983; Warren, Rosebery, & Conant, 1989), school policies and practices can change to assist ESL and other students at-risk of falling through the cracks of an American system with divided loyalties. Change will not come in the form of science remediation for students, or even specific language tutoring alone. Let us not be misled. Breaking from experience will be a difficult and uncertain task, but the enrichment of all students’ lives will be the reward of those who act.

Final Comments

Scientific discourse is quite different from most home-based discourse, and the different rules of discourse should be made explicit if we want persons outside the discourse to have access to it (Delpit, 1988). Scientific discourse, as modeled through science education reform, is one which needs to be acquired and not learned (Gee, 1989). Introducing a foreign discourse (such as science) into cultural context presents different types of challenges in each setting, and the progression of change from home-based to science discourse should be explored with the goal to develop ways for not just replacing one type of discourse with another. Rodriguez argues,

“Perhaps one of the greatest strengths of the NSPS is that it intends to an issue that sociologists of education have been pointing to for years: that there cannot be changes in the culture of teachers without supporting structural changes in the institutions of schooling.”

(Rodriguez, 1997, p 21)

Reforms, despite their national allegiances and contextual origins, challenge us to create ways that all students, including poor students and students of color, can learn scientific discourse and at the same time not give up their home-based discourse-their identity outside the science classroom. Differences in students transcend language, race, gender, and ethnicity and, since science is such a major component of our intra-and international comparisons we must all pay close attention to the implicit structures and artifacts of our nations’ schools. We must refrain from labelling and prescription in light of new findings and definitions of schools and science and assistance if we hope to assist students in the quest for any kind of national vision for equity.
in science. Instead, we should focus our efforts on sustaining connections between culturally-based and scientific discourses and sharing our knowledge to keep school science from promoting inequity.

SCHOOL LINKS INTERNATIONAL 1999
Celebration of School Science

Join hands across the world by sharing your science with a school from a different culture. Simply work on a similar theme and tell each other what you learn. Then join in our ‘Celebration of School Science’ by telling us about it. We’ll help with contacts and ideas. So don’t be left out!

All participants will receive certificates. The best group will be part of an international ceremony.

This project is being organised by the Association for Science Education (ASE) in cooperation with ICASE and UNESCO. For further information about how you can become involved in this project, please contact:

Operationalising Scientific and Technological Literacy
- a new approach to science teaching

Jack Holbrook
ICASE Secretary

I could repeat my example in many different areas where science impinges on our daily lives yet where school science education is of little use. Although school science tries to develop conceptual understanding in students and an appreciation of the way scientists do things, its relevance to society is suspect (Pak, 1997; Yager, 1996). The understanding and scientific method tends not to be relevant for functionality in our lives i.e. relevant to the home, the environment, future employment and most definitely for future changes and developments within the society. Rather the understanding tends to be geared to internal concepts within the subject itself. Concepts such as pressure or chemical bonding are almost universally chapter headings in science courses, yet in daily life, inflating car tyres correctly to minimise accidents, or selecting appropriate moisturising creams for the skin, are much more relevant starting points.
To a large extent science education in schools is not relevant (Champagne et al., 1985; Lederman, 1992; Novick and Nussbaum, 1981; Osborne and Freyberg, 1986; Ryan and Aikenhead, 1992). Largely, this can be suggested because it puts the subject first, the application second. It forgets that relevancy is in the processes and products we utilise, and only afterwards in the understanding by utilising scientific principles. Thus, in terms of relevant conceptual learning, it would seem the approach is suspect. It would seem we need to take note of the situation first so that the conceptual learning that follows can be seen by students to be relevant (Holbrook, 1994).

And relevancy goes beyond the acquiring of knowledge or conceptual understanding. It encompasses also attitudes towards the learning of science and the making of decisions geared to societal concerns e.g. ensuring sustainable development and the development of social values. These are areas that are rarely considered in science courses. Science courses forget that whilst education encompasses such goals, science education is an integral part of this very same education.

Scientific and Technological Literacy for All (STL)

Taking all the attributes and, for want of a better term, the relevant education for which we strive can be expressed as ‘Scientific and Technological Literacy’ (STL) (Holbrook, 1997). Unfortunately this is not a static target and also can be achieved in various levels (BSCS, 1993; UNESCO, 1997). And as a concept, there is no specific definition. It is ‘scientific’, because most definitely science concepts and the manner in which problems are approached (scientific method) are very much relevant to an understanding of our world of today.

It is ‘technological’, because, for relevancy, the processes of technology are heavily intertwined with those of science. It is probably fair to say that whenever you look around, it is the products from technology that you see; not the science. Yet the process by which the products are formed are likely to be based on scientific as well as technological know-how.

And ‘literacy’, because it is no good having conceptual understanding if it can’t be utilised. It is no good knowing science if it cannot be communicated to help solve problems or handle decision-making for concerns within the society. It is also no good if science education does not contribute to the development of social values, personal interests, personal responsibilities and career enhancement. And finally, it is no good if science education in schools is not preparing students for the world of tomorrow, able to face up to the multitude of changes and challenges - if you will, coping with change and learning to learn.

The literacy component

Even in situations where the scientific and technological learning within curricula can claim relevancy, the literacy aspect is sadly missing. Literacy is an area that goes beyond the textbook. It is an area that depends on the vision of the teachers, the recognition of research findings that stress the advantages of student involvement, constructivist approaches and the role of the teacher as a facilitator (rather than provider of knowledge). In some countries, the inadequacy of worksheets, unless used by teachers merely as support material, is of grave concern because they pay scant attention to the literacy dimension.

On the one hand it is the literacy dimension that suggests relevancy in science education curricula has a uniformity across education systems around the world. The striving for conceptual understanding and the process of tackling problems in a scientific manner have worldwide applicability. But, on the other hand, relevancy means that curricula around the world need to reflect the concerns, priorities, customs and heritage of the local society. In this aspect of relevancy, the context for science curricula needs to be unique to the different societies.

Education for Scientific and Technological Literacy

STL education sets about preparing citizens for life within the society, both for today and the future. By preparing for life within the society, it is intended that students acquire skills and attitudes so as to be able to:

(i) undertake further education of choice and be empowered to secure rewarding employment;
(ii) function in a positive social manner within society;
(iii) adapt to, and be prepared for, change in the future;
(iv) play a responsible role as a citizen within the society.

The goal of science education can surely be nothing less than to aspire to STL. This means it is a much more human, caring approach than an academic
pursuit, even though it still leads to an appreciation of the scientific method and the acquisition of scientific concepts. An important goal of science teaching is to meet the challenge of operationalising STL.

**Teachers teach students, not science**

So far, the approach to combatting the tremendous changes in modern technology, has been to design new curricula that strive to incorporate a more up-to-date image by including topics such as biotechnology, plastics, electronics, etc.

But surely this is not the answer. This merely modernises content. Such science education still carries an image of isolation from the needs of the ordinary citizen. The conceptual understanding is still inwards looking towards the subject discipline. And if we are not careful, science continues to be associated with pollution, danger and health hazards. The term ‘chemical’ refers to something poisonous and definitely not to be found in the home. The average person continues to be ignorant that foodstuffs are chemicals, the multitude of painkillers and other pharmaceuticals used at home are chemicals and even the petrol used in the car or the paints and other decorations of the home are also chemicals.

So what is the answer? Obviously it would not be fair to claim any one approach can be the sole response. Changing public opinion by attempting to combat ignorance of the role of science education is certainly a factor. But the factor put forward here, which has not received the attention it deserves, is perhaps the major component for the lack of change in school teaching of science subjects. That factor is *the vision of science teaching by teachers themselves.*

Perhaps more than in any other subject area, science teachers perceive their task as teaching the subject matter (Aikenhead, 1997). They see their task as imparting knowledge and understanding of the principles that underlie this knowledge (Romberg, 1985). The feeling is so strong that ‘completing the syllabus’, as exemplified in the textbook, is a common science teacher cry. Experimental investigations are given a low priority, especially if the external examination places little weighting in this area. Assisting students to develop skills of problem solving is not taken seriously, unless this simply means tackling a variety of numerical problems. Time is certainly not to be set aside for planning an investigation and then carrying it out, or for decision making situations where the answer is not clear cut and a multitude of factors can influence the decision, such as economic, social, environmental, political, or ethical considerations.

It would seem that teachers continue to teach the content of the subject for a variety of reasons. One important factor is that textbooks, for the most part, ignore non-conceptual areas, preferring to include applications within the society of science concepts studied, rather than starting from society’s way of utilising science. The textbook emphasis and approach, of course, is heavily influenced by the manner in which the curriculum is put together. For convenience, curricula are almost invariably put together based on science fundamentals, grouping science concepts together for scientific convenience. Curricula rarely group learning based on the way society makes use of science e.g. for solving issues/concerns in the kitchen, the bathroom, the local environment, industry and employment.

**Avoiding change**

Evidence suggests that teachers try to avoid change, especially change that demands their expertise may be undermined (Aikenhead, 1997). Science teachers have not had to deal with the development of societally useful problem solving or decision making skills in the past. Teachers have not had to deal with the development of the student as a member of society, or the development of societal skills (so as to be a responsible member of society) during science lessons in the past. Thus science teachers are uneasy about bringing ethical or social values into the science classroom, even when these have great relevance to the society (Gaskell, 1982).

So what happens, if a curriculum led change is contemplated? If the curriculum tries to introduce a greater range of educational skills and for this, reduces the science content, teachers tend to utilise this ‘extra’ time to delve more deeply into the subject matter. Teachers avoid the incorporation of student centred activities such as brainstorming, role playing, small group discussions, and creative activities such as developing posters, composing letters to officials, raising environmental awareness and participating in debates. These do not move the content forward. Teachers’ practical knowledge determines classroom practice (Duffee and Aikenhead, 1992). Even activities that have the potential to increase content knowledge are avoided e.g. library searches, location of secondary information sources, because these would not be under the control of the teacher.
The science teacher is thus happy teaching the subject. Their efforts are increasingly irrelevant to the modern society. They ignore cries for more feeling and caring in science lessons and a greater societal relevance. They have been given a subject curriculum and covering that is their perception of their task.

Teachers teach the way they are taught! (Gregorio, 1997) As a consequence, science becomes impersonal, increasingly irrelevant and in the hands of uninterested teachers, a memory exercise. It is in changing this viewpoint that Science Teacher Associations need to make headway (Haggis, 1991). These neglected areas in science education are important in educating students. No wonder in the past students found science difficult; no wonder girls tended not to choose this option; no wonder primary school teachers shied away from teaching science.

So what can be done? How to operationalise STL?

No innovation in science education has been successful without the support and expertise of classroom teachers’ (Holbrook, 1996; Pak, 1997; Purkey and Smith, 1982; Roy Singh, 1991; UNESCO, 1997). Helping and supporting the teacher is crucial.

First and foremost is the need to change the teacher’s perception of what science teaching is about. Science teachers need to be guided to teach students. And this means playing their part in meeting the educational goals put forward for schooling. Science teachers must realise that education is not solely about concepts and content, but requires attention to personal and societal skills, to ethical considerations and above all, it requires attention to the affective domain. Science education must be seen as part of education.

Whilst this is easy to say, it is not so easy to put forward guidance as to how change should be achieved. But at least 50% of the battle is in getting science teachers to perceive they need to change; the curriculum is wanting them to change and the society as a whole (this influences the Ministry of Education) wants them to change.

The task before us is to get science teachers to change for a new image of science education - STL for All. This image cares about the students as individuals. Science teachers reflect on how to teach students, not content. Teachers develop new approaches to teaching that encompass a greater degree of student-centred teaching (Gunstone, 1997), more attention to relevance within the society, to values education and above all, science teachers give attention to the development of personal qualities and positive attitudes towards the role of science in the society.

Without doubt, contemplating change means teachers need in-service support. But this in-service provision needs very careful consideration to address the real needs of teachers (Cho, 1997). Telling teachers to change is not likely to help the situation. They need to be shown how, and to appreciate why, this is the manner in which to change. Teacher trainers must be convinced of the need to change and for change to actually occur, teachers need to be convinced how the change can be successfully implemented.

Convincing teachers to embrace change

Two aspects are put forward here.

(a) One aspect is to provide research evidence showing change can lead to substantial gains by students and, very importantly, that students do not suffer in their ability to pursue science courses at a higher level (Boyer, 1983; Byrne and Johnstone, 1988; Goodlad, 1984). Such evidence is also needed to convince University science faculty staff, who are often the most skeptical of all persons involved in school science curriculum development. University teachers’ concern is that students will gain the required background and prowess to cope well with the demands of University science courses and, if coped with successfully, to then be able to continue (even though this applies to only a very, very small number of students) and be able to pursue scientific research.

What research evidence there is, shows that pursuing higher order thinking skills is more rewarding for students than factual memory exercises, even though they cover less material. Research evidence shows that positive attitudes are enhanced by greater societal relevance and by more student involvement, even though content coverage is much lower. And research evidence shows that positive attitudes leads to greater academic gains. Provided the examination, or the student assessment indicator, are well prepared, the students achieve higher when showing a more positive attitude towards the subject and are able to use a range of educational skills (Kellerman, 1993; Liu, 1997; McCormack, 1996; Weiss, 1993).

(b) A second factor is providing suitable in-service courses (Yager, Hiddayat and Penick, 1988). One approach that shows signs of success is to encourage teachers to reflect on the changing needs of science
education and then, with this in mind, to develop supplementary teaching materials that meet this need. Science Teacher Associations (STAs), whether large or small, can play an important role in this provision. Teacher workshops which pay great attention to the philosophy of STL, as developed by ICASE (Holbrook and Rannikmae, 1997; UNESCO Resource Kit on internet), can get teachers better prepared for science education for the 21st century. Giving teachers ownership of this philosophy, by teachers creating supplementary teaching materials which meet STL criteria, becomes the main focus of the workshops.

Criteria for Exemplary STL Materials
The criteria being suggested for the creation of exemplary STL supplementary teaching materials (Holbrook, 1997; Holbrook and Rannikmae, 1997) are:

a) Promotes student achievement in a range of educational goals
   - a wide range of education goals are stipulated and form the major focus of the material i.e. students are participating in the process of educational learning, appropriate for the goals of the country and their intellectual development. These goals not only relate to science concepts and scientific method, but also include social values and the development of personal skills.

b) Starts from a concern or issue in society
   - the material is societally related and draws on an issue or concern within the society. Students are familiar with the situation, can thus appreciate its relevance and are able to build on constructs already formed. The material is directly relevant in the eyes of the students. Creating material on pressure, or bonding or photosynthesis is not, it is suggested, directly relevant because the relevance is not overt. Creating materials on the correct inflation of car tyres, moisturising the skin, or the Amazon rain forests is relevant. The relevance is clear even though the conceptual science may not have changed.

c) Involves demanding (higher order) thinking skills
   - undertaking the activity is an appropriate learning exercise for the learner i.e. it provides an intellectual challenge at an appropriate level for the students. It utilizes constructivist principles - moving from information and understanding already in the possession of students, to the new learning situation. It involves analytical or judgemental thought.

d) Student participatory
   - the teaching approach and activities are designed to be student participatory i.e. students are involved either individually or in groups for a considerable amount (>60%) of the teaching time. This does not necessarily mean that the teaching material is experimentally orientated (although this is considered important), but it does mean attention is paid to the incorporation of a variety of teaching approaches through which students can participate.

e) Includes a communication skill component
   - due consideration is given to enhancing a wide range of communication skills appropriate for the dissemination of scientific ideas and social values.

f) Relates to science education
   - whilst the material links science teaching to social science, particularly by the scenario from which the material is developed, the teaching still contains a substantial component of 'standard' science and students are given ample opportunity to acquire scientific concepts. The material is definitely education through science, not a social science add-on.

g) Includes a comprehensive teacher’s guide
   - as problems, issues and concerns coming from society are often interdisciplinary in character, with the science ideas unfamiliar to the teacher, full explanations are needed to help teachers make use of the materials in a meaningful and interesting manner.

How should teachers acquire this direction and utilise STL materials?
The simple answer is for teachers to participate in STL in-service courses, be introduced to the criteria and then to try to create their own teaching materials. If teachers can do this (and it is by no means an easy task) and the newly created material reflects the new direction of teaching, then by using this they will be operationalising STL in the classroom (Rannikmae, 1997). The new material will take into account automatically the widening vision of science education.

If teachers choose not create the material themselves, but use existing material, they still need to ensure they are conversant with the new STL vision of education. This means they need to accept the idea that science education starts from a social concern or issue before progressing to the science method and scientific concepts. And that science
education involves social values and personal
development as well as science conceptual ideas.

**What else needs to be considered?**

A teaching goal, often stated in developed countries,
is that the teacher needs to become a facilitator,
helping and guiding the students, rather than a
fountain of knowledge, reproducing the textbook. STI
materials are designed for this.

Teachers will not wish to use the materials all the
time. The materials are not the actual curriculum. The
materials are simply ideas to guide and change the
direction of teaching. Teachers use the materials as
and when they feel it appropriate. But their use is a
start along the crucial path of change.

The approach to using the materials and exemplar
materials is described in Supplementary Teaching
Materials, an ICASE publication. Single copies are
available free, on request, to STAs that are members
of ICASE. Individuals can purchase a copy (£12.50
sterling, including postage. Contact the ICASE
European Representative - address given at the front
of the journal). The approach, and additional
materials, are further described in a Resource Kit
being compiled by UNESCO (contact STE,
UNESCO, Paris) and additional materials are given in
an Asian publication by UNESCO, Bangkok. A future
article will elucidate exemplary teaching materials
developed in this manner.

**Introduction**

Chem 0722 is an important subject in our Chemistry curriculum in the applied experimental chemistry department. This subject is a formal way of teaching students about research by studying the primary literature. Until recently we relied on a classical approach. Due to low student participation, we have revised the format entirely. Some authors have expressed similar dissatisfaction (Felder, 1988; Blackburn and Wiseman, 1990).

The applied experimental chemistry group at UNAM-Cuautitlan consists of six faculty members, and five to twelve senior majors graduate each year. All majors are required to take Chem 0722. The academic calendar consists of three 10-week terms and classes for one hour each week throughout all three terms. Students receive a single grade at the end of three terms and receive credit equivalent to a normal lecture course.

**Former Model**

Initially we followed a fairly typical design for our subject. During the fall term, each student selected a topic from a list provided by the faculty, for instance polymer chemistry. A leading reference to a recent research article was included with each topic. The student then wrote a short report, which was due at the end of the term. All classes during the fall term were given by the faculty and by invited speakers. In the fall term each student gave a 30-minute seminar based on the topic selected. Students were also required to write an expanded report paper, which was due at the end of the term.

During the spring term, students gave a 50-minute presentation either on their independent research project or upon a new topic. In fall and spring terms, classes by invited speakers were programmed during the semester.

The students made two presentations, wrote two papers, and attended more than 30 sessions.

Every year the faculty were unsatisfied with the result of Chem 0722, and we decided to modify the format because four problems were present:

- Too often student presentations demonstrated little work beyond reading a single research paper.
- The paper topics were not connected in any way, so there was no reinforcement of any of the material. After learning thirty different topics, students retained little.
- Most of the time, the students were not very active. Except when presenting his or her paper, a student simply listened to the presentations. Students were not asked to demonstrate that they had learned any thing (for example, by exams or quizzes).
- At the end of the year, students had read relatively few papers as part of the class activities.

**Novel Model**

Several years ago during the 1994 fall term, we decided to completely change our Seminar format. In doing so, we first formulated our goals. We
wanted students to learn to (i) read the chemical literature, (ii) discuss the literature, (iii) present a seminar, (iv) write a short paper, and (v) evaluate research strategies. Finally, we wanted them to get excited about research and research literature. To achieve these admittedly ambitious goals and to avoid our earlier problems, we made a number of changes in our approach to the learning-teaching activities. First, we decided to choose a specific topic for the presentations each year. For example, the first year we studied analytical chemistry techniques, and the second year we reviewed some topics in industrial chemistry. This action alleviates some of the disconnectedness of the old format.

Other seminar series have been organized around themes - for example, talks by alumni (Hill, 1978) - but our approach allows building upon the material learned each week. We also realized that giving everyone a common topic would allow students to participate more actively by the previous reading of the materials during others' presentations. Therefore, we now require from the students a discussion in addition to a presentation and besides the former activities, a group of four students has to make one video related to the presentation theme. This video should have fifteen minutes of running time.

As mentioned before, during the fall term, each student chooses a topic from a list provided by the faculty, accompanied by a leading reference, and a date is assigned for discussion. Each student then is responsible for reading and understanding the article. This, of course, involves further literature reading and background preparation in addition to carefully reading the paper. The student provides the paper and a list of discussion questions one week before the assigned presentation and discussion. The selected questions must be reviewed by one faculty member, before being distributed to the group. The student then leads a discussion of the topic and is graded upon his/her knowledge, preparation and quality of the presentation. Other students are given a satisfactory or unsatisfactory grade based on their participation on the discussion and questions. The list of selected questions not only helps students understand the paper, it also keeps the discussion focused. Students submit a short (4-6 pages) paper on their topic at the end of the term. Written evidence for a CAS on-line search must be submitted with the paper.

For the end of the fall term, students find a new topic within the common subject area, which must be approved by a faculty member, and they give a formal 45-minute presentation. It is required that the student practices in front of a single faculty member at least one week before the formal presentation. The student provides to the faculty and other students one leading reference for reading before the presentation. Participation by students in the audience during the answer/question period after the seminar is marked satisfactory/unsatisfactory. At the end of the term, each student submits a written 6 to 10 page paper on his or her topic.

By spring term, we feel that we have sufficiently explored our common topic. Each student makes another presentation, but the subject matter is unrestricted. Most students present the research from their independent study projects. Also during spring term, we invite outside speakers from nearby universities. It has become a tradition in the spring term to convene the junior chemistry majors to discuss the subject of Chem 0722 for the next year.

Table 1. Comparative analysis of the activities for the old and new format of classes in Chem 0722

<td>- get involved in the research process</td>
</tr>
</tbody>
</table>
Grading of discussions and presentations and criteria for the students' participation are discussed and shared by faculty members. Comments by faculty are recorded on a standardized form. It includes: student understanding, quality of discussion questions, ability to explain details, evidence of research and preparation, other comments and grade. A faculty member collects the comment sheets and discusses them with the student.

Students submit two copies of each paper, and two professors grade the papers independently. Each student receives the average of the two grades.

Discussion

Although we instituted the discussion requirement with hesitation, it has certainly been the most successful component of the Chem 0722. After four years of working under the new model, our students are very proficient at having discussions. They know how to support their point of view. Having topic areas with pertinence outside of chemistry generated more interest. Frequently discussions consumed more than the allotted time with no impatience shown by the students. Another benefit of the discussion is that the written papers are improved by the results of the discussion; weaknesses demonstrated in the discussion format can be addressed as the student researches and writes the paper. Finally, we have found that in the past three years, students are much more likely to ask questions at the end of formal presentations than they were in the past. We attribute this difference to the open atmosphere established by the group.

We want to point out that it is important to choose topics that are interdisciplinary within chemistry. For example, in the chemistry of the five senses (taste, sight, etc.), papers are largely biochemically oriented. This topic is reviewed in the first semester, which covers all areas of chemistry. Another problem is that in finding their own articles, students are tempered away from the primary literature for example by articles in Chemical and Engineering News or in the A-pages of Analytical Chemistry. We now encourage the students to have one research article and one article written for a more general audience. Both articles are discussed.

Finally, in their enthusiasm, professors sometimes take over the discussion. The student discussion leader usually is reluctant to assert himself or herself to regain control. To solve this, we have a single faculty responsible for discreetly directing attention back to the student. In fact this was a problem we had under the old format during the questions period after the presentation. We now apply the same solution during the questions period as well.

Conclusions

We have developed a new format for our Seminar with which both students and faculty members are very pleased. After three years in practice, we find that the new format encourages discussions, requires more reading and active participation and is more interesting than the former format.

Science Graduates’ Understanding of Science Processes

Hafiz Muhammad Iqbal, PhD
Department of Science Education
Institute of Education and Research, University of the Punjab,
Quaid-e-Azam Campus, Lahore, Pakistan

Introduction

About three decades ago when studying at college level, we were given the definition of science as “a collection of facts” or “an organised body of knowledge”. This view of science had implications not only for science teaching in the class, but for the development of curriculum, text-books and assessment practices as well. Text books of science gave information about those facts in an encyclopaedic manner and teachers transmitted this information to their students in expository fashion. Many times, text book recitation was a predominant method of teaching science. When it came to the assessment of students’ achievement in science, maximum care was taken to test memorisation and recall of facts.

Many years later, during professional training, we were told that science is not characterised only by “product”, that is, facts and information gathered by scientists over a long period of time. Contrary to this popular view, the way of collecting this information is also important. Then science is described as scientists’ ways of working and arriving at certain conclusions. That is, ‘processes’ of science are equally important as the ‘product’ of science.

But, paradoxically, this nature of science has not been emphasised effectively. Like many other developing countries, teaching and learning of science in Pakistan remained almost unchanged for years. Even today, the ‘product’ nature of science is kept in front and the process aspect behind. Despite their widespread recognition and importance, process skills are neglected in typical curricula. One reason is that many teachers are not trained to teach these skills to students. Thus, in spite of theoretical pronouncements at various occasions, actual practice of classroom teaching is the same as it was 30 years ago. Development of science process skills, an inquiry approach and constructive learning is still a distant reality. Many educators of science today believe that teaching of science that emphasises a traditional view of science has little pay-off. Development of real understanding of concepts and ideas in science necessitates the use of activities that provide students with opportunities of manipulating the material and exploring ideas by themselves. Use of science process skills during science teaching is as important as teaching of science itself. As Carre (1981) puts it:

“Modern science curricula are meant to provide a grounding for understanding the nature of scientific knowledge by developing the intellectual processes of science. The discipline of science demands a range of mental activities, processes such as classifying, communicating, controlling variables, designing experiments, interpreting data, hypothesising, predicting, and ....the most of all observing. But the point of these activities may be lost on many of the pupils if they are not accompanied by complementary activities which provide opportunities to reflect upon what is being done” (p. 6).

Similarly, Harlen (1983) further explains that there are two components of science. Firstly, the knowledge of specific facts and general concepts and secondly, the processes or investigation skills and
attitudes related to conducting an enquiry and finding out solutions to problems. The first component is called 'product' and the second the 'processes'. Both components are essential for learning and understanding science. Neither can be ignored. Both are part of the process of understanding nature.

It is because of this realisation that modern science curricula in many parts of the world have been changed drastically. These curricula put great emphasis on these skills in addition to imparting knowledge to students. During traditional teaching students are explained a particular topic or concept, and then at the end of a week or so they are required to spend about two class periods on practical activity. These experiments are meant to verify certain facts and prove, for example that the melting or boiling point of a substance is the same as given in the text. If the purpose of such activities is to help children learn specific facts about their environment, it will be achieved, though not to a considerable extent. On the other hand, if the purpose of science teaching is to develop concepts, more general ideas or enquiry skills that would help children to learn more about the environment through their own enquiry, such laboratory activities will not suffice. There is a need to provide multiple opportunities for exploring and manipulating materials, the cumulative effect of which will help develop general ideas and enquiry skills in children.

Science Processes

Harlen (1983) provides a list of skills relevant to young children. These skills are:

a. observing;

b. raising questions;

c. proposing ways to answer questions through fair tests or comparisons;

d. finding patterns in observations;

e. applying ideas to new situations;

f. communicating ideas to others; and

g. using simple measuring instruments.

She is of the view that older children of 10-14 years should be able to employ the following additional skills in their endeavour to make sense of the world around them:

a. defining questions which can be answered by experiments;

b. proposing an hypothesis;

c. identifying and controlling variables in carrying out investigations;

d. recording observations systematically;

e. using evidence critically and logically;

f. making measurements with appropriate accuracy; and

g. communicating information in the most appropriate form.

A rationale of emphasising these processes in science teaching is that these processes enable individuals and the society at large to approach their problems in a systematic and orderly fashion. They will develop an approach to problems that is not only scientific in nature, but social as well. These science processes are basically thinking processes that can be applied to any set of problems (Hernandez 1991). Thus, as claimed by DES (1985) "Each of us needs to be able to bring a scientific approach to bear on the practical, social, economic and political issues of modern life" (pp 2-3). The development of these skills is not sole prerogative of science. However, science does provide a context, opportunities and an environment conducive toward the development of these skills provided science instruction is arranged with this objective in mind. If these processes are made part of the instructional process, then there is every likelihood that a majority of children, if not all, will become more skillful in using these processes consciously and deliberately to make sense of natural phenomena. This may be one of the reasons that many educators and writers in the last decade or so, for example, Bentlely, & Watts (1989), Harlen (1992), RECSAM (1991), have stressed the development of these skills through science instruction.

But, despite their importance and despite the fact that the development of these processes has been advocated in many curricular documents, one is utterly dismayed to learn that nothing substantial has been achieved in this regard. In order to find to what extent science graduates and prospective science teachers are skillful in using these processes, the following survey was undertaken.

The procedure

A few years ago, I was demonstrating the "Cartesian diver" activity to explain to a batch of in-service science teachers various processes of science. The dropper that I used for demonstration was made of plastic and could not stand vertically in a bottle which was half filled with water. Thus, when the
plastic bottle was squeezed, it did not dive/sink to the bottom. When it was fully filled with water, it either sank down or movement of water into the dropper could not be observed when pressure was exerted on

![Image: The cartesian diver with a weight]

the walls of the plastic bottle. I made a little innovation. I fastened a small pebble to the stem of dropper as shown in Figure 1. It made the dropper stand vertically. When pressure was exerted on bottle’s walls, the dropper sank to the bottom, and when pressure was released, it floated again. During the demonstration one of the teachers asked why the dropper sinks when pressure is exerted. Instead of answering the question, I threw the question back to the teachers. To my surprise, one of the teachers said that the diver sinks because of the weight of the pebble. Many teachers agreed with her. They were unable to realise the apparent contradiction in their explanation, that when the bottle is not squeezed the weight is still there but the dropper did not sink.

Realising this state of affairs, I conducted a little survey of respondents answers to various questions relating to the same activity. This was a group of prospective science teachers, having a first degree in various science subjects and doing their masters degree in science education. This time, the activity was made a little bit more complex. Two droppers were used instead of one. One dropper was filled with water, less than half, and this floated on the surface of water more or less horizontally. The second dropper was filled more than half and this floated vertically in the bottle. When the bottle was squeezed, the vertical dropper sank down while the horizontal dropper still remained on the surface. The activity was demonstrated to trainee science teachers and they were asked to answer the following questions.

1. What change did you observe in the system?
2. What happened to the level of water in the bottle?
3. Why one dropper sank to the bottom?
4. Why second dropper floated on the surface?
5. How will you investigate the real cause of diving?

Survey Results

The purpose of the first question was to help respondents to focus on particular aspects of the system and on various events. Responses are given in Table 1. It is evident that all respondents noticed changes in the system, that is, the rise of water surface in the bottle, sinking of one dropper and floating of the second one. However, very few respondents were able to observe change of water level in the droppers, particularly in the ‘diver’.

<table>
<thead>
<tr>
<th>Questions</th>
<th>% of correct responses</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 What change did you observe in the system?</td>

<td>38</td>
</tr>
<tr>
<td>4 Why second dropper floated on the surface?</td>
<td>10</td>
</tr>
<tr>
<td>5 How will you investigate the real cause of diving?</td>
<td>zero</td>
</tr>
</tbody>
</table>

More importantly, only a few students could give a plausible explanation/hypothesise about the sinking of one dropper and not the other one. On the one hand, the results of this survey indicate an inability on the part of science graduates to employ science process skills to make sense of the natural phenomenon. On the other hand, this reflects a lack of understanding of an important scientific concept that these graduates have studied extensively during
traditional science courses. This fact alone shows that science graduates are unable to observe the system and its parts keenly and minutely and to propose a plausible hypothesis. It is understood that lack of this ability on the part of science graduates is because of a lack of such opportunities during their science classes that would help them to develop these skills. Surprisingly, all of the respondents did study ‘density’ in one of their physics course at matriculation and higher secondary levels. They should have been able to answer these questions had they really understood the concept of density. Science graduates should understand that if a dropper is floating on the surface, its density must be low. Because of pressure on walls of the bottle, more water enters into one dropper and not the other, thus increasing the weight of the diver and not the one that floats. If they are asked to explain the concept ‘density’ they can give full descriptions with the help of \[ D = \frac{M}{V} \] equation. So they have memorised the description of density but have not understood the concept.

Discussion

Since the independence of the country in 1947, various attempts have been made to change the science curriculum to fulfil the demands of a changing society. The first massive exercise of this nature was carried out twenty years after independence, that is, in 1967. A second effort was made in the early 1980s and a third one in the 1990s. But, if all these revised curricula are analysed from the point of view of its emphasis, it is clearly revealed that all these curricula put greater emphasis on the product nature of science. Despite claims made in the curriculum documents produced by the Ministry of Education, text books for these curricula and the actual classroom teaching remained the same.

Now the Government has recently announced its education policy in March 1998. This policy pronounces the enrolment at least 50% of students from matriculation to higher levels in science based disciplines. At the same time, reforms in the curriculum and assessment system are also being proposed. Thus, it is high time that the true nature of science be acknowledged and reform movements be carried out accordingly. If the real purpose of teaching science is to promote understanding of scientific concepts and the development of enquiry skills in students, then it is imperative that the process aspect of science be given an added emphasis. This does not mean that the subject matter content should be ignored. There is no denying the fact that some curricula in the past pressed process teaching so hard that they neglected the subject matter content to a large extent. On the other hand, traditional science courses, which are dedicated to covering an encyclopaedia of correct answers and showing the structure of a particular science discipline, tend to cover as many science facts as possible. Students are expected to memorise isolated bits of information for tests and credits rather than construct their knowledge for personal use in their everyday lives. Much factual material may be learned by the children from books or other sources. Both of these approaches to teach science are undesirable. There must be a balance between the process aspect and a product approach to science teaching, because both of these aspects are inseparable components of science. However, development of process skills will not take place through traditional teaching. It is to be recognised that subject matter content is important for development of science process skills. In Gagné’s words (Gagné 1985, p. 238), “Application of science processes requires an understanding of subject matter content”. But it is also imperative that students be provided with opportunities for processing information and data as they collect them as a result of their own effort. It is important that the curriculum should give children continuous opportunities to learn processes within a wide variety of subject matter and conditions if these skills are generally to be useful. Because of their physical and mental involvement, processing of data improves thinking skills of students. Hence, they must observe the phenomenon, classify objects, communicate with teachers and classmates, measure objects, plan and conduct investigations and make inferences in order to develop understanding of the subject matter as well as to develop science process skills. Thus, an effective curriculum provides chances to teach process skills within all topics at all grade levels.

There is an urgent need to improve teacher education programmes, particularly the pre-service education of teachers, and the assessment system. Both of these systems must be brought into line with the true nature of science. There is a need to develop awareness in teachers regarding the importance of these skills. And more importantly, if they need to incorporate process aspects of science in the teaching of science, then they need some practical help. It is imperative for them to understand the nature of each process, to identify these skills, to understand where they overlap, how they are inter-related and to decide in what part of the activity children are using a
particular skill or process. As Harlen (1983) puts it, teachers need to develop expertise in assessing the development of these skills by their students. There is a relationship between teaching and assessing. If teachers do not have the skills to assess students' achievement in terms of science processes the utility of teaching these skills will be lost. This then means that there is a need to include all these aspects in the pre-service education of science teachers. By way of implication, it is also necessary that the curricula of pre-service education of teachers needs thorough scrutiny and revision. Traditional teacher education curricula do not cater for this aspect of science. Unless this is done on a priority basis, the objective of the development of science processes, and thus the development of understanding of science concepts, will not be achieved. Science teaching in the classroom will remain traditional, bookish and product oriented, leading to lower understanding in students.

International Networking in Science Education at the ASE 1999 Annual Meeting
University of Reading
4 - 9 January 1999

The international programme of conferences will include: Models and modelling in science education; Information and communication technology in science education; Science and technology education; Environmental education.

This links to 300 programme items and 250 exhibits at the ASE Annual Meeting. These all provide opportunities for reporting on the latest developments and initiatives in advancing theScience Project 2000+ goal of scientific and technological literacy for all, as well as appraising recent research and developments in science education.

There are excellent preferential conference rates for members of associations and institutions affiliated to ICASE.

The science world view among Japanese people: their conceptions of the nature of science, technology and society

Yoshisuke Kumano
Shizuoka University, Japan

It is predicted that Japanese students may not possess clear images or frameworks concerning the relationship between science and technology in the context of society. This is simply because most of the high school science classes are taught using didactic methods within the framework of an outdated paradigm of science. In this study, using a questionnaire, the views of 2478 Japanese students or adults, concerning the nature of science, technology and society were examined. Interesting results were found and discussed within the context of Japanese culture.

Introduction

Japanese science education now is recognizing major problems and limitations within its traditional framework of education. As many countries have identified the need for improving science and technology education, so must Japan. Kumano (1993) analyzed the status of science education in Japan and compared traditional science classes to the classes in the US. Figure 1 indicates the contrasts found (especially, high school science classes for both countries might be easy to fit these explanations in Figure 1).

Figure 1: Contrasts between Japanese Classes and Traditional Classes in the US

This paper was originally prepared for the 8th IOSTE Symposium, 1996, Edmonton, Canada and edited and modified with the collection of 383 more data.
Creativity

- Students rarely ask questions. Teachers often ignore these questions in order to follow the course outline
- Students rarely ask unique questions that excite their own interests or those of students and/or those of the teacher
- Students and teachers only rarely consider causes and effects except those found in textbooks
- Students decline in their ability to question; the questions they do raise are often ignored because they do not conform to the course outline
- Students rarely ask unique questions
- Students are ineffective in identifying possible cause and effect relationships in specific situations

Attitude

- Students often do not generate ideas but accept ones from teachers and textbooks
- Student interest in science decreases as he/she gets older
- The major interest of students focuses on how to get high marks on science examinations
- Students have few original ideas
- Student interest in science declines at all grade levels with declines increasing as grade levels increase
- Science seems to decrease natural curiosity

Discussion

In Kumano’s studies (1991, 1995), he concludes that we need to reform Japanese science education in the direction of STS (Science, Technology and Society) education utilizing ‘constructivist’ teaching strategies. However, Kumano (1994) identified major difficulties when moving toward STS frameworks and constructivist teachings in Japan. Some of these include:

- Japanese students can not discuss the interactions of Science, Technology and Society very well; poor explanations are given of their own ideas; they have poor observation power and can not conceive of experiments needed;
- Japanese culture is seen to cause difficulties in using the STS approach;
- Entrance examinations make it more difficult to do STS within competitive high schools or colleges; because of the exams, teachers feel a need to follow the precise content within the textbooks; there is a feeling that it is impossible to do STS within a given semester;
- Students are extremely uncomfortable with the STS approach.

As Yager (1991 & 1993) mentions in his study, STS should be applied differently, depending upon the peculiar context of each country. Within each culture, a great effort is needed to develop models and practices for STS as innovation and reform for science classrooms.

For the development of STS instruction with constructivist teaching, we need to find the status of student views of science in Japan as well as their understanding of the relationship between science and technology, and the relationship among science, technology and society. In a pilot study involving 740 students, data were collected and analyzed using the World View Domain Questionnaire developed by Yager et al (1991). Results were presented at the Pacific Science Congress, Beijing, China (Kumano, 1995). In the instrument, there were some sentences which did not fit the context of Japanese culture, so after long discussions with Shizuoka STS teachers and undergraduate students at Shizuoka University the questionnaire was revised (Ono and Kumano,
1995). This revised questionnaire was used with 200 teachers in Shizuoka Prefecture, Japan. There were fourteen questions and each question had four multiple choice responses. The questions were divided into four categories as follows:

1. Nature of Science
   - Nature of scientific rules
   - Meaning of scientific innovation
   - What is science doing?
   - From what activities science will start?
   - Question No. 1, 3

2. Processes in Science
   - Meaning of scientific experiment
   - Reasons why scientific theory is accepted
   - Characteristics of scientific data
   - Scientists’ attitudes towards changing a law
   - Question No. 2, 3, 7, 10, 14

3. Sociology of Science
   - Social responsibility of scientists
   - Social natures needed for scientists
   - Reasons why scientific theory should drop out
   - Contribution of scientists towards society
   - Question No. 4, 8, 11, 15

4. Interrelation among Science, Technology and Society
   - Ethics of science toward scientific theory
   - Differences between science and technology
   - Question No. 5, 12

Results show that more than forty percent of Japanese teachers have not understood the so-called new philosophy of science. Many teachers believe that the nature of science is fixed and static; that under certain circumstances everybody can find exactly the same results with the same processes and materials. The results of this study indicate that the understanding of the relationship between science, technology and society is very limited. Without understanding the nature of science, the depth of understanding of STS is in doubt. Further studies were done, concerning 2095 people (Kumano, 1996) and 383 new data of college students were added in this paper. The number of people by category is indicated in Table 1, with those providing ‘desirable’ answers reported in Tables 2, 3 and 4.

Table 5 shows the matrix of Pearson correlation coefficients among all the groups. From the Pearson correlation coefficients it is clear that there are great similarities among most of the groups. Also it is possible to identify the three groups given in Tables 2, 3 and 4 above; group 1 (6th grade, 8th grade and Junior College), group 2 (9th grade, 10th grade, 11th grade and 12th grade) and group 3 (college students, college students of new data, science teachers and adults).

Conclusion

From all the data above, there are clear characteristics and tendencies, including the following:

1. There are great similarities over the entire population regardless of the age, sex and geography of each population if the population is older than high school or junior college. However, three groups are identified and the older population has slightly higher scores than the younger population, but statistically speaking there is not any significant difference.

2. Percentages of desired responses for the nature of science (average score of four questions out of fourteen) has lowest score among all of the contents. (Nature of science is not commonly well understood; it is expected that realism or experimentalism is still in the main position of science education area in Japan.)

3. For most of the population, social aspects of science and technology (application of science, advancement of technology, ethics of scientists or technologists and social responsibilities of scientists and technologists) are major concerns, as well as future function of scientists.

These results are not surprising at all since there has been so little information available and studies conducted concerning the nature of science throughout all forms of education in Japan – kindergarten to university. In order to harmonize with other countries, major efforts in terms of reform of science education are needed in many portions of education, especially science and technology education in Japan.

Implications for science education

The area of the nature of science has its own contexts and contents, however. The way of learning the nature of science should not be done within the framework of traditional classroom learning, but within the context of an STS approach where each student is encouraged to develop his or her own scientific world view. For every unit in science, it is highly possible to develop discussion time, for example asking, “What is science?” or “What kind of influence does this science have for technology or society?” It is obvious that discussion time for the nature of science does help the reform of science education, but we need more systematic reform strategies for the reality of reform of science education, such as the National Science Education Standards (1996). Consideration of the nature of science could be a good start and a needed step for the early stage of reform of science education in any country in this century.

Practicable taxonomy of basic skills of science practicals at secondary level for their assessment

R.S. Sindhu and Reeta Sharma
Regional Institute of Education
Bhopal – 462 013 (India).

A new taxonomy of basic skills of science practicals has been recommended for its use in the assessment of students of secondary level (approximately 15 year olds). The taxonomy includes the skills which take into account all the three domains of learning in the holistic perspective. A scheme of assessment based on the taxonomy also has been suggested. The scheme involves the evaluation of students through laboratory practical examination, observational assessment, viva and written record of full academic session. Some of the practicals which help develop these skills have also been recommended.

Introduction

One of the main emphases in science nowadays is its practical orientation brought about by new aims in science education which emphasise science as a process. This leads to the understanding of certain aspects of the nature of science, intellectual and conceptual development, positive attitudes towards science and certain problem solving and psychomotor skills. The importance of practical work in science warrants attention to finding out a valid, reliable and practicable assessment system that can test practical skills. However, practical assessment is not an easy task and doubts persist about its reliability, validity and practicability (Welford, 1990). There are three main technical difficulties which contribute to the problem of practical assessment. First is that there is no practicable taxonomy of practical skills which can be used in the assessment scheme. Several workers (Klopf, 1971; California, 1970; Minnesota, 1977; Ben-Zvi et al, 1977; Tamer, 1978; Doran, 1978; Ganiel and Holstein, 1982; Murphy and Gott, 1984) have made efforts to isolate and define domains of practical skills. However, in some cases these classifications are insufficiently defined and too many skills have been specified in too fine detail so that these can not be assessed in a practical class (Gott et al, 1988). Second, no fool-proof scheme of assessment of practical skills is available at present. Four schemes given so far are: written reports, test items, laboratory practical examination and observational assessment. However, these have been repeatedly criticised on technical grounds (Nuttall and Goldstein, 1986; Johnson, 1989). Third is the lack of defined practical skills at different levels, although some efforts have been made in this direction (DES, 1989; Sibanda, 1990).

The present work deals with the framing of a new practicable taxonomy of basic practical skills to be achieved by students at the age of fifteen (secondary level) and a scheme of assessment, which together address the problems related to assessment of practical skills developed in the students.

Recommended taxonomy of basic practical skills

A number of ways of classification have been suggested for isolating and defining the basic skills. Hofstein et al (1976) identified three practical domains which cover all basic skills as: (i) skill in the performance of routine laboratory tasks, (ii) ability to make observations, (iii) problem solving ability. Ben-Zvi et al (1977) have further divided the third domain into (i) planning and designing of investigations, (ii) performance of experiments, (iii)
analysis, application and explanation. Murphy and Gott (1984) have emphasised only the problem solving aspect of practical skills. Another taxonomy has been given by Kempa and Ward (1975) and Lunetta and Tamir (1978). This is: (i) planning and design, (ii) performance, (iii) analysis and interpretation, (iv) application. Sibanda (1990) has suggested the skills of (i) observation, (ii) recording of data, (iii) analysis of results of experimental work.

However, these classifications are either too thin or too thick to make the assessment of skills a practicably viable exercise. At secondary level, the introduction of skills such as the application of laboratory experiences for new situations is highly ambitious. Therefore, there is a need for framing a taxonomy which is simple in application and is suitable for secondary level. Here, a taxonomy that meets the above requirements is recommended:

1. Skill in setting up the apparatus.
2. Skill in handling the apparatus/specimen.
3. Skill in making observations.
4. Skill in recording the data.
5. Skill in analysis of data/doing calculations.
7. Skill in taking safety measures.

<table>

</tr>
<tr>
<td></td>
<td>(b) Viva, during practical examination</td>
<td>b = 1/2</td>
</tr>
</tbody>
</table>
The meaning of each skill is clear in itself, and does not need any elaboration. Some of the skills which overlap or envelope other skills in scope have been combined together to make the assessment scheme much simpler. The different skills mentioned above take into account all the three domains of learning, i.e. cognitive, affective and psychomotor in the holistic perspective.

</tr>
</tbody>
</table>

Table 2: Exercises for the development of basic practical skills at secondary level

The assessment scheme recommended above, the most suitable scheme will be a combination of the schemes in a complementary way for comprehensive assessment of these skills. Therefore a laboratory practical examination in which the observational and viva are fused together and practical record assessment is also taken into account for giving marks. However, in the case of practical record only the marks of continuous assessment should be added to the final marks. Thus, for a practical examination of 25 marks, the awarding scheme and mode of assessment are given in Table 1.

The assessment scheme can be applied for measuring the performance of students in different skills by combining the achievements of practical examination and of continuous evaluation of practical record.

Practicals for the development of basic skills at secondary level

Exercises of science practicals during the academic session are given to the students for the development of different types of practical skills. However, it is not necessary that each exercise should lead to the development of all types of skills. But in a holistic model wherein a number of exercises are performed during academic session, these skills should remain in-built and during practical examination two or three exercises which throw light on the acquisition of all the skills laid down for the secondary level should be set. Some of the practicals which lead to the development of different skills are listed in Table 2.

Implications of the present work

The recommended taxonomy of basic skills of practical science at secondary level can be applied to the present ongoing system of examinations by making some variations in the approach of the
examination. The awarding of marks is simple, valid and reliable.

International Conference on Learning Science in Informal Contexts
Location: Questacon – The National Science and Technology Centre, Canberra, Australia
Contact: Kayt Watts, Conference Secretariat, PO Box 3182, Manuka ACT 2601, Australia, fax: +61 2 6239 7948, email: <ingenue61@bigpond.com.au>
Organised by Questacon as part of its tenth birthday celebrations, in association with the Centre for Public Awareness of Science at the Australian National University, this conference will be the first of its kind in Australia. It will enable researchers and educators from science centres, museums, zoos, botanical gardens, wildlife parks, schools and tertiary institutions to share their views on learning science in response to the growing interest in the role that informal learning plays in increasing people’s understanding of science. See the conference website for further information: <http://sunsite.anu.edu.au/Questacon/conference.html>

September 3 - 5
International Conference on Science and Technology Centres/Museums
Location: China Science and Technology Museum, Beijing, China
Contact: Mr Ou Jiancheng, International Conference Secretariat, China Science and Technology Museum, 1 Bei San Huan Zhong Road, Beijing 100029, China, fax: +86 10 6237 9378, email: <cstmn@iwh.com.cn>
This international conference is being organised in conjunction with the First Conference of the Asia Pacific Network of Science and Technology Centres and focuses on the theme of 'Science and Technology Centres and Museums: Educating and Enlightening the People'. The conference will provide a forum for science and technology centre/museum professionals from across the world to share their ideas on how centres of non-formal and informal learning can promote scientific literacy for the general community. See the conference website for further information: <http://www.cicstc.org.cn/bicstcm’98>

September 24 - 27
International Working Seminar of Scholars for Technology Education
Location: George Washington University, Washington DC, USA
Contact: Prof. Dr. Michael Dyrenfurth, President, National (USA) Association of Industrial and Technical Teacher Educators, 105 London Hall, Technology & Industry Education, University of Missouri-Columbia, Columbia, MO 65211, USA, fax: +1 573 884 4095, email: <pavtmike@showme.missouri.edu>
The National Association of Industrial and Technical Teacher Educators, the European Society for Technology Education and the World Council of Associations for Technology Education invite you to participate in an international seminar on the theme 'Outcomes of Technology Education for 2000+: A Focus on Learning: Models, Criteria and Demonstrations of Applied Learning and Assessment Methodologies'. The following themes present an opportunity for the seminar participants to structure their remarks: subject centered and/or interdisciplinary orientations for technology education; what are the key outcomes/benefits that result from participation in technology education; which learning and assessment theories are significant with respect to becoming competent in
Calendar

technology teacher education; how can persons with special needs be better served and how can the diversity and inclusiveness of technology education be enhanced. See the website for further information: <http://unesco.uneb.edu/wocate>.

October 16 - 18
Symposium 'Education of Science Teachers'
Location: Nałęczów, Poland
Contact: Jarosław W. Dymara
Department of Chemical Education
Maria Curie Skłodowska University
Pl. M.C. Sklodowska 3
20-031 Lublin, Poland
fax: +48 81 533 36 69
email: jdmara@hermes.umes.lublin.pl

November 5 - 7
Annual Conference of the Science Teachers
Association of Ontario
Location: Toronto
Contact: Jon P McGoe, c/o John Paul II Secondary, 1300 Oxford Street East, London, Ontario N5V4P7
email: jmcgoey@quark.physics.uwo.ca
Information is on the website at <www.stao.org>

November 18 - 22
European Researchers in Didactics of Biology Conference
Location: University of Goteborg, Sweden
Contact: Dr Fred Brinkman, Secretary, IDO Vrije Universiteit, Amsterdam, Netherlands,
email: <fg.brinkman@ido.vu.nl>

1999

January 7 - 9
ASE Annual Meeting
Location: University of Reading, Reading, England
Contact: ASE Annual Meeting, The Association for Science Education, College Lane, Hatfield, Herts AL10 9AA, fax: +44 1707 266 532, email: <ase@asehq.telme.com>
The theme of this meeting is 'Science Education in the Computer Age'.
The Annual Meeting of the Association for Science Education attracts science educators from around the world. Don’t miss the substantial program of plenary addresses, papers, seminars, workshops, visits, displays and functions which makes this event one of the largest international gatherings of science educators. Following on the success of the 1998 ASE-ICASE-IOSTE International Seminar, a similar international seminar is being planned to precede the 1999 ASE Annual Meeting from 4 January.

March
ICASE NVON International Seminar
Location: Netherlands
Contact: Miia Rannikmae, ICASE European Regional Representative, Department of Science Didactics, University of Tartu, Lai 40 Tartu EE 2400, Estonia, fax: +372 7 465 813
email: <miia@queenie.lai.ut.ee>

March 25 - 28
NSTA National Convention
Location: Boston, Massachusetts, USA
Contact: NSTA Conventions Department, 1840 Wilson Blvd, Arlington, VA 22201-3000
email: <conventions@nsta.org>.
Join science educators from across the USA and around the world in a huge program catering to the needs of elementary/primary and secondary teachers of science and tertiary science educators. See the website for further information:

July 10 - 16
9th IOSTE Symposium
Location: Durban, South Africa
'Science and Technology Education for Sustainable Development in Changing and Diverse Societies and Environments'
Contact: Mr Alan Pillay, Chairperson IOSTE 9
Faculty of Education, University of Durban-Westville Private bag X54001, Durban 4000, South Africa
Fax: +27 31 204 4866
Email: spillay@pixie.udw.ac.za

September 15 - 19
5th International HPSST Conference
Location: Pavia University, Italy
Contact: Dr Enrico Antonio Giannetto, Dipartimento di Fisica ‘A Volta’, Universita di Pavia, Via A. Bassi 6, 27100 Pavia, Italy, email: <volta99@pv.infn.it>.
This conference is being held in conjunction with the European Physical Society’s Interdivisional Group on History of Physics and Physics Teaching. The joint conference will contribute to local celebrations of the bicentenary of Alessandro Volta’s creation of the battery at Pavia University in 1799. See the website for more information: <http://www.cilea.it/volta99>.
Calendar

October 4 - 8
3rd ICASE Latin American Symposium
Location: Curitiba - Parana State, Federal University of Parana, Brazil
Contact: Department of Educational Methods, School of Education, Federal University of Parana, Rue General Carneiro, 460 2o. Andar, Curitiba - Parana, CEP 80 060 - 150, Brazil.
Phone / fax: + 55 41 264 3574
Email: gioppoc@educacao.ufpr.br

The 3rd ICASE Latin American Symposium will be hosted by the Brazilian Association for the Advancement of Science - Parana Section, and will attract science educators from across the Latin American region and beyond.

2000

April 6 - 9
NSTA National Convention
Location: Orlando, Florida, USA
Contact: NSTA Conventions Department, 1840 Wilson Blvd, Arlington, VA 22201-3000,
e-mail: <conventions@nsta.org>.

July 19 - 21
ICASE-CEFIC European Education-Industry Seminar
Location: University of York, York, UK
Contact: Miia Rannikmae, ICASE European Regional Representative, Department of Science Didactics, University of Tartu, Lai 40 Tartu EE 2400, Estonia, fax: +372 7 465 813,
e-mail: <miia@queenie.lai.ut.ee>.

Science Across the World makes its website

A working example of how the Internet can bridge language and cultural differences has been given a facelift after two years in the field and a rising popularity among schoolchildren in 46 countries.

The Science Across the World programme, coordinated by the Association for Science Education in Britain, was one of the first to incorporate a website into an education programme. The programme aims to raise awareness of science and technology issues in society, industry and the environment. The Internet was used initially to allow teachers and students to send information to other schools.

But there is much more to the new site. It is easier to navigate and more visually appealing. Ease of navigation and speed of download are key features. There are no spinning logos: instead there are resource areas, with discussion forums and news sections to contribute to. Nor is it all dull text. Video clips are available. And the whole thing is available in six languages - English, French, German, Italian, Portuguese and Spanish.

Those who dream of using the Internet in schools might like to check how its done in Science Across the World. There are 1 200 schools worldwide using the BP-sponsored programme, and in the last six years it embraces schools in Africa, the AsiaPacific region, Europe and North and South America.

ICASE Homepage: http://sunsite.anu.edu.au/icase
Science Education International is the quarterly journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides a means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

A National Workshop about Science and Technological Education in the Environment "Taller Nacional Sobre Educacion Cientifica, Tecnologica y Ambiental Mar del Plata."

UNESCO, ICASE, Club de Ciencias "Albert Einstein", Ministry of Ed. Argentina

Argentina's history created a legacy of weakness at the human resource level of education. The desired changes that have come to light with the democratic government are not always easy to implement. People lack experience in discussing society-related topics. Group work, workshops and creative discussions are essential in order to redress this situation. A new curriculum has been written which allows regional and interdisciplinary approaches. Ten out of twenty-four Argentinian provinces have taken up the new curriculum and are setting their own parameters. Other provinces are more dictatorial, and some are more modern than others. Different standards and varying strategies are needed to combat the inequalities that exist today. Science related to Argentina must be a major parameter. Values, attitudes and social concepts must be taken into account. However, a contradictory situation exists as societal issues like health, consumers and the environment are areas that cross the boundaries of the subject disciplines. The training of many teachers has been in disciplines and not areas.

There is an urgent challenge to make the curriculum content significant. Curriculum and teacher changes have to be put in place in an order appropriate to the context. The differences within the country need to be respected. Technical capacity is not available everywhere and working conditions vary from province to province. The new basic science curriculum aims at allowing such flexibility. Implementing change is always a hard task. Teachers must be involved in the innovations and feel ownership of them.

The Argentina National Workshop for Science and Technological Education in the Environment - "Taller Nacional Sobre Educacion Cientifica, Tecnologica y Ambiental", was held in Mar del Plata in June 1998. This workshop was part of the National Programme for development of materials for Scientific and Technological Literacy for All. Jack Holbrook of ICASE led the workshop, which was sponsored by the

Presentation to Marta Moyano, organiser of the Argentinian STL Workshop and ICASE Latin American Representative
Ministry of Culture and Education. Laura Fumagalli represented the Ministry and set the scene for the event. The workshop was brilliantly organised by the ICASE regional representative, Marta Moyano of the Einstein Science Club in Mar del Plata. The programme was honoured by contributions from Orlando Rose Hall, Beatriz Macedo of UNESCO. Anna Garner, President of ICASE, also spoke.

The workshop gave teachers from all the provinces of Argentina, along with representatives from Bolivia, Brazil, Cuba, Paraguay and Uruguay, the opportunity to meet in groups for discussion and to create meaningful science teaching materials. Twenty-four papers and materials were created during the week. The created scripts are in context with the new central ideas and also reflect the teachers’ own local and cultural areas. The ‘ownership’ and ‘attachment’ of the teachers to their created materials is the best way to ensure their use in the classroom. This is perhaps one of the greatest strengths and values of workshops such as this. Hopefully each representative will now go on to encourage such workshops in their own provinces or countries. This will help the “alphabetization of science”, and reflect the aims of Project 2000+ in meeting the demands of society and the citizens.

The role of the teachers must be to guide and develop a new style of science in schools. Argentinian teachers have a good attitude and want to teach well. Without exception the participants of this workshop, were enthusiastic, open to new ideas, honest and open in discussion, and above all dedicated to better science teaching. It was a refreshing contrast to see the dynamic nature of discussions and the enthusiasm when working together. Opportunity for discussion is sometimes taken for granted in countries with a longer tradition of democracy.

Changes in Science education in Argentina are just starting. The spirit of Project 2000+ for teaching science within the societal context is certainly alive and growing in Argentina. I hope similar progress can be made in other countries of South America. This workshop was certainly excellent.

Congratulations go to the organizers of this very successful event.

**VAEST**  School science and the future of scientific culture in Europe. An EU Project also supported by industry

The original project of this name collected national reports on science education from fourteen European countries, and analysed them for features that would enhance popular scientific culture. A follow up project initiated by Dr Joan Solomon of the Open University UK, is the launch of the Virtual Association of European Science Teachers (VAEST).

VAEST is an opportunity to link all those involved in science education - informal and formal - and scientists across Europe using computer links.

The Launch Meeting of VAEST was held in Portugal June 27-29 1998. Countries with early involvement in the project, Portugal, Greece, Sweden and the UK, were well represented at the successful launch, as were Denmark, France, Germany, Iceland, Italy, Norway and Poland.

Anyone in Europe can join VAEST, at the present time for no cost, thanks to funding from the EU, Esso and BT. For more information look on the internet at [http://watt.open.ac.uk/VAEST](http://watt.open.ac.uk/VAEST). The four main communication groups currently established are Astronomy, Global Bioethics, Greenhouse Effect and sustainability and Perception. If you would like join a group, say what you are doing, say what went well in science teaching or contribute teaching materials or information to the resource pool these will be most welcome. The links can be hot lines for questions, provide a share centre for useful website addresses and become a resource pool in several languages. A CD-ROM of teaching materials is also being produced.

VAEST is a welcome member of ICASE and is a useful medium for individuals. We hope that many of the useful ideas shared among individuals in VAEST will also be brought to the Science Teacher Associations and so shared on a Europe-wide network.

Anna Garner
ICASE President
ICASE Continues to Promote Project 2000+ Workshops

ICASE has been involved in promoting its STL (Scientific and Technological Literacy for All) philosophy to its member organizations by running workshops for the creation of STL teaching materials. Following the publication of the book on Supplementary Teaching Materials (ICASE 1997), ICASE has been involved in running regional workshops in Europe, Africa, Asia and Latin America.

Second National STL Workshop (Argentina)

This year has seen Science Teachers’ Associations (STAs) interested in holding national workshops. The first was held in Nepal in March (see June issue of SEI). The second National workshop was held in Argentina (Mar del Plata, 8-12 June 1998) and is described in the President’s Report above. It was a very successful workshop and in total 24 scripts were created in Spanish. These are now being edited ready for piloting in schools. After modification, ICASE hopes to publish these materials on the internet.

The success of this workshop is in no small way due to the efforts of the ICASE Latin American representative, Marta Moyano and the team of people from the ICASE member organisations in Mar del Plata - Club de Ciencias “Albert Einstein”. Thanks also goes to the Ministry of Education in Argentina and to the UNESCO Regional Office for Latin America for their participation and support.

Third National STL Workshop in Hong Kong

The third national workshop on the creation of STL teaching materials was held in Hong Kong (22-26 June 1998). This was held under the auspices of the Hong Kong Association for Science and Mathematics Education and the University of Hong Kong. The 1st morning was a short symposium on STL so that the concept could be spread to a wider audience than could attend the workshop. The rest of the week was a workshop for 25 participants following the standard pattern but this time more attention was put into evaluating the achievements of the workshop in the eyes of the participants. Participants also incorporated criteria referencing assessment ideas into their scripts in line with the pattern established in the book on Supplementary Teaching Materials.

An evaluation activity on the last day involved participants putting forward, as individuals, their ideas on what the workshop had tried to achieve, then collectively in groups determining the main features of the workshop and finally collecting all these to create a list of ideas promoted. This will provide valuable information for future workshops.

There were observers at the workshop from Beijing and Shanghai as it is hoped to follow up the success of this workshop by running similar ones in these cities, possibly using some of the participants as resource persons. Whilst this workshop was held in English, the ones in Shanghai and Beijing are being planned in Chinese (Putonghua).

The success of this workshop was very much due to the efforts and energy of Or Choi Kuen, the main organizer in Hong Kong. Thanks go to the University of Hong Kong for the use of its excellent facilities (would you believe the presentations on the last day were by using an LCD projector linked to a computer using Power Point software), the HKASME for its support and to the Curriculum...
The photos on this and the opposite page show participants in the Scientific and Technological Literacy for All Workshop in Hong Kong. (June 1998.)
Development Institute of the Department of Education for ensuring teachers were able to participate and for their interest in this workshop. ICASE was represented by three resource persons, the secretary, Mia Rannikmae, the European representative and Robin Groves, the ICASE journal editor, who was able to inject new ideas into the presentation. Filocha Haslam from Australia was also a very valuable resource person. It is hoped the material from the workshop will be put on the internet and also translated into Chinese to be used as exemplars for the national workshops in Beijing and Shanghai.

A European Regional STL Workshop

UNESCO contracted ASE, the ICASE member organization for science teachers in the UK, to run a European regional workshop in London (June 1-5). Participants in this workshop came from ICASE member organizations in Belgium, Netherlands, Ireland, Iceland, Sweden and Finland. ICASE itself was represented by the ICASE European representative, the secretary, treasurer and two support persons, Norman Lowe and Dennis Chisman.

No teaching materials were developed by the participants but the criteria for these were firmly established based on the ICASE philosophy for STL. Much discussion centred around the STL philosophy and how it can be incorporated into the work of STAs in Western Europe.

Follow up involved giving ideas of materials to be developed and then piloting in each of the countries represented. Consideration was given to follow-up national workshops in each of the participating countries with the representatives present as the major resource persons. Thanks go to the ASE for organising this event under the sponsorship of UNESCO and especially to the hardworking team of Caroline McGrath, David Sang and Marianne Cutler.

a new Rusnet, a planned internet for Russians. ICASE looks forward to greater cooperation with St Petersburg and Russia in the future and hopes it becomes possible to run a national workshop next year with the help of Herzen University’s Department of In-service Education.

During the visit the ICASE Secretary and European Representative were able to visit a school in St. Petersburg and hold interesting discussions with a very distinguished chemistry teacher who had instigated many developments in the school supporting experimental work, creating visual aids and ways to make posters and charts more visible to the students and building up a school science museum.

Other National STL Workshops?

ICASE encourages STAs to follow up the STL philosophy developed by ICASE and make teachers more aware of these developments. A national workshop is an excellent way to do this. The current model, proving successful, is a five day workshop in which participants are involved in taking ownership of the idea by creating STL teaching materials.

ICASE is very willing to assist and make resources available if possible.

As a further follow-up ICASE is pioneering an ICASE-UNESCO Certificate to recognise teachers promoting STL. This certificate is designed in such a way that it can be administered and awarded by the local STA. For further details and expressions of interest for national STL workshops, or for the STL Certificates, please contact the ICASE secretary.

Jack Holbrook
ICASE secretary

STL Seminar in St Petersburg, Russia

The ICASE Secretary and European Representative were invited to give a seminar on STL to about 40 chemistry teachers in St Petersburg in May 1998. The teachers expressed much interest in the STL idea and were eager to try out materials once they had been translated into Russian. Thanks go to Andrei Zhegin and Herzen University for making the visit possible and for their interest in translating STL material into Russian with a view to putting these on
Feature Article

Teachers, teaching strategies and culture

Glen Aikenhead, Saskatchewan University, Canada

A Science Education Parable

"If the law of gravity is universal, then what is the force of attraction between two neutrons in a nucleus?" an inquisitive student asked.

"No, don't think about gravity in the nucleus," answered the teacher, "because strong and weak forces hold neutrons and protons together in the nucleus."

Teaching

Teaching is not a theoretical act that has universal application, but a very practical act that takes place in specific classrooms with unique students. Teachers may draw upon theories of instruction as inspiration in an eclectic way, but success in the classroom depends on the decisions that teachers make based on their practical knowledge about teaching. Therefore, the topic 'teaching strategies' must not be taken out of context and treated as a universal to follow. Instead, 'teaching strategies' must be contextualized as one part of a teacher's practical knowledge about instruction.

Research into this practical knowledge sheds light on some of its complexity (Duffee & Aikenhead, 1992). Decisions about what teaching strategies to use are invariably filtered through a teacher's image of a good teacher. Dilemmas arise when this image cannot be maintained, and stress results have accumulated through past experiences. Decisions are strongly influenced by practical principles (rationales for action). Practical principles are related to the goals of teaching in the current situation, and involve reflection over the choices and constraints at hand. Decisions are also contextualized by the teacher's students, colleagues, school administration, physical and material environment, community, and legislation. The choice of what teaching strategy to use is potentially a very complex decision.

On the other hand, teaching can be seen as an act of cultural transmission (Spindler, 1987). The conventions of culture can greatly simplify choices that teachers make. For instance, the assignment to read and memorize the language of science is a cultural convention in many countries where thin walls between resource-poor classrooms of 70 or more students require silence because the teachers in the adjacent classrooms should not be disturbed. Instructional innovations (such as requiring students to interact) that are developed in more affluent countries may seem foreign to the culture of the less affluent school. Interactive teaching strategies, therefore, cannot be misconstrued as being universals for teaching science.

The conventions of culture can also explain why changing teaching strategies involves more than technical training to manage, for example, interactive
students. Reforming teaching strategies certainly causes changes in the microculture of a classroom which is embedded in a microculture of a school which in turn is a living social icon of the culture of the community or nation. Jegede (1994) clarifies a problem found in African nations where the conventional respect for authority contradicts the scientific ‘habit of mind’ of questioning current explanations about nature. Another teaching strategy associated with science education reform is inquiry. Scientific inquiry harbors values belonging to the culture of Western science. These values may be perceived as inappropriate for some classrooms. Rampal (1994) describes the tension and fear that ensued after inquiry was successfully introduced into a school in India. Even when this scientific inquiry solved a local puzzle for the community, students had to learn to cope with the community’s backlash. My point is not to dismiss inquiry or other teaching strategies associated with reform. Rather, my point is that we need to recognize that teaching strategies must be discussed in the cultural context of culture transmission in a particular school.

A technical rational ideology (prevailing in many education systems in Western industrialized countries) isolates teaching strategies from their context of culture. Teachers are assumed to be educational technicians. Science education standards developed in such countries need to be scrutinized for their ideologies, the technical rational ideology and others (Fourrez, 1989).

Science education worldwide is not culture-free, of course, and ideologies enrich every country’s expectations of schools. Teaching strategies are, in part, expressions of those expectations. Therefore, if we are to reform science teaching in classrooms, we must also reform those ideologies that inhibit reform, ideologies that are subtly framed within the social structure of schools (the ‘hidden curriculum’). For example, some teaching strategies (a student-centred discussion of a local health issue, for instance) may only be successful when the hierarchical authority relationship between teacher and student is modified. But cultural conventions may sustain a teacher’s image of good teaching, and may sustain a fundamental ideology of the community and country. Science education reform, if taken seriously, is ideological reform. Schools, not just science classes, will have to be reformed accordingly. This is the cultural reality that reform must acknowledge.

Research

Reform in science education has been studied in terms of movements such as science-technology-society (STS), environmental education, and scientific literacy, all of which call for teaching strategies that actively involve students, for example, in divergent thinking, small group work, student-centered class discussion, community problem solving, simulations, decision making controversesies, debating and using the media and other community resources (Aikenhead, 1988; Holbrook & Aikenhead, 1997; Solomon & Aikenhead, 1994; Yager, 1992a, 1992b). Research into teaching strategies, conducted in both developed and developing countries, invariably shows improvement in student learning associated with most outcomes of reform efforts, without diminishing the average success on traditional science content examinations. In Byrne and Johnstone’s (1988) review of research, they concluded:

1. In terms of learning science content, simulations and educational games can be just as effective as traditional methods. In terms of developing positive attitudes, simulations and games can be far more effective than traditional methods.

2. In terms of attitude development, the strategies of role playing, discussion and decision making can be highly effective; but the essential ingredient is the achievement of interactivity, rather than the exact format, whether it be simulation, group discussion or role playing, which is central to attitude development (p. 44).

3. “Group discussion can stimulate thought and interest and develop greater commitment on the part of the student” (p. 45).

4. In terms of promoting an understanding of the processes of science, an analysis and evaluation of historical case studies is effective.

Making concrete connections between the content studied in class and the students’ everyday world piques student motivation, commitment and a personal responsibility towards learning.

Some excellent research has taken place in developing countries by people exploring the consequences of introducing interactive teaching strategies that relate school content with the students’ everyday world. In Nepal, for example, a researcher introduced a strategy he called ‘a narrative approach’ that focused on questions such as: Can snakes really
retain the visual memory of those who harm them? or Crows don’t die a natural death, do they, sir? (Brajacharya and Brouwer, 1997, p. 436). These class discussions had the same results as found in the research summarized above. Moreover, the cultural disruptions caused by the innovations were also researched. The teaching strategy apparently has promise: “Its greatest strength seems to be that a story-telling, or story-sharing, mode of teaching can be introduced into the classroom in a very natural, unobtrusive way, without interfering with the traditional goals of science teaching” (p.445). The collaborating teachers were not as successful in their first try as the participant researcher was. However, one finding (only mentioned in passing in the research report) has significant implications to the discussion above on cultures and ideologies: “the various school administrators in the participating schools were intrigued by the idea of teachers collaborating in addressing some of the pedagogical and curricular problems faced by Nepalese teachers” (p.435). There would seem to be ample opportunity to investigate innovative teaching strategies introduced into cultures that might otherwise seem to be supportive, as long as the teachers are collaborating (action research) and the school’s microculture is part of the study.

Other research on teaching strategies has taken place within the paradigm of cultural anthropology. A cultural perspective on teaching science recognizes teaching as cultural transmission, science as the culture to be transmitted, and students as having their own cultural identities that may or may not correspond to the culture of Western science. For the vast majority of students of any culture, their cultural identities are at odds with the culture of science. For these students (for whom ‘science for all’ is a goal), it was recognized that learning science is a cross-cultural experience. Thus, these students must cross cultural borders (between their own world and the world of Western science) before they can learn science in any meaningful way. The act of cultural border crossing has direct implications for using appropriate teaching strategies.

One set of implications was summarized by Aikenhead (1997):

1. make border crossings explicit for students;
2. facilitate those border crossings;
3. substantiate the validity of students’ personally and culturally constructed ways of knowing;

and

4. teach the knowledge, skills and values of Western science in the context of science’s cultural roles (social, political, economic, etc.).

In order for teachers to accomplish these, they need to put themselves in the role of a culture broker – an agent who guides students from one culture to another (Aikenhead, 1996). A culture broker may act like a travel guide who makes the culture of Western science, for example, the ‘narrative approach’ discussed above. A tour-guide teacher introduces students to another culture by using a high degree of guidance (in keeping with many national cultures). This role is associated with the learning process of acculturation (Aikenhead, 1997).

Alternatively a culture broker may act like a travel agent. A travel agent teacher makes the culture of Western science accessible to the ‘traveller’ students by also using teaching strategies predicated on cross-cultural instruction, but uses a much lower degree of guidance by establishing academic bridges to help students manage their own cultural border crossings into science. This role is associated with the process of ‘anthropological’ learning. The difference between guided tours and academic bridges is a matter of degree, not of kind. Academic bridges will have more academic abstraction, analysis, and self-initiated participation (in keeping with the idea of travel agents arranging passages for clients but travelling along with their clients).

Conclusion

Specific teaching strategies appropriate to the role of culture broker must still be investigated and developed. ‘Culture broker’ is a fairly new idea, but one that can make intuitive sense to teachers. We all can imagine how we would introduce a ‘foreigner’ into our native culture, under the constraints of formal schooling. The idea of culture broker has potential for reformulating teaching strategies to harmonize with a teacher’s practical knowledge and the classroom microculture. Reform must be sensitive to the culture and ideological milieu of instruction. Universals do not work.

**ICASE Distinguished Service Award**

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

A listing of past award recipients can be found on the ICASE Website at <http://sunsite.anu.edu.au/icase/i_awards.html>

Nominations for this award must be forwarded by member organisations of ICASE. For full details of how to forward nominations, contact::

Dr Jack Holbrook, ICASE Executive Secretary,
ICASE Secretariat, PO Box 6138, Limassol, Cyprus

The Baltic Sea Project
- A network of schools within UNESCO's Associated Schools Project working for environmental awareness, international co-operation, problem solving and finding solutions in order to achieve sustainable development.

Birthe Zimmermann
Sondre Landevej 18
DK-6400 Sonderborg
Denmark

Deserted beach
where everything is grey
and shiny, oily water with no winds
the empty road to the other coasts

Slimy algae choke the bottom
greenish grey and brown,
and there are piles of rotting seaweed
on the beach

Here at life's forgotten place
the clouds stand still
with bowed heads
and black shadow birds
point their sharp beaks
at the barrenness

and the raucous throats
grate on the dry, empty boats of the beach

Ole Sarvig, Denmark

(from "Working for Better Water Quality in the Baltic Region",

Environmental awareness concerning the suffering Baltic Sea and the perception that pollution knows no borders made the starting point for the Baltic Sea Project at a time (1989) where the borders gave limited access and prevented students and teachers from exchanging points of view person to person.
The Baltic Sea has a surplus of water. Salt water from the oceans enters through the narrow Danish straits as the heavier bottom layer and surplus fresh water flows out from the entire drainage area as the surface layer. So in all, the Baltic Sea consists of brackish water with great differences in salinity. The bottom conditions show thresholds preventing the salt water intake, and deep depths in the Baltic proper makes it a very vulnerable sea. The turnover time of salt water has been estimated at 70 years. The Baltic Sea is therefore utterly vulnerable to the impact of human interference, the run off through rivers from different land use and through downfall from the atmosphere.

Within the Baltic Sea Project a joint programme has been elaborated to trace the impact of humans, making a scientific method that can be used in the whole Baltic region. The programme is called Water Quality. A Learners' Guidebook has been published for use within the programme; an educational video has been made to introduce the programme to students, and a computer programme "WaQua" has been made to store the data enabling long term comparisons. Students investigate the presence or absence of certain species on the beach; they measure the numbers of individuals of each species in 1 square metre of the bottom at approximately knee deep waters; they measure redox-cline in the bottom sediment and the amount of organic material; they measure visibility, salinity, oxygen saturation, amount of nutrients such as nitrogen and phosphorus in the water; water samples are taken to examine and determine the amount and constellation of plankton. Often the amount of epiphytes that grow on larger plants or algae can tell that the water is eutrophicated, too enriched with nutrients. By having many schools investigating many different localities around the Baltic Sea and by using the same often simple methods at the same place over and over, the data become comparable. Reports are made to a programme co-ordinator who stores the data in a computer file, and who sends all updated data to participating schools. So the same tests made at the same place can show if conditions have turned better or worse. Data can also be compared with data from other localities in the Baltic region for discussions and understanding of the importance of factors such as salinity, oxygen saturation, amounts of nutrients, redox-cline etc.

In one place, one school might find very high production rates by measuring the (low) visibility in the water bodies and by examining the plankton in the microscope, and they can then search for the possible causes be it sewage not being treated properly, or let outs from industries or agricultural land use, and they may confront the decision makers with their observations and results, and ask what they will do about it. So through participation in the Water Quality programme within the Baltic Sea Project they can use their accurate observations not only to obtain knowledge on the Baltic Sea, but also as a means of active participation in the process of creating a sustainable future.

The Baltic Sea Project took its starting point with the Water Quality programme. But since then a number of programmes have been elaborated: Rivers, Air Quality, Phenological studies, BSP-CoastWatch, Bird ecology, Environmental history - all with a programme co-ordinator (teacher) in charge of getting the protocols and reporting back to active schools. However, new themes develop as sustainability demands teaching a necessary change of lifestyle, and an Agenda for the Baltic Region has taken into environmental education sectors on agriculture, energy, fishery, forestry, industry, tourism, transport, water, health and medicine. These innovative ideas add new perspectives to the Baltic Sea Project, and enable many more teachers teaching a wide variety of subjects to achieve a holistic, interdisciplinary approach.

Science and technology education at the secondary level in Thailand

Associate Professor Pachara Davivongse, Ph.D.
Programme Specialist in Science and Technology in ACEID
UNESCO PROAP, Bangkok

Introduction

This paper emphasises the importance of science and technology education in Thailand which is one of the member states in the APEID network. APEID is the Asia-Pacific Programme of Educational Innovation for Development, which has 199 Associated Centres in 29 countries. There are six associated Centres in Australia. ACEID (the Asia-Pacific Centres of Educational Innovation for Development) is the hub of the APEID and several other networks which UNESCO, Bangkok services.

APEID aims to help member states strengthen their capabilities for creating and using education innovation to solve educational problems. It has paid a lot of attention to the development of science and technology education, sharing appropriate teaching methods and working collaboratively to develop science teaching, learning materials, kits, and equipment in order to strengthen teacher training for science education. Furthermore, as teachers become more competent, given the proper tools and training, they will be able to use their knowledge to control new information technologies and to make use of them in their work and daily lives. Even though most of the countries in the Asia-Pacific region are suffering on account of the economic crisis, every country still recognizes the need for developing its future generations in science and technology, in order to cope with problems which will arise in their future lives.

The Thai Educational System

The Thai educational system provides for six years of primary education, three years of lower secondary education, and three years of upper secondary education. Educational administration is centralised. All schools throughout the country use the same curriculum, authorised by the Ministry of Education. Primary education is compulsory for all children from the age of 6-12. Preparations are being made to extend compulsory education to include lower secondary education. Study at the secondary level is not compulsory but depends on the parents' attitudes, finance and the student's ability. The Ministry of Education is responsible for the provision of primary and secondary education, with the Ministry of University Affairs responsible for tertiary education. Education after the second level is separated into two programmes: the four-year bachelor degree programme and the three-year diploma programme, focused on the training of technicians and skilled workers.

The Department of Educational Techniques within the Ministry of Education is in charge of curriculum
development for primary and secondary schools in all subjects except science and mathematics. In 1972 the Government of Thailand established a semi-autonomous body in the form of a state enterprise with the task of promoting the teaching and learning of science. That organization is the Institute for the Promotion of Teaching Science and Technology (IPST). Many new science curricula have been developed and implemented by IPST.

The revised curriculum is now more technologically oriented. Activities and practical problem solving concerning students' own communities, added to the IPST Science Design Team, have attempted to develop a Thai-oriented modern science programme for Thai students.

**Science Teaching in the Secondary Schools**

There are three levels in the lower secondary education programme and science is a required subject for all students in all grades. The science course offered is an integrated one rather than following separate sciences disciplines.

The lower secondary school science courses are intended to interest, motivate and involve students in understanding science, helping them to identify problems and to look for methods of solving them. All curriculum materials and activities are designed to enable students to observe their environment, enrich their experiences and develop scientific skills. Through science studies, students gain knowledge of scientific facts and principles and have a better understanding of nature and their environment. The practical experience of doing science also develops students' scientific attitudes. As to the emphasis on scientific process skills or relating science to students' daily lives, schools are encouraged to offer more science elective courses. Elective courses should relate to students' interests, such as "Fun with electronics", "Home electrical appliances", etc. Hence, the elective science courses are more locally oriented. Each school can develop its own science course or can select any other science course for its students. It is expected that the study of science and technology will be more locally oriented and will be more relevant and suitable for students' interests, needs and abilities.

In upper secondary education, students who plan to further their education in science or science related fields are guided into taking science discipline courses such as chemistry, biology and physics. Science courses in the upper secondary schools are obligatory for students who want to take up science and science related careers at the university level. Elective courses for upper secondary students allow for students to follow their interests in a wide range of after school activities.

Students who plan to further their education in fields not related to science are required to take Physical and Biological Science (PBS) which is specially designed for these non-science destined students. There are fourteen independent modules. Students are required to study eight modules, in any sequence of four semesters, in three years. The fourteen modules are: Solar Energy, Light, Coloring Matter, Electrical Appliances, Invisible Rays, the Earth and Stars, Synthetic Materials, Sound in Everyday Living Natural Resources and Industry, Good Living, Medicine and Life, Our Body Evolution, Heredity and Environment.

Since the manpower needs in Thailand in the fields of Science and Technology, especially in the areas of material science, computers, electronics, will be very acute during the next decade, the science and mathematics curricula from the primary to upper secondary school will be influenced by that need. It is therefore to be expected that elective courses in new subjects of science, related to technology, will be introduced to provide opportunities for students to develop skills for work and daily life. However, at the upper secondary level, specialised studies in these areas are sometimes directed towards a more vocational orientation, such as electronics, computer science, and user applications.

**Toward developing science and technology education in Thailand**

Science has become a part of our everyday experience, thus it has been made an essential component of the school curriculum at all levels in Thailand. Teaching science realises the potential and scope of science in two basic student activities, which relates to asking questions and solving problems. As such, they constitute an intellectual strategy that every learner should adopt for day-to-day finding, learning, knowing, understanding and doing things in a better way for a better life.

In the past, the science curriculum in Thailand was focused on scientists' work, their method of developing and testing scientific knowledge, concepts and theories that are central to the scientific...
discipline, and understanding some of the methods, concepts and theories that scientists used and applied in our everyday lives. Less effort was made to link this knowledge, these skills and attitudes to a technological application and to the social concerns and the daily experience of the students. In response to the rapid changes in developing science and technology education, the content of science education should be enriched and place greater emphasis on technology that relates to science learning for today and into the future and assists in attaining a better life for all.

IPST has been most active in its efforts to achieve science literacy rather than science being merely a school subject. In Thailand, science curricula had been revised in order to make them compatible with the concept of scientific literacy. What we have emphasised is not so much scientific understanding; the curriculum has the main objective of integrated science rather than thinking of science as physics, chemistry and biology.

School science curricula should provide a variety of learning experiences. It seems that science and technology education in Thailand is not far behind other countries and is moving in the right direction. At the primary and secondary school level, the nature of the disciplines of science and technology and their roles relate to work and daily life. Courses in science and technology are considered to be important and can be related to the real-life situation of the learners. They should provide opportunities for thinking and doing through the active involvement of the student. These courses are then meaningful to the learners in that they want to solve problems by using their scientific skills. Problem solving should be considered more and requires more attention especially at the primary and lower secondary education. Problem solving should be taught at an early age so those children will know how to solve problems better and be able to do it naturally. We should motivate children to think and develop the skills for solving problems when they are young and perceptive.

In order to solve problems, students should recognise that a new situation is indeed a problem situation. They must be able to identify the problem, reduce the problem into manageable sequential sub-problems, recall the relevant knowledge and skills previously learned, and search for alternative answers to the problems. Students develop skills for solving problems by repeated exposure to the problem situation. Teachers should have access to a variety of resources to enable them to encourage the development of problem solving abilities in their students. The problem may be a simple one intended for students to encourage them to think from experiences, to express their own ideas, to take responsibility for their own learning and also to encourage learning experiences that promote creativity across a wide range of interests.

Teaching and learning science have been examined in the context of their effectiveness to enhance students' creativity and science ability, especially their problem solving abilities. In order to promote understanding of scientific knowledge at the lower secondary level, more time is given to experimenting. More emphasis is given to exploratory learning. Problem solving skills are built into these activities to encourage learning experiences that promote creativity. Students may work individually or in a group situation applying their skills to problems that require a high level of performance.

At the upper secondary level, there have to be differences in the elective science courses such as electronics and computer science. Students need to be trained well enough to open up discussions of real problems on science and technology issues, such as CAI, experiments in science, computerised simulations, as well as access to the vast information within the internet. Students also have the opportunity to conduct independent research activities, like science projects in their own particular field of interest. This enables them to show creative ability, a strong task commitment, high interest, and gain knowledge about science and technology and the context in which they are used. They can apply these critically and creatively to solve problems and make decisions to improve the quality of life for the present and into the future.

The educational system in Thailand still produces many students who do not like science or are not willing to learn science. Many students are not interested or quickly lose their interest in science because these subjects seem too difficult and abstract, and seem not to be related enough to their environment and life. It has been observed that science teachers in rural areas are still teaching only information and skills with no emphasis on the students’ abilities and interests. Furthermore, there is a lack of qualified science teachers. Most science
teachers in rural areas are not competent and lack opportunities to obtain new knowledge for improving teaching skills. There is evidence that students, when taught by good science teachers, are likely to be more interested in science.

Science teachers need opportunities to improve their teaching status and condition of work. In a world increasingly dominated by technology, emphasis must be placed on the way for teachers to be acquainted with the use of information technology both in the way of using the technology to service education as well as being prepared to master it for working and teaching. There seems to be a shortage of prospects for science teachers. More recently, science education seems to have particularly suffered from the slowing economy which has led to a decrease in the number of teachers, especially in science and technology education.

The tackling of new challenges and directions in science education, such as an integrated disciplinary approach to science in the solving of technological and social problems, requires new concepts of the science teacher. Well-trained and motivated science teachers will have a new challenge in teaching science that balances content and process in learning.

Computers in Science Education

All countries, however, are aware of the need for alternative innovation approaches to make teaching and learning more effective and try to make use of modern technology for improving the teaching and learning process. One example is the use of computers, which are already being used with success to promote scientific literacy. We should accept that computers are effective tools in improving student achievement and to keep pace with the rate of progress of technology in teaching and learning science. There is an increasing emphasis on the use of computers in Thailand. We may identify the use of computers in two ways; first, using the computers as teaching aids (CAI, CAD, CBT) and secondly, the study of computers as a discrete component of the curriculum or in user applications such as word processing and statistical applications, etc. However, the use of computers still varies from school to school. Most schools do not have computers due to the cost involved in purchasing and maintaining the hardware and the software to establish programs. Above all, there is a shortage of trained teachers to operate computer centres.

You should know that, in Thailand, the government is responsible for education policy based on equity, quality control, and standards. Financing education adequately is an urgent task and the government must assume the responsibility for protecting against corruption, and for securing the largest budget share possible for education, which is not an easy task. Above all, for science and technology education, the government should give special attention to promoting equality of opportunity. It should recognise the need to give science teachers and students competence in the use and control of information technology necessary for work and life. The government should also recognise the specific challenge before our country, in facing the twenty-first century. It should accept that the way of life is changing. We must therefore help establish in students a positive attitude toward science and technology in the hope of attaining a rational outlook, open-mindedness, persistence, co-operativeness, critical thinking and tolerance of various opinions, honesty in preserving observations, etc.

The development of science and technology education has been slowed due to national problems flowing from the economic crisis with which Thailand has been struggling painfully. On the one hand, students need to compete in learning science; but on the other, the government is concerned with providing equal opportunities for learning science. Although the students need to take every opportunity for learning and self-improvement, they will not be able to realise their potential unless courses in science are offered to them. They should have increasing opportunities for access to data. Computer technology should enable everyone to gather information and to select, arrange, manage and use it. This is the effective use of modern media. However, science and technology should be a social experience through which everyone in the society learns about themselves, develops interpersonal skills and acquires basic scientific knowledge and skills. It should enable all students to develop an awareness of themselves and their environment. In many cases, such competence and skills are more readily acquired if students have opportunities to try out and develop their abilities by becoming involved in work experiences.

Science is the work of specialists and, therefore, confined to those with special abilities for undertaking hard, experimental work, with the view that scientific knowledge for the understanding of
everyday problems can be part of the tools of every person and should be taught in schools. In order to advance toward a learning society, the government realised the role of science education in economic progress but it seems that it has not equally shared a tendency towards making science available to all students. There is a particular need to emphasise the updating of the curriculum for science and technology education to ensure they respond to the demands of society. Furthermore, there should be an opportunity for people who have left the formal education system due to a lack of financial resource and in order to work with their parents on a farm or plantation. They should have the opportunity to acquire more knowledge in science and technology through short courses in order to apply it in their daily work and life and to teach others in the community. These people also represent a vast resource of experiences that they can share in school. It is becoming more and more difficult to keep up with this intention to make science available for all. While science education is an on-going process of improving the knowledge and skills of talented students, the government will promote specific science schools for them, despite the serious warning of economic and financial crisis in Thailand.

Conclusion
Science and technology education in Thailand is seen as an important issue for the government as well as for AOEID. Even though IPST has managed the development of science and technology education very well so far, there are still too few students who have succeeded in science and science-related areas. Most students study science because it is required for entry to university in order to enter prestigious careers such as those in medicine and engineering. Science and technology should be the subject that all students must learn in order to have a good life and should not be restricted to those students who learn or work in science-related fields. Working in the environment with continuously developing technology, all students should be able to use and control this technology. The teacher’s role will change from teacher to facilitator. Both teachers and students will not be able to avoid new technology and media such as computers, cable and satellite TV education broadcasting, video teleconference, multimedia equipment, interactive information exchange systems (including e-mail and online access to public library databases), computerised simulators and virtual reality systems. The teacher will help their students to evaluate and use effectively the information they have gathered for themselves in their real life situations. Both teachers and students should not fear technology. Science and technology education is not only for science students but also for all people.

Example of a ‘concept practical’ –
giving meaning to the concept of acceleration

Peter J.J.M. Dekkers
Faculty of Physics and Astronomy
Institute for teaching and Educational Practice
Vrije Universiteit, De Boelelaan 1081
1081 HV Amsterdam

What is a practical concept?

Practical work can be used for different purposes: Berg and Giddings (1991) distinguish process labs, skill labs and concept labs. In process labs, students develop investigative skills such as formulating a research question, designing a research plan, etc. In skill labs they learn how to use a particular piece of apparatus, a measuring technique, etc. Concept labs are meant to help students gain conceptual understanding. Practical work can be used to illustrate the validity of a theory or show an application, but then it follows the introduction of the theory. However, the theories of physics are (at least to some extent) based on empirical events, not vice versa. Can practicals form the basis on which the concepts of physics are built? The answer is yes, but only if the practical is designed for that purpose. This paper presents an example of a concept lab: the worksheet is given in the box at the end.

How can concepts be developed in a practical?

Phenomena can be described and explained in numerous ways - that is why we have so many arts and sciences. That is also why a few observations in a practical cannot lead to the development of the unique concepts of physics. However, a lab can often show students that their usual, informal descriptions and explanations are not fully consistent or incomplete. If the students themselves reach this conclusion, they may start looking for better descriptions and explanations. Often, they can find these after a suitable adjustment of their existing concepts. To start and maintain this search it is imperative that the right questions are asked by the teacher, the worksheet and fellow students. Discussing the answers in a class debate is an excellent way of making the search explicit. During this debate it is important to check that new explanations and descriptions (1) match the facts, and (2) are coherent and in accordance with the scientific knowledge the students already have. Because students generally lack the necessary overview to deal with the second criterion, the teacher has a guiding and controlling role during this so-called ‘Socratic’ debate.

White and Gunstone (1992) designed a clever structure for this kind of practical called POE (Predict-Observe-Explain). If students predict what will be observed in the practical, they become aware of, and committed to, their existing explanations and descriptions. Observing the facts can make them aware of unsatisfactory aspects of these descriptions and explanations. The phase of explaining, finally, is supposed to contain the Socratic debate indicated above.

Illustration: a concept lab for the concept of acceleration

The worksheet below shows how these ideas were
elaborated in a practical about the concept of acceleration. The practical was used with students in post-O-level courses in Botswana and South Africa. The design, implementation and evaluation of this and two other practicals was part of my PhD study into the role of concept practicals (Dekkers, 1997, 1998). The practical is meant to address the following problem (see also Trowbridge and McDermott, 1981). The students in the target group knew the definition of acceleration quite well. For example, about 75% of them answered question 1 (see the box below) correctly in a pretest. However, in qualitative descriptions of moving objects they did not distinguish between the speed and acceleration of objects. For example, an average of 43% of the students answered in this test that speed and acceleration always change in the same way. This means that for question 2, these students stated that the speed and acceleration of the cricket both decrease during the upward, and both increase during the downward part of its motion. Similarly, 24% stated in question 3 that an accelerated movement in which the acceleration decreases does not exist. 41% stated that the decelerating motorcycle 3 moves in this way, and only 7% stated correctly that motorcycle 2 does. How would your students answer these questions? It appears that students who know the definition of acceleration, and are able to calculate its value in simple standard problems, do not necessarily understand the full meaning of the concept. The practical is meant to help students construct an empirical meaning of the concept. To do so, they must learn to distinguish between speed and acceleration in a qualitative way.

**The ‘scenario’ - what happens during the practical**

The structure of the practical has a ‘path’ for students to follow to the intended conclusions. Of course, what happens in the classroom always differs from what one has planned. However, after several revisions of the worksheet, what happened in class agreed sufficiently with my ‘scenario’ for the most important conclusions to be reached. The practical can be conducted in small groups or with the whole

1 a A car is driving at 10 m/s. It accelerates uniformly in the next 4 seconds to a final speed of 16 m/s. Find the acceleration.

   a = ..............

b The car is going at 16 m/s. Then it brakes; the car gets a constant deceleration of 3.2 m/s². After how many seconds does the car stop moving?

   t = ..............

2 A cricket jumps vertically upwards passing positions 1 then 2 then 3. (See figure 1). Neglect friction. Delete what is incorrect. As the cricket passes point 1:

   The speed is increasing / constant / decreasing.
   The acceleration is increasing / constant / decreasing.

As the cricket passes point 3:

   The speed is increasing / constant / decreasing.
   The acceleration is increasing / constant / decreasing.

3 For three motor cycles, the speed was measured at t = 1s, t = 2s, t = 3s and t = 4s.

   The results are shown in the table. A student states "One of the motor cycles was accelerating, while the value of the acceleration was decreasing."

   This statement is

   A incorrect. A motion of that kind is impossible.
   B correct - motor cycle 1 moves in this way.
   C correct - motor cycle 2 moves in this way.
   D correct - motor cycle 3 moves in this way.
   E incorrect - a motion of that kind is possible, but no motor cycle was moving in that way.

class as one team. In both methods, however, it is very important that the students get the opportunity to answer the questions by themselves and forward, discuss and evaluate their own and each other's arguments. The teacher should carefully avoid, at least in the initial and middle stages of the practical, to forward his own view as the correct one. The 'scenario', summarised in figure 2, is as follows.

It is expected that most students predict that the speed and acceleration of objects change in the same way. Next, in section C of the worksheet, they study a ball that rolls down straight rails at different inclines. They are expected to confirm a valid rule that most of them already use; on a downward incline, the speed of the ball increases (if friction can be neglected). Next (section D) a ball rolls down an incline PQTU of which section QT is curved and has a decreasing steepness. A problem is expected to arise; something 'must' decrease, because 'the rail is getting less steep. The speed is the only available candidate to play the role of this 'something': however, the speed increases according to the rule established in section C.

In one class, students formulated the dilemma as follows:

S1: I do not think the rule will be true here [on QT], because the gradient of the slope decreases. And therefore, the speed decreases.

S2: [disagrees] As long as there's a slope, the gradient is a certain number, a positive number, the speed will go on increasing.

Then the students study the balls rolling down the same straight inclines again (section E). They should now focus on the differences rather than the similarities: the speed increases more quickly on a steeper incline. The initial rule is expanded: the speed of objects on downward inclines increases, and the steeper the incline, the quicker the increase. This is used to solve the earlier problem; it can be concluded that the speed of the ball on the curved incline continues to increase, but increases less and less quickly as the ball rolls down.

In the class of S1 and S2, most students agreed with S1 in their predictions. However, they became excited when they watched the ball roll down rail PQTU. A class debate followed that is summarised here. Many students changed their initial view, but S3 still agreed with S1:

S3: The speed changes, and it depends on the slope. If the slope is steep, the speed is higher. Then when it reaches that curve, the steep is rather less. Then the initial speed decreases, at that point.

[A lively debate follows, in which S3, supported by several students, defends his opinion against arguments of many other students. The teacher (T) clarifies the positions and reminds the students of their earlier observation: the speed of the ball increases on the straight inclines, even on those that are not very steep.]

S3: Okay, we observe that the speed increases, faster, on a steep slope. Here we have a

Predict: If a ball rolls down the rails shown in the diagrams, how do v and a change?

Figure 2. Structure of the concept practical about acceleration
steep slope, that is PQ. Then from Q to T.

T: So what happens to the speed, on this slope PQ?

S3: It increases fast.

T: And on QT.

S3: It increases... slow...

T: What did you say now? [All burst out in laughter, become excited.]

S3: [Sounding wronged:] There is a difference! The fact that it increases slower is a difference from the first one. That gives us the decrease.

S4: If the initial velocity was 40 here, then here it will be 44 and here it will be 44.4, but it's increasing. [Later:]

S5: [S3] confuses speed and acceleration. You're talking about the change of speed, you're saying it changes slower. What is getting slow is the acceleration, but the speed will go on increasing. If it was increasing at a rate of 2, say now here it would be increasing at a rate of 0.11.

After discussions of this kind and an overview and evaluation of the arguments at the end, these outcomes are phrased more precisely as: on the curved incline, the speed increases, while the acceleration of the ball decreases. These findings are applied in exercises (section F), that include a comparison with the predictions and relate to prior knowledge.

Prior knowledge

This practical does not involve the introduction of new theory. However, it is essential that the students have the proper knowledge at the start: we want them to be able, in principle, to resolve by themselves the conceptual problems the practical points at. At the start of the practical, well-prepared students identify time, position, distance, displacement and speed as relevant quantities in descriptions of motion. They know the relations between these quantities, and distinguish between descriptions of an instant in time and those of a time interval. In particular, they can distinguish instantaneous from average speed. They can qualitatively describe movements they watch in terms of these quantities. These are not trivial conditions, many students mix up descriptions of instants with those of time intervals. See for example McDermott (1996) for teaching materials that address the conceptual problems involved here. The practical was written for students who know the definition of acceleration and can do simple calculations involving this quantity. The practical is meant to help students relate the definition of acceleration to the proper aspects of real observed events, thus giving the quantity a qualitative, empirical meaning.

It is not difficult to modify the practical for students who do not yet know the definition of acceleration. The modified practical can help them to note that a proper description should specify how quickly the speed changes. It could pave the way for a definition of acceleration by showing the relevance of a quantity that indicates this 'quickness'. All movements studied in the practical are in forward direction and are described as if they are linear, so that we can identify velocity with speed. This means that we describe the movement of the ball on section QT of figure 2 as one in which the speed increases while the acceleration decreases. In a fully correct description, we should distinguish between the tangential and radial velocity and discuss the centripetal acceleration. These considerations were ignored in the practical so as to avoid confusing the students with too much detail. The acceleration involved in changes of the direction of the velocity was dealt with at a later time.

Apparatus

- One steel ball.
  I used ballbearings with a diameter of 2.5 cm, smooth but not new, a gift from a company specialised in drilling rigs for the Kalahari Desert.

- One straight rail, retort stand and clamp: see figure 4 of the worksheet.
  I used a curtain rail (length 1 m, width 1 or 1.5 cm) nailed to a wooden plank.

- One partly straight, partly curved rail PQTU: see figure 2 of the worksheet.
  I used a curtain rail nailed to a wooden frame. Point P was about 0.7 m above ground level, sections PQ, QT and TU were each about 0.8m long. Note: the real set-up was much less steep than figure 2 suggests. The speed of the ball on TU easily gets too big so that you cannot see whether the ball still accelerates or not. My advice: before you build the wooden frame, try out a few shapes PQTU.

Results

The mean score on test questions like question 2
increased from 15-20% before to 60-65% just after the practical. 4 months later the average score was 40-45%. For question 3, the scores before and after the practical had stayed almost the same (for details, see Dekkers 1997). In short, concept practicals can play a positive role in conceptual development, but no miracles are to be expected. In particular, it is quite difficult to properly manage class discussions, especially if you are not used to the method. Class discussions take quite a bit of preparation (can you anticipate the students’ views and answers?), creativity (can you make sense of what they are trying to say and ‘translate’ it for the others?) and flexibility (until the end of the practical, exchanging views is more important than finding the ‘correct’ answer). A poorly conducted class discussion has either no clear conclusions for the students or, conversely, is in fact a teacher-centred lecture. In a well-conducted discussion, however, you will really put your students to work. In my experience, they eagerly respond to this challenge. As a result, you will learn a lot from them about what makes your subject so difficult and interesting. They, in turn, will learn a lot more about physics than can be tested in standard, quantitative questions. Several students in my study stated that for the first time in their school career, these practicals had really forced them to think.

# Concept Practical:

## Study of a ball rolling down a curved slope

### A. Aim

In this practical you will learn what makes acceleration a different quantity from speed. First answer the questions below on your own, to find out what you already know about acceleration and speed. You will check your answers in the experiments that follow.

### B. Predictions

Answer the questions below by filling in the boxes labelled 'Answer before the lab'. Fill in S (stays the same), I (increases), D (decreases) or 0 (is zero). If you want to change an answer later, please do so by writing S, I, D or 0 in the box labelled 'At end'. This way, you can quickly see later what you learned in the lab.

In this worksheet, the word 'speed' means 'instantaneous speed'. In all questions you may ignore effects caused by friction. You may assume that the force of gravity that acts on an object is the same no matter where the object is.

Science Education International, Vol. 9, No. 3 September 1998 23
C. Observing moving objects

In the following experiments, determine whether your predictions were correct.

Release a ball from the top of a straight, downward rail (see figure 4). Observe what happens to the speed of the ball as it rolls down the slope.

8. The speed of the ball

Next make the slope less steep (see fig. 5) and again observe the ball, released from the top.

9. On the slope that is less steep, the speed of the ball

Pay special attention to the movement between points T and U (this is needed in section E).

10. From T to U, the speed

Use the answers to questions 8-10 to draw a conclusion in question 11.

11. For a ball rolling down a straight slope, the speed............. . (Provided that the effects of friction can be ignored.)

12. Does this rule make sense? Why, or why not? Does it agree with your experiences?.........................

13. Do you think the rule is also true for a curved rail (like QT in figure 6)? Why, or why not? .........................

In section D you will determine by experiment whether the rule holds for a curved rail like section QT.

D. Predictions and observations for a ball on a curved rail.

See figure 6. Imagine that a ball is released from point P. Use question 11 to predict how the speed will change. (Fill in 'predicted in questions 14-16.) Please fill in all predictions before you observe the event.

Then, release a ball from P and observe how the speed changes. (Fill in 'observed' in questions 14-16.)
14. As the ball rolls from P to Q, its speed
15. As the ball rolls from Q to T, its speed
16. As the ball rolls from T to U, its speed

It can be difficult to observe the speed on TU. To answer question 16, the following can help. Release the ball first from T, then from halfway between T and Q, then from Q, then from halfway between Q and P. For each case, observe the final speed at U. Observation: When the ball starts closer to P, its final speed at U becomes greater / stays the same / becomes smaller.

Conclusions:

17. As the ball rolls from Q to T the speed . . . . . . . . because

18. Check question 11, where you found a rule for straight rails. Use your observations to decide whether it is true for curved rails....

Note: In the experiments there was very little friction between ball and rail. If there had been a lot of friction, the speed would first have increased, then become constant (terminal speed). In our case the effects of friction are small and can be ignored.

B. Observing accelerating objects

See figures 7 and 8.

19. Compare the steepness of slopes PQR and STU: the steepest slope is ....

A ball is released from the top of slopes PQR and STU.

20. Compare how quickly the speed of the ball increases for the two slopes: the quickest increase of v occurs on slope . .

21. If the same rail is made less steep, the speed increases more / less / equally quickly.

Remember that acceleration is defined as the change in the velocity per unit time.

22. Compare the acceleration of the ball for slope PQR and slope STU:
   Acceleration on slope . . > Acceleration on slope . .

The two slopes of figures 7 and 8 are combined into one slope: figure 9. The ball would experience a bump on this slope. Therefore we make it smooth, as in figure 10.
Note: section PQ in figure 9 is just as steep as PQ in figure 10. The same is true for sections TU in both figures.

A ball is released from the top of the rail of figure 10. It rolls from P to Q, to T, then to U.

23. Compare the acceleration of the ball on PQ to its acceleration on TU. (Fill in: >, = or <.)
   Acceleration on PQ ...
   Acceleration on TU ...

24. Conclusion: As the ball rolls from Q to T the acceleration ...
   because ...
   ...

Conclusions: Comparing speed and acceleration

Consider the motion of the ball as it rolls from Q to T. Use your answer to questions 17 and 24. It is important to note that the rails of figures 6 and 10 are the same.

25. For a ball rolling down any slope without friction, the speed .........

26. For a ball rolling down a slope, if the steepness of the slope decreases then .........

27. For a ball rolling down a slope, the acceleration does not depend on the ...
   ......... but on the ...

28. Return to questions 3-5. Were your predictions correct? (Fill in answers 'at end'). If some were incorrect, state what you have learned now.

F. Examples and applications

If the results of this practical surprised you, you may have learned something new. You may have learned that the acceleration can decrease even if the speed increases. Perhaps it is still difficult to see how this can be true. The following questions may help.

29. Ball 1 rolls down a slope at 1.8m/s. 2.0s later, its velocity is 2.4m/s
   Ball 2 on another slope starts from rest. After 2.0s the velocity is 1.0m/s
   Find the acceleration of: Ball 1: a=  ms\(^{-2}\). Ball 2:a=  ms\(^{-2}\).
   After 2.0s, which ball has the greatest velocity? .. the greatest acceleration? ...

30a. Answer questions 1 and 2 (page 1, under 'At end'). Explain your answer:
   As the trolley rolls down, the acceleration.. because .........

   b. Assume: The rail is made so steep that it is vertical. Now the trolley
      just falls down! Does the speed change, as it falls?: .........
      Does the acceleration change as the trolley falls?
      The acceleration ...... because .........

   c. Use question b. to answer questions 6 and 7 (page 1, next to 'At end').

(Series #1)

OSHA Laboratory Standard
(29CFR part 1910 Subpart Z)

Providing a safe working environment for employees and students is a serious responsibility for science leaders. In the United States during 1990, OSHA (the government’s department of labor division responsible for employee safety) issued the Science Laboratory Standard for employees working in laboratories (including academic laboratories such as middle and high schools). The term 'laboratory' is defined as “a facility where the laboratory use of hazardous chemicals occurs. It is a workplace where relatively small quantities of hazardous chemicals are used on a non-production basis.”

Most employees are covered by another standard called the Hazard Communication Standard. However, because of the dangers and uniqueness inherent in laboratory work, employers are required to cover laboratory workers (including science teachers) under the Laboratory Standard.

The standard is performance based. This means that OSHA provided the basic outline requirements and then each employer writes a plan tailored to their own needs. For example, plans may vary from district to district but all plans must contain standard operating procedures. Below is a summary of the plan’s basics tenets.

Elements of Plan:

i. Standard operating procedures

ii. Criteria to determine and implement control measures to reduce employee exposure including engineering controls, use of PPE and hygiene practices.

iii. Requirement that fume hoods and other protective equipment are functioning properly and within specific measures.

iv. Provisions for employee information and training

v. Circumstances where laboratory operation requires prior approval from employer

vi. Provisions for medical consultation and examinations

vii. Designation of personnel responsible for implementation of CHP including Chemical Hygiene Officer (CHO) and if appropriate, Chemical Hygiene Committee. The Committee Hygiene Officer is an employer designated employee who is qualified by training or experience to provide technical guidance in the development and implementation of CHP.

viii. Provision for additional employee protection when working with particularly hazardous substances, eg. reproductive toxins, carcinogens.

OSHA compliance officers initiate inspections by reviewing the employer’s plans. They then focus on plan implementation and policing.

No matter where you are geographically, this standard is just that! It is a level of expectation in order to provide for a safer working environment.

Future safety articles in Science Education International will deal with various components of the plan and other safety issues.

(Editor's note: This will be a regular column on safety in future issues.)
Stepping into Science & Technology Project
Workshop Pack

A new pack has been prepared for ICASE Member Associations to promote pre-secondary science and technology.

The purpose of the Pack is to assist you to mount an exhibition table in your school, in the community, at a conference, or in meetings of your Science Teachers’ Association. Or it would help you to run a workshop of pre-secondary practical science and technology activities as a come and share session for delegates.

The theme is international since ICASE is international - remember the ‘I’- but, more importantly, for scientific and technological literacy for all to become a reality the communication and exchange of information between teachers of science and technology on a world-wide basis is essential. On a more national / local scale, communication within the community is equally important, so that community members are aware of what is going on in science and technology education. Working with pre-secondary or primary teachers is also a public understanding of science activity when teachers have not been trained in science and associated subjects.

The Conference Pack is a guide to producing a visual means of communication to a wide audience. We hope you find it useful and are sure that once you have staged your own Come and Share workshop or exhibition you will want to make the next one even better.

Finally, please bear in mind that the Stepping Into Science & Technology Project is not about examinations and tests, it is about learning. Young people undertaking simple projects or activities at an early stage in their lives, without the pressures of examinations, may become more efficient learners in formal classroom situations. The aim of the project is for students to do; to undertake a hands-on activity and explain what they have been doing in their own words. As they progress through the Steps a certificate is awarded at each stage as a means of encouraging and recognising achievement.

We wish you every success with the use of this Pack and only ask that you communicate with ICASE so that you can share your experiences and ideas with others through the Stepping into Science Newsletter.

A copy of the Stepping into Science and Technology Project Workshop Pack will be sent to each ICASE Member Association.

Enquiries should be directed to:

18 Octavia, Bracknell, Berkshire RG12 7YZ, United Kingdom
Cyprus children’s images of scientists

Ritsa Maria Hadjikyriacou (BSc DIC MSc MSc)
City University, Cyprus

The purpose of this study was to determine if there were gender/age differences in the images that 11 to 14-year-old students have about scientists. From the data we found clear evidence that, as the female students get older they adopt and project a more stereotypic image of the scientists. On the other hand the male students seem, as they get older, to harbour a less stereotypic image of scientists.

The purpose of this study is to investigate what image Cypriot students have of scientists and to examine the effect of gender and age differences on the image of a scientist that they perceived and projected. It is a well-known fact that, in comparison to men, fewer women are found in scientific careers and, as a result, fewer girls elect to study science at school and in higher education (Harvey 1980). Thus in recent years issues of science attitude and gender have been explored through qualitative and quantitative studies. Gender differences have been found in scientific achievement, activities, interest and attitudes.

Furthermore, J. B. Kahle (1988) and A. Kelly (1985) reported that many high school students have a stereotypically masculine image of science. L. Flick (1990) reported that his sample of 47 fifth graders also drew more males than female figures before visits from female scientists. The 549 students in high school biology classes surveyed by Mason, Kahle and Gardner (1991) also tended to draw male scientists. Ormerod and Wood (1983), concluded in their research that sex differences in the direction of children’s interest in science are established well before secondary school age.

In addition to the above, in one of the largest studies, D. C. Fort and H. L. Varney (1989) found that among the 1,600 responses from students in grades 2 through 12 a vast majority of both male and female students depicted male scientists. Overall they concluded that students perceive a scientist mostly as a benevolent white male. Also S. Katsambis (1995), showed that female students had a less positive attitude towards science, participating in fewer relevant extra curricular activities, and aspired less often to science careers.

Background and design of the study

The study focussed on the gender and age of subjects and their perception of scientists. The questionnaire collected the respondents’ pictorial representation of scientists as well as their written ideas.

Each class teacher at each participating school was requested to ask the students in the class to answer the study’s questionnaire. Teachers were asked not to discuss any possible answers or prompt or influence students’ answers in any way.
developed by the author in 1997 for the sole purpose of gathering information for a world-wide investigation into adolescents’ images of science. The questionnaire consisted of eight open-ended, non-factual / subjective questions, since they dealt with aspects of the state of mind of the respondent, and a request for the children to draw their image of a scientist. Also the questionnaire contained three personal questions for gathering background information about the respondents’ gender, age and nationality. The data gathered by the questionnaire were both in written and pictorial form.

The questionnaire had an uncommon structure that was developed to make its image more acceptable to the young respondents. All the questions, along with the request for the drawing, were placed at the top of the questionnaire leaving the rest of the A4 paper blank. The request for the drawing of their image of a scientist was made on a separate line from all the other questions in bold type and underlined in order to ensure that all the children noticed it. The children could answer the questions as well as add any other beliefs or thoughts they had about the scientists.

The students had the option of answering the questionnaire either in English or Greek. The questionnaire was translated into the Greek language in order to give the opportunity for subjects with a poor command of English to participate in the study.

Results

The data gathered were in both pictorial and written form, but for the purpose of this study only the written part was analysed.

Table 1 provides information about the gender and age of the students in this study. The total percentage of male students who participated was 53.8% and of female 46.2%.

Even though an effort was made to gather approximately the same number of questionnaires from each age category we found that a higher number of eleven-year olds returned completed questionnaires.

The results indicate that the majority of the male students perceived a scientist to be male. On the other hand, none of them conceived a scientists to be, in general, of the female gender. In particular it is evident from the results that a slight majority of the eleven year olds stated that a scientist could be both male and female. On the other hand the majority of the twelve and thirteen year olds maintained that a scientist was primarily male. However, the bulk of the fourteen year old students perceived scientists to be of both genders.

From Table 2 we find that the majority of the female students believe that scientists can be of both genders. In particular the majority of the eleven year olds believe that scientists can be male or female and the bulk of the twelve and the thirteen year olds believed that also. On the other hand the majority of the fourteen year olds believed that scientists are mostly male.

</tbody>
</table>

Overall we can conclude that as the male students grow older their views about the gender of scientists were less stereotypic. On the other hand the opposite happened with the female students who tended to, as they grew older, adopt and project a more stereotypic gender image of scientists.

### 2 Age of scientists

On the whole the majority of the children perceived a middle aged scientist. In particular eleven year olds claimed that scientists could be either middle aged or
young. On the other hand the twelve and thirteen year olds stated that scientists were old. The majority of the fourteen year olds envisaged a middle aged scientist.

Male gender and age

The majority of male eleven year olds stated that scientists could be either middle aged or young. On the other hand, the twelve and thirteen year olds perceived an old aged scientist. The fourteen year olds claimed that the majority of scientists are middle aged. Altogether a majority of male students perceived a middle aged scientist.

Female gender and age

The majority of the female eleven year olds believed that a scientist is young or middle aged, whereas the majority of the twelve year olds believed that a scientist is middle aged to old and the majority of the thirteen year olds believed that scientists are mainly old. On the other hand, the majority of the fourteen year olds believed that a scientist is middle aged or young. The majority of the female students perceived an old aged scientist.

Overall, it can be concluded that the female students have expressed the more stereotypic old age looking image of a scientist whereas the male students have opted for a middle aged scientist.

3 Lifestyle of scientists

The general perception that students put forth for the lifestyle of scientists was that they are dedicated to science (34.4%). On the other hand 32.5% stated that their lifestyle was ordinary, only 2.1% stated that a scientist is always lonely and only 1.8% claimed that scientists have a hyperactive social life

Male gender and age

The majority of male eleven and twelve-year-olds, 45.6% and 36.4% respectively, claimed that the lifestyle of a scientist is ordinary. On the other hand the majority of the thirteen (37.5%) and fourteen (44.2%) year olds claimed that scientists have a lifestyle dedicated to science.

Female gender and age

The majority of the female eleven-year-olds (36.4%) believed that the lifestyle of scientists was ordinary. On the other hand the majority of the twelve, thirteen and fourteen-year-olds, 30.6%, 48.6% and 42.9% respectively, believed that the life of a scientist was dedicated to science.

Overall, we find that the majority of the male students (34.7%) projected the idea that a scientist’s lifestyle is ordinary. It is also evident that as the male students got older they supported the more stereotypic image of a lifestyle dedicated to science. On the other hand the majority (36.7%) of the female students projected the perception that a scientist’s lifestyle was dedicated to science. It is also apparent that as the female students got older they supported the more stereotypic image of a scientist’s lifestyle.

4 Marital status of a scientist

On the whole, and irrespective of gender and age, a slight majority of the students stated that a scientist is normally married. The second most common answer was that a scientist might be married or he might not be, hence leaving as the third most popular answer the one of an unmarried scientist.

Male gender and age

The majority of the male eleven, twelve and thirteen year olds stated that a scientist is in general married. On the other hand the slight majority of the fourteen-year-olds stated that a scientists is normally single, as he was always busy.

Female gender and age

From the results we find that the majority of the female eleven year olds believed that some scientists are married and some are not. On the other hand all the other age categories believed in general that a scientist is single. The main reason they put forth was that a scientist is too busy to get married.
We can conclude from the results that the female students seemed to have a more stereotypic image about the marital life of scientists. Even though both genders seemed to put forward the same reason for the scientist's lack of a partner.

5 Mental abilities of the scientist

Female gender and age

The main bulk of all the age groups of the female students stated that, in general, scientists are very clever individuals. Also a considerable number of students from all age groups, stated that a scientist is a genius.

Overall, we can conclude that all the students irrespective of gender and age perceived a scientist to have superior mental abilities. Also many of the students designate mental ability as the main criterion for becoming a scientist. Characteristically, one of the students stated that "... in order to become a scientist you have to be very clever, otherwise you will not be able to understand all the scientific things." (No: 281, male 14 years old)

The majority of the students stated that a scientist is in general a very clever individual. Also there was a small number of students claiming that, in order to be a scientist, you have to be a genius.

Male gender and age

The majority of all the male age groups stated that all scientists are always very clever. Also it is noticeable that a high number of thirteen year olds perceived a scientist to be a genius. One twelve year old stated that "women can't be scientists because they haven't got enough brains."

A typical representation of a scientist.
No.254 - Female 14 years old
Discussion

The analysis of these data suggests that, among this sample of Cypriot students, females often expressed a more stereotypic image of scientists. It was especially noticeable that there was a difference not only between genders but also between the different age groups. Also it was quite evident that the older female students projected a more stereotypic image of science.

In recent years, in many countries, issues of science attitude and gender have been explored through qualitative and quantitative studies. For example, in the United States of America, textbook companies, teacher training programs and testing agencies take into account gender differences in science as teachers are trained, texts revised, and test items authored (Boone 1997). The whole program aims to increase the number of students, especially women, who pursue science successfully.

In the case of Cyprus, as is evident from the Cyprus government educational statistics, the number of females pursuing a scientific career is reducing, even though the number of students pursuing further education is increasing. It is therefore essential to remedy the situation and eliminate the kind of scientific illiteracy that seems to exist. The situation can be improved by developing a more science friendly curriculum and by retraining science teachers in order to entice female students to pursue a scientific career.

Science Clubs.

Science Clubs allow members and leaders to choose areas of study according to their interests rather than being constrained by an imposed syllabus. Lateral thinking, enthusiasm and imagination are characteristic of members of science clubs, and they share, develop respect for others and the environment and behave in safe ways. Science and technology follow naturally when real problems are tackled. The photo of members of the International Association of Science Clubs in action illustrates these points.

Oliver Harris, an IASC Committee Member, at the London BAYSDAY Exhibition, with the windmill he had made

For further information about the International Association of Science Clubs please contact: Mr B.J.K. Tricker, The Firs, Southdown Road, Freshwater Bay, Isle of Wight, PO40 9UA, United Kingdom.
Science Across the World remakes its website

A working example of how the Internet can bridge language and cultural differences has been given a facelift after two years in the field and a rising popularity among schoolchildren in 46 countries.

The Science Across the World programme, coordinated by the Association for Science Education in Britain, was one of the first to incorporate a website into an education programme. The programme aims to raise awareness of science and technology issues in society, industry and the environment. The Internet was used initially to allow teachers and students to send information to other schools.

But there is much more to the new site. It is easier to navigate and more visually appealing. Ease of navigation and speed of download are key features. There are no spinning logos: instead there are resource areas, with discussion forums and news sections to contribute to. Nor is it all dull text. Video clips are available. And the whole thing is available in six languages - English, French, German, Italian, Portuguese and Spanish.

Those who dream of using the Internet in schools might like to check how its done in Science Across the World. There are 1 200 schools world-wide using the BP-sponsored programme, and in the last six years it embraces schools in Africa, the AsiaPacific region, Europe and North and South America.

Note to Member Organizations

Please ask your members to submit material to Science Education International. We are looking for:

• Teaching activities and lessons
• Action research articles which talk to the practising teacher
• Research articles which focus on practice, not research strategies
• Informal and non-formal articles which address 'things to do' in these settings

Please include photographs, pictures and drawings

Manuscripts may be sent to: Robin Groves, ICASE Journal Editor
PO Box 244, Mt Hawthorn
WA 6016, Australia

or by email to: grovesr@ozemail.com.au

International Networking in Science Education
at the ASE 1999 Annual Meeting
University of Reading
4 - 9 January 1999

The international programme of conferences will include: Models and modelling in science education; Information and communication technology in science education; Science and technology education; Environmental education.

This links to 300 programme items and 250 exhibits at the ASE Annual Meeting. These all provide opportunities for reporting on the latest developments and initiatives in advancing the Science Project 2000+ goal of scientific and technological literacy for all, as well as appraising recent research and developments in science education.

There are excellent preferential conference rates for members of associations and institutions affiliated to ICASE.

ICASE Homepage: http://sunsite.anu.edu.au/icase
Science Education International is the quarterly journal of the International Council of Associations for Science Education. ICASE was established in 1973 to extend and improve education in science for all children and youth by assisting member associations throughout the world.

This journal provides means for associations, institutions, centres, foundations, companies and individuals concerned with science education, to share perspectives, concerns, ideas, and information which will foster cooperative efforts to improve science education, and which will serve as a chronicle of the advancement of science education throughout the world.

ICASE Summer Symposium at Utrecht

Dennis G Chisman

They drew on examples from chemistry, physics and biology taken from several European countries and from India, USA and Taiwan.

The papers and discussions are being edited by the science education team at the University of Utrecht and will be available in printed and electronic form through the ICASE network within six months. Further information is available from Onno de Jong, Centre for Science and Mathematics Education, Princetonplein 5, 3384 CC Utrecht, Netherlands (Fax: +31 30 253 7494; e-mail: o.dejong@chem.uu.nl).

Dr Onno de Jong (left) and other participants at the ICASE Summer Symposium in Utrecht, June 1998

The successful series of biennial symposia on science education research, held in Dortmund Germany and organised by Hans-Jürgen Schmidt over many years, was continued in June 1998. The symposium, attended by about 50 participants, held in the University of Utrecht, was organised by Dr Onno de Jong, Centre for Science and Mathematics Education.

The theme of the 1998 symposium was Bridging the gap between theory and practice: what research says to the science teacher. The papers presented included learning science through modelling, the transfer of research findings into practice, models of teacher development, exploring aspects of scientific literacy in the classroom and students’ conceptions.

A practical demonstration at the Utrecht ICASE Summer Symposium in June 1998
1998 CEFIC Science Education Award goes to France

Dennis G Chisman

On the occasion of the CEFIC, European Chemical Industry Council, General Assembly in Berlin on 12 June, 1998, Mr Byran Sanderson, newly elected CEFIC President, presented the 1998 CEFIC Science Education Award to Ms Sylvie Riou and her class of students from Collège Jean Moulin, Le Havre, France.

An international Jury selected the winning team from among 26 finalists from 16 European countries. Mr Alain Vassor, Headmaster of the Collège Jean Moulin, received the Science Award Trophy and a cheque for 5000 ECU for the purchase of scientific or pedagogic equipment for the school, while Ms Riou received a cheque for 1500 ECU and the Excellence in Science Education Award Diploma. As part of the Award, the class will be invited to a one-week educational trip to Great Britain.

The winning project, entitled 'Preambule' dealt with the use of artificial and natural molecules in the field of fragrances. It resulted in the creation of a new and original perfume. The International Jury described this work as showing an integrated multidisciplinary
Polish teachers (above) and British teachers (below) receiving their Commendation Awards from Mr Bryan Sanderson, President of CEFIC
approach including science, arts, languages and geography. The project was well presented and close to the interests of young people, enabling both boys and girls of all abilities to make a good contribution.

The second prize went to Ms Regina Dittman of Humboldtschule, Bad Homburg, Germany for the ‘A sip for your health – The Mineral Springs of Bad Homburg’ project.

The third prize was given to Ms Sirpa af Ursin and Ms Anja Lindholm of Sipoo yläast, Sipoo, Finland for the “Glues and Adhesives” project.

Four Honourable Mentions were awarded to schools in the Czech Republic, Poland, United Kingdom and Slovak Republic.

In his comments as President of the Jury, Mr Wilfried Sahm, Director General of the VCI, the German Chemical Industry Association, said “We were impressed by the excellent quality of all European Finalists which may demonstrate that the examples and the experiences of previous Awards had a beneficial effect in creating new pedagogic initiatives”.

The Association of Biology and Geography Teachers in Finland

The Association of Biology and Geography Teachers in Finland (Biologian ja maantieteellinen opettajien liitto BMOL ry) sends our best regards to all the other Member Organizations of ICASE. Our Association has for many years been a passive member of ICASE and now we want to provide some information about our aims and activities.

As a pedagogical association our most important aim is to promote and improve the teaching of biology and geography. In order to do that, among other things we arrange teacher training in different ways and in different kinds of connections. In our annual meetings - the spring, summer and autumn meetings - teacher training is the most important part and we have lectures and workshops about topical issues. Environmental education, health education and international education are the crucial interests of our Association. We are also very interested in all ways of promoting science education.

The main theme of our autumn meeting in October 1998 was the Future. We had lectures about the future of teaching, the future of assessment in schools, the future of biodiversity and the future of the globe. Currently teachers have a growing interest in workshops. This time we had the following topics in our workshops: How to teach astronomy, Geography of hazards, Environmental chemistry, How to organize international projects, How to meet different cultures, Oil and oil damages, Water lab, Computer-aided teaching. This year we were especially pleased with the contribution of ICASE. Ms. Miia Rannikmae, European representative of ICASE, in her workshop demonstrated the STL philosophy by means of example materials.

The Association of Biology and Geography Teachers in Finland was established in 1927 and so last year was the jubilee year with many special activities, when our Association reached the age of 70.

If some Member Organizations of ICASE are interested in getting more information about our Association, please contact:

1999 CEFIC Science Education Award

This annual Award created by the European Chemical Industry Council and its National Federation Members, recognises excellence in science education achieved by a European secondary school class of pupils aged 12 to 18.

For the winning team the Award comprises:

An invitation to the Award Ceremony;
A one week all expenses paid trip to another European country;
5,000 ECU for the purchase of scientific or teaching equipment for the school of the winning team;
1,500 ECU plus a Diploma of Excellence for the teacher;
Award trophies.

In addition, various other prizes will be awarded to other particularly meritorious entries.

Entries should be sent to your National Industry Federation by April 1 1999.

An independent international Jury will select one team comprising a teacher and a class of pupils who by their innovative project have demonstrated a more effective and attractive way of teaching chemistry or science in general. The Award will be presented at the CEFIC General Assembly in Madrid on 11 June 1999.

For further information contact:
Science and Technology Department, Avenue E. Van Nieuwenhuyse, 4 Box 1, B-1160 Brussels.

NVON/ICASE European Conference
15 – 17 April 1999, Utrecht, Netherlands

The theme for this meeting is Science, communication and cooperation and it is being organised in two parts.

- The Annual meeting of NVON, the Dutch science teachers association is on 16 April. The meeting is also open to international science educators, both to participate and make presentations relevant to the theme to a predominantly Dutch audience.

- An international symposium is being organised by ICASE for Saturday 17 April, for representatives of European STAs and all science educators interested in international science education. Members from all science teachers’ associations are invited to attend and make presentations. ICASE wishes to take this opportunity to present its efforts to rethink the teaching of science in schools through greater attention to STL (scientific and technological literacy). Specifically, the ICASE publication on supplementary teaching materials will be presented, a proposal for an STL certificate award for teachers put forward and details given of a Year 2000 conference on education-industry partnerships will be given.

Contributions to one or both parts of the conference are invited. For NVON members please contact NVON. For others, please contact the ICASE European Representative, Miia Rannikmae (email: miia@lai.ut.ee or fax: + 372 7 465812). For more details please contact the ICASE European Representative.

Update on the ICASE Website
http://sunsite.anu.edu.au/icase

Check out the contact details of more than 140 member organisations of ICASE! Each member organisation with its own website is requested to send details so that a link can be established from the ICASE website.

Find out about the worldwide scientific and technological literacy project called Project 2000+. Exemplars of curriculum materials which have been developed in Project 2000+ workshops conducted by ICASE, will be progressively added to the site as a resource for science teachers.

For further information or to send updates for inclusion on the ICASE website, contact:

Feature Article

STL teaching - theoretical background and practical findings

Miia Rannikmae
ICASE European Representative
Researcher, Centre for Science Didactics, University of Tartu, Estonia

Abstract

This study set out to find out science teachers’ attitudes and opinions about using a STL teaching approach. Six STL modules were tried out, by 20 teachers with 470 students. All teachers were interviewed after the intervention. The students were asked to express their opinions by replying to a number of open-ended questions. The data were analysed, based on three domains: process, attitudinal and instructional domains. The outcomes emphasised the need for in-service guidance to teachers for better understanding of the intention of the module. The study showed gaps between students’ wishes and traditional teaching which influenced heavily science teachers’ attitudes.

Participants at the seminar on 'Scientific and Technological Literacy for All' for Chemistry Teachers in St Petersburg, Russia in May 1998. The resource person is Miia Rannikmae, the ICASE European Representative.
Introduction

Increasingly in the literature, the goal of teaching science is to promote scientific and technological literacy (STL) among students. This is usually taken to mean developing the ability to creatively utilise science knowledge in everyday life; to solve problems, make decisions, etc. The rationale suggested is that students need to cope with the ever increasing pace of change that is taking place in their lives, especially in the area of science and technology. Besides developing these abilities, it is recognised also that education, and this includes science education, needs to promote developments at the intellectual, attitudinal, societal and interdisciplinary levels (NSTA, 1993; Haggis, 1991).

Research has shown that science curricula have traditionally focused on the technical content of science, particularly academic science concepts (Yager, 1993). The teaching sequence has been from fundamental principles, leading to applications of science and technological advances. In such an approach, teaching stressed theoretical aspects over applications and with this, the isolation of school science from social issues. Whilst this meant that school science was presented in a logical fashion (at least from the scientific standpoint), it was free from social values and the impact of economic concerns. And this has led, in the eyes of students, to the impression that science subjects are more difficult, compared with other subjects. And worse, the theoretical approach has meant that science has become divorced from technology, the visual impact on our lives in the home. Science has been considered a pure, rather than an applied, subjects (Holbrook, 1992).

If science education is to play its true role in the education of the child, then it is important that science education objectives should not be separated from general educational goals. This means that, besides promoting empirical knowledge of chemical, physical and biological systems, science education needs to include learning geared to the scientific method of investigation, acquisition of social skills geared to the development or aspirations of the society, development of personal skills of the student and career awareness (Bybee, 1993). And clearly, specifying the goals and objectives is not only important for the teacher. Research carried out by Melton (1978) showed that 64% of students, who recognised the educational objectives, achieved better results on acquiring teaching material essential to these objectives. Hence objectives in the social skills part of science education, specified in the curriculum, should be particularly emphasised to balance acquisition of cognitive gains. In fact, science carefully taught in an everyday context has been shown to give higher motivation to learners and help them prepare for their future careers (Yager, 1996).

In recent years there have been big changes in the economy of post Soviet countries. Linked to this, post Soviet countries have started educational reforms to help faster integration into European society. In the new curriculum compiled in Estonia, emphasis is placed on science content which has an interdisciplinary character. The methodology of teaching is based on promoting scientific method. Not developed, nor emphasised, is the way of teaching science for all students and hence attention to motivational aspects. The general part of the new curricula, which indicates the need for social and personal development, has not been linked with the science curriculum. And as the assessment objectives for science are very poorly expressed, there is little incentive for teaching materials to develop the social aspect.

Yet there is urgent need in Estonia, with the rapid changes in lifestyle and the economic developments of the country, to work out an approach which will help students and teachers cope better with the changes in the society and at the same time appreciate the new curriculum developments.

Research, carried out (Holbrook and Rannikmae, 1996; Rannikmae, 1996) has shown that the methodology of teaching science is a very important factor in promoting higher order thinking skills among students. Methodology of teaching here includes developing a set of supplementary teaching materials meeting STL criteria geared to student participation, promoting educational goals, relating to a concern or issue in society, encouraging higher order thinking skills, including a communication skill component (Holbrook and Rannikmae, 1997). Aikenhead (1994) has pointed out that there are different models for the teaching of STL. In the Estonian context, it would be possible to motivate students through the adoption of a suitable STL approach. This is taken to mean utilising teaching materials which are related to promoting STL among students whilst maintaining students' conceptual development as per conventional courses. In the current study, teaching materials were created in the
Estonian context (Otsnik and Rannikmae, 1997) following Aikenhead’s (1994) classification - casual infusion of STL content. The materials were directly relevant to the classroom situation and were used as one period resources. As this paper follows Holbrook’s paper (Holbrook, 1998), a more detailed description of the criteria used in the creation of the STL materials is not given here.

Research design and methods

Four STL modules were created accordingly to specified criteria (Holbrook and Rannikmae, 1997). These were made applicable to biology, as well as chemistry lessons. Great attention was paid to the title of modules - keeping them as far from science content as possible. The design of the scenario was heavily linked with a common problem in Estonia, often indicating situations familiar from childhood (see titles in Table 1). 20 biology and chemistry teachers were asked to try out the created modules. Teachers were not made familiar with the STL philosophy, all information needed was gained from the teaching materials, which included a teacher’s guide giving teaching/learning objectives and a full teaching strategy. Teachers had a free choice in which grade to use the materials, they were only asked to indicate their choice to the research staff.

All teachers were interviewed after the intervention using half structured questions to determine:

- the goals of the lessons where the materials were used
- what students were learning and the teachers teaching during these lessons
- what were students feelings and concerns
- how the teachers likes these materials and the approach

The students were asked to express their opinions immediately at the end of the lesson by replying to three open ended questions in written format:

- what did you learn during the lesson ?
- how did you like this lesson and why ?
- would you like to have more, similar lessons ?

All data collected were analysed qualitatively based on three domains:

- process domain (what students were learning and teachers teaching)
- attitudinal domain (feelings and concerns related to personal and social development)
- instructional domain (understanding the goals of teaching - learning)

The total number of students taught by 20 teachers was 470. However, the number of completed replies was smaller - some students felt a lack of time for replying at the end of the lesson.

Research findings

A. Students’ learning

Students’ written answers were analysed against the goals of learning set up in the modules. Following the expressions used by students, learning was divided into three domains: subject knowledge, subjects skills and educational skills (Table 1) (Otsnik, 1998). Students had been used to learning mainly new knowledge, facts and concepts - in many cases these different expressions had the same meaning as more detailed analyses showed. Students had been learning what teachers were assessing in everyday teaching. Thus the learning domain depended on the type of module - modules where students had to use their subject knowledge in solving problems, or making decisions, were evaluated as equal to the subject skills domain. The major concern for the study was in the educational skills domain, which was little seen by students as a learning component. A different proportion of learning components in the module ‘More than a refreshment …’ was influenced by the teacher’s assessment procedures, where group reports were numerically assessed. Numerical assessment of group reports highlighted the importance of communication skills (oral as well written) in the eyes of students.

B. Teachers’ teaching

The STL materials, as used by teachers, did not introduce new concepts, because teachers used the scripts as revision (following an earlier introduction of the topic linked with the particular STL material). But the thrust of teaching by most teachers was still to give major attention to concepts and skills, with skills useful for everyday life emphasised less (Table 2).

Interviews showed that teachers saw scientific skills in a narrow sense - very few teachers (3 from 20) mentioned planning skills, controlling of variables, etc. The interview showed also similarities between students’ learning and teacher’s teaching - students do understand correctly what is in the teacher’s mind. So much so that when the teacher does not see

Clearly the objective of teaching, students do not take the associated activity seriously.

Table 3 (Otsnik, 1998) shows that students had very low abilities in planning an experiment and presenting a good record of their activities (tasks). Two STL modules were directed towards planning an experiment which would help to solve a socially important problem (using adsorption in medicine; conditions needed to keep juice fresh). Students were able to follow the simple experiment, memorised from earlier lessons, and did not pay attention to a

* 15 teachers gave several reasons

C. Feelings and concerns

The biggest differences between students’ wishes and teacher’s teaching appeared in the attitudinal domain. Students liked the lessons because of having a possibility to think by themselves without subject centred guidance. They could apply science knowledge in solving everyday problems and communicate with each other (Table 4). Previously, communication within science lessons had been acceptable only in terms of subject oriented tasks between deskmates. Group discussions and groupwork were seen as new phenomena in Estonian schools. Many students linked thinking and communication as dependent events - students had different tasks which push them into thinking before discussion.

In a comparison of students’ opinions with the criteria for STL materials (see the paper by Holbrook), research showed students supported lessons which help them cope with a changing society.

The following characteristics for STL materials were highly appreciated by students:

- Development of higher order thinking skills - represented by students thinking (27%)
- Socially oriented scenario - everyday life knowledge (13%)
- Development of communication skills - communication (18%)

need to widen their skills. They did not record the group discussions in many cases, as that was not a usual requirement by the teacher. Most groups did not give the plan for the experiment (equating it with giving the resources) and more than half of the groups were not able to draw conclusions (15 from 25 groups). These data illustrate also that most teachers did not understand the goal of the lesson (materials), as all groupwork was assessed numerically with high marks. The target of assessment was a poor description of the experiment carried out and influenced little the existing conclusions.

Table 5 lists the reasons why some students, overall 11%, did not like STL lessons. There were a number of students who thought the materials had been too difficult (15 students) or too simple (11 students). Approximately the same number of students had been passive, based on teacher’s opinions during the lessons, but at the same time teachers had not seen their role as improving the student involvement.

Public opinion and the examination system influenced student beliefs - STL type of teaching does not help to pass an entrance examination. That was the main argument against a willingness to use STL materials in every lesson. Students suggested to have STL lessons no often than once in month (There are 8 science lessons in one subject area per month in Estonia).

Development of students’ thinking skills was not appreciated by teachers (only 2 teachers from 20). Teachers did like the groupwork, but in many cases acted as passive observers whilst students were in action. Teachers liked the materials, because these included modern topics.

Interviews showed that teachers expressed their understanding about the scenario as a modern topic. They could find new applications for science knowledge in the STL materials scenario. At the same time, however, they continued to think in the direction from science to society, i.e. how to explain societal problems with the help of previously acquired science knowledge.

D. Understanding the goal of teaching

The STL materials included a teacher’s guide, to help teachers better understand the philosophy behind the teaching, had a full description of teaching strategies and also additional information needed for using the materials in different science subject lessons. (most Estonian science teachers have backgrounds in one subject area). Teaching strategies were linked with the goals of the lessons, which were presented in an unusual order - emphasising general educational goals, rather than subject centred goals.

Interviews with teachers showed that most teachers saw the development of subject skills as the main goal for the lesson (Table 6). This goal was highly prioritised, and separated from a possible social context. Teachers did not pay attention to the development of higher order thinking skills in a social context; higher order thinking skills were understood only in a pure subject context. Teachers’

wording for the goals for the lesson differed from that given in the teachers' guide and hence tended to indicate that teachers:

a) did not understand the goal and philosophy behind the materials; and
b) were so influenced by traditional teaching that they were not able to express the thoughts of others.

Development of subject knowledge had been seen traditionally as the most important goal of teaching, linked with the current assessment practice. The influence of STL materials seems to affect the sequencing of that goal, placing it after the goal of developing subject skills. Teachers who saw both goals as important, still emphasised skills versus knowledge. Future discussion should determine the reasons why educational goals were mentioned by only 4 teachers (from 20) !.

E. Role of teachers' guide

Teachers did not pay much attention to teaching strategies. That was taken as an already 'known and familiar' domain which did not need special explanation. Teachers did mention that there was a number of students not actively involved in lessons, but they did not recognise this as a sign of a lack of their own expertise in guiding the lesson. Only two teachers thought student-centred teaching needed special preparation.

Teachers appreciated additional materials - these were resources where they could find some interesting facts, or explanations, to understand the modules. It appeared that Estonian teachers had a lack of interdisciplinary knowledge. However, the same additional materials were evaluated differently by biology and chemistry teachers. Chemistry teachers liked more biological explanations, but the biology teachers wished to see more chemical equations to illustrate the processes behind the STL materials. (A careful analysis of the reports of groupwork showed that students had written these differently in chemistry and biology lessons: possible calculations were dominating in chemistry lessons, whereas in biology lessons, biological reasoning, unfortunately without links with chemistry, was emphasised).

Conclusions

1. The outcomes of this STL classroom intervention study emphasises the need for in-service guidance to teachers for better understanding of the intentions of the material. The STL modules help teachers broaden their teaching goals, but do not clarify the STL philosophy of teaching. The teachers (four teachers), who did understand the philosophy

* 10 teachers emphasised several goals

behind the STL materials, did highlight general educational goals and their achievement using student centred teaching strategies.

2. Using socially oriented, student-centred teaching materials enhanced the positive motivation of students towards learning science. Students appreciated opportunities to think and develop co-operative learning skills as well as
3. The study showed gaps between students’ wishes and traditional teaching which influenced heavily teachers’ attitudes. Students were inclined more towards STL learning than it was acceptable to teachers. Students liked STL lessons because they enriched socially oriented goals, yet at the same time, teachers continued to highlight subject oriented goals for the lesson.

4. STL materials illustrated a lack of interdisciplinary science knowledge among science teachers. The teachers’ narrow understanding of one science subject (chemistry or biology) influenced students’ learning outcomes. The effectiveness of using STL materials suffered because of the poor expertise of science teachers in interdisciplinary areas.

5. Both students and teachers were concerned about the need for assessment based on the STL materials. Students learn what teachers assess. Teachers need detailed guidelines on formative assessment and ownership to encourage change from the old paradigms of assessment.

6. Interviews have been a useful tool for developing better understanding of the STL philosophy. During the discussion, teachers clarified difficult moments in their teaching. The need for teachers ownership in the teaching process was highlighted.

Inclusion of the nature of science in Turkish science education curriculum (K-11): as a different approach

Lutfullah Turkmen (1) and Ronald Bonnstetter (2)
(1) College of Education, Afyon Kocatepe University, Usak-Turkey
(2) The University of Nebraska-Lincoln, Nebraska-USA

What is the nature of science?

In spite of the fact that K-11 science teachers have both a science content and science education background, they rarely think or teach much about the processes of science. Many fail to overlay their teaching with an understanding of the nature of science or go beyond a lock step introduction of the scientific method. The scientific method that scientists use in their research and studies can be summarized as follows: (1) observation and problem statement (2) establishing hypotheses (temporary solutions) (3) experiment, design or conduct research in order to disprove the hypothesis (in some cases prove the hypothesis), (4) reach a conclusion and in some cases this conclusion becomes a theory or even a scientific law through further research (Kimball, 1968; Griffith, 1995). Many teachers know these steps and have their students memorize them in science courses. However, do we as teachers know why we follow these steps? Do we leave our students with an understanding of the science behind them?

Although science has very complicated definitions, in essence it is a human endeavor to understand the universe, following the rules of science. Therefore, it becomes important to differentiate between science and non-science. One of the basic differences between science and non-science is that science is observable, experimental, measurable and repeatable by other scientists. Science is not based on faith, tradition or custom. All the above explanations lead to a definition of the nature of science (Kimball, 1968; Kuhn, 1962; Lederman, 1992).

The nature of science is based on our human nature because science is a human endeavor. What is the basic force that leads us to conduct science? Of course, the answer to this question is human curiosity about our physical universe. Since we have a driving
How is the nature of science dealt with in the USA National Science Education Standards?

The recently released USA National Science Education Standards have a number of underlying beliefs including: science is for all students, learning science is an active process, school science reflects the intellectual and cultural traditions that characterize the practice of contemporary science, and improving science education is part of systemic education reform (NRC, 1996).

The standards contain a match to the basic tenets of science previously mentioned, including descriptions on: scientific inquiry, the human aspects of science, and the role that science has played in the development of various cultures (NRC, 1996; Stanley and Brichouse, 1994).

In the nature of science section for grades K through 4, teachers focus primarily on developing the curiosity of children, such as allowing students to ask questions, to find answers to the questions, and to conduct group investigations as well as introducing children to some of the great scientists in history.

In grade levels 5 through 8, in addition to the objectives mentioned above, the standards introduce tentativeness, greater observation skill development, experimentation through inquiry, the testing of explanations and some mathematical models.

The nature of science section for grades 9 through 12, emphasizes the difference between science and non-science. It clearly states that explanations based on myths, personal beliefs, religious values, mystical inspiration, superstition or authority may be personally useful, but they are not scientific.

By the time students graduate from high school, they are supposed to be aware of the nature of science. However, much previous research has shown that high school students and most adults do not understand the nature of science. It will be interesting to see if these non-binding national guidelines have any effect on science curricula and ultimately lead to an improved understanding of the nature of science in the USA.

Why include the nature of science?

Currently, there are a number of problems in the USA and in other parts of the world with regard to science education. Generally, students' enthusiasm for

curiosity to figure out the universe and the world that we live in, every person may be considered a scientist. Therefore, it can be said that curiosity is one of the basic tenets underlining the nature of science. Curiosity is also an essential component of inquiry-based science teaching. In fact, the inquiry method can be accepted as another form of the scientific method. Just as the scientific method defined above, inquiry is based on evidence, a blend of logic and imagination, where science explains and predicts, and where scientists work to avoid bias. However, the order of events and emphasis may differ greatly. Thus, one can start to see that science has more than one approach or method. This thing called science is in fact far more dynamic and exciting than seen by most K-11 science students. This concern will be revisited later in this paper.

Other components

Another important tenet of the nature of science is tentativeness. It means that nothing in science is an absolute truth. This is one of the misconceptions about the nature of science. There is a tendency for students to believe that scientific facts, laws, and theories are unchangeable.

Another tenet relates to the fact that by definition science is a human endeavor in which scientists explore the physical universe by means of certain tools. These tools reveal to us the universe and are constantly subject to change. Therefore, science is a dynamic and on-going activity, not static. This requires open-mindedness so that the nature of science and scientific attitudes, such as curiosity, objectivity, and open-mindedness (no bias) may overlap (Thelen, 1987).

Even though these tenets are commonly accepted within the scientific community, much of the general public believes that science is not for ordinary people but belongs in the world of academia. This flawed understanding places the public outside the scientific community at a time when this basic human endeavor is crucial to addressing our complex social issues and should be of interest to everyone. For example, the most recent science education reform components emphasize "science for all," "science literacy" and "science, technology and society." We must help our teachers, students and the general public to understand the nature of science and that it includes curiosity, tentativeness, and is a human enterprise (Meichtry, 1993; Scharmann, 1988).
science courses declines dramatically after the 5th grade (Baykul, 1990). The general attitude of students toward science is that science is not necessary and that science courses are mostly boring. Students, also, do not seem to understand the purpose of science courses. In some ways, they are right because many school science curricula focus mainly on content rather than on the nature and history of science. Many believe that if curriculum planners and science teachers deal with the nature of science at the same time as with other science objectives, students will be less likely to give up science (Baykul, 1990). Moreover, the nature of science in science curricula may better fit students’ learning styles, such as curiosity, and inquiry teaching and learning.

One of the important concepts in science education reform world-wide and certainly within the U.S.A. national science education standards, is hands-on science. It refers to using simple materials, science projects, and observations. By doing hands-on science in school science courses (K-12 grades), the nature of science would be promoted and supported. Also, the nature of science and scientific method can not be taught merely by including a chapter about the nature of science and scientific methods at the beginning of every science textbook. Instead, the nature of science should be spread throughout the entire curriculum. Many believe that by spreading out the nature of science throughout the whole science curriculum, students’ attitudes toward science would be more positive (Griffiths and Barry, 1993; Meichtry, 1993; Griffiths, 1995).

Cultural differences in understanding the nature of science

Throughout human history, different countries, cultures or civilizations have dominated at different times and have led other cultures and civilizations. For example, some of the major old world dominators included the ancient Greek, Roman, Eastern, Chinese, and several Middle Eastern civilizations. Following these old world cultures, religion served as a major regional influence with the Islamic civilization dominating the middle eastern while the European culture and civilization were heavily influenced by Christianity. During the dark ages or middle ages in Europe, other parts of the world were at their peaks, such as the Chinese, the Mayan in South America, and the Islamic civilizations in the Middle East. Later, the renaissance in Europe gave rise to Western Civilization which in turn influenced the whole world, including science.

The driving force behind this new Western Civilization, whose roots go back to the Roman and especially the Greek Civilizations, was religious reform. The result of this eighteenth century movement in Europe was the separation of church and state and the development of positivism within the science community. Eventually, it spread beyond Europe, to Continental America and the Soviet Russia. In this climate, the nature of science took shape.

During the nineteenth century, through the dominance and influence of the super powers, Western civilization had reached every corner of the world. Many countries adapted western ideals for their countries with minor changes creating a somewhat monoculture for scientific thinking. However, during the twentieth century a new philosophical movement called post-positivism or post-modernism has emerged. The influence of post-modernism can be seen in some aspects of education, especially in the nature of science. This new notion gives credit to the differences and views knowledge as far more contextual than its dogmatic positivist predecessor.

As we enter the next millennium, it is normal that even people who are living in different cultures and countries should share some common values as human beings: values derived from past experiences, such as human rights, welfare and even democracy. However, the protection of our environment and natural resources, as well as our cultural differences must also be priorities.

What role should education and particularly science education play?

Educational research, even cross cultural research, suggests that many of the basic science education tenets described earlier are valid everywhere on earth, such as, hands-on science, science for all, and scientific literacy. Every country should include these ideas in their national science standards or curricula. But we also must recognize that the gathering of scientific knowledge can be accomplished through different scientific methods. In other words, there is not one single process or approach in the scientific method. For example, one research initiative, using western agricultural techniques, replaced indigenous agricultural methods in Africa which resulted in
famine and food and water shortages due to incorrect irrigation. Those people who live in Africa had developed their own agricultural methods over hundreds of years; methods which were suited to the local ecology and had withstood the test of time.

Other countries have had similar experiences and have found that without localizing educational reform components, borrowing or imitating a system or notion sometimes has negative effects resulting in the collapse of the educational system (Griffiths, 1995; Solomon, 1991).

Adapting the nature of science to another culture

With these explanations as background, the final question is how the nature of science can be adapted to another culture in the world. In this case the country of Turkey. Turkey has had many experiences in changing her own educational system throughout history. The country is located between Asia and Europe and has been very close to some major changes in world history. In the past, most of her people immigrated from Central Asia and colonized Asia Minor or Anatolia and were converted to Islam from their native religion. Over time they established their civilization, culture and state which was called the Ottoman Empire. When the empire collapsed, the republic of Turkey emerged and has been through several major transitions since 1923. The ultimate goal of the new young republic was to model western civilization and for that reason education became the focus. Early on many of these changes seemed to be pure imitation, but later efforts recognized the need for contextual adaptation (Turkmen and Bonnstetter, 1997).

As mentioned earlier, the general concepts and tenets of the nature of science in national science standards or curricula should be similar throughout the world. The differences lie in their application and modification for K-11 application. In Turkey, the most recent educational changes involve three focal areas; primary schools (K-8 grades), secondary schools (9-11 grades), and colleges or universities. The primary schools have two levels; elementary (K-5) and middle levels (6-8 grades). Obviously, educational reform must include all levels of education, but due to space limitations, we will focus on the K-11 grades.

First of all, education in Turkey is centralized and science curriculum is the same in every part of the country. In spite of the fact that Turkey is a relatively large country and has geographical, and social or cultural differences between regions, the nature of education is very similar throughout the country.

As previously discussed, during the first level of primary school, the main emphasis should be on building the children's curiosity and problem-solving skills by doing very simple hands-on science projects. This focus allows students to build a firm foundation for understanding their environment and relating to natural phenomena. However, due to the shortage of lab materials for science courses in K-5 grades, teachers tend to not provide these experiences. It would be extremely helpful if teacher guides would show how simple materials can be easily accessed and used from their environments. In addition science school curricula must give credit to group and peer study groups.

In the second level of primary schools (6-8), the current science curriculum is dominated by far too many objectives, a focus on memorization, and is very math dependent. Much of the material is taught in abstract terms making most of the present curriculum cognitively inappropriate. The solution for including the nature of science in the science curriculum between 6th and 8th grades may be: (1) spend more time on observation activities and group projects, (2) for teachers to welcome students' natural curiosity and questions, (3) to give a chance to students to report their own data obtained by them with very simple mathematical and graphical models, (4) to make students understand how scientific explanations should be different based on different interpretations by scientists and give them an opportunity to interpret their own data and projects, and (5) to show tentativeness in science by using texts related to the history of science that relate how scientific ideas or theories have changed over time. In this way the science curriculum will be able better able to promote hands-on science, scientific literacy and the nature of science.

The high school science curriculum (9-11 grades) must build on the previous grade level components plus expand the nature of science discussion to include refinements, such as differentiating science from non-science and exposing the difference between religion and science. Just as science teaching in the U.S.A. has been influenced by Christianity, Turkey has been shaped by the Islamic religion. Williamson, 1987, describes how Turkish voters have in the past mandated that politicians impose strict teaching rules based on social values.
As a result, many science teachers do not address crucial points that would help students understand the differences between science and religion.

To find a solution for this problem, the science curriculum should focus on the differences between the methods of science and religion, including the tentativeness of science, so that students can understand what is science and what is non-science. Although many of our cultural and societal values are not scientific, they are socially meaningful and relevant to the society. Students also should understand that the purpose of science is not to create conflict with religion, but to employ the tools of science to help understand and interpret the physical universe.

Conclusion

We must remember that the scientific method is not a single unique path but must be altered based on the context of the problem and the cultural setting. Only the basic tenets of science are constant. Acknowledgment of these factors allows science teachers to remain true to their cultural and social differences as well as the universal nature of science. By paying attention to these social and cultural differences, the nature of science can be adapted to any national science curriculum without losing the basic tenets of science. Therefore, countries must realize that their goals for science education can only be met by adapting and modifying curriculum to match their unique needs.

Please Note: The editor would like to remind ICASE member organizations and individual readers that all articles in Science Education International are available for reprint in your own journals. All copyrights are extended to members. This is a wonderful opportunity. Please consider starting an international section for your journal and use our fine articles to expand global awareness. All we ask is that you give credit to the author and the ICASE Journal.
ICASE Distinguished Service Award

This award is made to individuals who have a career history of distinguished service to international science education through their involvement in the international activities of local, regional and global science education organisations.

A listing of past award recipients can be found on the ICASE Website at <http://sunsite.anu.edu.au/icase/i_awards.html>

Nominations for this award must be forwarded by member organisations of ICASE. For full details of how to forward nominations, contact:

Dr Jack Holbrook, ICASE Executive Secretary,
ICASE Secretariat, PO Box 6138, Limassol, Cyprus
Email: icase@logos.cy.net

International Networking in Science Education at the ASE Annual Meetings
1999 University of Reading, UK 4 - 9 January
2000 University of Leeds, UK 3 - 8 January

The international programmes includes Models and modelling in science education, Information and communication technology in science education, Science and technology education, Environmental education and an international reception.

These link to 300 programme items and 250 exhibits at the ASE Annual Meeting. These all provide opportunities for reporting on the latest developments and initiatives in advancing the Science Project 2000+ goal of scientific and technological literacy for all, as well as appraising recent research and developments in science education.

There are excellent preferential conference rates for members of associations and institutions affiliated to ICASE.

Enhancing science teachers’ learning through pedagogical content knowledge

Harcharan Pardhan Senior Instructor, Science Education
& Alan E. Wheeler, Associate Director (Academic)
Institute for Educational Development, The Aga Khan University
Karachi, Pakistan

This paper examines the process undertaken to develop and implement a coherent and relevant structure for a field-based Subject Specialist Teacher (SST) Programme in Pakistan. While many of the features in the approach are of particular interest to science and mathematics educators in the developing world, the model presented here is also seen to hold promise for teacher education in other contexts. The basic premises for the programme were the strong need for both relevancy and quality in the context of the classroom realities, and were defined in terms of content enhancement together with improved pedagogical skills for the overall improvement of classroom practice. An experimental year-long offering of the SST Programme in both mathematics and science was initiated in mid-1997 at the Institute for Educational Development (IED) at the Aga Khan University in Karachi, Pakistan in collaboration with a number of cooperating schools. The mathematics and science SST Programmes were conducted separately but concurrently. The centrality of attempting to implement specific Pedagogical Content Knowledge (PCK) over a realistic period of time in the candidates’ home schools led to the SST Programme design, which consists of a number of content oriented components and appropriate teaching strategies interwoven with regular classroom practice. This paper examines both formative and summative findings associated with efforts to foster teachers’ PCK learning through a specially designed professional development programme. Specific features of the SST Programme are presented in relationship to both the contextual quality and relevance of the initiative. Challenges and possibilities associated with the basic SST Model are discussed in terms of its viability to serve as a significant change agent within and across schools.

Background

"There was a change in my teaching after attending this programme. I realized that now I can give the students better teacher and better ways of conceptual understanding. It was also noted by me that students were taking a keen interest in the activities." (SST Participant)

The Institute for Educational Development, at The Aga Khan University, has a vision to be instrumental in education reform and improvement in Pakistan. An integral part of this reform has been the on-going cycle of courses offered under the rubric of the Visiting Teacher (VT) Programme which began in 1995. The VT Programme was designed as a two month “Grassroots” teacher education initiative in five areas (Social Studies, English, Maths, Science and Primary Education) and has made an important contribution to IED’s overall efforts in the re-professionalisation of teachers. However, after reflections on experiences acquired during the various offerings of the VT components, it became
knowledge in the respective subject fields through a longer, more in-depth treatment which draws heavily upon their own classroom practice. This need led directly to the development of the Subject Specialist Teacher (SST) Programme which began in July, 1997. This was attempted on an experimental basis and represents another of IED's efforts to meet the expressed professional needs of teachers in the cooperating schools. The broad aims of SST Programme were to clarify and enhance the subject content knowledge of the candidates and to increase their competence and confidence through a field-based professional development process. In short, to enhance candidates 'Pedagogical Content Knowledge (PCK)'. Secondary objectives of the programme were to encourage and support stronger collaboration and collegiality among the participants, and to better prepare them to plan and implement professional in-service projects and other appropriate professional activities.

The enhancement of candidates' Pedagogical Content Knowledge (PCK) leading to improved teacher and student learning, formed the basic rationale of the SST Programme. Course participants holding the pre-requisite VT program certificate were nominated by the cooperating schools and selected in consultation with IED. The strong field-based component of the programme restricted the intake to Karachi schools. However, candidates on the programme represented a cross-section of IED's Karachi 26 cooperating schools reflecting all three systems (government schools, private and Aga Khan Schools).

Basic Model

The SST Programme was designed as a one year, field-based model for participants' professional and academic development. Although the emphasis was primarily on content knowledge, pedagogical aspects were also an integral part of the programme. Most of the programme took place in the participants' home schools. This basic SST model consisted of five major components consistent with current field-based models of teacher preparation (Coker and Wilkerson, 1997)

The initial three week full time content focused component, was held in the summer of 1997 at IED. During this Component, content knowledge for teaching was emphasized through a variety of "hands-on and minds-on" experiences. Importance was also given to teaching and understanding of required content. As such, concepts associated with specific topics with reference to the curriculum, were clarified and immediately applied through micro-teaching with peers.

After the summer vacation, SSTs returned to their respective home schools to carry out their first field-based assignments, for the period August-December 1997. Candidates carried out normal classroom practice but were required to prepare exemplary lessons that permitted students to learn content more directly by active manipulations and sharing their understandings. Selected lessons were formally observed, discussed and improved upon. On the average, at least two classroom observation visits per month per candidate were made by faculty members and Professional Development Teachers (PDTs) during this component. During this period the candidates were also provided with maximum school support by IED for classroom practice. Both the exemplary classroom teaching and unit plans formed part of the assessment for this component. To complement this field-based component, regular seminars were held at IED on selected Saturdays. These seminars addressed the evolving needs of the candidates, and encouraged the sharing of experiences, ideas and other pertinent concerns and content knowledge in the light of the candidates level of subject knowledge and understanding (Harlen, 1997). Saturday seminars also proved to be very appropriate for updating and scheduling of observation visits.

Following this the participants returned, on a full time basis to IED, for one week for component three of the programme with the focus on sharing and discussing difficult content areas and building on the various successes experienced over the first field-based period. In addition to enhancing and clarifying certain scientific and mathematical concepts, time was spend on planning for the second field-based component.

From January-May, 1998 the SST participants once again were in their home school, for the second field-based assignment component. The nature of this fourth component of the programme was similar to the first field-based component, however, candidates were also given limited opportunities to conduct professional development workshops within the ongoing Visiting Teacher Programme at IED.

The full time final component took place at IED,
during the late spring of 1998. Further content knowledge was emphasized and participants also prepared and delivered workshops for their peers. Candidates were also required to prepare specific action plans for their continued professional development responsibilities after the completion of the SST Programme.

**Pedagogical Content Knowledge (PCK)**

It is well known that teachers draw heavily upon their general pedagogical knowledge and their specific subject matter knowledge while teaching. However research indicates that teachers also draw upon knowledge that is specific to the teaching of various disciplines. Shulman (1986) termed this body of teacher knowledge, Pedagogical Content Knowledge (PCK) and argued that PCK went beyond mere knowledge of the subject matter per se to a dimension of subject matter knowledge for teaching.

"Within the category of pedagogical content knowledge I include for the most regularly taught topics in one’s subject area the most useful forms of representations of those ideas, the most important analogues, illustrations, examples, explanations and demonstrations – in a word, ways of representing and formulating the subject that make it comprehensible to others. Pedagogical Content Knowledge also includes an understanding of what makes the learning of specific topics easy or difficult; the conceptions and preconceptions that students of different ages and backgrounds bring with them to the learning of those most frequently taught topics and lessons.” (page 9 – 10)

The construct of Pedagogical Content Knowledge is also related to Dewey’s suggestion that teachers must learn to “Psychologize” their subject matter for teaching to reflect upon disciplinary topics and concepts to make them more accessible to students. PCK also requires teaching, as a central activity, to interpret specific content in light of what they know about the prior knowledge and interest of students.

Pedagogical Content Knowledge as used in the SST Programme was seen to consist of three central components. The first component of PCK included knowledge of students’ understanding, conceptions, and alternate conceptions of particular topics in the subject. To generate meaningful explanations and illustrations, teachers must have sound knowledge about what their students already know about a particular topic and where they are likely to encounter difficulty. A second component of PCK built into the SST Programme was that of curricular knowledge. This includes knowledge of the prescribed “horizontal” curriculum for teaching a particular subject, as well as knowledge about the “vertical” curriculum for that subject. For example, in the SST Science Programme, candidates drew heavily upon their knowledge of the prescribed provincial curriculum for a particular class level (e.g. horizontal component), as well as their knowledge of what students had studied about the topic in the past and what they are likely to encounter in future studies. The third component of PCK refers to knowledge of instructional strategies and representations for teaching particular topics. The SST programme attempted to incorporate ways candidates could add to their repertoires of metaphors, experiments, activities, or explanations which are particularly effective for a specific topic.

Overarching all three central components of PCK (Knowledge of Students’ Understanding, Curricular Knowledge, and Instructional Strategies) was that of the context in which the SST Programme was embedded. Clearly, candidates also must draw upon their understanding of the particular contexts in which they taught and adapt their more general knowledge to specific school settings and individual students. To be effective, PCK must be context-specific and context-sensitive.

While the various components of PCK are difficult to clearly separate in practice, the concept of PCK and its components served as a useful focus for the SST Programme. Continuous assessment was used to evaluate participants throughout all components of the Programme. A variety of evaluative measures were incorporated into the programme which placed strong emphasis on candidates’ ability to operationalise PCK in the context of their own classrooms.

**Classroom Realities of the Programme**

“I come with happiness because I would like to learn more and want to clear my concepts”. (SST Participant)

The SST Programme, as noted earlier, grew out an expressed need to enhance the Pedagogical Content
Knowledge (PCK) of selected candidates in Mathematics and Science who could further promote its continued development in their home schools. The decision to initiate the programme in both Mathematics and Science proved a challenging task with notable successes and challenges.

Thirty One (31) candidates (15 in Mathematics, 16 in Science) all experienced teachers, began the SST Programme, and only one candidate dropped out. Overall, the attendance and punctuality was commendable, given the many contextual difficulties faced by the participants.

Course participants consistently worked hard to complete all required major assignments and other programme related activities. It should be noted, in general, that candidates received strong support from their school administration. Candidates’ progress was monitored and documented through relevant assignments and strategies including unit plans, reflective journals, and other measures of performance. These included pre-test, post-test, assignments, candidates’ own personal reflections, and documents relating to both formative and summative indicators of classroom observations.

Pre-test and post-test measures revealed significant content growth with respect to major concepts and topics like energy, forces in science and, algebra, geometry and number sense in mathematics contained within the intended Pakistan curriculum. The enhanced content knowledge was seen as a major achievement for the Programme and far exceeded any such gain in the pre-requisite Visiting Teacher (VT) Programme.

Generally the candidates’ personal reflections moved well beyond the initial descriptive stage to where they were able to identify certain factors which inhibited student learning in a particular lesson. Many candidates were also able to plan subsequent lessons based upon these reflections and implement new learning.

“I also observed that many weak students were able to complete their work in the given time, which was good progress.”

(SST Participant)

During the initial stage of the classroom observation visits, candidates’ ability to properly manage the classroom for cooperative learning including small groups was one of the areas of general concern noted by the faculty. The regular post-conference discussions following each visit proved invaluable in working out appropriate strategies in consultation with candidates to overcome many of the needed organizational and instructional strategies required for better classroom management. There was a strong and highly visible improvement in the classroom management skills of the candidates, especially evident during the latter part of the programme. With the improved managerial skills candidates were able to provide more time on learning tasks for their students. Coincident with their enhanced managerial skills, candidates were better able to incorporate more directly focused applications of the acquired learning.

“Science teaching and learning can become very interesting if science teachers give demonstrations and then involve students in performing experiments, which can then lead to better understanding and retention of different topics” (SST Participant)

Many of the constraints faced in the programme were related to the heavier than anticipated human resource demands of the initiative. This was exacerbated by the unavailability of two members of the Mathematics SST Team due to maternity leave and the cancellation of an overseas consultant’s visit due to unforeseen circumstances. As a result, a number of programme adjustments were made which proved very demanding for both the faculty members and Professional Development Teachers (PDTs) involved.

The challenges faced by the participants themselves centered largely on the reality of the context in which they attempted to implement the programme objectives. Factors presenting significant challenges included the resistance to change encountered given the nature of the traditional school culture, the large number of students in classrooms, the number of different disciplines taught, and the lack of adequate preparation, planning time, and the necessary skills needed to improvise needed equipment, coupled with the scarcity of classroom resources.

“The most important thing we have learnt is that science teaching does not require costly materials, it can be well taught by using low cost materials which are easily available. The subject can be

24  Science Education International, Vol. 9, No. 4  December 1998
taught in a more practical way than just teaching it as a theoretical subject.” (SST Participant)

“I think concrete materials are very useful in learning because this way students can learn more easily.” (SST Participant)

Conclusion

While clearly a challenging initiative, the SST Programme was considered highly successful in terms of the degree of professional and academic growth achieved by the candidates. Overall programme records, observational visits to schools, SSTs’ sharing of experiences, written reflections and presentations of ‘success’ stories revealed a number of formal and informal indicators for candidates’ ability to continue to work for self-improvement in their pedagogical content knowledge.

It would appear that the SST Programme was, in fact, addressing the contextual needs and realities of selective schools in Pakistan and their demands upon classroom practice. The basic SST model is considered viable in spite of its relatively initial high resource implications, and is seen to hold potential for other subjects and areas (e.g. English, Social Studies, and the field of Primary Education). The school-based strand in the SST Programme lends itself well to the planning and implementing of a part time modular graduate programme. Plans are being made to draw upon the SST experience to enable candidates to acquire cumulative graduate accreditation, over time, leading to an M.Ed. degree. Further, with appropriate modifications, the model is also being applied in another developing country context within the region in the August to December, 1998 period.

Efforts in the SST programme to enhance PCK in the programme included exploring the conceptual and procedural knowledge that candidates brought to their teaching, misconceptions that they hold about certain topics, and the stages of understanding that they are likely to pass through in moving from a state of having only cursory understanding of the topic to a deeper mastery of it. PCK also included candidates’ knowledge of assessing students’ understanding, and diagnosing students misconceptions, and the use of instructional strategies to enable students to connect what they are learning to the knowledge they already possess.

The clear focus and emphasis on the professional development of the classroom teacher in situ, with appropriate and timely content and pedagogical enhancement in an integrated PCK fashion, has been found to have both encouraging and motivating outcomes. Several factors have contributed to these outcomes including the heavy emphasis on the field-based assignments conducted in the candidates’ own context, over a realistic time period. Collectively these factors have undoubtedly led to the successful enhancement of both Pedagogical Content Knowledge (PCK) and the Professional Continuous Karachi based classroom teachers’ development.

An inset project for science teachers in Rio de Janeiro, Brazil: a grassroots approach

Sandra Escovedo Selles
Espaço UFF de Ciências, Universidade Federal Fluminense, Brazil

Introduction

It is widely accepted that in-service education of science teachers must be incorporated into their school practice in order to improve the quality of their work, to overcome difficulties or lack of information from initial teacher training and to update new scientific knowledge. Researchers consider that INSET programmes are necessary because many of the classroom problems cannot be anticipated in the initial training courses and only make sense to teachers when they are effectively working at schools (Pessoa de Carvalho & Gil-Perez, 1992). Besides that, they argue that an initial training which included all the requirements of professional work would imply an increase in the length of the courses, which is considered not to be viable. Thus, in-service education becomes part of a ‘continuum’ of the process of professional development.

In Brazil, over the last decade there has been an increase in in-service education initiatives, especially short-term courses and training. Mainly, these initiatives come from the universities and local educational authorities together or not and, lately, federal initiatives have been offered with more frequency. Despite that, little has been published focusing on an evaluation of such initiatives. It is necessary to concentrate on the results of projects dealing with in-service education as well as carrying out research focusing on whether or not the projects have responded to what is both required and desired by the teachers themselves.

This article focuses on an evaluation of the In-Service Education of Science Teachers Project in Rio de Janeiro, Brazil over three years. A description of the general features of the project under evaluation will be given, the methodology used and, finally, comments will be made on the results found.

The project: an analogy

The project, called “One Swallow does not make summer” started in 1995 as the result of a Universidade Federal Fluminense initiative to promote greater interchange with science teachers within a partnership between the ‘Espaço UFF de Ciências’ (for details, see Queiróz and Selles, 1996) and state schools. The analogy is appropriate to explain the way teachers view their work at school and, at the same time, to point out a possible approach for overcoming difficulties. From this perspective, the project targeted science teachers and it was set to improve their practice by offering both theoretical and methodological support. The team responsible for the development of the project included university lecturers and five science teachers with the role of multiplying the ideas raised within the project (they are called ‘multiplier teachers’).

The project was organised into three phases and each of them followed the analogy path. The first one was called ‘the swallows make their nest’, which meant the time to organise the first meetings, to raise questions and themes with the teachers and to decide on a methodology. The second, ‘the swallows set flight’ saw the development of the project in the regions. The third phase represented by ‘the swallows fly back’ is still being run and it means a return to the schools to carry on the work done before.

The project methodology

The main methodological strategy of the project consisted of regional meetings at state schools lasting eight hours each and divided into two parts. The first one was dedicated to discussing educational issues from a theoretical point of view and it offered an opportunity to improve teachers’ awareness of the problems they have to face in everyday school life. The second part of the meetings consisted of workshops within a range of science topics chosen previously by the teachers. Although the project’s main concern was the classroom issues that potentially enable teachers to put new ideas into practice, it also reached another dimension of science
teaching. By recognizing the value of the teacher's work, the project invites other higher hierarchical sectors of the school (such as the head teacher and the local authorities) to get involved in a broader discussion of the questions related to science teaching in schools.

During the three years of the project it has reached 1300 teachers over five regional meetings per year in four cities of the metropolitan area of Rio de Janeiro.

Evaluating the project

An evaluation of the project has been conducted since its first year. It made use of questionnaires and a record of all activities developed by the team. Questionnaires were distributed to the participants on two occasions during the regional meetings. The questionnaires provided data on whether or not the project fulfilled the teachers' needs: the methodological approach; the level of the content; the topics chosen; the real possibility to put the ideas presented into practice; etc.

From a quantitative point of view, the fact that the numbers of participants increased over the time the project has been evaluated was taken as a first indicator of the fulfilment of the objectives proposed.

From the data analysis some results were evident. The first was related to the dynamic used in the meetings which was regarded as appropriate and successful. The fact that the project team went to schools instead of the teachers going to the university was considered a good choice of strategy. The teachers' participation, both in the discussion and in the workshop, enhanced the circulation of new ideas and methodological suggestions within the school environment.

The methodological strategy was considered to be successful and two aspects were highlighted. The first was the role of the 'multiplier teachers' involved in the team responsible for the work being done in the region. Their role was both coordinating and organizing the meetings to spread the ideas of the project in their region. This double function has shown to be the core of a strategy of mediation between the schools and the University. Their role can be defined as 'dissemination agents' within the region in which they work as science teachers. As the teachers themselves were responsible for the organisation of the meeting, they had to make more contact with their colleagues than they normally do in their everyday lives at school. Also, 'teachers who talked to other teachers' seemed to have a greater power of persuasion than being invited by university lecturers. It seems that teachers feel threatened by academics and they also tend to consider the 'multiplier' teachers closer to their 'real world' (Selles, 1992).

The second aspect was the fact that being school based, which is not very frequent in the Brazilian context, the project allowed some teachers, who have little opportunity of in-service education programmes, to become involved in university ventures without leaving the school grounds. Many of them felt stimulated and went back to the university to continue their education.

The strategy takes into consideration that the interaction between university and schools allows the construction of school knowledge in a two-way direction. The fact that teachers talked to teachers about classroom issues appeared to be taken into account more carefully by the participants. On the other hand, the university also benefited from going to schools by building an empirical basis for the theoretical knowledge and introducing many of the academic ideas to the school level. These issues are part of a discussion of the construction of knowledge which, generally, only occurs in academic fields. The shift towards fruitful interchanges which allowed such construction is, undoubtedly, a research source, present in different countries (refer Elliott, 1993 in England and the work of Brandão, 1982 and Demo, 1990 in Brazil).

Another point that was highlighted by the evaluation was that the project did not prioritize the content rather than the pedagogical approach. Theoretically, the project was founded on understanding that content and methodology must come together and discussing one in isolation does not contribute to improve the teaching quality. About this, McDermott (1990) states:

*The effective use of a teaching strategy is frequently guided by the content. If the teaching methods are not studied in the context in which they have to be implemented, teachers could not identify the essential aspects, nor adapt the methodological instructions - presented to them in abstract terms - to their specific subject or new situations.* (p. 2)
Therefore, the project was intended to offer the opportunity for teachers to reflect upon teaching and learning science and also to enhance research and continuing education.

Another aspect is the fact that eighty percent of the workshops were led by science teachers, not by academic lecturers. As these teachers became involved in the project they felt encouraged to present themselves the work they develop in classrooms. Also by participating in the project they went back to an academic environment and continued their education at university. In short this can be considered as a short-term result of the project and their work added an important contribution to the success of the project.

The development of the activities during the years had the institutional support of the Universidade Federal Fluminense, particularly the ‘Espaço UFF de Ciências’ and the Fundação de Amparo à pesquisa do Rio de Janeiro, FAPERJ (Foundation for Research Support of the State of Rio de Janeiro). This fact stresses that a partnership between schools and universities depends on institutional support.

Final comments

The project was a successful partnership between the university and schools, demonstrated by the growth in the number of participants and the acceptance of the project proposal. On one hand, the strength of the project appeared to be the participation of teachers who shared new strategies to be used in science classrooms with others. On the other hand, the academic partner gave the theoretical framework for the teachers that allowed them to introduce innovation and made it possible to understand why they should. The fact that much of the work of the workshops was already developed by other science teachers made the participants more confident in implementing new strategies in their classrooms. This project is defined as short-term in-service education; however, the fact that it occurs periodically places it in between short-term and long-term. The first step of the evaluation gave a broader view of the project, but the impact on the classroom was not investigated; in other words, to what extent the project generated what is called ‘didactic change’ (Gil-Perez, 1995). This aspect represents an expansion of the initial objectives and it seems that it is necessary to focus further on this aspect.

Education industry partnership (ICASE/CEFIC)
ICASE and CEFIC (European Chemical Industry Council) have created a partnership linking education and industry, and there have been four conferences on this theme over the last twelve years. The next conference is planned for York, UK in 2000.

As part of the planning for the York conference, and as a means of providing input with a strong ICASE flavour, a two-day workshop is being planned for 19 & 20 April 1999 at CEFIC headquarters in Brussels. Attendance of European teachers representing STAs at the April workshop will be sponsored by the chemical industry. Letters and details have been sent to European members of ICASE by the European Representative. For more details please contact the ICASE European Representative, Miia Rannikmae (email: miia@lal.utt.ee or fax: +372 7465812)
Chemical hazard resource information sheet

In schools where hazardous chemicals (chemicals which, based on scientific research, have proven to be a threat to body health) are used, respect of that chemical for its inherent danger to employees and students needs to be addressed. This can start when an employer purchases a new chemical. The manufacturer or supplier of the chemical should provide a chemical hazard resource information sheet (CHRIS) like a Material Safety Data Sheet (MSDS). In turn, the CHRIS should be made available to the employee who will use or be exposed in some way to the chemical in the workplace. CHRISs are documents that need to provide information about the chemical; e.g., common and chemical name, physical properties, health hazards, reactivity information, control measures and other information.

In a school’s science laboratories, CHRISs are critical to science laboratory safety plans. Access is a priority given the fact that exposure to certain hazardous chemicals can be life threatening for both employees and students. In the spirit of a safety plan, teachers should keep a folder of CHRISs for chemicals being used during an experiment in the laboratory. Should an accident occur, the teacher can simply send the person exposed to the chemical to the nurse or medical support person with the CHRIS. Minimally, a CHRIS notebook of all chemicals used in the laboratory should be available in the science workroom or office areas.

It is recommended that schools that use purchase orders have a printed statement noting CHRISs are required for chemicals and payment for chemicals will be withheld until CHRISs are provided. If a chemical is purchased at a local store, a CHRIS type of document should be secured. Consider the scenario of an employee bringing the chemical into the workplace and another employee being allergic to it. Remember, employees need to have the right of access to this information.

It is advisable that safety plans require the employer to train employees each time a new chemical is introduced into the workplace environment. Science supervisors and teachers should also have documentation of such training programs. It is a good idea to include a standing agenda item on safety in writing for each department meeting. During these sessions, new chemicals and precautions can be addressed.

It would also be prudent to have other chemical reference material above and beyond the CHRIS available. In the United States of America all of these recommendations are required under the Laboratory Standard by the Occupational Safety and Health Administration. The bottom line is accessibility to chemical reference information in a CHRIS-like document and training for employees when new chemicals are introduced into the workplace. Training should also be required for new employees entering the workplace. This helps to secure and maintain a safe work place for employees and students working with hazardous chemicals.
Stepping into Science & Technology Project Workshop Pack

A new pack has been prepared for ICASE Member Associations to promote pre-secondary science and technology.

The purpose of the Pack is to assist you to mount an exhibition table in your school, in the community, at a conference, or in meetings of your Science Teachers' Association. Or it would help you to run a workshop of pre-secondary practical science and technology activities as a come and share session for delegates.

The theme is International since ICASE is international - remember the 'I'- but, more importantly, for scientific and technological literacy for all to become a reality the communication and exchange of information between teachers of science and technology on a world-wide basis is essential. On a more national / local scale, communication within the community is equally important, so that community members are aware of what is going on in science and technology education. Working with pre-secondary or primary teachers is also a public understanding of science activity when teachers have not been trained in science and associated subjects.

The Conference Pack is a guide to producing a visual means of communication to a wide audience. We hope you find it useful and are sure that once you have staged your own Come and Share workshop or exhibition you will want to make the next one even better.

Finally, please bear in mind that the Stepping Into Science & Technology Project is not about examinations and tests, it is about learning. Young people undertaking simple projects or activities at an early stage in their lives, without the pressures of examinations, may become more efficient learners in formal classroom situations. The aim of the project is for students to do; to undertake a hands-on activity and explain what they have been doing in their own words. As they progress through the Steps a certificate is awarded at each stage as a means of encouraging and recognising achievement.

We wish you every success with the use of this Pack and only ask that you communicate with ICASE so that you can share your experiences and ideas with others through the Stepping into Science Newsletter.

A copy of the Stepping into Science and Technology Project Workshop Pack will be sent to each ICASE Member Association.

Enquiries should be directed to:

Effect of Bio-Cosmos I overhead projector films on student learning for middle school biology
Mie-Sook Choi (1), Hae-Ae Seo (2), Sung-Ho Park (3) and Bang-Ho Song (3)
(1)Teagu Seobu Middle School, Teagu, (2) Korean Education Development Institute, Seoul
(3) Department of Biology Education, Teachers College, Kyungpook National University, Taegu, Korea

Abstract

This study aimed to find out the effect of uses of colorful overhead projector films as teaching resources on students' science learning and assess their quality. Song, et al. (1997) developed 208 colorful overhead projector films, named as Bio-cosmos I, including photographs, pictures, concept maps, and diagrams related to the areas of biology in middle school science textbooks. To examine its effect on student learning and quality, Bio-cosmos I targeted 162 female students of 7th grade during the first semester of 1997 in a girl's middle school, Taegu, Korea. The researcher utilized appropriate films during science classes for 40% of class hours for experimental groups and there was no colorful films used for the control group. An achievement test and questionnaires were developed and administrated. The research results showed that students of the experimental group scored significantly (p < .05) higher on the achievement test compared to the control group. The results also showed that there were significant (p < .05) increases in student scientific thinking ability, comprehension of content, retention of knowledge, and interest while there were no significant increases (p < .05) in creativity and problem solving skills related to science-technology-society issues for students of the experimental group. For the production of quality overhead projector films, it was found that various features of content organization, screen structure, printing quality and instructional strategy needed to be carefully designed. It was concluded that colorful visual teaching resources such as Bio-cosmos I films can improve middle school student science learning. The results of the study also called for further research on the development of high quality, colorful overhead projector films.
Introduction

In 1996, the Korean Ministry of Education revised the existing science curriculum, which became the 6th revised curriculum for school science including middle school level from 7th to 9th grades (Korean Ministry of Education, 1992, 1995). New middle school science textbooks were also published according to the 6th revision. The 6th revision emphasized inspiring students to ask questions with interest and curiosity about natural phenomena, as the newly published textbooks tried to effectively achieve the goals of the 6th revised middle school science curriculum (Kim, 1996). Updated science knowledge and inquiry-based investigation and experiments were added to the new textbooks. However, the new textbooks consist mostly of written texts and a few pictures and diagrams in white and black. Such textbooks would easily make students get bored of science learning and decrease students' curiosity and interest in science.

TIMSS (1996) reported that 97% of 8th grade science teachers in Korea used textbooks during science classes and 77% of them decided topics for science teaching from textbooks. It implied that students in Korean middle school science classrooms spend most of their time referring to textbooks. If Korean science teachers do not use any other teaching resources than textbooks in white and black without colored pictures and diagrams for science teaching, students would rarely become interested in science and curious about natural phenomena and student achievement would hardly be improved.

Teaching can be considered as a process of communication, as teachers introduce the topics of lessons to students and facilitate students' understanding. Teaching resources will effectively enhance communication between teachers and students. Such teaching resources, including colorful overhead films, VTR and multimedia stimulate student interest in lesson topics and enhance student achievement with different instructional strategies (Wright & Govindarajan, 1992).

Overhead projector films have been utilized for a long time since electronic equipment and projectors were introduced in school classrooms. However, there have been few studies to analyze the effectiveness of those films in teaching and learning. Most teachers produce simple overhead projector films with handwriting for their prompt use. Commercial overhead projector films are poorly produced in terms of instructional strategies and graphic skills. Necessary computer hardware and multimedia resources are not properly utilized for their production (Trowbridge & Wandersse, 1996).

Song, et al. (1997) produced a set of colorful overhead projector films for middle school biology teaching. The content of the films was organized based upon the analysis of eight different science textbooks approved by the Ministry of Education.

The films were designed based on various instructional strategies and manufactured using multimedia with newly developed educational software. However, their effectiveness as teaching resources have not been examined.

This study aimed to find out whether the application of colorful overhead projector films, Bio-Cosmos I, increased student understanding of science and interest in natural phenomena. In addition, the quality of overhead projector films was also analyzed through the assessment of student opinions. These findings would provide further information of the elements of enhancing student science learning and improving the quality of overhead projector films as effective teaching resources. The overhead projector films of Bio-Cosmos I would also be powerful teaching resources for the successful implementation of the 6th revised science curriculum in Korean middle schools. Therefore, this study focused on the following two questions: (1) Do the uses of overhead projector films positively impact on student achievement, scientific thinking ability, comprehending content, retaining knowledge, creativity, interest, and problem solving skills related to science-technology-society issues? and 2) What are the characteristics of the overhead projector films in terms of improving instructional efficiency?

Method

Subjects

The population for this study consisted of 162 female 1st graders (12-13 years old; four classes) in a girls' middle school in Taegu, Korea. Four classes were randomly selected from 11 classes and divided into two groups; experimental (82 students of two classes) and control groups (80 students of two classes). There were no significant differences (p<0.05; t = -0.16, df = 160) in student achievement between experimental and control groups at the beginning of this study.

Treatment

The study was conducted during 1st semester from early March to the middle of July in 1997. One of the researchers taught a 'general science' for experimental and control groups. For the experimental group, 33 colorful overhead projector films, which were some of 208 Bio-cosmos I films developed by Song, et al. (1997) were utilized for the study while teaching the unit 'life of plants' of the general science course. The teacher tried to use 33 overhead projector films for 40% of the time period of the classes at least. For the control group, the teacher did not use any of those films at all.

Achievement test and survey instruments

Achievement test

To find out the difference of student achievement
between the experimental and control groups, 20 items based on the content of the unit, 'life of plants' were developed. The twenty items were designed as five-choice and open-ended questions. The test was administered at the end of the semester for the experimental and control groups. The highest score for each item was 5 points and the total score of the test was 100 points at maximum. The content validity and reliability was tested by split-half reliability. The Pearson's correlation coefficient was .60 and this value was compensated to .75 by the Spearman-Brown formula (Byun et al., 1996a).

Science Learning Skills and Attitude Questionnaire

The changes of student scientific thinking ability, comprehension of content, retention of knowledge, creativity, interest, and problem solving skills related to science-technology-society issues were measured by the administration of a thirteen item survey questionnaire at the beginning and end of semester for the experimental group. All of the thirteen questions were responded to through the use of a five-point Likert scale (Byun et al., 1996b).

Science Education International, Vol. 9, No. 4 December 1998
Bio-Cosmos I Film Evaluation Questionnaire

To evaluate the quality of the films, Bio-cosmos I used for the study, an evaluation questionnaire was developed regarding content organization, screen structure, printing quality, instructional strategy and overall opinion (Dick & Carey, 1990; Na & Jung, 1996). There were six items for content organization, five items for screen structure, five items for screen quality, five items for instructional strategy and one item for overall evaluation. Each item was responded to through the use of a three point scale. The indicators, “poor,” “average,” and “excellent” were used for measurement (Cho, 1996). The evaluation questionnaire was administrated at the end of semester for the experimental group.

Results and discussions

Student achievement test

Table 1 shows that the students in the experimental group scored significantly (p < 0.05) higher than those in the control group. It was suggested that student achievement was considerably improved by the uses of Bio-cosmos I films-aided instruction.

Science learning skill and attitude questionnaire

Student scientific thinking ability, comprehension of content, retention of knowledge and interest were significantly (p < 0.05) changed between the beginning and end of the semester for the experimental group. The creativity and problem solving skill related to science-technology-society issues were not significantly changed (see Table 2). Consequently, the student scientific thinking ability, comprehension of content, retention of knowledge and interest were improved by the films-aided instruction.

Screen structure

The five items of the screen structure asked for students’ opinions of harmoniousness, letter size and style, grammatical correctness, emphasis, and appropriate amount of content for structuring screens. Most students agreed that harmoniousness, letter size and style, grammatical correctness and emphasis were ‘excellent’ in quality (see Table 4). However, 50.0% of students assessed the film quality as ‘average’ for appropriate amount of content.

Printing quality

There were five items concerning colorfulness, gracefulness, clearness, brightness, and distinctness of the printing quality. Most students agreed that the clearness of printing quality was ‘excellent’. (see Table 5).
Instructional strategy

The five items of the instructional strategy were asked for student’s opinions of motivation and interest, sequence to prior learning, summarization of lesson content, connection to lesson objectives, and active participation. The most students agreed that summarization of lesson content and connection to lesson objectives were 'excellent' in quality (see Table 6).

Overall evaluation

The highest percentage (59.8%) of students assessed the quality of Bio-Cosmos I films as 'excellent' while 28% of student assessed them as 'average.' There was 8.5% of students who assessed the quality as 'very excellent' and 3.7% as 'poor.' There was no student who assessed the quality as very poor. Therefore, 68.3% of students agreed that the quality was excellent or very excellent.

Conclusions and suggestions

The findings in this study concluded that the use of colorful overhead projector films, Bio-Cosmos I, in middle school general science classes significantly enhanced student achievement, scientific thinking ability, comprehension of content, retention of knowledge and interest. However, student creativity and problem solving skill were not much improved by the overhead projector films. Rather, creativity and problem solving skill would be enhanced by other teaching strategies such as hands-on activities, experiments, project-oriented instructions and so on. Or, if the overhead projector films provide students with opportunities to engage in experiments and hands-on activities, the overhead projector films might improve student creativity and problem solving skill. The use of overhead projector films for science teaching may not be the best teaching resource in terms of learner-centered and activity-oriented learning. However, teaching resources of

overhead projector films can be effective for communicating scientific information between students and teachers and for enhancing student scientific thinking ability and interest.

There were also various features of quality overhead projector films as the study revealed from the evaluation results: The strategies for presenting content need to stress appropriateness for the learner’s level, accuracy, summarization, richness and diversity, consciousness and definiteness. The screen should be structured in terms of harmoniousness, letter size and style, grammatical correctness, emphasis and the appropriate amount of content. Colorfulness, gracefulness, clearness, brightness, and distinctness are graphically designed for printing quality. Overhead projector film producers should carefully refer to various elements of instructional strategies in order to produce quality films for improving science learning. The elements of instructional strategy include motivation and interest, sequence to prior learning, summarization of lesson content, connection to lesson objectives and active participation (Cho & Pak, 1995). Various features identified from the study also provide insights for effective and innovative features in developing overhead projector films, as well as hypertext and multimedia of screen-oriented teaching-learning resources.

Science Across the World remakes its website

A working example of how the Internet can bridge language and cultural differences has been given a facelift after two years in the field and a rising popularity among schoolchildren in 46 countries.

The Science Across the World programme, coordinated by the Association for Science Education in Britain, was one of the first to incorporate a website into an education programme. The programme aims to raise awareness of science and technology issues in society, industry and the environment. The Internet was used initially to allow teachers and students to send information to other schools.

But there is much more to the new site. It is easier to navigate and more visually appealing. Ease of navigation and speed of download are key features. There are no spinning logos; instead there are resource areas, with discussion forums and news sections to contribute to. Nor is it all dull text. Video clips are available. And the whole thing is available in six languages - English, French, German, Italian, Portuguese and Spanish.

Those who dream of using the Internet in schools might like to check how its done in Science Across the World. There are 1200 schools world-wide using the BP-sponsored programme, and in the last six years it embraces schools in Africa, the Asia-Pacific region, Europe and North and South America.

Location: University of Reading, Reading, England
Theme: Science Education in the Computer Age
Contact: ASE Annual Meeting, The Association for Science Education, College Lane, Hatfield, Herts AL10 9AA, fax: +44 1707 266 532,
email: <ase@asehq.telme.com>

An ASE-ICASE International Seminar will precede the 1999 ASE Annual Meeting from 4 January.

January 14 - 17
International Meeting of the Association for the Education of Teachers in Science
Location: Austin, Texas, USA
Theme: Passport to professional excellence in science teacher education
Contact: Jim Barufaldi, email: jamesb@mail.utexas.edu
Website: <http://www.aets.unr.edu/AETS/aets99reg.html>

January 17 - 19
4th National Conference for Primary Teachers and Educators
Location: Australian National University, Canberra, Australia
Theme: Literacy in science
Contact: Conference Secretariat, Australian Science Teachers Association, PO Box 334, Deakin West, ACT 2600
Fax: + 6 2682 9477 Email: <asta@asta.edu.au>

March 25 - 28
NSTA National Convention
Location: Boston, Massachusetts, USA
Contact: NSTA Conventions Department, 1840 Wilson Blvd, Arlington, VA 22201-3000
email: <conventions@nsta.org>
Join science educators from across the USA and around the world in a huge program catering to the needs of elementary/primary and secondary teachers of science and tertiary science educators. See the website for further information: <http://www.nsta.org>.

March 28 - 31
National Association for Research in Science Teaching (NARST) Annual Meeting
Location: The Boston Park Plaza Hotel, Boston, USA
Contact: Art White, Executive Secretary of NARST, The Ohio State University, 1929 Kenny Road, Columbus, OH 43210, USA
Fax: + 614 292 1595
Email: awhite@POP.SERVICE.OHIO-STATE.EDU
NARST Website: <http://science.coe.uwf.edu/NARST/NARST.html>

April 15 - 17
NVON / ICASE International Symposium
Location: Utrecht, Netherlands
Theme: Science communication and cooperation
The NVON Annual Meeting will be on 16 April and the ICASE European Symposium on 17 April. A welcome international dinner will be held on 15 April.
Contact: Mia Rannikmae, ICASE European Regional Representative, Department of Science Didactics, University of Tartu, Lai 40 Tartu EE 2400, Estonia, fax: +372 7 465 812
email: <miia@lai.ut.ee>

June 26 - July 1
World Conference on Science
Location: Budapest
Theme: Science for the Twenty-First Century: A New Commitment
Contact: Secretariat, World Conference on Science, UNESCO, 7, Place de Fontenoy, 75352 Paris, France
Fax: + 33 1 45 68 58 23
Email: <confsci@unesco.org>

June 26 - July 2
9th IOSTE Symposium
Location: Durban, South Africa
Theme: Science and Technology Education for Sustainable Development in Changing and Diverse Societies and Environments
Contact: Mr Alan Pillay, Chairperson IOSTE 9 Faculty of Education, University of Durban-Westville Private bag X54001, Durban 4000, South Africa
Fax: +27 31 204 4866
Email: <spillay@pixie.udw.ac.za>
June 27 - 30
ChemEd99
Location: University of Waikato, Hamilton, New Zealand
Contact: Bev Cooper, Fax: +64 7 838 4382
Email: <becooper@waikato.ac.nz>

July 4 - 9
CONASTA - Conference of the Australian Science Teachers Association
Location: University of Adelaide, Adelaide, Australia
Theme: The Spirit of Science
Contact: CONASTA 48 Secretariat, First Floor, 211 Flinders St, Adelaide SA 5000, Australia
Fax: +61 8 8224 0805
Email: <conasta@cobweb.com.au>
Website: <http://www.science.adelaide.edu.au/sasta/conasta>

September 15 - 19
5th International HPSST Conference
Location: Pavia University, Italy
Contact: Dr Enrico Antonio Giannetto, Dipartimento di Fisica ‘A Volta’, Universita di Pavia, Via A. Bassi 6, 27100 Pavia, Italy, email: <volta99@pv.infn.it>.
This conference is being held in conjunction with the European Physical Society’s Interdivisional Group on History of Physics and Physics Teaching. See the website for more information: <http://www.citea.it/volta99>.

September 26 - 29
BioLive99
Location: Waipuna Lodge, Auckland, New Zealand
Contact: BioLive Conference Secretariat, PO Box 900040, Auckland, New Zealand

October 4 - 8
3rd Latin American and Caribbean Symposium of ICASE
Location: Curitiba - Parana State, Federal University of Parana, Brazil
Themes: Promoting scientific and technological culture for all in the 21st Century
Contact: Department of Educational Methods, School of Education, Federal University of Parana, Rue General Carneiro, 460 2o. Andar, Curitiba - Parana, CEP 80 060 - 150, Brazil.
Phone / fax: + 55 41 264 3574
Email: <icase3sl@garoupa.bio.ufpr.br>
Website: <www.ufpr.br/eventos/icase/>

The 3rd ICASE Latin American and Caribbean Symposium will be hosted by the Brazilian Association for the Advancement of Science - Parana Section.

2000

January 6 - 8
ASE Annual Meeting
Location: University of Leeds, Leeds, England
Contact: ASE Annual Meeting, The Association for Science Education, College Lane, Hatfield, Herts AL10 9AA, fax: +44 1707 266 532,
email: <ase@asehq.telme.com>
An ASE-ICASE International Seminar will precede the 1999 ASE Annual Meeting from 4 - 5 January, with an international reception on 3 January.

April 6 - 9
NSTA National Convention
Location: Orlando, Florida, USA
Contact: NSTA Conventions Department, 1840 Wilson Blvd, Arlington, VA 22201-3000,
email: <conventions@nsta.org>.

July 19 - 21
ICASE-CEFIC European Education-Industry Seminar
Location: University of York, York, UK
Contact: Mija Rannikmae, ICASE European Regional Representative, Department of Science Didactics, University of Tartu, Lai 40 Tartu EE 2400, Estonia, fax: +372 7 465 813,
email: <mija@queenie.lai.ut.ee>.

August 21 - 27
16th International Conference on Chemical Education
Location: Eotvos University, Budapest, Hungary
Theme: Healthy Living World and Applied Chemistry
Contact: Hungarian Chemical Society, 16th ICCE Secretariat, Theresa Mihalyi, Budapest Fo u. 68, H-1027, Hungary Fax: +36 1 201 8056
Email: mail2.mke@mtesz.hu Preliminary registration is requested by January 31, 1999.
How to subscribe to

Science Education International

Send payment for four issues (cheques payable to 'ICASE') with your title, first name, last name and postal address to:

ICASE Secretariat, College Lane, Hatfield, Hertfordshire AL10 9AA, United Kingdom.
The subscription rate is £16.00 for individuals or £32.00 for institutions and libraries.

If you prefer to send the subscription to USA, Australia or Canada the rates and addresses are given below.

<table>
<thead>
<tr>
<th>USA $25.00</th>
<th>Individual</th>
</tr>
</thead>
<tbody>
<tr>
<td>USA $50.00</td>
<td>Library or institution</td>
</tr>
</tbody>
</table>

Professor John Penick
Dept of Maths, Science and Technology Education
North Carolina State University
Raleigh, NC 27695-7801 USA

<table>
<thead>
<tr>
<th>Aus $35.00</th>
<th>Individual</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aus $70.00</td>
<td>Library or institution</td>
</tr>
</tbody>
</table>

Mr Brenton Honeyman
10, Hawken Street
Monash, ACT 2904
Australia

<table>
<thead>
<tr>
<th>Can $30.00</th>
<th>Individual</th>

SCHOOL LINKS INTERNATIONAL 1999
Celebration of School Science

Join hands across the world by sharing your science with a school from a different culture. Simply work on a similar theme and tell each other what you learn. Then join in our ‘Celebration of School Science’ by telling us about it. We’ll help with contacts and ideas. So don’t be left out!

All participants will receive certificates. The best group will be part of an international ceremony.

This project is being organised by the Association for Science Education (ASE) in cooperation with ICASE and UNESCO. For further information about how you can become involved in this project, please contact:

Caroline McGrath
Schools Links International 1999
The Science Centre, TheRunnymede Centre
Chertsey Road, Addlestone, Weybridge KT15 2EP, UK
